The LIFE project WetFlyAmphibia: When the needs of flora and fauna make a restoration program difficult

Thomas Abeli[1], *Graziano Rossi*[1], *Davide Alberti*[2], *Marcello Miozzo*[3]

1. University of Pavia

2. Parco Nazionale delle Foreste Casentinesi

3. DREAM Italia

The project "Conservation of amphibians and butterflies of open wet areas and their habitats at the Foreste Casentinesi National Park" (WetFlyAmphibia) is a restoration project funded in 2014 in Italy under the EU LIFE scheme. The aim of the project is to increase the reproductive performance of four amphibian species, including the Appenine Yellow-bellied Toad *Bombina pachypus* and the Italian Crested Newt *Triturus carnifex*, and two butterflies (*Euplagia quadripunctaria* and *Eriogaster catax*) in the Northern Apennines (Italy). Here, land abandonment and changed agricultural practices have negatively affected the wetland flora and fauna. The most important action in the project is the restoration of the wetland flora that would enable both amphibia and butterflies to reproduce. In particular, *B. pachypus* and the two butterflies have quite specific requirements in terms of plants that can promote their reproductive performance. After two years of project implementation, results indicate that *B. plachypus* prefers aquatic vegetation with *Chara* sp. and *Myriophyllum* sp. forming little shade, while *T. carnifex* prefers deeper ponds with abundant shade provided by broad-leaved aquatic plants such as *Potamogeton* sp. and *Ranunculus trichophyllus*. The two butterflies largely rely on *Eupatorium cannabinum* as food plant for their caterpillars. Moreover, all the species use large vegetation stands of megaforbs as a connection between wetlands and woodlands. The challenge of the project is to identify areas that match the ecological requirements of both animals and plants to maximize the success of the restoration (reintroduction/reinforcement). Because few natural wetlands are still available with these characteristics an interesting solution is proposed, especially for *B. pachypus*. Old drinking troughs for cattle will be restored and used as unnatural ponds, in which *Chara* sp. and *Myriophyllum* sp. will be introduced from nearby wetlands to facilitate the colonisation by *B. pachypus*. In addition, new ponds will be excavated beside historical ponds and a megaforbs stand planted according to a soil humidity gradient, using Ellenberg indexes to identify the right distance of each plant species from the pond.

Isolation and identification of fungi associated with some Nigerian bird's nests using internal transcribed spacer primer

Adedotun A. Adekunle[1], *Uchenna C. Kanife*[2], *Abosede M Ebabhi*[3], *Temitope O. Samuel*[1], *Oluwagbenga O. Adeogun*[1]

1. University of Lagos

2. Yaba College of Technology, Lagos

3. Distance Learning Institute, University of Lagos

Studies on identification of fungi associated with Nigerian bird nest was carried out using internal transcribed spacer primers, a method designed for the simple and rapid isolation of DNA from tough to lyse fungi. The fungal samples were rapidly and efficiently lysed with the ultra-high density bashing beads. Sixteen fungal isolates were studied with *Aspergillus niger* occurring most frequently (44%), *Fusarium solani* and *Fusarium verticilloides* occurred at 19%, *Aspergillus flavus* 13%, *Aspergillus tubingiensis, Aspergillus terrus* and *Talaromyces pinophilus* occurred at 24% respectively. One species has no identifiable sequence and another one could not be tacked to any match. DNA fragments from the isolates were amplified by PCR using forward primer (ITS 4TCCTCCGCTTATTGATATGC) and reverse primer (ITS 5 GGAAGTAAAAGTCGTAACG) which demonstrated that the extracted DNA were truly fungi. The phylogenetic tree showed a high level of genetic similarity between these organisms. This study provides a useful data for discovery of unknown fungi and probably species which could be causal organisms of several bird diseases. These results can also lead to understanding the inter-relationship between the bird, nesting material and fungi within the nest. The results also provide information on additional source of thermotolerant fungi.

P0003

Freshwater diatoms diversity of National Parks in Nigeria I: Okomu National Park, South-South, Nigeria.

Taofikat Adesalu

University of Lagos

This study represents the first taxonomic and ecological description of the diatom flora of water and sediments in two freshwater lakes within Okomu National Park Edo State, Nigeria, using light and scanning electron microscopy (SEM). Twenty-nine species of diatoms belonging to fifteen genera, *Achnanthes*, *Achnanthidium, Chamaepinnularia, Cymbella, Discotella, Eolimna, Eunotia, Frustulia, Gomphonema, Luticola, Nitzschia, Pinnularia, Placoneis Sellaphora* and *Stauroneis* were identified.The taxa were dominated by *Eunotia* spp. Water chemistry of 5.9-6.3 pH and surface water temperature of 28^{o}C probably implies that the diatoms especially *Eunotia* spp. are exploring an ecological niche that is probably favourable for its growth. Okomu National Park appears to be a hotspot for *Eunotia* species diversity, and further study of the oligotrophic waters of this site is certainly recommended.

Incidence of *Hydnora abysinnica* A. Braun in Nigeria: First report

Otuwose E. Agyeno[1], *Emmanuel I. Aigbokhan*[2], *Adeniyi A. Jayeola*[3], *Emmanuel B. Elisha*[1], *Christiana J. Dawurung*[4], *Yilnya J. Gosomji*[5], *Oluwatobi A. Oso*[3]
1. Department of Plant Science and Technology, Faculty of Natural Sciences, University of Jos, Nigeria
2. Department of Plant Biology and Biotechnology, Faculty of Life Sciences, University of Benin, Nigeria
3. Department of Botany, Faculty of Sciences, University of Ibadan, Nigeria
4. Department of Physiology, Pharmcology & Biochemistry, Faculty of Veterinary Medicine, University of Jos, Nigeria
5. Behind LGEA Primary School, Nekong, Kanke LGA, Plateau State, Nigeria

Hydnora species (Hydnoraceae) are endemic to Africa and until now literature accounts show that their distributions occur only within the Sudano-Zambezian region of Africa. We report here the occurrence of several stands of *Hydnora abyssinica* A. Braun (syn. *Hydnora johannis* Becc.) in Nekong, Wusali ward, a lowland Sudan savanna area in Kanke Local Government Area, Plateau State, Nigeria. It was found in association with the following potential host plant species: *Acacia hockii* De Wild*, Piliostigma thonningii* (Schum.) Milne-Redh., *Acacia seyal* Del., *Boswelia dalzielii* Hutch., *Anogeissus leiocarpus* (DC) Guill. & Perr., *Zizyphus mauritiana* Lam., *Tamarindus indica* L. and *Annona senegalensis* Pers. This represents the first recorded occurrence of any *Hydnora* species in the Guineo-Congolian region which when combined with its well-known Sudano-Zambezian existence, enlarges and establishes its distribution range as an Afrotropical endemic.

The impact of treated waste water at Khartoum Refinery on plants diversity

Salma Alamin
Environment, Natural Rrsources and Desretification Instittute

Khartoum Refinery (KR) is located north of Khartoum State. This work aims to assess the impact of treated water from KR on plant diversity. Twelve field trips were carried out to cover dry and wet seasons. the study area was divided into control site (merely received rain water) and treated one (received rainwater and treated water). In KR, the treated area was subdivided into four units planted with *Eucalyptus camaldulensis* (Ban) based on age of plantation (6,4, 2 years and 2 weeks). Plant specimens were collected, pressed, dried, identified, mounted according to the standard methods and then incorporated in the herbarium. Scientific names were updated from the website of the international plant list version 1.1. Measurement of plant diversity was carried out using the quadrate method (1×1 m) for ground flora. Percentages of the following parameters were calculated: plant frequency, ground cover, bare soil, plant litter, stone and gravel, and plant dominant species. For trees and shrub cover the number of plants was counted in 50 m^2 areas to determine the dominant species. Statistical analysis of data was carried out by statistix 9 program. Sixteen plant species belonging to nine families were recorded in Khartoum refinery. Percentage means of plant ground cover was high in the rainy season compared to the dry season, bare soil was high in both rainy and dry seasons, plant litter was low in the rainy season and high in the dry season; rock was low in both rainy and dry seasons; plant diversity was high in the rainy season and it was low in the dry season. The dominant herbaceous species in the control site was *Aristida adscensionis* while the dominant tree is *Acacia tortilis* ssp. *spirocarpa.* In the treated site, also *Aristida adscensionis* (except for 6 years plantation) and *Acacia tortilis* ssp. *spirocarp* were dominant associated with *A. seyal, Fagonia cretica, Senna alexandrina*, *Corchours depressu, Panicum turigdum*, and *Chloris virgata.* This study concludes that treated water has indeed effect the biodiversity since many plant species growing and dominating the treated area and not observed in the control area. On the other hand this was prominent from disappearance of *Aristida adscensionis* (Gao) in treated area of six years old *Eucalyptus camaldulensis*. The study recommended periodic monitoring of vegetation.

Digitization of Mississippi Herbarium specimens aids in understanding plant diversity in the southeastern U.S.A.and improves K-12 education

Lisa Wallace[1], *Mahboubeh Hosseinalizadehnobarinezhad*[1], ***Mac Alford***[2], *Nina Baghai-Riding*[3], *Megan Fedrick*[4], *Lucile Mccook*[5], *Heather Sullivan*[4]
1. Mississippi State University
2. University of Southern Mississippi
3. Delta State University
4. Mississippi Museum of Natural Science
5. University of Mississippi

The southeastern United States is well known for high levels of plant diversity, but availability of natural history collections and associated resources documenting this diversity has been limited for some areas. For example, no flora has been published for the state of Mississippi, and a checklist produced more than 15 years ago was not based on an exhaustive review of herbarium specimens across the state. Missing data, such as these, result in an incomplete inventory of biodiversity for the Southeast and can impact inferences about ecological drivers of biodiversity. A collaboration of six of Mississippi's herbaria has worked to make available the content of Mississippi herbaria through active digitization of more than 200,000 specimen sheets and determination of georeferenced locales. Here, we present an update of these efforts. Specimen data from this project are available through the SERNEC Symbiota project (www.sernecportal.org). We have contributed >207,700 specimen images, skeletal or detailed label information for >310,700 records, and georeferenced locales for >58,500 specimens. The majority of specimens in this dataset were collected in Mississippi or elsewhere in the Southeast. Additionally, some collections contain multiple records from a single locale, which may permit in-depth examination of plant community structure on a local scale. As an example of how this dataset improves on existing resources on plant diversity for the state, we conducted a comparison of species diversity in Cyperaceae (excluding *Carex*) based on specimen records in Mississippi herbaria, Flora of North America, USDA Plants, BONAP, and Flora of the Southern and Mid-Atlantic States. In total, 266 species collected in Mississippi were found in herbarium records, compared to

184–229 species recorded for Mississippi in the other resources. Some of these differences are accounted for by synonyms, but some species were simply not included for Mississippi in these references. Use of the specimens in this manner is aiding in completion of an updated checklist of plants for Mississippi. Through a partnership with the Mississippi Museum of Natural Science, we have also developed a number of outreach projects, including a plant-themed workshop for K–12 teachers and plant ID cards showcasing notable species around Mississippi. We have also been active in using the specimen database in classes we teach at our respective institutions. We welcome use of the specimen data and images in the SERNEC portal and invite experts to contribute to on-going curation of the collections.

Biodiversity situation in Palestine—West Bank

Banan Alsheikh
National Agricultural Research Center

Palestine is situated in South West Asia in the east of the Mediterranean basin, where the Mediterranean Basin is the third richest hotspot in the world in terms of its plant diversity. Palestine (27,000 square km) extends from the Jordan River and Wadi Arava in the east to the gulf of Aqaba in the south, to the Mediterranean Sea in the west and the Sinai desert in the south west and Lebanon in the north. Palestine is home of 2,600 vascular plant species, while West Bank (5,856 square km) has 1,600 vascular plant species, tremendously high plant diversity for such a small area; it has four phytogeographical regions delineated in this region. These are: Mediterranean, Irano-Turanian, Saharo-Arabian and Sudanian. However, Sudanian elements do not occupy a discrete phytogeographic region in the area but constitute scattered outposts of penetration within Jordan valley. Palestine has a unique dramatically climatic gradient in the Mediterranean Basin. In a distance of 25 km, elevation drops from 914 m above sea level in Jerusalem to -420 m (below sea level) in the Dead Sea shore, i.e. 1,334 meter depth in 25 km distance from Jerusalem to the Dead Sea shore, while mean annual rainfall drops from 540 mm to less than 60 mm. The richness of Palestine in biodiversity is due to its situation as a meeting point between Asia and Africa, wealth of many habitats as a result of climatic transition from Mediterranean in the north to extreme desert in the south, Jordan Rift Valley in the east, different rock types, soil types, long period of human influence. A trading passage between Asia, Africa and Europe, long history of cultivation and grazing which enabled the introduction of many alien species. West Bank has around 500 rare species, some are globally threatened like *Iris lortetii* and *Iris haynei*. Many are on the way of extinction like *Ajuga orientalis, Amgdalus Arabica*. Some extinct in the West Bank like *Avena fatua, Salvia bracteata*. Now we are facing a wave of rapid rate of extinction which is a calm process. What is threatening biodiversity in West Bank? Heavy anthropogenic effects by Palestinians and a long period of continuous implementation of destructive measures by the Israeli occupation like confiscation of land for settlements (establishment of seven settlements in Wadi Qana Nature Reserve), military purposes, bypass roads, over abstraction of ground water, separation wall, urbanization, infrastructure, intensive agriculture, chemical fertilizers, pesticides, heavy grazing, reduced habitat quality, overharvesting of medicinal plants, fire and land reclamation.

Indigenous edible ferns in southern Philippines: Utilization and conservation

Victor Amoroso[1], *Rainear Mendez*[1], *Reggie Dela Cruz*[1], *Fulgent Coritico*[1], *Annabelle Villalobos*[2]
1. Central Mindanao University
2. Consultant, Johnson & Johnson (USA) and DOST Balik Scientist

The high incidence of cancer, atherosclerosis, and other degenerative diseases among Filipinos seem to be due to environmental pollutants and to the type of food we eat. Ferns in the Philippines had been used by native people as food, tea and medicine for a long time. We then conducted a study to survey the species of edible ferns in southern Philippines, determine bioactives and proteins in ferns to demonstrate their health and wellness benefits, and conduct *ex situ* conservation. Field and ethnobotanical survey revealed ten species of indigenous edible ferns. These were studied in terms of protein content by the Bradford assay, antioxidant activity by the DPPH assay and relative component proteins by SDS-PAGE. These 10 species of ferns contain quantifiable amounts of antioxidants and proteins. Based on these data, ease in propagation, availability and palatability, six species are chosen as potential alternative food source. These species are *Diplazium esculentum, Marsilea crenata, Stenochlaena palustris, Acrostichum aureum, Angiopteris palmiformis* and *Asplenium nidus*. Laboratory tests showed protein content by the Bradford assay ranging from 0.08 to 4.39 mg/g and antioxidant activity by the DPPH assay as high as 83% that of ascorbic acid or at 143 to 588 ORAC units/g. *Marsilea crenata* gave the highest protein content as well as antioxidant activity. From these 10 edible species, 27 gourmet fern recipes were prepared by the participants during the gourmet cooking contest and evaluated by a sensory panel. We prepared brochures for the propagation of these fern species to educate the public of the health and wellness benefits of ferns in the diet. We held trainings and seminars, which were participated by farmers and local government units. The aim was to share and spread the findings and practices so many Filipinos would benefit from including these species of edible ferns in their food. To conserve these edible ferns, a university fernery was established for mass propagation and as part of the *ex situ* conservation. Moreover, members of the Balinsasayao people's organization were trained on how to identify, utilize and propagate these species of ferns and to establish their own fernery as an income generating project.

Restoration of Merapi Volcano National Park, Indonesia after the eruption in 2010 using Coconut Fiber Bag and Cocopeat Diamond Method

Sulfiantono Arif
Merapi Volcano National Park, Ministry of Environmental & Forestry

Ecosystem restoration is an important activities to restore ecological services of Merapi Volcano National Park (MVNP) post eruption in 2010. The eruption impacted to the destruction of local people residents, vegetation, water systems and the loss of endemic species. Restoration activities were started through an assesment of the eruption impact to local people, vegetation habitat, wildlife, natural succession and invasive alien species. Some technical approaches such as vegetation analysis, endemic species identification and local people participation. This study aims to determine the efficiency of the technique of planting by seed directly in the area of restoration. The method chosen is growing methods are fast, cheap and produce plants that can grow and live in areas where conditions are extreme. In this study, using methods of planting with Coconut Fiber Bag and Cocopeat Diamond and tested at 8 native species of Merapi Volcano. In the test of Coconut Fiber Bag's method for 600 units per hectare shows Bawangan seed (*Dysoxylum densiflorum*) growing well. While in the test of Cocopeat Diamond's method for 594 units per hectare shows 240 units found Cocopeat Diamond have germinated (a success rate of 57%). The type most widely germinate are Cangkring (*Erythrina fusca*) and Tesek (*Dodonaea viscosa*). These tests also involves the local people to raise awareness of the importance of the region MVNP as a provider of environmental services.

Air Pollution Tolerance Index (APTI) and dust capturing potential of few selected angiosperms of industrial belt in West Bengal, India for environmental optimization

Swastika Banerjee, *Sumita Mondal, Moumita Das, Abhijit Bandyopadhyay*
The University of Burdwan

Bio monitoring studies are extremely relevant in the field of air pollution science in relation to urban ecosystem restoration. On the onset of this the present study was undertaken to evaluate the air pollution tolerance index and dust capturing potential of 16 angiosperms from industrial area (Burnpur, IISCO) of West Bengal, India. While determining the APTI values, chlorophyll content was found to ranges from 0.1050 mg/g (*Butea monosperma*) to 0.5083 mg/g (*Cassia fistula*), relative water content from 35.68% (*Clerodendrum indicum*) to 93.02% (*Leonotis nepatifolia*); ascorbic acid from 182.432 mg/L (*Pongamia pinnata*) to 1140.541 mg/L (*Swietenia mahagoni*) and leaf pH from 5.00 (*Cassia siamea*) to 7.83 (*Ficus benghalensis*). APTI values ranged from 116.326 (*Cassia siamea*) to 814.855 (*Swietenia mahagoni*), thus indicating all selected species to be highly tolerant to air pollution, hence suitable for greening parks and gardens in polluted areas. Highest dust deposition was found in *Ficus benghalensis* (0.00574 g $cm^{-2}$and lowest in *Eucalyptus globulus* (0.00030 g cm^{-2}) at study site. The present study has suggestions for attenuating and reducing adverse health impacts from constant exposure to air pollutants and also providing regulating ecosystem services thereby modifying the local urban ecology.

Production, dispersal and predation of diaspores of *Euterpe edulis* Mart. (Arecaceae): Evaluation of natural regeneration in the Atlantic Forest, Brazil

Hector Barros Gomes, *Bruno Takami Fujiwara, Eliana Akie Simabukuro*
University of São Carlos

The regeneration of plants consists on a number of processes that regulates the structure and the distribution of species in vegetation. The study of recruitment of individuals in natural populations is a challenge in landscapes with high environmental heterogeneity, common in tropical forests. In this regard, a study was conducted in a remaining area of the Atlantic Forest in southeastern of Brazil, to evaluate the effect of producing, seed rain and germination of diaspores and the role biotic dispersers on the natural regeneration of *Euterpe edulis* Martius (Arecaceae). The study was conducted in three areas of Atlantic Forest with different densities of seedling stages of *Euterpe edulis* (H- High density; M-medium density L - low density). In a previous survey it was determined that seedling density in the areas was 1.58 (HD), 1.08 (MD) and 0.46 (LD) individual/m^2. The production diaspores presented low synchronism in the three areas (20-60% of trees) and low intensity of fruiting. The area with high density of seedlings (HD), had high production of mature diaspores distributed throughout the year. Low synchrony results in diaspore over a longer period, increasing the possibility of seedling establishment. The amount of propagules in diaspores rain did not vary between locations. However the HD area presented the diaspores with larger diameter and integrity. There was reduced dispersion of the diaspores at long distance, with few records in the distant collectors of the parental plant, characteristic of the species, known to form a seedlings bank next to adult individuals and an aggregate distribution pattern. The removal was higher for the control treatment and permeable exclusion (small mammals access). And the removal of diaspores was higher in MD and smaller in HD, corroborating the information that invertebrates would not be dispersers of *E. edulis*. The seedlings of *E. edulis* had higher mortality at the HD, in amounts of 20% when native and less than 10% when planted. Germination above and under the litter was higher than diaspores buried in all areas. The results indicate that there is variation in the production, availability of diaspore and microscale removal between areas of different seedlings densities, as factors that act synergistically in keeping the conservation of population in natural areas.

Literature mining on Dipterocarps: Towards better informed regeneration and reforestation in the Philippines

Roselyn Gabud[1,2], *Riza Batista-Navarro*[3], *Vladimir Mariano*[4], *Eduardo Mendoza*[5], *Sandra Yap*[6]
1. Institute of Computer Science, University of the Philippines Los Baños
2. Department of Computer Science, University of the Philippines Diliman
3. School of Computer Science, University of Manchester
4. Centre of Technology, RMIT University
5. Max Planck Institute of Biochemistry
6. Far Eastern University

Access to comprehensive information is critical in Natural Resource Management (NRM). The decision-making process of regulators on conservation policies, for example, is largely shaped by information resources at their disposal. Significant barriers could however present themselves at any point along the NRM information supply pipeline. In this respect, managing the natural regeneration and reforestation of lowland dipterocarp forests in the Philippines is no exception. Dipterocarps are the medium to large forest trees belonging to the tropical plant family Dipterocarpaceae, which are the dominant species and the skeletal backbone of lowland tropical rainforests. About 65 species in six genera have been recorded in the Philippines, and more than 65% are endemic. They are economically and ecologically important: the primary source of timber, the home of Philippine eagle and other wildlife, the stronghold that regulates water releases from the uplands, and a major contributor to ecological and climatic balance. Once the primary base for the logging industry in the Philippines, the dipterocarps have been heavily exploited that the government has begun conservation, protection and reforestation initiatives. The supra-annual mass flowering of dipterocarps occur in irregular intervals of two to ten years, possibly synchronously across Asia. Predicting the likelihood of their regeneration, to subsequently make plans regarding species for reforestation, is thus an extremely complex task. While regeneration patterns could potentially be derived from historical data and inform NRM policy-makers in the implementation of reforestation policies, access to complete and comprehensive information is currently hindered by: (a) failure to maintain data collected over long-term periods, due to interruptions brought about by short-term funding and political cycles; and (b) decentralized data collection resulting in largely fragmented information which come in a variety of formats. In order to fill in the information gaps, we propose to exploit published literature on dipterocarps by means of text mining: the automatic process of extracting structured information from documents written in natural language, e.g., scientific publications, books and agency reports. As a step towards capturing occurrence information from the literature, we have developed a schema for annotating taxon names, geographic locations, dates, habitat descriptions, authorities, and names of herbaria (in the case of collected specimens). Also covered is the annotation of any specimen's reproductive state which will enable the derivation of phenology and masting patterns. We present results based on two domain experts' manual annotation of a document collection which currently contains: (a) documents from the Biodiversity Heritage Library (BHL); (b) agency reports from the Philippines' Department of Environment and Natural Resources (DENR), and (c) article sections from various online journals. The resulting labelled corpus will form the basis of the text mining tools that we will develop as part our next steps, which will ultimately provide NRM policy-makers with a searchable database containing literature-derived information on the distribution and mass flowering of Philippine dipterocarps. In turn, this will help inform their efforts for dipterocarp species regeneration and reforestation.

Floristic richness in Mulshi watershade catchment area, Northern Western Ghats (NWG), India

Rani Bhagat
PDEA'S Anantrao Pawar College, Pirangut, Tal-Mulshi, Dist-Pune 412115, Maharashtra, India

The Western Ghats (WG) are one of the globally recognized "hot spots" of biodiversity and are a UNESCO World Heritage Site in India. Physiography and climate of the Northern Western Ghats (NWG) support tropical semi evergreen to moist deciduous type of forest vegetation with immense global significance for conservation of biodiversity. Biogeographically the study area comes under Sahyadri ranges and spans varied ecological regions from crestline of Western Ghats, hill ranges and gently sloping part bordering the Deccan Plateau, thus supporting diverse plant communities. Due to high rainfall, processes of soil formation are relatively faster than low rainfall areas on plains, though happening at geological time scale. All these special physical features have formed unique habitats supporting endemic biodiversity. With the backdrop of fragile ecosystems, this biodiversity happens to be extremely essential and valuable. The study area selected is centrally located in NWG at 18°25' N to 18°41' N and 73°20' E to 73°25' E, which covers 240 sq. km from Mulshi tehsil of Pune district, Maharashtra. Extensive field surveys in region reported 1,404 flowering plants species from 774 genera and 154 families from diverse habitats. Number of species belonging to dicotyledones were 1,067 and 337 from monocotyledones, of which 142 species are found to be endemic. Also 40 sacred groves were also reported during the study. In Mulshi region, existing data of plant species is scanty and limited to only representative localities. The state government has declared one wild life sanctuary in Mulshi i.e. Tamhini in year 2013. The important water catchment includes- Mulshi Dam, Temghar and Varasgaon Dam and Pawana Dam in adjoining area. A private planned cities like Lavasa, Sahara and Amby valley lies in the study region. Further, more hill cities are proposed in various parts of Mulshi region threatening rich biodiversity of region. With this background the documentation of floristic diversity was carried out for future management of ecosystem.

Rapid digitization of herbarium specimen

Jeroen Bloothoofd
Picturae

Picturae has digitized nearly 10 Million herbarium sheets since 2013 and at the moment we have 4 active herbarium digitization projects in the world knowing: Montpellier-France, Washington-US, Meise-Belgium and Geneva-Switzerland. Imaging of herbarium sheets and transcription of herbarium labels has always been a time consuming and costly task with varying results in quality. The objectives was to find a way to make the process of herbarium digitization fast and economical but also safe and reliable. Picturae has proven in the last three years that rapid digitization of herbarium specimen is possible by digitizing almost 10 million individual herbarium sheets that were all validated in quality, all accounted for and all safely returned to the archives. Picturae has developed a conveyor belt system to image the sheets and software and protocols to transcribe the label in close collaboration with Naturalis (Leiden), The Natural History Museum (London) and the Smithsonian National Museum of Natural

History (Washington). With millions of new specimen available in full visual detail and searchable on full label information new discoveries are made in existing collections every day. Less loans are processed and the loans are more accurate. Collections are far better accessible and Big Data analysis gives many new research possibilities. It is very well possible to digitize the vast herbarium collections of the world in our lifetime. And this is just the beginning as we are convinced we can do the same for the other natural history collections that are hidden from the world.

Phytochemical investigations of *Atraphaxis spinosa* L. (Polygonaceae)

Xinhui Wang, *Robert Borris*

School of Pharmaceutical Science and Technology, Tianjin University, Tianjin, China

The genus *Atraphaxis* L. (Polygonaceae), comprises approximately 25 species of shrubs distributed particularly in North Africa, southwestern Europe and Asia. China has 11 species, including *Atraphaxis spinosa* L. which can be found in Xinjiang, in Northwest China. Previous phytochemical investigations have shown that *Atraphaxis* L. species are a rich source of phenolic and polyphenolic compounds. The major constituents of the *A. spinosa* are flavonoids and flavonoid glycosides. The limited nature of the known phytochemical constituents from this genus makes it an attractive target for further investigation. In the present work, a number of flavonoids, flavonoid glycosides, isoflavones, flavanols, phenylpropanoid amides, fatty acids, monoterpenes and acylphloroglucinol glucosides were isolated from the methanol extract of a sample of the entire plant of *A. spinosa* from the Republic of Georgia. The structures were elucidated by 1D and 2D homonuclear and heteronuclear NMR spectroscopy and by comparison with closely related compounds published previously.

Is Hengduan Mountains really a biodiversity hotspot?

Hongyu Cai[1], *Nawal Shrestha*[1], *Xiaoting Xu*[2], *Zhiheng Wang*[1]

1. Peking University, Beijing, China

2. Sichuan University, Chengdu, China

Phylogenetic diversity can show the relatedness of species, which can to some extent, reflect the evolutionary history. It is also important in identifying the biodiversity hotspots for conservation priorities. In this study, by showing the patterns of Faith's phylogenetic diversity for 11,163 woody plants in China and correcting the results by a null model approach with different sizes of species pools, we demonstrated that Hengduan Mountains is not a biodiversity hotspot at least on the basis of phylogenetic diversity, which is quite different from previous studies. Despite high species richness, the species in Hengduan Mountains are phylogenetically close to each other. In contrast, Southwest China contains both high species richness and phylogenetic diversity, which highlights the importance of biodiversity conservation in facing the uncertain future.

Orchid flora in Amapá: Situation and prospect

Patrick Cantuária

Instituto de Pesquisas Científicas e Tecnológicas do Estado do Amapá

The Orchidaceae Family is considered, by various authors, as one of the largest plant families in number of species. The orchids are distributed throughout the planet, with the exception of the polar regions and and desert, with greater diversity in tropical and subtropical regions. The present work aimed to raise the species of family Orchidaceae in the State of Amapá, contributing to the knowledge of the group to the Amazon and, consequently, to Brazil. For the organization of work, were carried out 9 inventories in unknown areas in Amapá, between 2013 and 2016 and consult in the herbaria: AMES, B, BBS, CAY, CEN, CPAP, F, GH, HAMAB, HB, HBRA, HRB, HUEFS, IAC, IAN, INPA, K, L, MG, MICH, MO, NY, P, R, RB, SP, SPF, U, UB, UC, UFP, US. And data from all the geographic coordinates were treated for establishment of the pattern of distribution of Orchidaceae in Amapá. And were still made and synopses of habit and illustrations of important morphological characteristics in the characterization of the species. Were recorded 277 species and 90 genera, being 60 new occurrences for the Amapá, as well as a map showing the distribution pattern of orchids in the State of Amapá in Brazil. We noted three major centers of diversity: Guaiana Plateau, savanna transition-coastal zone and Valley of the Jari. Although many species have increased considerably, there is a need for surveying new areas not yet known.

Vast amount of *Bletilla striata* (Orchidaceae) seeds cultured in liquid media and seedling establishment in the field quickly

Xiao-Yong Cao, *Huan-Ge Song, Xuan-Ping Hu, Gong-Wei Qin, Yi-Song Zou*

Shaanxi University of Technology, School of Biological Science and Engineering, Shaanxi Key Laboratory of Bio-Resources, Hanzhong 723000, China

Bletilla striata is a type of Chinese traditional herb and its pseudobulbs were used for medicinal purpose. Because its habitat fragmentation and over collection, it is an endangered species under current situation and artificial reproduction is the sustainable way to satisfy the healthcare and medical demands. Currently, there are three different ways for its reproduction: 1. vegetative reproduction (division); cut the pseudobulbs apart and each piece has one or more growing points; disadvantage: low efficiency and accumulation of viral infections over time; 2. sowing seeds in the ground; disadvantage: the result is unstable; necessitates a long time careful management approach to watering and ventilation in protected culture systems before root formation (3 months after sowing) and plantlets are vulnerable to infections; 3. asymbiotic germination; disadvantage: high cost and low efficiency; solidified agar media (expensive ingredient), higher labor cost, pseudobulbs formation will take 3 months, a small number of seedlings cause high density in a glass flask. The seeds sowing in MS liquid media under light developed into a protocorm with its diameter nearly 1.6mm in 60 days, the protocorms were placed on peat directly and the seedlings established in a short term. Based on this method, we have developed a rapid propagation protocol and apply for a patent. Green capsules were rinsed with ethanol 70% (V/V %) for one minute and 1% mercuric chloride solution for 15 minutes, and then washed with sterile distilled water 3 times. The disinfected capsule was cut and released its content (about 10,000 seeds) to 250 ml glass media bottle containing 200 ml MS medium with 3% w/v table sugar. The bottles were kept statically in a temperature-controlled growth room at 25^{o}C with illumination provided by cool white fluorescent tube at a fluency rate of 2000 Lux and a 16-h/8-h light/dark photoperiod. The frequency of seed germination is high, reached more than 95%, and the seeds become swollen in three days, the embryos become green and testa rupture in fifteen days, rhizoid and leaf primordia formed in twenty days; the protocorm grow at average speed of 26 g/d in 60 days, and the weight of protocorm attained to 1.6mg (FW) and its diameter is about 1.6 mm. The protocorms were taken off from bottles and wash it with tap water, packed up with cotton gauze and remove water with spin-dry machine. The protocorms in loose state can be scattered on peat medium (thickness: ~1 cm) evenly and possesses a higher resistance to desiccation. Temperature, humidity, shading and ventilation should be controlled in protected culture systems (cloches or cold frames, polyhouse). The leaf of protocorm grows and elongates immediately and roots appeared within 20 – 40 days with 2 – 3 leaf blades (~1 cm long). After 3 – 7 month planting, the seedlings form small pseudobulbs (diameter: 0.5 - 1 cm) at its base and these pseudobulbs may used for sale or field planting.

P0020
The historical plant specimens collected from Korea by French missionaries, Faurie, Urbain Jean and Taquet, Emile Joseph

Kae Sun Chang[1], *Kyung Choi*[1], *Chin-Sung Chang*[2]
1. Korea National Herbarium, National Arboretum
2. T.B.Lee Herbarium, Department of Forest Sciences and The Arboretum, Seoul National University

Faurie, Urbain Jean (1877-1915) and Taquet, Emile Joseph (1873-1952) were missionaries for Missions Etrangeres de Paris (Foreigh Missions of Paris). Faurie and Taquet collected plant specimens of Korea from 1901 to 1912 and sent them to herbaria mainly in Europe and Japan. They made a great input to the understanding of flora of Korea at the primary stage of its exploration. Those specimens were studed by Leveille, Augustin Abel Hector (1864-1918), who was a French botanist and clergyman, Nakai, Takenoshin (1882-1952), who was taxonomist of Tokyo University, and other Japanese and European Taxonomists. Faurie arrived in Niigata, Japan in 1874. During his stay in Niigata, he has got a request for collecting Japanese plants from French botanist Adrien Franchet (1834-1900) of Museum National D'Histoire Naturelle at Paris (P). Over 40 years, until his death on July 4,1915 in Taiwan, he continued making botanical collections mainly from Japanese archipelago, as well as occasionally his journey East Asia expended southwards to Taiwan, through Korea, and northwards to Sakhalin and Kurile Islands. He visited Korea in 1901,1906, and 1907. The main localities visited were Seoul, Busan, Jinnampo and Wonsan of Hamgyeongnam-do, Mt. Geumgangsan of Kangwon-do, and Jeju-do. In 1907, he visited Jeju-do and collected specimens with Taquet. During his explorations, Faurie collected numerous specimens of Poaceae and Cyperaceae. Based on Faurie's specimens that are deposited at KYO, P, TI and *etc.*, we may suggest that no less than 4,800 plant specimens from Korea. Taquet arrived in Korea in 1898. Based in Mokpo, Korea, he was responsible for missionary work on many islands around the south-western peninsula of the country. He was in Jeju-do from 1902-1915 and collected specimens from 1907-1912. Based on his specimens deposited at E. KYO, TI, A, and K, he collected more than 6,000 specimens of *ca*. 1,600 taxa mainly from Jeju-do. More than 2,500 specimens are deposited in E, because Leveille is an important botanist to examine his specimens. While there are few his Cyperaceae specimens in E, 323 among 378 specimens are Cyperaceae in P.

Hawaiian seed storage behavior: A case study for tropical native flora

Marian Chau[1], *Timothy Kroessig*[1], *Lauren Weisenberger*[2], *Matthew Keir*[3]
1. Lyon Arboretum - University of Hawaii
2. U.S. Fish and Wildlife Service
3. Laukahi Hawaii Plant Conservation Network

The Lyon Arboretum Seed Conservation Laboratory and the O'ahu Army Natural Resources Program conduct research to determine germination, propagation, and long-term storage protocols for some of Hawaii's rarest native plant species. The seed banks aim to create viable *ex situ* collections to preserve genetic representation of each species and to provide propagules for recovery efforts. Over the last two decades, the seed banks have gathered data from 68 angiosperm families and from taxa representing over 25% of the Hawaiian flora. Seed storage behavior has been classified into two major categories; desiccation-tolerant (which includes species that are orthodox and storable long-term, but also those that are short-lived or sensitive to freezing) and desiccation-sensitive (recalcitrant, not storable by conventional seed banking). Data are available for 303 taxa, and storage classifications have been estimated for another 506 taxa. Approximately 96% of the 809 taxa studied have desiccation-tolerant seeds, representing 55 families. This proportion is higher than the worldwide estimate that 80% of species have desiccation-tolerant seeds. These data support the hypothesis that long-distance dispersal selects against species with desiccation-sensitive seeds. However, another 25% of Hawaiian taxa were either short-lived or freeze-sensitive; therefore a third of taxa investigated cannot be conventionally banked for long-term storage. A high incidence of intermediate seed storage behavior is not known in other regional flora and may be informative for tropical areas. Current and future research efforts of the Hawaii Seed Bank Partnership focus on developing protocols for species in these categories, and expanding our knowledge of other native species' seed storage behavior.

Information technologies supported citizen science approach for plant diversity survey

Bin Chen[1], *Jianping Chen*[1], *Keping Ma*[2]
1. Shanghai Chenshan Botanical Garden, Shanghai, China
2. Institute of Botany, Chinese Academy of Sciences, Beijing, China

Plant species occurrence data are the basis information to map and to monitor the change of plant diversity. Herbarium specimens collected from field surveys are the most important reliable data source of species occurrence. Although there are millions of specimens collection records digitized and shared online, if we look into a certain area, we always encountered with data deficiency of plant distribution information. The high cost and low efficient of traditional specimens collection make it impossible to dramatically increase the data volume in future. With the evolution of information technologies, since from 2006, we have adopted “digital specimens” concept that use digital photography as vouchers of species occurrence. To make this concept practical and efficient in field plant survey, we developed new technologies for field work and data management, including field work designing with Google Earth, field navigating with OruxMaps, digital photography, collecting specimens with digital photography, barcode label and GPS tracklogs recording, online data management with the Chinese Field Herbarium (CFH) platform. On CFH website, users can easily deposit their field survey datasets online, help each other to identify species, reorganized the datasets by classification trees, map the occurrence data on Google Earth and get automatically updated checklists. These technologies are useful for amateurs, researchers and any other people who are interested with plants. Then the CFH users work together and form into an information technologies supported citizen science to survey, identify and study plant diversity. As the result, now there are more than 14,000 users and 8 millions of digital photos on the websites, covering more than 40,000 species, including 20,000 Chinese native plant species in which more than 13,000 species have precise geographic coordinates. According these data, at least 3 new species are described and hundreds of provincial new distributions are observed and thousands of living plant populations are geo-referenced. CFH become one of the largest data centers of original plant occurrence of living plants in the world. In future, we will continue to use more technologies to facilitate plant field surveys, such as artificial intelligence technologies based auto-identification of species from digital photos.

The effects of environmental stress on sesquiterpenoids accumulation in *Atractylodes lancea* (thunb.) DC. plantlet and mechanism investigation

Fei Chen, *Chuan-Chao Dai*
Nanjing Normal University

Atractylodes lancea (Thunb.) DC. is an endangered traditional Chinese medicinal herb with broad pharmacological activity, reflected by an abundance of sesquiterpenoids. Although the main active components of *A. lancea* have been clarified, there are still several problems existing. On the one hand, the resources of wild *A. lancea* have decreased sharply. On the other hand, the artificial cultivation of *A. lancea* is difficult and the active components of cultured *A. lancea* are different from those of wild ones. Therefore, the regulations of active component have showed a plateau phenomenon. Compared to other species, *A. lancea* originated in the Maoshan region of Jiangsu province where it is the most representative subspecies. In this study, we studied the effects of three kinds of environmental stress of high temperature, drought and microbiological factors on different growth periods of *A. lancea* sterile tissue culture plantlet from Maoshan. The accumulation patterns of tissue-specific sesquiterpenoids in different environmental stress factors were found to be very different. In order to reveal the regulation mechanism of environmental stress in the sesquiterpenoids of *A. lancea*, we first discussed the relationship between stress factors and plant growth from the physiological and biochemical aspects of plants. Then we studied the relationship between stress factors and sesquiterpenoids accumulation from the perspective of differentially expressed genes based on the data of transcriptome analysis (RNA-Seq). Finally, we further validate the key proteins that are susceptible to biotic and abiotic stress regulation at the proteomic level. In this study, we systematically investigated sesquiterpenoid distribution and regulation mechanism in different environmental stress factors of sterile tissue culture plantlets of *A. lancea* via metabolite quantitative, plant physiological and biochemical analysis, and omics technologies. This study provides a central theoretical basis for the manipulation of sesquiterpenoid biosynthesis in *A. lancea*.

Reinvestigation on processing chemistry of ginseng: Steaming qualitatively and quantitatively changes ginsenosides and carbohydrates by chemical and physical transformation

Shan-Shan Zhou[1,2], *Jun Xu*[1], *Song-Lin Li*[2], *Hu-Biao Chen*[1]
1. Hong Kong Baptist University
2. Hospital of Integrated Traditional Chinese and Western Medicine Affiliated to Nanjing University of Chinese Medicine

The processing chemistry of red ginseng (RG), a ginseng product processed by water-steaming, has been examined, but the relevant studies only focused on ginsenosides in ginseng materials. However, carbohydrates and ginsenosides in ginseng are both important bioactive components. Here we reinvestigated the processing chemistry of RG by simultaneously qualitatively and quantitatively analyzed ginsenosides and carbohydrates (total polysaccharides, oligosaccharides and monosaccharides) in both ginseng materials and steaming liquid. The experimental results revealed that the contents of investigated chemicals in the processed RG were simultaneously and differently altered along with the increment of steaming time. Moreover, the steaming-produced distillate transferred the RG components into the steaming liquid, therefore resulting in the chemical loss of processed ginseng materials. The potential chemical and physical transformation mechanisms involved in the quantitative variation of multiple components were proposed and discussed, i.e. the deglycosylation and dehydration of ginsenosides, the changed water solubility and polymerization degree of polysaccharides, the hydrolysis of polysaccharides and oligosaccharides, the dehydration of monosaccharides, Maillard reaction. The study improved the research on processing chemistry of ginseng, and therefore should be instrumental in elucidation of the differences between RG and white (unprocessed) ginseng. With this illustrative example, we would like to highlight the research on processing chemistry of RG, and it should be helpful for elucidating basis of RG preparation and application.

Use of automatic species recognition engine of plants in studies on plant diversity and distribution

Mingquan Chen, *Tingting Yao*
Hangzhou Dana Technology Inc.

Xingse App is an automatic plant recognition engine based on deep convolutional neural networks (CNN). Now it's able to identify more than 4,000 kinds of plants, with an accuracy of 88% (top-3 classification). The recognition engine is still being optimized, and it's expected to identify 10,000 kinds of plants with an accuracy up to 90%. By internet crowdsourcing, Xingse mobile App is able to take the public's involvement in plant data collecting, and it has collected about 10 million plant pictures from millions of active users so far. The tremendous amount of pictures for plants with their spatial and temporal distribution information are very helpful for studies on the plant distribution and diversity, as well as endangered and new plant species discovering. In future, Xingse will work closely with non-profit organizations such as Chinese Field Herbarium (CFH) in environmental protection, establishing and completing the plant map of each province, building a comprehensive incentive system, and enlarging the plant database.

Pine rust fungi of phylogeography and international quarantine

Momei Chen
University of California, College of Natural Resources, Berkeley, CA, 94720.

Pine rust fungi (*Cronartium*) causes economically costly disease throughout the Northern Temperate geography region, resulting in malformation, reduced vigor, and ultimately death of pine plantation and nursery pine plants. *Cronartium* are heteroecious specific plants having coevolved with their obligate hosts. *Cronartium* have the most complicated lifecycles of the fungal taxa in the ecosystem. The geographic pattern is diverse in North America and East Asia. Chen (2006) recently identified 3 major species (available through CABI): *Cronartium ribicola* parasitized 12 white pine species, and 24 *Ribes* or *Pediculris* in the United States, Canada, China, Japan, South Korea, Pakistan, Ireland, and Switzerland; 27 pine species and 28 *Quercus* species susceptible to *Cronartium quercuum* in North America: United States, Canada and East Asia China, Japan, Korea, Russia. *Cronartium coleosporioides* is known only in USA and Canada with seven pines hosts and a number of Scrophulariaceae alternative hosts. Chen (2004) provides new evidence and theories on the famous white pine blister rust flora. It has been suggested that white pine blister rust was introduced to the US from externally source, but the lineage evidence is lacking. Factors in the invasive forest pathogens infestation and establish always resultant with unbalances ecosystem, poor plantation. Design, and lack of integrate pest management. An improved phytogeography will depends on information gathered from molecular evolutionary genetics, natural history, population biology, paleontology and speciation analysis as well as improve the control of tree rust spread and International Quarantine on tree host plants.

Species delimitation of some *Argyreia* (Convolvulaceae) using phenetic analyses based on anatomical evidence

Natthaphong Chitchak[1], *Paweena Traiperm*[1], *George Staples*[2,3], *Pantamith Rattanakrajang*[1], *Pirada Sumanon*[1]
1. Department of Plant Science, Faculty of Science, Mahidol University
2. Herbarium, Royal Botanic Gardens, Kew
3. Departamento de Biologia, Universidade Federal Rural de Pernambuco

Argyreia Lour. is one of the most taxonomically complex genera of the morning glory family (Convolvulaceae). The number of named species is now 135 and new species are regularly being described. There are several complexes of species that are morphologically similar and difficult to tell apart. Character states intergrade and overlap and the phenomenon of "mosaic evolution" is well documented in the family. Research techniques such as anatomy are required to find new characters to help discriminate cryptic species. Therefore, the aim of the present study is to explore species identification criteria for *Argyreia,* especially new sources for taxonomically informative criteria. Ten populations representing three morphologically similar *Argyreia* species were collected from their natural habitats. Plant materials were investigated using leaf peeling technique and paraffin sectioning method for anatomical characters. Anatomical character states were examined by two phenetic analyses, clustering analysis (CA) and principal component analysis (PCA). Three distinct clusters were clearly separated in both PCA and CA at the internal similarity coefficient of 0.36. Twenty-one effectively distinguishable character states were derived from the high loadings of the first two components such as the width and the length of the epidermal cells, the stomatal density, and the thickness of leaf blade. In conclusion, two separated groups were authenticated as two known species, and the third separated group has high potential to be a new species.

Aquatic and semi aquatic angiosperms diversity, palynology and their conservation from the wetlands of sub-Himalayan West Bengal, India

Monoranjan Chowdhury[1], *Anurag Chowdhury*[2], *Payel Paul*[1]
1. Taxonomy of angiosperms & Biosystematics Lab. Department of Botany, University of North Bengal, Darjeeling, West Bengal
2. West Bengal Forest Department, Aranya Bhawan, Sector III,

Salt lake cit, Kolkata-700106

Sub-Himalayan areas includes terai, duars and the plains of North Bengal are blessed with various perennial or annual fast flowing streams, rivers, rivulets are coming from the Darjeeling & Sikkim Himalayas are associated with several varied sized palustrine and lacustrine having great biological diversity. Around 436 species representing 239 genera of 72 families of aquatic and semi-aquatic angiosperms are widely growing on those water bodies. These nature wetlands are the store house of various Indian endemic species (*Rotala macrandra* Koehne, *Limnophila pulcherima* (Griffith) Hooker *f.*, *Aponogeton appendiculatus* H. Bruggen, *Aponogeton crispus* Thunberg, *Aponogeton natans* (Linnaeus) Engler & Krause, *Cryptocoryne retrospiralis* Fischer *ex* Wydler, *Crinum defixum* Ker-Gawler), exotic species (*Adenostemma suffruticosum* Gardner, *Potamogeton gramineus* Linnaeus, *Murdania keisak* (Hasskarl) Handel-Mazzetti, *Polygonum hastatogagittatum* Makino, *Ludwigia peruviana* (Linnaeus) H. Hara, *Hygrophila erecta* (N.L. Burman) Hochreutiner, *Soliva anthemifolia* (A. Jussieu) R. Brown and *Carex phacota* Spreng.) and wild relatives (*Oryza rufipogon* Griffith, *Oryza latifolia* Desvaux, *Rosa clinophylla* var. *glabra* (Lindley *ex* Prain) C. Ghora & G. Panigrahi) and a unique place for speciation. These floral rich ecosystems are the life line of wildlife's of various *in-situ* conservatories of this region. In last few years, rapid climate change badly affect on the regularity of rainfall which is crucial for the sustenance of stable wetland ecosystem and during summer dried wetlands creates the severe food scarcity for wildlife's. The Human colonies surrounding various wetlands are continuously taking various benefits including foods, medicines, irrigated water *etc.* Pollen study of 58 species of the aquatic flowering plants (6 rooted with floating leaves, 2 submerged, 2 suspended and 48 emergent species) from different wetlands were investigated and most of the grains are mostly prolate-spheroidal, spheroidal or triangular, circular, rarely prolate or elongated, tectum psilate, granulate, reticulate or echinate. On the basis of aperture types pollen grains of most families are grouped under three distinct types, namely colporate, colpate, sulcate and porate. On the other hand, pollen grains of some species e.g. *Sagittaria guayannensis* & *Eleocharis tetraquetra* are inaperturate. Regarding the evolutionary and phylogenetic point of views the polarity, symmetry, apertural types and exine sculpturing of grains are the most important characters to differentiate between the different pollen types and are extensively used in APG III & IV. Unscientific withdrawal of plants as medicine, food, fodder etc, anthropological (excessive agricultures, urban sewages, monoculture etc) and natural (climate change) threats badly effects the wetlands ecosystem in this area. Scientific conservation measure will be taken design and implement is essential steps to protect these important ecosystems.

Genome size variation in the grape family of Vitaceae

Zhao-Fu Chu[1], *Jun Wen*[2], *Ze-Long Nie*[1], *Ying Meng*[1]
1. Jishou University, Jishou, Hunan
2. National Museum of Natural History, Smithsonian Institution, Washington, DC

Genome size variation is of fundamental biological importance and has been a longstanding puzzle in evolutionary biology. The phylogenetic, evolutionary and ecologically significance of nuclear genome size variation in angiosperm have received considerable attention over the years, but little work has focused specifically on Vitaceae. The aim of this study is to analyse the genome size variation within Vitaceae in a phylogenetic framework in order to evaluate the systematic significance of this trait to provide insights into the dynamics of genome size evolution and to assess relationships among DNA content, biogeographic distribution and ecological features within the grape family. In present study, genome size from 61 accessions corresponding to 10 genera and 50 species of Vitaceae and Leeaceae (*Leea guineensis*) is determined using flow cytometry. The DNA 1C-value of 38 species are first reported here, and the largest genome (*Cyphostemma humile*, 1C=3.25pg) is roughly 10.48-fold larger than the smallest (*Vitis vulpina*, 1C=0.31pg). Our results suggested that genome size variation in Vitaceae is largely congruent with the phylogenetic backbone relationships. The three temperate-dominant clades (*Ampelosis-Rhoicissus*, *Parthenocissus-Yua* and *Vitis-Ampelopcissus* clade have relatively small genome sizes (mean=0.59,0.60,0.50pg, std.=0.14,0.13,0.07, respectively). However, the tropical *Cayratia-Cyphostemma-Tetrastigma* group has the largest mean genome size (1.84pg, std.=0.71) with variation region from 0.66pg to 3.25pg. The other tropical clade contains only one genus *Cissus*, with genome size variation ranging from 0.37pg to 1.03pg and a mean size of 0.57pg (std.=0.22). The genome size for the outgroup *Leea guineensis* is 1.13pg. Our data suggested that tropical lineages have larger genome sizes than temperate groups. The highest level of DNA contents found for the *Cayratia-Cyphostemma-Tetrastigma* clade could be correlated with their highly species diversification in tropical areas in the Old World. The result of this study suggests a possible ecological adaption of genome size evolution that was associated with phylogenetic divergence across the biogeographical range of major lineages within Vitaceae.

Supporting genomics, research and public access through the digitization of national collections

Heather Cole, *Anissa Lybaert, James Macklin*
Agriculture and Agri-Food Canada

Agriculture and Agri-Food Canada (AAFC) houses over 19 million specimens of insects, plants, fungi, bacteria and nematodes that are among the most comprehensive in the world and support Canada as a major contributor to biosystematics and nomenclature. The collections are supported by a critical mass of scientists working with them. In 2016, the Treasury Board of Canada awarded 30 million dollars to support research in agricultural genomics, accelerate the digitization of specimens, and improve public access to AAFC collections. As a result, three projects were funded. 1) Data Capture and Imaging: creating a digital inventory of each collection, virtual collections for public access, and enhanced digital resources for specimens, including images, data capture, and georeferencing. 2) Molecular Characterization: producing DNA barcodes and partial or complete genome sequences as appropriate for agriculturally relevant species using protocols developed for high throughput sequencing and data analysis. 3) Data Integration and Sharing: implementation of a centralized collection management system for AAFC collections and a biodiversity portal for sharing specimen and molecular data within AAFC, other government agencies and the public. Efforts are on-going to determine the most effective protocols, technologies and best practices to achieve the goals outlined in each project. Projected outcomes include complete imaging and data capture for the 1.7 million vascular plant specimens in the National Collection of Vascular Plants (DAO).

Flora NT – an online flora for the Northern Territory of Australia

*Donna Lewis, **Ian Cowie**, David Albrecht*
Northern Territory Herbarium, Department of Environment and Natural Resources

Flora NT - Northern Territory Flora Online is a web based system to access a comprehensive range of information on the NT flora, the NT Herbarium specimen data and the NT vascular plant census. The first production release was November 2014 and is the first of its kind for the NT. Flora NT allows users to search or browse for information on the entire NT flora of approximately 5500 vascular plant taxa and users can also view and extract threatened and introduced species information. Flora NT enables users to download checklists across user defined areas and by family/genus. A factsheet for each plant taxon can be viewed and downloaded. These include floristic descriptions, conservation status, ecological attributes, ethnobotanical information, images of plants and distribution maps generated dynamically from specimen data. Spatial searches of the data can be performed using mapping tools, various spatial layers or geocodes. Identification keys are also available for many families and genera, as well as key regions and habitats such as mangroves, wetlands and a LUCID-based key to the flora of the MacDonnell Ranges bioregion. The content for Flora NT and the ‘label’ data for over 270,000 vascular plant specimens are maintained in the Herbarium’s HOLTZE database and continue to be enhanced by adding new data and images, and by improvements to overall functionality. Flora NT is available at http://eflora.nt.gov.au.

Novelties of genus *Terminalia* in India

Arvind Dhabe
Dr. Babasaheb Ambedkar Marathwada University, Aurangabad 431004

Genus *Terminalia* is characterized by trees or shrubs, leaves alternate or sub-opposite crowded at the ends of the branches, presence of glands and/or domatia, inflorescence spikes or racemes, petals absent, fruits drupes or samara. It has 150 species distributed in the tropical and subtropical regions of the world and 13 species are reported from India. While working on the genus from India, some novel specimens were collected which are presented in the paper. *Terminalia arjuna* with different kinds of Samara like small thick winged, large triangular winged, wings grow beyond tipare collected from Assam, Maharashtra and Kerala. *Terminalia bellirica* with small spherical drupes with long elliptic leaves collected from Kerala, short and broad winged samara of *T. bialata* from Andaman. About 40 cm long inflorescence of *T. catappa* from Maharashtra. *Terminalia chebul*a with 2 forms - elliptic elongate long stalked, 4.5-7 cm long drupes and ovate ellipticshort stalked, 2.5-4 cm long drupes collected from Gujarat state. Elliptic lanceolate 4-6.5 cm long drupes of *T. citrina* colected from Meghalaya. 3-7 winged samaras of *T. tomentosa* from many places in India. Large oblong drupes with white patches of *T. travancorensis* are collected from Kerala. These are desrving the rank of new species or varieties.

The Useful Plants and Fungi Portal, an ambitious worldwide collaborative initiative

*Tiziana Ulian, Abigail Barker, **Mauricio Diazgranados**, William Milliken, Robert Turner, Bob Allkin, Nicola Kuhn, Alex Hudson, Mark Nesbitt, Melanie-Jayne Howes, Monique Simmonds*
Royal Botanic Gardens, Kew

Plants and fungi are essential to human wellbeing, providing benefits to society and our economic prosperity, supplying food, medicine, fibres, fuel, building materials and many other products, and supporting important ecosystem services. With a rapidly growing global population, increasing energy, health and food security needs, and a reliance on increasingly scarce natural resources, effective management of plants and fungi becomes a critical component of finding solutions to address the Sustainable Development Goals. Plants and fungi are still significant underexploited natural resources, and research and innovation are fundamental to tackle global challenges such as human and animal health, nutrition, bioenergy, antimicrobial resistance, and industrial biotechnology. However, access to information about these plants and fungi, their properties, their distribution, their identification and their management, remains a major bottle-neck. Although much has been published about useful plants and fungi, these data are fragmented and inconsistent, being stored in any number of local or specialist databases and widely scattered in the scientific and technical literature. Finding all reports of a single plant is further complicated by the use of erroneous or ambiguous names in these published resources and the multiplicity of scientific names associated with many species. For example, medicinal plants on average have more than ten scientific synonyms. Effective research prioritisation and access require information from diverse disciplines being brought together. Facilitating access to all relevant information about useful plants will require partnerships and an innovative joined-up methodology for dynamically sharing and disseminating data. The Useful Plants and Fungi Portal (UPFP) aims to develop a unique information infrastructure capable of supporting a global, authoritative, expert-driven, open access, online resource, providing ready access to information on the economic, potential and traditional uses of plants and fungi. It will be designed to meet the needs of as broad an audience as possible including the public, scientists, policy makers, rural development and conservation agencies. Initially data are to be drawn from existing Kew’s databases, including robust taxonomic and nomenclatural frameworks linking all synonyms as well as our plant distribution and use data. We actively seek partners to increase the scope, depth and global coverage of this resource. The UPFP will publish content and provide data access through diverse means (e.g. Kew's Plants of the World Online POWO), including through existing partner portals to address the needs of diverse audiences. The UPFP will respect intellectual property rights, local ownership of knowledge and appropriate benefit sharing as outlined by the Nagoya Protocol and FAO's international Treaty, by using information already available in the public domain and deploying it under CC BY license. The UPFP is one of Kew's 2020 Strategic Outputs aligned with the institutional Science Strategy, which will be dynamically linked to other collections, datasets and portals. Utility and longevity of the portal will depend further upon the full participation of potential users and international partnerships with those holding information in other domains or parts of the world.

Methodological approach for the implementation of Important Plant Areas (IPAs) in Colombia

Mauricio Diazgranados[1], *Carolina Castellanos*[2]

1. Natural Capital and Plant Health Department, Royal Botanic Gardens, Kew

2. Ciencias Básicas de la Biodiversidad, Instituto de Investigación de Recursos Biológicos Alexander von Humboldt

Plants are essential to life on Earth. Unfortunately nearly two thirds of plant species are under threat, for causes related to human demographic expansion, land use change, deforestation, over-exploitation, invasive species, pollution and climate change. Most countries are committed to have by 2020 at least 17% of their land area under protection, according to the Aichi Biodiversity target 11. However, these areas are often established without the appropriate baseline to maximize the conservation efforts, leaving important species unprotected. To inform conservation plans, a common approach has been the systematic identification of key biodiversity areas (KBA), including Important Plant Areas for conservation (IPAs). The target 5 of the Global Strategy for Plant Conservation aims to have at least 75% of the IPAs in each region protected with effective management in place. However, there is a notable lag in the implementation of IPAs, particularly in some of the most diverse countries. Colombia is arguably the second most diverse country, with 85 general ecosystems and more than 28,000 plant species. Of those, 798 species are in the red list and over 300 are considered keystone species. Currently 13.71% of Colombian continental land is under protection in 640 nature reserves. The government organization responsible for research on biodiversity, the Humboldt Institution, is moving forward to the implementation of IPAs in Colombia. After analyzing various methodologies, a suite of goals, criteria, indicators and methods that fit the interests and needs of the country is now being presented. This methodology, deeply discussed with experts, is based on the general principles of transparence, simplicity, inclusiveness, and coherence. Using ecosystems as units of analysis, it approaches both important species and communities, with no prioritization of criteria. The first implementation is presented here, with the hope of informing future conservation plans for Colombia.

Studies on phylogeography and industrialization of *Dendrobium officinale* Kimura et Migo

Xiao-Yu Ding

College of Life Sciences, Nanjing Normal University, Nanjin, China

The genus *Dendrobium* could be used as a case study to elucidate the evolutionary history of Orchidaceae in the Sino-Japanese Floristic Region (SJFR) and Southeast Asia region. These evolutionary histories remain largely unknown, including the temporal and spatial distribution of the evolutionary events. The present study used nuclear and plastid DNA to determine the phylogeography of *Dendrobium officinale* and four closely related taxa. Plastid DNA haplotype and nuclear data were shown to be discordant, suggesting reticulate evolution drove the species' diversification. Rapid radiation and genetic drift appeared to drive the evolution of *D. tosaense* and *D. flexicaule*, whereas introgression or hybridization might have been involved in the evolution of *D. scoriarum* and *D. shixingense*. The phylogeographical structure of *D. officinale* revealed that core natural distribution regions might have served as its glacial refuges. In recent years, human disturbances caused its artificial migration and population extinction. The five taxa may have originated from the Nanling Mountains and the Yungui Plateau and then migrated northward or eastward. After the initial iteration expansion, *D. officinale* populations appeared to experience the regional evolutionary patterns in different regions and follow the sequential or rapid decline in gene exchange. In the aspect of industrialization of *D. officinale*, an important research institute named "Jiangsu Provincial Engineering Research Center for Technical Industrialization of *Dendrobiums*" has been established to cooperate successfully with many companies in Jiangsu Provice of China. The germplasm identifying system, the breeding system and the optimized method of tissue culture have been set up by the institute for many years. The organic cultivation methods have been applied for the cultivation of *D. officinale* at mountain regions in southren China, where the adult individuals of *D. officinale* have been cultivated on the surface of stones and the tree trunks. Series of food, health and daily products made from *D. officinale* have being developed for sales. Our researches have played an important role in the conservation and sustainable utilization of *Dendrobium officinale.*

Can butterflies cope with city life? Butterfly diversity in a young megacity in southern China

Kong-Wah Sing[1], ***Hui Dong***[2], *Wen-Zhi Wang*[3], *John-James Wilson*[1]

1. Institute of Biological Sciences, Faculty of Science, University of Malaya

2. Fairy Lake Botanical Garden, Shenzhen & Chinese Academy of Sciences

3. State Key Laboratory of Genetic Resources and Evolution, Kunming Institute of Zoology, Chinese Academy of Scienc

During 30 years of unprecedented urbanization, plant diversity in Shenzhen, a young megacity in southern China, has increased dramatically. Although strongly associated with plant diversity, butterfly diversity generally declines with urbanization, but this has not been investigated in Shenzhen. Considering the speed of urbanization in Shenzhen and the large number of city parks, we investigated butterfly diversity in Shenzhen parks. We measured butterfly species richness in four microhabitats (groves, hedges, flowerbeds, and unmanaged areas) across 10 parks and examined the relationship with three park variables: park age, park size, and distance from the central business district. Butterflies were identified based on wing morphology and DNA barcoding. We collected 1,933 butterflies belonging to 74 species from six families; 20% of the species were considered rare. Butterfly species richness showed weak negative correlations with park age and distance from the central business district, but the positive correlation with park size was statistically significant ($p = 0.001$). Among microhabitat types, highest species richness was recorded in unmanaged areas. Our findings are consistent with others in suggesting that to promote urban butterfly diversity it is necessary to make parks as large as possible and to set aside areas for limited management. In comparison to neighbouring cities, Shenzhen parks have high butterfly diversity.

Global Genome Biodiversity Network – Unlocking the hidden treasures of botanical DNA and tissue collections

Ole Seberg[1], *Katharine Barker*[2], *Jonathan Coddington*[2], *Gabriele Droege*[3]

1. Natural History Museum Denmark

2. National Museum of Natural History, Smithsonian Institution

3. Botanic Garden and Botanical Museum Berlin-Dahlem, Freie Universität Berlin

Genomic research depends upon access to DNA or tissue collected and preserved according to high-quality standards. At present, the collections in most natural history museums do not sufficiently address these standards, making them often hard or impossible to use for whole-genome sequencing or transcriptomics. In response to these challenges, natural history museums, herbaria, botanical gardens and other stakeholders have started to build high-quality biodiversity biobanks. Unfortunately, information about these collections remains fragmented, scattered and largely inaccessible. Without a central registry of relevant institutions, it is difficult and time-consuming to locate the needed samples. The Global Genome Biodiversity Network (GGBN) was created to fill this gap by establishing a central access point for locating samples meeting quality standards for genome-scale applications, while complying with national and international legislations and conventions (e.g. the Nagoya Protocol). The GGBN is rapidly growing and currently has 56 members. Mobilizing currently scattered DNA and tissue samples by providing access to their data through a common platform will boost research, democratize their use, conserve genetic resources, help train the next generation of genome researchers, and make the Convention on Biological Diversity ABS a reality. Molecular research results in an exponentially increasing number of sequences and hundreds and hundreds of publications every year. Knowledge of biodiversity biobank content is urgently needed to enable concerted efforts and strategies in collecting and sampling new material. The GGBN Data Portal together with the GGBN Data Standard provides an infrastructure for making genomic samples discoverable and accessible. Additionally, it will facilitate identification of gaps in the collections, thereby empowering targeted sampling efforts, increasing the breadth and depth of preservation of genetic diversity. The GGBN covers all branches of the Tree of Life, except humans, but here we focus on vascular plants. While current efforts are centred on getting the existing samples of all GGBN members online, a pilot project, GGI-Gardens, has been launched as proof of concept. Over the next 6 years GGI-Gardens aims to add to the GGBN high-quality genetic material from at least one species from each of the approx. 460 vascular plant families and one species from half of the approx. 15,000 vascular plant genera.

The causes and countermeasures to the degenerate of *Salix matsudana* communities at Xi'an Chan-ba National Ecological District

Xichun Du

Xi'an University

The communities of the *Salix matsudana* at Ba River in Xi'an Chanba National Ecological District were investigated. Comparison and correlation analysis on DBH, lodging, bark cracking and mortality of the *Salix matsudana* in different environments were conducted using the SPSS software. The results showed that: there are no statistically significant differences on DBH between the *Salix matsudana* in different environment, but there are statistically significant differences on lodging, bark cracking and living situation. The correlation analysis showed that there are positive correlation between lodging with skin cracking and mortality. There are also significant negative correlation between cracking and the mortality. So, the lodging and the bark cracking are the direct reasons for the high mortality of *Salix matsudana*. The mortality of *Salix matsudana* had significantly reduced, after the water level of the rubber dam were reduced, the frequency of water storing and draining were reduced, and the speed of water storing and draining were slowed down, which can forming a more stable wetland ecosystems on the river.

The reaserch of bloom warning of *Bashania fargesii* in Shaanxi Foping National Nature Reserve

Xichun Du

Botanical Society of Shanxi Province

Shaanxi Foping National Nature Reserve is one of the regions with the highest density of giant pandas in China. The *Bashania fargesii*, one of the main food species of Giant Panda. But the death of *Bashania fargesii* will be widespread after flowering, which will have great impact on the growth and breeding of giant pandas. The studies was mainly foucus on the characteristics of early flowering, early warning, and early countermeasures of *Bashania fargesii*, which is of great significance for the protection of the giant pandas. The results showed that, there were no significant differences of the chlorophyll and nitrogen content between bamboo culms of different ages (neonate, annual and perennial) at the same position. There were no significant differences of the chlorophyll and nitrogen contents between the leaves of the same position (the first, secondary and tertiary leaves) on the same branch.But the chlorophyll and nitrogen content of Bashania fargesii were significantly different between the four different flowering status group (vigorous growth group, flowering signs appear group, will flower group, flowering group). The most obvious difference were between vigorous growth groups and the flowering groups, which chlorophyll content was 45.7 and 37.9 respectively, and the mean values of nitrogen content were 3.77 and 3.21 respectively.

Principles of collections formation and management in the Botanic Garden of the M.V. Lomonosov Moscow State University under present-day conditions

Sergey Efimov, *Galina Degtjareva, Elena Terentieva, Tatiana Varlygina*
M.V. Lomonosov Moscow State University

Plant collections of the botanic gardens have not only scientific significance but also contribute into their conservational and educational roles. University botanic gardens have more opportunities to carry out integrated research projects uniting the efforts of their university researches – not only botanists but of other biological disciplines. The Botanic garden of the M.V.Lomonosov Moscow State University founded in 1706 is one of the oldest in the Russia and possesses successfully developing collections of wild (the arboretum, the alpine section, the taxonomic section, the useful plants section, as well as tropical and subtropical plants) and ornamental plants (roses, peonies, irises, phloxes, lilac, apple-tree, *etc*.). The Botanic garden participates in and coordinates the projects on biodiversity conservation of the wild flora of Russia. Here grow 105 rare and endangered species included in the Red Data Book of Russian Federation, 60 species included in the Red Data Book of Moscow region and 8 species from Appendix I of Bern convention. Since 2014, the Moscow State University realizes the project "National depositary bank of living systems" dedicated to preserve the biodiversity and create new ways of biological material use. The important part of the project is the information system containing comprehensive data about samples from biological collections, including the use of molecular and genomic technologies. The peony plant collection of the Botanic garden can serve as a good model object for work in the given direction. The collection includes 280 cultivars demonstrating all selection trends, as well as 18 species, many of which included in the Red Data Book of Russian Federation. As is known, high intraspecific variability of morphological characters and hybridization events obscure relationships between *Paeonia* species. Collection of samples from different populations and geographic regions, supplemented with information about different morphological characters especially that used as diagnostic, chromosome number, geographical distribution, state of populations, and nucleotide sequences of different DNA regions provides a basis for various fundamental studies. Moreover, the peony plant collection can serve as an example of cooperation between fundamental and applied strategies. The knowledge about species helps to identification of origin of cultivars and its ecological preferences during cultivation. While knowledge about cultivars allows to compare results of natural hybridization events with results of the similar processes passing by creation of cultivars. Conduction of comprehensive inventory of the material deposited in the modern electronic databases can improve the way in which garden plant collection is documented. This helps not only in the everyday work with the collections but also in storage and research of the collected plant.

The gymnosperm trees of highlands of East Asia and its perspective for introduction at Saint Petersburg (Russia)

Aleksandr Egorov[1], *Aleksandr Afonin*[1], *Vyacheslav Byalt*[3], *Larisa Orlova*[3], *Nikolay Vasiliev*[2]
1. St. Petersburg State University
2. St. Petersburg State Forest Technical University
3. Komarov Botanical Institute Russian Academy of Sciences

The mountains of East Asia are the center of origin of plants, where a high diversity of them exists. Forests and woodlands are located at the upper border of forests in the highlands of East Asia are influenced by the rather harsh climate and can be considered as areas of donor introductions of these plants to the Northern territories of temperate climate. To determine the potential opportunities of the mountains of Eastern Asia, as regions-donors, we have conducted a comparative analysis of the taxonomic diversity of gymnosperm trees, located at the upper border of the forest of these mountains and in the Botanical collections at St. Petersburg. The upper limit of the forest in the mountains of Eastern Asia are located at 3500-4000 m alt. Analysis of the climatic characteristics showed that the average January temperature at 3000-4000 m alt. in the mountains of Eastern Asia is in the range from slightly above 0°C in the southern regions of China to below -10°C in Northern areas. In St. Petersburg January temperature over the past 30 years are -8°C. In Flora of China (2008), the distribution of plants is given, indicating the regions of their growth and height above sea level. Height is not differentiated across regions, so as to identify the particular location of the common species at altitudes in different provinces in the Flora of China (2008) is not possible. Therefore, we carried out the analysis of taxa of gymnosperm trees, at least partially located in the mountains above 3000 m alt. All identified 61 such species. The conditions of the highlands of China at certain altitudes are climate analogues of regions of Northern Eurasia in terms of the growing degree days during the growing season and winter temperatures. However, seasonal changes in day length in the southern highlands is very different from the length of the day in high latitudes, which can lead to out of sync with the rhythm of the development of introduced plants. Therefore, the success of plant introduction in the Northern regions of Eurasia from the highlands ofChinaremains in question. The analysis of the taxonomic diversity of gymnosperm trees showed that the collections of Saint-Petersburg in the open field for last 150 years was tested at least 23 species of 61 (37.7%). Analysis of winter hardiness of these trees allowed us to divide them into the following groups: Winter-hardy and winter-hardy enough (4 species): *Larix sibirica, Picea asperata*, *P. likiangensis, P. schrenkiana*. Relatively hardy, but in the abnormal winter can significantly damaged (3 species): *Juniperus semiglobosa*, *Platycladus orientalis*, *Pinus wallichiana.* Not hardy plants significantly frosted over, sometimes completely on the level of snow or die; also, this group includes taxa that died for an unknown reason (15 species): *Juniperus pseudosabina, J. squamata, Abies delavayi, A. ernestii, A. fargesii, A. forrestii, A. georgei, A. spectabilis, Larix griffithii, L. potaninii, Picea brachytila, P. smithiana, Pinus armandii, P. yunnanensis, Tsuga dumosa.* And 1 species still pass the test. Thus, it can be concluded that of the 24 tested taxa of highlands East Asia at St. Petersburg, winter-hardy and winter-hardy enough are 4 taxa of 16.7%. However, due to climate change can be re-introduced a number of gymnosperm trees.

Design, testing and evaluation of best practices for *in-situ* conservation of economically important wild plant species in Morocco

Jalal El Oualidi
Institut scientifique, Mohammed V university in RABAT

The present study concerns the wild and semi-wild vegetal species of economic importance. Such a project appears at the appropriate time for Morocco that has several assets from which it can benefit, and which can permit to achieve this project. Indeed, the country has since a few years the results of two very important surveys at its disposal, which are the National Study on Protected Areas and the National Survey on Biodiversity. The main components of the study are: (1) Development of the national strategies and methodologies based on the best *in situ* conservation practices relative to wild vegetal species of economic importance; (2) Setting up of demonstration projects; (3) Setting up of monitoring systems; (4) long term assessment; (5) Dissemination of information. The objectives of the study in Morocco emphasized three points: 1. The presentation of the general data relative to the country, its biological resources, the cultural and socio-economic aspects and the type of legislation adopted concerning plants of economic importance and the protected regions, as well as a brief overview of the programs and projects concerning the *in situ* conservation of the genetic resources of the plants existing inside and outside the protected areas. 2. Identification of target taxa by listing the main wild vegetal or semi-domestic species of economic importance (*s.l.*). 3. The prioritization of target taxa from the potential list by proposing a list of about ten target species and their sites, chosen by taking account the criteria of FAO.

Weed distribution and abundance index (AI) at New Halfa Agricultural Scheme, eastern Sudan

Mohamed Elkhawad, *Mohamed Khir, Abosofian Osman*
Agricultural Research Corporation

A field survey was conducted during season 2014/2015 to determine the weed flora and weed dominance at New Halfa Agricultural Scheme, eastern Sudan. The scheme divided into three geographical sites, each site consist of two sectors, from which fifty-six fallow fields were selected and ten quadrates (1 m^2) from each field were taken randomly. Individual weed species, mean field density (MFD), frequency (F) and uniformity (U) of each field were determined. Forty-two species belonging to nineteen families (sixteen dicotyledonous and three monocotyledons) were recorded. The most dominant weeds were *Brachiaria eruciformis*, *Brachiaria reptans*, *Dinebra retroflexa*, *Abutilon glacum* and *Alysicarpus rugosus*. *Brachiaria reptans* recorded highest abundance index (AI) for center and south sites (234.72 and 292.23) and *Alysicarpus rugosus* for north site (215.69). *Alysicarpus rugosus* recorded highest mean field density (MFD) and uniformity (U) values (43.47 and 72.22) for north site, while highest frequency value (100) recorded by *Abutilon glacum*, *Alysicarpus rugosus*, *Brachiaria eruciformis*, *Sesbania sesban*, *Echinocloa colona*, *Rhynchosia minima* var. *minima* and *Corchorus* spp. *Brachiaria reptans* recorded highest MFD and uniformity for the center and south sites (76.94,68.89 and 107.79,84.44). Highest frequency values (100) were recorded by *Brachiaria reptans*, *Corchorus* spp. and *Alysicarpus rugosus* for center site and *Brachiaria reptans*, *Corchorus* spp., *Abutilon glacum*, *Xanthium brasilicum*, *Dinebra retroflexa* and *Cynotis axillaries* for south site. For north site, lowest MFD value recorded by *Ipomoea cordofana* and *Withania somnifera* (0.01), lowest frequency value by *Withania somnifera*, *Urochloa* sp., *Solanum dubium* and *Phyllanthus niruri* (8.33) and lowest uniformity value by *Withania somnifera* and *Phyllanthus niruri* (0.83). *Ipomoea cordofana* recorded the lowest MFD, frequency and uniformity values (0.01,11.11 and 1.11) respectively, at center site. For south site, lowest MFD and uniformity values recorded by *Withania somnifera*, *Tribulus terrestris* and *Acalypha indica* (0.01 and 1.11), while lowest frequency values recorded by *Sonchus cornutus*, *Setaria pallide-fusca*, *Senna obtusifolia*, *Withania somnifera*, *Tribulus terrestris* and *Acalypha indica* (11.11).

Herbaria in the digital age: Promises and pitfalls of using herbarium records to assess phenological responses to climatic change

Aaron Ellison[1], *Charles Willis*[1], *Charles Davis*[1], *Edith Law*[2], *Alex Williams*[2]
1. Harvard University
2. University of Waterloo

Central events in plant life history, including setting and emergence of buds, leaves, flowers, and fruits, are being affected strongly by climatic change. Contemporary time series of phenological events often are too short to draw strong inferences about relationships between these events and climatic change. Expressions of phenological events, including flowers and fruits, are clearly visible on many herbarium sheets and many recent papers have shown that herbarium data can be used to extend phenological time series. Ongoing digitization efforts at herbaria around the world have expanded greatly the potential database of phenological records, but have raised new challenges for efficient and reliable data collection. We have developed a crowd-sourcing tool, *CrowdCurio*, that can be used to collect phenological data from digitized herbarium specimens. We have tested its utility by having experts and novices (Amazon Turk) collect phenological data (number of flower buds, open flowers, and fruits) from two common members of the New England (USA) flora: *Chelidonium majus* and *Vaccinium angustifolium*. We also created a computer-based mechanism, *Deja Vu*, that distributes at random intervals duplicate tasks to individual workers and assesses their consistency in collecting phenological data. Estimates of flowering and fruiting time derived from digital herbarium data were associated significantly with temperature: both species showed an approximately 2 day per degree C shift in flowering and a 3 day per degree C shift in fruiting. Standard measures of data consensus suggested that data quality differed little between non-experts and experts, but that non-experts collected data more rapidly, efficiently, and cost-effectively than the experts. Our measures of consistency provided by the *Deja Vu* software also provided an estimate of the reliability of data collected by each worker. These measures revealed that differences in estimation of phenophases differed among them and between the species, and that workers experienced fatigue as they evaluated more herbarium sheets, leading to poorer quality data. We conclude that there is great promise in using herbarium data to assess effects of climatic change on plant phenology but that care must be taken to ensure that the data derived from digitized herbarium data is of high quality and leads to reliable and repeatable conclusions.

Reproductive biology of *Trichocereus bridgesii* (Cactaceae) an endemic cacti from dry valleys (La Paz, Bolivia)

Mariela Escobar-Torrez
Herbario Nacional de Bolivia

In recent years it has been suggested that exist a geographic dichotomy in pollination system for columnar cacti. In extratropical regions the columnar cacti show more open and generalized pollination system, meanwhile, in tropical regions columnar cacti tend to have specialized pollination system. As pollination data for South America are scarce, the aim of this study was to analyze the reproductive biology of *Trichocereus bridgesii* an endemic cactus in Ananta a dry valley located in La Paz (Bolivia). An exclusion experiment was conducted to measure the breeding systems, and the relative contribution of nocturnal and diurnal floral visitors to fruit set and seed set, also, I observe the floral visitors, their frequencies and behaviors. In addition I evaluated if *T. bridgesii* has a specialized pollination system or generalized pollination system. The experiment revealed that *T. bridgesii* exhibits a complementary general pollination system demonstrating that both pollination groups (diurnal and nocturnal) were important for plant reproduction. The importance of floral visitors on the breeding system indicates an obligate xenogamous system, self-incompatible. Seeds produced in the experimental treatments: control, xenogamy and obligate xenogamy were viable, except for the treatment of geitonogamy. During the day native bees (*Ischnomelissa* sp., *Habralictus* sp.) and the introduced *Apis mellifera* were the most frequent visitors and during the night Nitidulidae beetles, moths or bats were not registered. *Trichocereus bridgesii* shows more affinity with columnar cacti from extratropical regions than with those from tropical regions, these results demonstrated that as latitude increases in tropical regions of South America, Cactaceae have a generalist pollination system. Therefore, I recommend to carry out comparative studies from cacti species located within and outside the tropics according to variations in their geographic distribution. It is expected that in very isolated fragments of vegetation, two possible consequences are generated: 1) existence of specialized pollination systems when the main pollinator is abundant and 2) existence of generalized pollination systems when the main pollinator is scarce, in this case comparative studies in disturbed and conserved areas are recommended.

P0048
Distribution pattern of epiphytic mosses from Orthotrichaceae family in China

Lucie Fialová[1], *Lukáš Číhal*[2], *Zuzana Skoupá*[1], *Vítězslav Plášek*[1]
1. University of Ostrava
2. Silesian Museum in Opava

The distribution structure of bryophytes shows considerable variability. One of the main aims of the project is to clarify impact of environmental conditions on distribution pattern of epiphytic bryophytes in China. For evaluation of the distribution patterns of epiphytic bryophytes the data obtained from Chinese herbarium collections and from field survey were used. Collection of these data was carried out during 2014–2016. For analysing, methods of species distribution modelling (SDM), specifically we used the method of Maximum Entropy Modelling (MaxEnt). MaxEnt is now a common SDM tool used by conservation practitioners for predicting the distribution of a species from a set of records and uncorrelated environmental predictors (e.g. Mean Diurnal Range (Mean of Monthly (max tempt – min temp), Min Temperature of Coldest Month, Precipitation of Wettest Month, Precipitation of Driest Month). MaxEnt is a machine-learning method and it calculates a raw probability value for each pixel of the study region. These raw probabilities are scaled to sum to 1, and do not represent probability of occurrence, but rather an index of relative suitability. However, it would be inappropriate to interpret the modelled distributions as actual borders of a species range. Rather, the models identify regions that have similar environmental conditions to those where the species currently maintains its populations. For all species, we considered an initial set of environmental variables representing various candidate predictors that were potentially relevant for the distribution of epiphytic bryophytes. In total, 19 environmental variables (Bioclim) were downloaded from WorldClim (http://www.worldclim.org/), which is a set of global climate layers generated through interpolation of climate data from weather stations. These data were available at the resolution of 30 arc-seconds (approximately 1 km^2 resolution). Because we modelled species that are mainly epiphytic, we also included in our model Percent Tree Coverage (PTC) Global version data, which show the ratio of tree canopy coverage (i.e., density of trees on the ground) (http://www.iscgm.org/, Geospatial Information Authority of Japan, Chiba University and collaborating organizations). These data are based on MODIS data 2008 (Terra & Aqua satellites) and available in 15 arc-second resolutions. All environmental data were acquired in the WGS84 geographical coordinate system (EPSG: 4326). For preparing environmental layers, we used functions from the GDAL library. For the graphics visualization of map output we used geographic information system DIVA-GIS (free computer program). During each next field research, it would be most appropriate to test the models directly in the field, because such research could improve validity and precision of predicted distributions. Until then, models can serve as a guide to future survey expeditions, conservation of the target species, and understanding of their ecology. These methods can minimize substantial financial costs, as well as lot of time consumption, because field survey realized under such a scenario can achieve better and more precise results in shorter time.

Medicinal plants native in Argentina: Two model species with social inclusion

Renée H. Fortunato[1,2,3], *Hernán G. Bach*[1,4], *Paola A. Faroni*[1,5], *Viviana G. Spotorno*[1], *Nicolás Nagahama*[1], *María M. Manifesto*[1]
1. Instituto Nacional de Tecnología Agropecuaria (INTA)
2. Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET)
3. Facultad de Ciencias Agroalimentarias, Universidad de Morón
4. Facultad de Farmacia y Bioquímica, UBA
5. Facultad de Agronomía, UBA

In Argentina grow more than 10,000 spp., and of which close to 1,500 spp. have records on medicinal use. The information is mainly from ethnobotanical, chemical and biochemical studies, but up to now there are few species in which the chemical compounds have been analyzed and registered towards production of phytopharmaceuticals. During 1993 to 2003 the Institute of Biological Resources, INTA, made screening on search medicinal and agrochemicals active compounds. The proposal was based in agreement with national (Argentina National Constitution, 1994) and international legislation (CBD ratification, 1994). According to this from 2010, we have begun to develop a technological model in two species groups with medicinal background, each of which has importance in the Norwest and South (Patagonia) regions of the country. A) *Bauhinia* (Caesalpinioideae, Leguminosae) "cow's hoof", "cow's paw", "monkey's ladder": Hypoglycemic, antioxidant, analgesic, anti-inflammatory and diuretic. B) North Patagonian species of *Valeriana* (Caprifoliaceae) "valerian": sleep disorders, sedative and anxiolytic effects. To carry out it has been studied morphological characterization, biochemical and molecular (including expression libraries), and after that the germplasm conservation of the populations that showed promising biotypes (Germoplasm Bank INTA). Later on, the cultivation of selected species/populations has been initiated to be available the Biological Resource for domestication and long-term improvement programs. This strategy has made possible to propose designs and technological processes for the quality of life in rural territories and sustainable growth through an integral and rational use of the resource with the preservation of wild populations and their habitat.

Biomorphological study and *ex situ* conservation of *Aquilegia colchica* Kem.-Nath

Laura Gabedava
National Botanical Garden of Georgia, Department of Plant Conservation

This is the first time we have studied reproductive biology, ontogenesis and growth rhythm, considering the life cycle periods of *A.colchica* - Georgian endemic species, primarily having the status of conservation of the Red List of Caucasus. As a result of the investigations we have estimated that formation of generative sphere and its functioning passes normally. High energetic potential of male sphere. Stamen is four locular. Meiosis passes naturally and 7 bivalents are formed. Tetrad is formed by simultaneous mode. Ready pollen grain is binuclear and pollen fertility is high (90%). Seed bud is anthropous, crassinucelate with two integuments. The plant is entomophilic characterized by protandria. With the purpose to start an *ex situ* collection the quality of seed germination and intergrowth was defined under laboratory conditions. Seeds maintain germination ability for three years. The percentage of germination differs under the controlled regime of temperature and lighting. High percent of germination is attained if seeds are sown as soon as they are collected (92%). Potential and real possibilities of seed formation were defined. *A.colchica* is characterized by high productivity of seed formation (1260 seeds within the sample) and rapid development of its shoots. The anthropogenic stress that leads to a destruction of the habitat must be the reason why it is reduced in nature. *Ex situ* activities were carried out. The collection of seedlings was set up and the Seed Bank was created.

Systematic study of Acanthochlamydaceae—A new endemic family of China

Baochun Gao
Chengdu Institute of Biology, Chengdu, China

Acanthochlamys bracteata is a Chinese endemic plant that was first discovered, descripted and named by Kao in the West Hengduan Mountains of Sichuan Province. The anatomical characteristics of *A. bracteata* are very unique in monocotyledonous plants, such as the eustele in rhizome, protostele in root, and the leaf-stem compound structure in scape. These characters were found for the first time in monocotyledonous plants. The coexistence of eustele and protostele in vascular bundle system suggests that Acanthochlamydaceae not only retains the ancestral character, but also evolves derived type. It is absent of scattered bundles, which is the most derived bundles type in monocotyledons, but shows a transitional type between protostele and scattered bundles. The family, Acanthochlamydaceae, is a new monotypic family, which contains only one species. Phylogenetic results showed that Acanthochlamydaceae is a sister group of Velloziaceae. The close relationship with the two families indicated that the close floral relationship between Hengduan Mountains and African tropical regions. In this paper, a comprehensive study was performed on the morphological characteristics, the status in the world flora, geographical distribution, phylogeny, origin, and other issues of *Acanthochlamys bracteata*.

Seed abortion in *M.indicus* (L.) All

Nidhigautam Gautam

Daulat Ram College, University of Delhi

Legumes serve as the best and cheapest source of plant proteins, hence an integral part of our vegetarian diet. These plants play another significant ecological role because of their unique ability of nitrogen fixation maintaining soil fertility. Members of the family Fabaceae therefore, have been a favorite material for embryological, physiological, ecological and molecular studies. Being one of the largest groups of plants it shows a variation in its reproductive biology. The embryological studies on *Mellitus indicus,* a wild fodder legume exhibits many interesting features at light and electron microscopic levels. This fabaceous plant flowers during winter months in Delhi and bears small, yellow papilionaceous flowers in axillary racemes. The small, spindle shaped ovary is covered with tiny glandular trichomes that persist after fertilization and have a defensive function. *M .indicus* produces two superimposed campylotropous, bitegmic ovules on marginal placenta. Embryo -sac development follows the Polygonum- type of development and the embryo development is of Solanad type. Interestingly only one of these ovules matures into a hard seed while the other ovule aborts at an early stage. The hard seed coat derives from outer integument in a sequential manner and the inner integument is consumed during the ontogeny. The pod is single seeded and the seed shows insignificant enlargement. The causes and significance of seed abortion in *M .indicus* will be discussed in the present study.

Genomic mechanisms of the breakdown of dioecy: A unique case study of the Waterman Mountain elephant tree, *Bursera microphylla*

Xingyue Ge

University of Arizona

Plant sexual and breeding system evolution has long been one of the most intriguing issues to evolutionary biologists. A well-known and commonly accepted breeding system evolutionary pathway is the trend from hermaphroditism (cosexual) to dioecy (separate sexes among individuals). *Bursera microphylla,* it's a semi-succulent tree species native to subtropical dry forest across the Sonoran Desert. Most of the populations of this well-known dioecious species exhibit an unbiased sex ratio of 1:1 throughout its distribution range. Curiously, in an isolated peripheral population in the Waterman Mountains, Ironwood Forest National Monument in Southern Arizona, along the northeastern boundary of the species distribution range, *B. microphylla* has been found to have a strongly female biased gynodioecious (one population that has cosexual and female individuals) sex ratio. Heraphrodites are found in this population with the female individuals. Moreover, by examining the female reproductive success and pollination biology, researchers have shown that the female biased gynodiecious population has lower reproduction success and severer pollen limitation comparing to the traditional dioecious populations with equal sex ratios. All of these empirial ecological patterns indicate a reversal to gynodioecy from dioecy, one breakdown pathway that is theoretically possible yet has never been tested empircally. In this study, we attempted to examine the gemonic signatures of the mechanisms underlie this breakdown of dioecy. We applied novel NGS methods to detect the signals of 1) interspecific hybridization; 2) polyploidization and 3) reverse mutation on Y chromosome. Specifically, we further inquired the three questions: 1) whether this special population result from the hybridization between different species? 2) whether the hermaphrodites result from polyploidization? And 3) whether the hermaphroditic biased genes located on Y chromosomes thus possibly are reverse mutations result in novel sex morph in the Waterman Mountain population? We sequenced and *de novo* assembled 6 flower buds transcriptomes from both sex morphs: hermaphrodite and female individuals in this population. No signal of hybridization or polyploidization was detected from the distribution graph of duplicated gene pairs along evolutionary time. We then calculated and compared the evolutionary rate of sex specific genes found exclusively in each sex morph. Hermaphrodic genes have a significant higher evolutionary rate compare to female genes. Moreover, we conduct the gene annotation of the 93 genes that showed higher evolutionary rate in hermaphrodites compare to TAIR database, 35% of them are associated with biological processes, most of these candidate sex specific genes are involved in reproductive process. Taken together, our results demonstrated the potential genomic mechanism of a breakdown scenario of dioecy: there is very likely to be reverse mutations on the Y chromosomes as the hermaphrodite specific genes are most likely to be located on the Y chromosome. The mutations enable hermaphrodite to re-gain female function as the populations are very pollen limited while the hermaphrodite have a higher reproductive success from selfing. As a unique example of the reverse evolutionary process by breaking down dioecy to gynodioecy, our result has provided the very first empirical evidence to further complete the pathways of plants' breeding system.

The conservation of critically endangered species Yuanbanshan fir (*Abies yuanbaoshanensis*)—Based on the intergrated capacity building approaches in southern China

Yanjing Geng[1], *Dingming Luo*[2], *Xiaoya Li*[1], *Tao Ding*[3], *David Gill*[1], *Georgina Margin*[1]

1. Fauna & Flora International (FFI)

2. Yuanbaoshan National Nature Reserve, Yuanbaoshan, China

3. Guangxi Institute of Botany, Guilin, China

Over 9,600 tree species are threatened with extinction around the world. To safeguard the world's threatened tree species, the Fauna & Flora International (FFI) and Botanic Gardens Conservation International (BGCI) formed the only international programme called the Global Trees Campaign (GTC) in 1999. As part of GTC, FFI's China has been working on the conservation of threatened trees in southern China since 2006. The area is home to more than 200 threatened tree species, many of which are covered by nature reserves. FFI's work mainly focused on empowering the nature reserve staff to protect those threatened tree species to address the major gap that many practitioners lack the skill and experience for the plant conservation. From 2010-2016, FFI supplied six training courses to the technical staff of the nature reserve, In the meantime FFI worked with local experts and stakeholders within four reserves and developed some pilot practices. From 2012 to 2017 *Abies yuanbaoshanensis* is one of the target species. *Abie Yuanbaoshanensis* with a global population of less than 800 individuals, is a Critically Endangered conifer species, endemic to Yuanbaoshan National Nature Reserve, in North Guangxi, China. The main threats are human disturbance and high sapling mortality, young trees were totally absent, the main action constrained by low capacity and poor information. To address the threat and constraint, FFI team gave the training to the staff nature reserve, including involved the staff in the FFI training courses programmer, and improved their capacity through a series of practices together: action plan, monitoring, patrolling, habitat management, sustainable seeds collection, propagation, nursery management, reinforcement, co-community management, awareness raising, eco-tourism relevant to Yuanbaoshan fir. Major results of this work include: (1) the nature reserve upgraded from provincial level to national level, secure more fund and human resource; (2) the main staff and rangers of the nature reserve applied the training to the daily work of nature reserve; (3) some directive impacts including reduced pressure on the core zone in reserve compared to levels before the project started, and reducing ongoing pressure on natural regeneration; increased natural regeneration of both species; increased ownership of these activities (evidenced by work being carried out independent of outside support). Increased involvement of community members in management, evidenced by involvement in patrols, increased dialogue between community members and reserve staff and increased awareness and understanding of the reserve limits and the local and global importance of fir tree populations.

Taxonomy in big data use cases

Gerald Guala
US Geological Survey

The Integrated Taxonomic Information System (www.itis.gov) is a systematically curated, standardized, machine readable, standard global hierarchy and classification of all organisms. It is global in scope for may groups, including many groups of plants, and comprehensive for vascular plants in North America. In a long term collaborative effort, Species2000 aggregates other data sets with ITIS to produce the Catalogue of Life and it is used inside thousands of other databases in government, industry and academia. Extensive web services allow the direct connection of ITIS to automated workflows and analyses. Examples of this relevant to big data will be illustrated and discussed. These incluse a recent paper (dx.doi.org/10.1371/journal.pone.0162648) showing the substantial deficit incurred when not using ITIS synonyms in literature searches and the role of ITIS in taxonomicly informed searches in BISON (bison.usgs.gov) and other large data repositories and analysis packages.

Studies on the medicinal plants of gaziantep in Turkey

Salih Gucel[1], *Mehmet Yilmaz*[2]
1. Near East University
2. Gaziantep Health Directorate

A total of 117 taxa belonging to 42 families were collected from the city of Gaziantep. Out of these 43 taxa were observed to be used for medicinal purposes with 54 applications. Lamiaceae dominated the list with 12 taxa followed by Asteraceae with 5 species and Malvaceae, Liliaceae, Urticaceae with 2 species each.The most commonly used taxa are *Origanum majorona*, *O. onites*, *O. vulgare* ssp. *hirtum*, *Salvia fruticosa*, *Sideritis perfoliata*, *Thymus longicaulis* ssp. *chaubardii* var. *chaubardii*, *Lavandula stoechas* ssp. s*toechas, Teucrium polium*, *Urtica dioica*, *Malva sylvestris*, *Portulaca oleracea*, *Urtica pilulifera*, *Tilia rubra* ssp. *caucasica*, *Vitex agnus-castus*, *Vitis vinifera*, *Asparagus acutifol*ius*, *Foeniculum vulgare*, *Juniperus oxycedrus* ssp. *oxycedrus,* and *Hypericum perforatum*. The taxa recorded here have been mostly used for the treatment of cough (18.6%), stomachache (13.4%), kidney ailments (11.6%), cold, analgesic, diüretic and hemorrhoid (9. 3%), injuries, tonic, abdominal pain, laxative and dyspepsia (6.9%).

Exploration of moss flora along an altitudinal gradient at selected areas in the Central Province, Sri Lanka–preliminary survey

Nadeeka Prasanthi Thenna Gunawardena
National Herbarium, Department of National Botanic Gardens

Sri Lanka's moss flora is very diverse with 60 families, 190 genera, and 561 species of which 11% is endemic to Sri Lanka. As the diversity of moss flora in mountain areas are higher than the other parts of the country, great fraction of this island wide data may represents by the central province moss flora of Sri Lanka. Due to lack of expert knowledge and identification facilities in the country, most of the information regarding this vital group of plants is still at a very fundamental level. The main objectives of the present study are to study the diversity of moss flora at the different micro habitats of the selected location which have higher diversity of moss flora, describe the distribution pattern of terrestrial and epiphytic moss flora along an altitudinal gradient specially in some selected hill top areas in the central province, prepare a check list to the mosses find in Central Province in Sri Lanka and prepare and maintain of herbarium specimens of mosses collected during the study and thereby enrich the national collection of the National Herbarium, Peradeniya, Sri Lanka. The plants were collected from 8 selected localities, which have highest diversity of mosses in Central Province, namely Loolkandura (elevation; 1,200-1,500 m), Dolosbage-Watekelle-Kelabokka (elevation; 1,200 m - 1,350 m), Knuckles-Tangappuwa (elevation; 1,400-1,560 m), Seven Virgin Hills (elevation; 650-815 m), Hantana (elevation; 800-1,200 m), Hakgala Botanic Gardens and adjacent forest reserve (elevation-1,500-1,800 m), Peak Wilderness Area (elevation; 800-1,500 m) and dry phase (Mandaram Nuwara ; elevation-1,200-1,500 m) and wet phase (elevation 2,200-2,250 m) of Pidurutalaga. During the survey twenty field excursions were conducted from April to December 2014. Sampling were done in along non-permanent line transects. All first occurrence of mosses along 10 m x 2 m transects were collected for laboratory verification and field identification. Approximately 2 km in each location along the elevation gradient were sampled. Mosses find on rock surfaces, on soil surfaces and the tree trunks up to 2 m from the ground level, were collected. During this survey, a total of 53 genera and 63 species belonging to 25 families were investigated from 8 different localities of central province of Sri Lanka. Based on the species and generic abundance the most dominant family was Meteoriaceae. The species *Homaliodendron flabellatum* (Sm.) M. Fleisch., *Entodon macropodus* (Hedw.) Müll., *Aerobryopsis longissima* (Dozy & Molk.) M. Fleisch.of and *Circulifolium exiguum* (Bosch & Sande Lac.) S. Olsson, Enroth & D. Quandt were common taxa found in study areas. The highest richness of moss flora has been recorded in Loolkandura forest reserve and the epiphytic forms are found to be the most successful taxa in study areas.

The structure of mangrove ecosystem in Batangas, Philippines

Mariko Gunchi
Chiba University

This study was conducted in a mangrove forest, Lobo, Batangas, Philippines aiming to evaluate relationships between mangrove vegetation structure and disturbances and to design appropriate rehabilitation strategies. A total of 25 plots of 10 x 10 m was set up over three barangays, Fabrica, Lagadlarin and Olo-Olo in Lobo in three zones: seaward, midward and landward. Dominant mangroves were identified using relative density. The species were further classified using cluster and ordination analyses. Eighteen (18) woody species were encountered and 14 of them were true mangrove species. Three zones were identified and named after the dominant species: ZONE1) Ceriops zone, ZONE2) Avicennia-Ceriops- Scyphiphora zone and ZONE3) Bruguiera- Acacia zone. Canonical correspondence analysis (CCA) illustrated strong relationship between the species density and soil nitrogen and potassium. Other factors influencing species density were soil pH and disturbances. Observed disturbances included encroachments due to agriculture, residential villages, resort construction and bioinvasion of *Acacia farnesiana.* Conservation strategy is necessary to regulate extraction of resources and sustain the livelihood of local people dependent on mangrove forest.

Chromium resistant cyanobacteria and plant microbe interaction

Abdul Hameed[1], *Shahida Hasnain*[2]
1. Botany Department, Govt. College of Science
2. Women University, Multan

Fourteen chromium resistant cyanobacterial strains were isolated from polluted (*Arthrospira* sp, *Synechocystis* “MK”, *S.* “P2A” and non-polluted sites *Lyngbya* sp, *Oscillatoria* “G”, *O.*“BJ2”, *O.* “BJ”, *O.* “A”, *O.* “O”, *O.*“F.W”, *O.* “S.A” *Anabaena* sp, *Gloeocapsosis* sp, *Cyanosarcina* from different of Lahore, Pakistan. All strains showed best growth in BG 11 medium except *Arthrospira*sp. All these strains could resist variable concentrations of hexavalent chromium in liquid medium; however strains with more sheath showed more resistance to different metallic salts and antibiotics. In majority of the strains optimum chromium (VI) reduction was observed at pH 7 and 30 °C. *Cyanosarcina* sp, *Gloeocapsosis* sp, *Synechocystis* “MK (S”) and *Synechocystis* “P2A” were very efficient in the reduction of hexavalent chromium into trivalent chromium. Cyanobacterial strains were used to inoculate seeds of *Triticum aestivum*, *Zea mays* and *Vigna radiata*, which were subsequently germinated and grown under chromium stresses (300 g mL^{-1} of Cr Cl3 and K_2CrO_4) for 10 days under controlled light (195 µE m^{-2} s^{-1} for 16 hours) and temperatures (22-25°C). Under chromium stress, different growth and biochemical parameters of all three crops (*Triticum aestivum*, *Zea mays* and *Vigna radiata*) were severely affected. In general cyanobacterial inoculations caused pronounced effect in certain growth, biochemical and other parameters of plant microbe interaction, particularly after more toxin chromium hexavalent treatment. The strains *Arthrospira* sp, *Anabaena* sp, *Gloeocapsosis* sp and *Cyanosarcina* sp strains were more efficient in improving growth parameters of *Triticum aestivum Zea mays* and *Vigna radiata*. These strains were also used for pot experiments under natural conditions for *Triticum aestivum* and *Vigna radiata*. Chromium resistant cyanobacterial strains *Anabaena* sp, *Gloeocapsosis* sp and *Cyanosarcina* sp significantly increased the growth and yield parameters not only in the chromium free but also in the presence of both trivalent as well as hexavalent chromium stresses. Among these isolated cyanobacteria strains, two chromium resistant cyanobacteria strains *Synechocystis* “MK (S)” and *S.* “P2A” were isolated from the chromium contaminated area of tanneries effluents. These were first tested for probable mechanisms of heavy metal detoxification by studying the non-protein thiols, the strain *Synechocystis* “MK (S)” showed very high induction of non-protein thiols after exposure to chromium stress over other strains of same genus. Both strains used for the genetic study of this mechanism and glutaredoxin (accession No. DQ398587 for *Synechocystis* “MK (S)”) and glutathione synthetase genes (accession No. DQ381962 and DQ398588 for *Synechocystis* “MK (S)” and *Synechocystis* “P2A”) were amplified and sequenced. These two strains *Synechocystis* “MK (S)”and *Synechocystis* “P2A” were, finely selected for 16S rRNA gene sequence analysis and their homologies with reference strains *Synechocystis* sp. PCC 6803 were 98 and 97% respectively. They were identified as *Synechocystis* sp AHZ-HB-MK (accession No. DQ381960) and *Synechocystis* sp AHZ-HB-P2A (accession No. DQ398589). Hence these strains could be easily used in the bioremediation of chromium contaminated waste waters/ soil as well as plant growth promoting tool for various economically important cash crops.

What makes the red maples and their tropical ally silver? An investigation of the phylogeny and leaf surfaces of red maples, *Acer* section Rubra, and the tropical, Southern Hemi-

sphere maple, *A. laurinum* of sect. Hyptiocarpa.

***A. J. Harris**, Susan Lutz, Jun Wen*
Smithsonian Institution, Department of Botany

Our work unites *Acer laurinum* Hassk. of section Hyptiocarpa with *Acer* section Rubra according to molecular phylogeny and cuticle morphology. *Acer laurinum* is unique among maples for having a distributional range in tropical Asia that includes locations in the southern hemisphere, especially in Indonesia and the Philippines. In contrast, *Acer* sect. Rubra has a temperate distributional range and comprises *A. rubrum* and *A. saccharinum*, which are commonly encountered in eastern North American forests, and *A. pycnanthum*, which has a scattered distribution in the mountains of Japan. Species of *Acer* section Rubra are iconic for their silvery abaxial surfaces, which are the source of the name *A. saccharinum*, or silver maple. In this study, we used chloroplast and nuclear internal transcribed spacer (ITS) to reconstruct phylogenies of *Acer* including *A. laurinum*, all species of sect. Rubra, and representative samples from 19 taxonomic sections previously based on leaf and fruit morphology. Additionally, we examined cuticle morphology of *A. laurinum* and species of sect. Rubra using scanning electron microscopy, because we expected that they would possess similar epicuticular wax configurations, which may partially explain the silvery color of the abaxial leaf surfaces. Our phylogenetic results confirm prior studies based on chloroplast DNA and ITS in showing high support *A. laurinum* as sister to sect. Rubra. Abaxial surfaces of the leaves of all species exhibited roughly similar, dramatic epicuticular wax configurations that were topped by wax splatters. Some late season leaves of *A. pycnanthum* lacked the characteristic silvery color on their abaxial surfaces and the dramatic epicuticular wax configurations. We suggest that *Acer laurinum* can be combined within *Acer* section Rubra based on our results as well as fruit and inflorescence morphology. Section Rubra may have experienced a striking increase in chromosome number associated with its temperate radiation as it has $n = 78{,}91$, or 108 compared to $n = 26$ in *A. laurinum*. Future work must consider whether *Acer laurinum* represents additional species, especially *A. garrettii* Craib and *A. pinnatinervum* Merrill.

P0062
Metro moss: Integrating ecology and physiology to study the effects of urbanisation on plant diversity

***Alison Haynes**, Kristine French, Sharon Robinson*
University of Wollongong

Urban plant-environment interactions are complex since they involve variability across numerous factors including plant traits, the strength of urban stressors and qualities of local environments. Given the rapid rate of global urbanisation, it is increasingly important to understand these responses, for reasons of conservation, restoration and to improve the quality of urban habitat through urban greening projects. Moss, and the biocrust communities they associate with (liverworts, hornworts, lichen, cyanobacteria, fungi and bacteria) are little studied in urban environments, but may provide important ecosystem services such as preventing soil erosion, enhancing water holding capacity, reducing microdust and cycling nitrogen and carbon. Studies of higher plants suggest up to 75% of native plants of an area become locally extinct when it is urbanised. Numerous urban filters have been proposed to explain this phenomenon: habitat transformation, population fragmentation, novel characteristics of the urban environment such as pollution or disturbance, and human preference. From the limited number of surveys of urban bryophytes, patterns are mixed. Some show a prevalence of species that prefer humid, nutrient rich and disturbed soil; while others find predominant species are those with high tolerance to drought and light. Sexual reproduction tends to decrease, while vegetative reproductive effort tends to increase, especially with increasing pollution. Changes in community assemblage may occur as pollutant tolerant species increase in abundance when their more sensitive competitors cannot thrive; and communities as a whole may represent lower succession stages than in natural environments. In the relatively new discipline of urban ecology, investigation of urban filters has largely been in the form of correlation of environment characteristics with plant traits. An experimental approach is needed to determine the key drivers of urban biodiversity and to identify important thresholds. Key points of such an approach are: 1) Using gradient analyses of cover, diversity and assemblage from natural to urban areas, employing robust simple urbanisation indices such as substrate cover that can be calculated from satellite imagery and used to compare different regions. 2) Since microhabitat is important to moss communities, these analyses should be conducted along a variety of microhabitats such as pavement, grass verge, brick wall *etc.* 3) Manipulative experiments such as reciprocal transplants, common garden studies and colonisation experiments with carefully chosen species. Different stress responses following these planting treatments, combined with altered exposure to contaminants, light, water or heat may explain changes in diversity and abundance along the gradient as well as estimate the extent to which urban habitats promote adaptation and evolution. 4) Investigation of multiple stress responses may explain inconsistencies in current survey findings. Studies of species responses to two or more stresses is rare outside of agriculture - despite this being a common fact of life in the field. As well as aid conservation and restoration, findings from such research could be used to develop novel urban applications that exploit the characteristics of moss such as green roofs, stormwater management and air quality control.

Influence of climate change on yield and biochemical composition grain of wheat in Tajikistan

A. Abdullaev
Institute of Botany, Plant Physiology and Genetics, Academy Science Republic of Tajikistan

In recent years the attention of many researchers is aimed at the possible impact of global climate change on ecosystems. The reason is that under the influence of global and anthropogenic factors on the environment are substantial changes in climate that may negatively affect the life of the plant. Rising temperatures cause atmospheric drought and long period of time can increase evapotranspiration, resulting in desiccation of the root layer of soil cause drought and increase the salt content on soil. This has negative impact on growth and development of agricultural crops. In this regard, studies on the physiology of resistance of crops to climate change and finding ways to improve sustainability become urgent task of modern crop production. Study of the content of starch, protein and cellulose showed that soil drought and ozone help reduce starch content and high protein content in the grain of both varieties, extreme temperatures contribute to the reduction of the level of starch and protein content. High temperatures, drought, and increased concentration of CO_2 have negative influence on the content of starch and protein content in wheat. Analysis of the cellulose content in the seeds of wheat showed that the highest of its contents was observed in the seeds of wheat, grown under conditions of drought, and it was more by 25%, than in the wheat seeds, grown under optimum water supply. In variant of drought in the seeds of the sort Alex cellulose content increased by approximately 30% than that of the control group of wheat grown under optimal water supply. Increase cellulose content observed in conditions that are unfavorable for plant in stressful conditions. The spectra of the studied proteins gliadin wheat varieties contain up to 21 components, which differ in intensity and electrophoretic mobility in PAGE. Among them are the components with the highest, medium and low intensity. Comparative analysis shown that in the protein component composition Zafar varieties grown in conditions of drought, there are intensive components that are completely absent in the same varieties grown under normal climatic conditions. Comparative analysis of the samples gliadins electrophoregram both varieties showed that, despite the presence of very similar structure, there are variations in the number and intensity of protein components. Component of the protein composition of varieties Zafar varies considerably, depending on the growing conditions, not only in intensity, but also on the presence or absence of individual components. It should be noted that almost all classes, the maximum temperature of large number of protein components is absent or present in trace amounts. The paper discusses the effect of elevated CO_2, heat, water deficit, and air and soil drought on yield and biochemical composition of wheat differing in origin. Also influence of climate change on productivity and qualities of grain wheat growing in different climatic zones is discussed.

Collection, germplasm introduction and conservation of *Allium* in Xinjiang and its collection garden construction

Hikmat Hisoriev, Guan Kaiyun Guan, ***Jiang Li***

Xinjiang Institute of Ecology and Geography, Chinese Academy of Sciences, Urumqi, China

The very diverse genus *Allim* L. shows a nearly exclusive distribution across the northern hemisphere with a main centre of diversity in Southwest, Central Asia and in China. Since 8,000 years, common onion has been probably used by men kind as edible, spice and vegetable. Currently, rhizomes or bulbs, extracts of those or green parts of several species like *A. cepa, A. sativum, A. stipitatum, A. rosenorum, A. rosenbakhianum, A. oschaninii, A. chinense, A. fistulosum, A. porrum* and *A. tuberosum* are intensively used by the native Asian populations. Also today *Allium* crop species have world-wide importance as spice, medicinal, and food plants. Thus, they own an eminent economical importance and are involved in intensive breeding programs world-wide in order to improve yield, quality, and agriculturally important characters. There are 138 species and 24 varieties (50 endemic, five introduced) of *Allium* species were found in China. Our short investigation on *Allium* collection mission in different regions of Xinjiang Province of China which belong to Tianshan and Altai mountains (around Urumqi, Bozhou, Jinghe, Yining, Zhaosu, Teksi, Xinyuan, Hami, Balikun, Qitai, Fuyan, Altai, Buerjin, Emin, Tacheng and Bole) shows that totally in natural landscapes of Xinjiang Province distributed 50 species of *Allium.* Most of these species (up to 23 species) were found in around Yili, Urumqi and Altai territory. Among them 22 species were found in around Urumqi, belonging to Tianshan Mountains, 23 species – in around Yili (Tianshan territory), and 23 – in Altai Mountains. Between 50 wild species of *Allium* in Xinjiang, several species, such as *A. ramosum, A. atrosanguineum, A. polyrhisum* and *A. przewalskianu*, *A. polyrhisum, A. senescens* have wide distributed area in China. But next species, as *A. carolinianum, A. hymenorrhizum, A. pallasii, A. grisellum, A. caricoides, A. schoenoprasum* and *A. schoenoprasoides* are presented with a small local populations in several places only in Xinjiang region. By chaotic pasture and anthropogenic pressure distribution area most of them became very small, and at present above mentioned species should be named as rare and endangered plants, and to be included in next Red Data Book of Xinjiang Province or Red Data Book of China. Finally in 2016 more than 70 Accessions of newly collected wild *Alliums* in Xinjiang region and collected also from Tajikistan and Uzbekistan were planted in newly established Yili Botanical Garden for future monitoring, collection their germplasm, and bio-morphological investigations.

Tajikistan botanical gardens as a valuable fund of the aborigine and introduced plant species

Hikmat Hisoriev

Institute of Botany, Tajik Academy of Sciences, 27 Karamova str., Dushanbe-17, Tajikistan, 734017

There are five botanical gardens in Tajikistan, which situated in different zones: Khudjand Botanical Garden in North Najikistan (8 ha, 350 m above sea level); Kuljab Botanical Garden in South Tajikistan (14 ha, 650 m above sea level); Central Botanical Garden in Dushanbe – the capital of the Republic of Tajikistan (41 ha, 800 m above sea level); Varzob Mountainous Botanical Station in Central Tajikistan (1,000 ha, 1,050-2,600 m above sea level); Pamir Botanical Garden in East Tajikistan (near 100 ha, 2,200 m above sea level). The main scientific research of the gardens are exploration of plant diversity in natural landscapes of Pamir-Alai Range, including endemic, rare, endangered species and ecosystem conservation and investigation on adaptation of introduced from another climatic zones plant species in different botanical gardens. Tajikistan botanical gardens are a permanent research and trial facility designed for multi-faceted research efforts of the National Botanical Institute. It always had its own peculiar highly articulated body of scientific research work, whose core consisted of the study of forest vegetation of Tajikistan and Pamir-Alay as a whole, establishment of floristic (species) composition of the country's dendroflora, the study of morphological and biological features of trees and bushes of Pamir-Alai, development of ways to create on high altitudes highly efficient fruit and forest and other erosion control plantings. A critical reassessment of the native flora has shown that forests of Tajikistan are surprisingly diverse in their species composition. The whole collection of more than 2,000 species of trees and bushes have already collected and cultivated in four parts of Central Botanical Garden: Ancient Mediterranean plants (639 species), East Asia plants (837 species), North American plants (488 species), Middle Europe plants (226 species). Many hitherto undiscovered species have been detected, including *Acer ovczinnikovii, Myrtama elegans, Prunus tadshikistanica, Pyrus tadshikistanica, P. cajon, etc.* But in multiple cases there were no clear-cut boundaries between wild and domesticated plants. This led to a conclusion that the range of fruits cultivated on high altitudes grew on site by means of cultivation of their wild counterparts. The mountains of the Pamir-Alay Range are recognized as one of the global centers of the origins of cultivated, as well as fruit plants. In this regard, the study of the issues and the development of scientific basis for the conservation of food, medicinal and forage plants of the region is one of the major environmental challenges. Up until now, many wild and highly threatened species of food, medicinal and edible plants, are characterized by a narrow ecological amplitude of distribution (as a stenobionts), and are not developed specific actions or recommendations for growing or cultivating in experimental pilots in botanical gardens, and transfer to the place of their natural habitat. In this regard, there is an urgent need to conduct a complete inventory renewal, management and sustainable use.

Freshwater algal diversity of the South-Tajik Depression in a high-mountainous extreme environment

Mario Boboev

Khatlon Scientific Center, Tajik Academy of Sciences, 12 Shark str., Kulob-25, Tajikistan, 734025

The effects of altitude on freshwater algae distribution is widely discussed in the recent literature but still remains a problem. Our investigation in freshwater algal communities' comparisons and infraspecific levels of comparison gives us a method for a productive approach when there are visible climatic responses in the eco-regional, river basin floras. South-Tajik Depression algae from low- to high mountain habitats of the Vakhsh, Kafirnigan, Kyzylsu, Yakhsu, Tairsu river basins, Muminabad and Selbursk reservoirs have been studied during last 50 years. The aim of the current study was to reveal the response of algal communities in this region to altitude and altitude-related climatic conditions of its habitats, and we tried to implement diverse bioindicational and statistical methods, which represented some new approaches in freshwater algal diversity analysis. The research on algal communities' response to altitude and altitude-related climatic conditions is sparse, and a full, accessible list of algae from the water bodies of the South-Tajik Depression has not been available yet. We compiled an algal species list of 1,190 species and varieties that were revealed by us or listed in references in the South-Tajik Depression water bodies. The altitude gradient of the studied area is about 2,500 m above sea level. An altitude-related algal diversity analysis was done with help of statistics and bioindication. The Willis curve for the distribution of species to genera had a trend line of $R^2 = 0.92$. A multivariate analysis was used for quantitative estimates of the ecological tolerance ranges of critical species and for detecting cardinal factors and trends at local water bodies to global levels of biodiversity evolution. Our analysis shows that species distribution was strongly affected by altitude and altitude-related climatic variables. Statistical methods revealed that temperatures stimulate algal species diversity, while precipitation and altitude suppress it. One of the floristic complexity criteria is the average species richness of the algal genera or the infraspecies to species ratio, which increased from 1.12 to 1.20 and reflects increases in structural complexity with altitude. Therefore, high altitude stresses algal communities and stimulates species polymorphism as a compensatory mechanism for algal species survival. A comparison of the Tajik Depression freshwater algae with other regional algal floras of high mountains shows that altitude and altitude-related climatic variables play a major role in species distribution: temperature stimulated algal diversity, while precipitation and altitude suppressed it. The study of high-mountain algal flora showed increases of structural complexity with altitude. This means that many species per genus in lower-altitude habitats showed evidence of stable development, whereas a high ratio of monotypic genera can be related to climatic, or anthropogenic impacts such as what was seen in the high-altitude communities of the South-Tajik Depression: high altitudes not only stress algal communities but also stimulate species polymorphism as a compensatory mechanism for the survival of algal species.

Diversity of spore plant in Pamir region (Tajikistan)

Parvina A. Kurbonova, *Hikmat Hisoriev*

Institute of Botany, Tajik Academy of Sciences, 27 Karamova str., Dushanbe-17, Tajikistan, 734017

The Pamir (which means "roof of the world" in the Tajik language) is unique not only geographically, but its remarkably rich and highly endemic vegetation including many plants of great promise for about 64,000 km^2 (43% of Tajikistan Republic). Tajikistan's Pamir borders on Afghanistan (> 500 km) on the South, China on the East (430 km), Kyrgyzstan on the North. The complex relief of Pamir a result of prolonged history of geological formation – is characterized by Docembrian formations in the Southwest and Paleozoic-Mesozoic formations in the Southeast. Pamir is divided geographically into two parts, western (Badakhshan) and eastern (Pamir). There are more than 10 big and hundreds small lakes and a lot of rivers, springs, thermal and mineralized water bodies in Pamir. In spite of this, the climate of western Pamir belongs to the northern dry subtropical zone of the Mediterranean area and has a maximum annual precipitation of 300 mm, but the climate of eastern Pamir belongs to the Central Asian area, (100 mm), continental high mountainous plateau with cold summers and stern winters. There are four zones of vegetation in western Pamir: ephemeral deserts, wormwood steppes and feather-grass, mountainous xerophytes, and cryptophytes (uplands). There are near 2,000 species of vascular and more than 1,500 species of spore plants (algae, lichens, bryophyta and fungi) in Pamir, including 180 endemic, rare and endared species. Among the endemic plants more than 80 species listed in the Red Data Book of Tajikistan (2015). With the current destruction of habitats occurring at critically rapid pace throughout the western and eastern Pamir, and also the global climate change the degree of potential loss of species makes this region a high priority for study of biodiversity and development of conservation programs. During the 27 years since the first publication of the Red Data Book of Tajikistan (1988), extraordinary economic events in Pamir degraded large areas of the landscape and have adversely affected environmental crises. Many trees and shrubs were cut down for firewood, and many areas were cleared for pastures to raise livestock. As a result, the Pamir region currently faces a critical situation. A few botanical surveys or inventories have been conducted for a last period, and it is feared that many plant species have disappeared or are in danger of extinction. There are 1,100 species with more than 300 varieties of algae were found in water bodies and in soils of Pamir, belonging to 10 Division (*Cyanophyta, Euglenophyta, Cryptophyta, Dinophyta, Chrysophyta, Xanthophyta, Bacillariophyta, Chlorophyta, Charophyta, Glaucophyta, Rhodophyta*), 19 classes 91 families and more than 220 genus. Among the 91 families of whole algae flora, such families as Oscillatiriaceae, Euglenaceae, Naviculaceae, Cymbellaceae, Scenedesmaceae, Desmidiaceae, Closteriaceae and Ulothrichaxeae were dominant. There are more than 15 genus are as a dominants: *Navicula, Synedra, Cymbella, Pinnularia, Euglena, Trachelomonas, Oscillatoria, Phormidium, Ulothrix, Scenedesmus, Cosmarium, Closterium etc.*

Plant biodiversity conservation in Tajikistan

Hikmat Hisoriev
Plant Biodiversity Conservation in Tajikistan

Tajikistan is a typical mountainous country and covers the whole territory of Pamir-Alai Range with a most complex physical and geo-morphological structure with elevation from 300 to 7,495 m above sea-level and characterized with a wide range of ecological conditions and has a correspondingly rich natural flora (more than 9,500 species of spore and vascular plants) with a wide range of plant ecosystems. There are 2,200 species of Algae, 2,000 - Fungi, 600 species - Lichens, 400 species - Bryophytes and more than 4,500 species of vascular plants found in Tajikistan. Among them more than 800 species are endemic and 267 species (or 2.75%) are included in Red Data Book of the Republic of Tajikistan. The vast majority of Tajikistan plants are edible, medicinal and food species. In the whole pasture and meadows ecosystems occupy more than 24% territory of country; forest ecosystems – 3%; cultivated or agro-ecosystems – 6% (irrigated and non irrigated); nearly 67% are unused natural landscapes, which covered with forests in the past and now damaged by aridization and the anthropogenic pressure, rocky and stone slopes covered with a sparse vegetation, snow-patches and glaciers. Lacks of knowledge about the diversity of life in Pamir-Alai and the effect of scientific activities on this invaluable resource pose the most significant barrier to their management and conservation. The current destruction of habitats occurring at critically rapid race throughout the country, the degree of potential loss of plant species and whole landscapes makes this region a high priority for future monitoring of a whole ecosystems and development of conservation programs. Grazing by animals, as well as cutting of trees, shrubs, uprooting of medicine and food plants have greatly reduced the coverage of the ecosystems and its structure. Notwithstanding the increase of desert and xerophytic ecosystems in the contemporary period and also in near future great significance is put to such ways of realization of species formation as aridization of vegetation in Pamir-Alai Range. During last 50-70 years in the mountainous territory of Zerawshan-Turkestan, Gissar-Darwaz, Karategin-Peter First, in pasture landscapes the population of Traganthoid associations or thorn (bur) plant species, are formatting xrephyllous and hemixerophyllous ecosystems, mainly with thorn and cushion plant species (*Onobrychis echidna, Astragalus* species (sect. Aegacantha), *Acantholimon diapensioides, A. hedinii, Cousinia pannosa, C. franchetii etc.*) have already increase. Furthermore, under the climate change and anthropogenic pressure forest's ecosystem zone in country became narrow: upper forest line came down, but the reverse, lower forest line went up (under anthropogenic pressure). Thus, divers ecological and geographical conditions, ranging from hot deserts and humid subtropical regions to high alpine regions, as a Pamir-Alai Range have favored the establishment of a complex and varied composition and structure of ecosystems, are also greatly influenced by a long history of over-exploitation which has led not only to the almost complete loss of forests but also to widespread degradation of formerly rich woodland and semi-arid ecosystems.

Climate change, ecological calendars and the Yulong Mountain

Jianchu Xu[1,2]*, Pete Hollingsworth*[3]*, Antje Ahrends*[3]
1. Kunming Institute of Botany
2. World Agroforesty Centre
3. Royal Botanic Garden Edinburgh

Climate change can have particularly marked effects in mountain systems which may then lead to profound consequences for local communities and livelihoods. Although climate change is a global phenomenon, its impacts occur at all scales and will vary in nature and strength from place to place. Ecological calendars are traditional knowledge systems based on phenological indicators that have served to link biological and cultural activities to seasonal change. In this presentation we will explore the role of ecological calendars coupled with climate change projections as a strategy for integrating traditional indigenous knowledge with climate change science to facilitate dynamic adaptive responses by local communities.

The spatial distribution of *Primulina* (Gesneriaceae) favorable habitats and the predication of the habitat changing in the future

Xin Hong[1,2]*, Fang Wen*[2,3]*, Yi-Gang Wei*[2,3]
1. School of Resources and Environmental Engineering, Anhui University

2. Gesneriad Conservation Center of China (GCCC), Guilin Botanical Garden, Guangxi Institute of Botany
3. Guangxi Key Laboratory of Plant Conservation and Restoration Ecology in Karst Terrain,

Thirteen eco-environmental factors, including elevation above sea level, slope, aspect, minimum temperature of coldest month, maximum temperature of warmest month, average temperature of growth, precipitation of growth, Isothermality, mean Temperature of wettest quarter, mean Temperature of direst quarter, precipitation of direst month, precipitation of warmest quarter, precipitation of coldest quarter, were used to build the assessment system of habitat niches for *Primulina* (Gesneriaceae) in South China. Then we calculated the weight of various ecological factors which affected habitat suitability through the application of maximum entropy model. Lastly, the multiply models and geographic information system (GIS) were joined up and used to seek the spatial distribution of suitable habitat range in *Primulina*. At the same time, we also predict and assess the spatial distribution of habitat suitability of *Primulina*, and the optimum regions for optimal growth of the *Primulina* in China in the future.

Study on distribution and ecological effect of *Usnea* lichens in three parallel rivers based on niche modeling

Lihui Hu, *Deshun Zhang*
Tongji University

Usnea Dill.ex Adans.belongs to the family of *Usnea* sneaceae. Most of the species are widely distributed and the morphological characteristics are highly varied. As the main food source of *Rhinopithecus bieti*, it is of great significance to *Rhinopithecus bieti*, which accounts for more than 60% of the main food sources, and 91% of their feeding time. In addition, *Usnea* lichens is a typical environment sensitive plant, which has obvious reaction to environmental and climatic factors such as air pollution, climate change and altitude. Therefore, by analyzing the geographical distribution pattern of Usnea lichens in the three parallel rivers and predicting its potential suitable area, the influence of environment and climatic factors on its geographical distribution pattern is discussed. Based on its distribution data in China, combined with climate, altitude, vegetation and other environmental data, the use of MAXENT modeling and ArcGIS software to simulate the combination of pine in the three parallel rivers of the potential suitable area. Combined with field investigation and specimen data, the geographical distribution was drawn with the elevation layer and the vegetation cover layer as the base map. Moreover, the predictive data was tested and verified by receiver operating characteristic (ROC), and the influence of the main environmental variables on distribution of *Usnea* lichens was analyzed with Jackknife test. According to the results of the study, the annual average precipitation, temperature seasonal variation, air pollutant index, standard normalized vegetation index, and altitude are the main environmental factors affecting the spatial distribution of *Usnea* lichens. Increase the coverage rate of trees, reduce the habitat fragmentation caused by human disturbance, and ensure that air cleaning is the main measure of *Usnea* lichens protection. According to the above main ecological environment factors, the optimum area, suitable area and unfavorable area of the distribution distribution of the pineapple in the Sanjiang parallel area are divided. With the interference of global climate change and human activities, the potential suitable area is obviously narrowed. Distribution area decreased. According to the above main ecological environment factors, the optimum area, suitable area and unfavorable area of the distribution of *Usnea* lichens in the three parallel rivers area are divided.With the global climate change and human activities of the interference, the potential suitable area was significantly reduced, the optimal distribution area decreased.

Genetic diversity of the Bahamas *Pinus caribaea* populations in south subtropical zone of China estimated by SSR markers

Yichen Zong[1], *Ping Huang*[1], *Yongqi Zheng*[1], *Furong Lin*[1], *Chengrong Xu*[2], *Shaoying Zou*[2]
1. Research Institute of Forestry, Chinese Academy of Forestry
2. Research Institute of Forestry, Hepu County

Pinus caribaea var. *bahamensis* is native to Bahamas in the Caribbean, and it is a kind of fast-growing conifer in tropical zone. *Pinus caribaea* var. *bahamensis* was introduced to China in 1983, and the provenance trial of this species was conducted 1990s. This species has straight trunk, narrow crown, natural pruning, good resistance, which are advantage of condensed planting. *Pinus caribaea* var. *bahamensis* is a good selection of planted forest in the south subtropical and tropical area in China. Aim to enhance the understanding of *Pinus caribaea* var. *bahamensis* genetic resources which were introduced and conserved in the field. In the study, eight SSR markers was screened and used to analysis the population genetic diversity of *Pinus caribaea* var. *bahamensis*. The result showed that forty-eight alleles were detected in eight loci, and most of loci were Hardy-Weinberg equilibrium. And the fisher test result showed that all loci were genetic linkage disequilibrium and it suggested that genetic linkage between loci did not exist. Moreover, the population genetic parameters indicated that there was not wide variable between populations. However, it was worth noting that the observed heterozygosity was less than expected heterozygosity, this result suggested that heterozygote deficiency was main problem in the exotic populations of *Pinus caribaea* var. *bahamensis.* The results of population genetic differentiation showed that the intrapopulation variation was more dominant to interpopulaiton, the Fst was 0.094 and 0.006 respectively. This indicated that no significant genetic drift happened in the exotic populations. Based on the genetic distance, seven different provenance populations were divided into two groups, and it is helpful to select breeding material. On the basis of existing genetic resource of *Pinus caribaea* var. *bahamensis*, these results were able to guide us to make more crossbreeding work in the future.

Continuous existence of Chinese pepper suggests limited impact of the cooling trend on climate in southwestern China

Yong-Jiang Huang[1], *Hai Zhu*[1], *Tao Su*[2], *Xue-Ping Ji*[3], *Zhe-Kun Zhou*[1,2]
1. Key Laboratory for Plant Diversity and Biogeography of East

Asia, Kunming Institute of Botany, Chinese Academy of Sciences
2. Key Laboratory of Tropical Forest Ecology, Xishuangbanna Tropical Botanical Garden, Chinese Academy of Sciences
3. Department of Paleoanthropology, Yunnan Institute of Cultural Relics and Archaeology

The late Cenozoic cooling trend has profoundly influenced the plant diversity and distribution worldwide, particularly in middle and high latitude regions, e.g., Europe. Its impact on the vegetation of lower latitude regions, e.g., southwestern China known as a biodiversity hotspot, however, remains debatable. Pantropical plants such as *Zanthoxylum* L. (Chinese pepper) preferably grow in warm areas of southeastern Asia, and thus its biodiversity may reflect a warm climate. In this study, fossil seed remains of *Zanthoxylum* are studied/consulted from five localities in southwestern China that extend from early Pleistocene into early or middle Miocene in age. These fossil records, together with the modern high diversity and wide distribution of *Zanthoxylum* in southwestern China, imply that the genus likely has continuously existed in the region at least since the early to middle Miocene. In contrast to the post-Pleistocene disappearance of *Zanthooxylum* in Europe, in southwestern China the genus has survived through the harsh Quaternary ice house climate to today. This may allow us to further presume that the dramatic Quaternary cooling trend has had limited impact on the climate and vegetation in southwestern China.

Studies on plant community structure and plant diversity of mountain areas in Shenzhen

Yu-Yuan Huang[1], *Li-Jun Yang*[2], *Xin-Fan Yu*[2], *Kang-Sai Zhao*[2], *Hong Liang*[2], *An-Qiang Dong*[1], *Shi-Zhen Lin*[1], *Yu-Feng Zou*[1], *He-Yin Wang*[1], *Yong-Heng Chen*[1], *Hao Liu*[1]
1. College of Life Sciences, Zhongkai University of Agriculture and Engineering
2. Shenzhen Environmental Monitoring Center

The communities structures and plant diversity in Yangmeikeng of Qiniang Mountain, Chiao of Tianxin Mountain, Lianhua Mountain, Yingrenshi of Yangtai Mountain and Xiaonanshan Mountain, Shenzhen, China were carried out research. The aim is provide theory reference for the plan, management and optimization of ecosystem of local region, and prove theory references to more argument problem on which kind community is biodiversity higher? Is natural forest, artificial forest or more artificial disturbed forest higher? Research according to the several facts chose and divided community: (1) Natural forest; (2) half-natural forest; (3) Artificial disturbed forest or artificial forest. In very community, measured the height of plant, coverage, DBH (tree), density and frequentness *etc.* indices; meanwhile, calculated Simpson index, Shannon–Wiener indices and Odum, Menhinnick richness indices and Pielou evenness index, Sorenson β-diversity, and the richness indices of family and genus. The result showed that the structure and plant diversity of natural forest of Yangmeikeng and Xiaonanshan Mountain obvious better than artificial disturbed forest or artificial forest, the half-natural forest were the middle level of the forests of Lianhua Mountain and a community of Yingrenshi hill area. In the indices of height, DBH and coverage of tree layer, natural forests and half-natural forests were more obvious higher than that of artificial disturbed forest or artificial forest; in some forests of artificial disturbed forest or artificial forest, though their richness indices of family and genus were a slightly higher, but this contribution major was herb layer plants, and some shrub layer plants. Analysed three kinds communities, the tree species more of natural forest, every diversity index value highest, half-natural forest was second, artificial disturbed forest or artificial forest was lowest; in shrub layer, although the some indices of artificial disturbed forest or artificial forest were higher, but the values were not obvious difference to natural forests; in herb layer, some β-diversity indices of artificial disturbed forest or artificial forest were higher than some natural forests, but the integral values of the diversity indices of natural forest and half-natural forest were obvious higher than the former. These results showed that artificial disturbed forest or artificial forest maybe can temporary raise the plant diversity of community, the major contribution is herb and some shrub plants, the tree layer species diversity is very low, although thus, the integral values of diversity indices still are natural forest, half-natural forest, artificial disturbed forest or artificial forest. However, in tree community, because tree biomass is more than 5 times, some more than 10 times than that community was composed by shrub and herb plants, thereby the ecological effects of the former are high many times than the latters. Therefore, author thought that in respect of vegetation protection, restoration and optimization can not only see the value which one layer plant diversity raise, it should be mainly to see whether the diversity raise of high and large tree plant species, and the community structure of tree composition is well in the area where is can grow trees.

Evaluating the supercritical extraction effects on the chemical compositions of the extracted nutmeg (*Myristica fragrans*) oil using GC/TOF-MS

Ahmad H. Ibrahim[1], *Sawsan S. Abdulhameed Al-Rawi*[1], *Mohd. Omar Abd Kadir*[2]
1. Biology Department, University of Zakho, Duhok, Kurdistan Region, Iraq
2. Biology Department, University of Zakho, Duhok, Kurdistan Region, Iraq

Gas chromatography time of flight mass spectrometry (GC/TOF-MS) is becoming an attractive and alternative full-spectrum technique against others traditional instruments. In this study, the GC/TOF-MS was used to evaluate the effect of supercritical parameters, temperature, and pressure on the chemical composition of the nutmeg extraction yields. A general factorial design of 3x4 was used. The first independent studied variable was extraction pressure (MPa) with 4 levels as follow (20.7, 27.6,34.5 and 41.4 MPa). The second independent variable was a temperature with three levels (40, 50 and 60 °C). The response is the oil yield at each design point was recorded. A total of 12 samples of nutmeg oils were obtained from the extraction and then were analyzed for it chemical components using GC/TOF-MS. A large list of compounds was identified and matched to the NIST library with a hit over 80% on the basis of the specific mass determination of their molecular ions and their major fragments. All the overlaps peaks were separated. The aromatic ethers groups were successfully identified as the main group in the supercritical extracts with the presence of Myristicin as the highest peak. Moreover, all the extracted oils possess similar chemical components but varied in each compound concentration. However, increasing the extraction temperature increased the presence of many compounds in the extracted oil such as elemicin, eugenol, and farnesene. Increasing the extraction pressure increased the presence of pinene, terpinene, thujene, phellandrene. In addition, nutmeg oil was extracted using Soxhlet and was the extracted yield was compared to the supercritical extraction in terms of chemical composition. The result showed the presence of the aromatic ether group in the Soxhlet extraction was lower than the concentration of the same group in the supercritical extractions using GC/TOF-MS. This result reveals that the extraction condition and method has the great effect on the chemical compositions of the extracted oil and on the concentration of each compound. Moreover, the use of GC/TOF-MS confirmed the effect of supercritical extraction parameters such as temperature and pressure represented by the various presences of chemical compounds. This finding indicates and confirms the potential use of the supercritical extraction method in producing richer extract and fractions.

Bryophyted diaspore bank of peatlands

Nele Ingerpuu, *Kai Vellak, Tiina Samson*
University of Tartu

The area of peatland is declining drastically in the whole world. Therefore conservation and restoration of peatlands has become more actual. The main peat forming plants in temperate regions are bryophytes. Restoration capacity of disturbed peatland depends largely on the available diaspore bank. Our study includes three types of peatland communities in Estonia: rich and poor fens, and raised bogs, three study sites in each community type. The above ground vegetation was registered in four 1 m^2 plots. The thickness of living peat was measured and underneath it diaspore bank was sampled from two depths: upper peat layer (0-7 cm) and deeper peat layer (7-14 cm). From each community type 48 samples were collected. The diaspore bank was grown in controlled conditions in growth chambers for six months. The results showed that the number of species in bryophyte diaspore bank was lowest in raised bog and higher, but quite similar in poor and rich fens. This corresponds well with the species richness of the above ground flora of these communities. The composition of the diaspore bank consisted mainly of the species belonging to the above ground flora of the same community. This indicates that the diaspore dispersal might not be very effective and the quick restoration of the bryophyte cover of disturbed communities relies greatly on the local diaspore bank.

Evolutionary distinctiveness and conservation priority of the endangered *Najas ancistrocarpa* (Hydrocharitaceae)

Yu Ito[1], *Chigaya Enju*[2], *Jie Li*[1], *Norio Tanaka*[3]

1. Xishuangbanna Tropical Botanical Garden, The Chinese Academy of Sciences
2. Tsukuba University
3. National Science Museum of Nature and Science, Tokyo

Phylogeny is vitally important to evaluate evolutionary distinctiveness and conservation priorities of species. *Najas ancistrocarpa* is among the ca. 30–40 species of the aquatic plant genus *Najas* (Hydrocharitaceae) and is one of the rarest and least known ones in East Asia. We used a recently discovered collection of this nationally endangered species in Japan to assess whether *N. ancistrocarpa* is a distinct species or an abnormal form of other *Najas* species and to evaluate its conservation priority in a phylogenetic context. The sample set of our previous study exploring worldwide phylogeny of the genus with *N. ancistrocapra* in it was used to delimit species boundaries in Najas and obtain conservation priority scores calculated by multiplying evolutionary distinctiveness and global extinction risks converted from Red List categories. Species delimitation analysis objectively assessed that *N. ancistrocarpa* is phylogenetically distinct. Phylogenetic conservation prioritization ranked *N. ancistrocarpa* as the second prioritized *Najas* species. Overall, in terms of biodiversity conservation, *N. ancistrocarpa* represents an important Najas species in Japan and probably in the world.

Flower color and pigments in *Amherstia nobilis* endemic to Myanmar

Tsukasa Iwashina[1], *Nobuyuki Tanaka*[1], *Mu Mu Aung*[2], *Tomohisa Yukawa*[1]

1. Department of Botany/National Museum of Nature and Science
2. Forest Research Institute/Ministry of Natural Resources and Environmental Conservation

The genus *Amherstia* (Leguminosae) consists of only one species, *A. nobilis* Wallich and endemic to Myanmar. The species is widely cultivated and generally regarded as one of the most beautiful of all flowering trees. However, its wild population in Myanmar is not known. Flower color is orange-red and its pigment has been reported as anthocyanin, pelargonidin (Beale *et al.,* 1941), but detailed data of the flower pigment were hardly known. In this survey, the authors fully analyzed their flower pigments. The flowers were collected in the Tsukuba Botanical Garden, National Museum of Nature and Science, Japan, and University of Yangon, Myanmar. Fresh flowers were extracted with MeOH:HCOOH (97:3). The extracts were applied to prep. PC using solvent systems, BAW (*n*-BuOH/HOAc/H_2O = 4:1:5, upper phase) and 15% HOAc and prep. HPLC and pigments were finally purified by Sephadex LH-20 column chromatography using solvent system, MeOH/H_2O/HCOOH (70:25:5) for anthocyanins or 70% MeOH for flavonols. Each three of anthocyanins and flavonols were isolated from the flowers. Major anthocyanin was cyanidin 3-*O*-glucoside (absorption maxima λmax 325 nm) with minor cyanidin 3-*O*-glucuronide and cyanidin 3-*O*-pentoside, in spite of absorption maxima of intact flower of λmax 506 nm. However, the presence of pelargonidin and carotenoids were not shown in this survey. Three flavonols were identified as isorhamnetin 3,7-di-*O*-glucoside, isohamnetin 3-*O*-glucoside and isorhamnetin

7-O-glucoside by UV, LC-MS, acid hydrolysis and direct TLC and HPLC comparisons with authentic samples. As the results, in spite of flowers of *A. nobilis* expressed orange-red color, anthocyanins in the flowers were cyanidin glycosides (red color). The factor of hypsochromic shift of the flower color may be due to lower pH of the vacuole. We now survey about its factor in progress.

Circumscription of taxa in *Scutellaria multicaulis* Boiss. complex based on molecular and morphological traits

Keivan Safikhani[1]*,* ***Ziba Jamzad***[2]*, Hojatolah Saeidi*[3]
1. Agricultural and Natural Resources Research Center, Agricultural Research, Education and Extension Organization (AREEO)
2. Research Institute of Forest & Rangelands, Agricultural Research, Education and Extension Organization (AREEO)
3. University of Isfahan

Scutellaria L. (Scutellarioideae) is a genus of Lamiaceae and grows both in Old and New Worlds. The Irano-Turanian Region, particularly Central Asia and Afghanistan, is the center of maximum diversity for the genus. However, Eastern Mediterranean and the Andes are the second centers of its speciation. In the Plant List data base there are 465 accepted species names for *Scutellaria*. It is among the medicinal plants list with a wide range of pharmacological actions, such as antitumor, anti-angiogenesis, hepatoprotective, antioxidant, anticonvulsant, antibacterial and antiviral activities. There are 27 species of *Scutellaria* in the flora of Iran of which 9 are endemics. Most species have limited but a few have a wide distribution range in Iran. *Scutellaria multicaulis* Boiss. is one of those with wide range of distribution including south east, centre and west of Iran. Due to the wide range of distribution, rather high variation in morphological features is known for this species. Three subspecies of this taxon were reported in Flora Iranica, including subsp. *loringensis* (Rech. f.) Rech f. endemic to Afghanistan, subsp. *multicauls* endemic to Afghanistan and Iran and subsp. *koelzii* (Rech. f.) Rech f. endemic to Afghanistan and Pakistan. The morphological variation in *Scutellaria multicaulis* was studied with the aid of molecular makers including nr DNA ITS and chloroplast *trn*L-F sequences to be able to define the taxa within the mentioned species complex. Phylogenetic analyses were performed on the aligned data matrices separately using the model suggested by MrModeltest 3.7. The estimations of phylogeny were done with Bayesian inference. Based on morphological data two main groups were recognized, the taxa with yellow flowers and short retrorse hairs in lower and middle parts of stem and simple and glandular patent hairs in inflorescence region (group 1) and those with dark violet flowers with yellow spot in lower lip and short, simple antrorse hairs, intermixed with sessile glands in inflorescence region (group 2). Furthermore, morphological variations could be defined within group 2. The nucleotides sequences of ITS and *trn*L-F markers represent differences between the two groups. Based on morphological and molecular data three new taxa were identified and described.

Taxonomic study based on database of Iris (Iridaceae) specimens from Middle Asia in LE

Chang Gee Jang[1]*, Nu Ree Na*[1]*, Jeong Mi Park*[2]
1. Department of Biology Education, Kongju National University
2. Plant Resources Division, National Institute of Biological Resources

The family Iridaceae is a well defined assemblage of approximately 1,800 species belonging to the *Liliidae (*the monocotyledons). The distribution of this family is worldwide, the family has a marked concentration in Africa south of the Sahara, including Madagascar. About genus *Iris*, is composed of ca. 225 to 300 species which is distributed in mainly northern hemisphere. This genus is perennial herb and is taxonomically the member of Iridaceae under Asparagales. The type of rhizome, inflorescense, presence and hairy of outer perianth segments, and shape of fruit and seeds are used as the taxonomical characters in many systematic study. There are about 60 species in the genus Iris L. in the flora of Middle Asia (khassanov & Rrakhimova 2012) and more than a dozen new species were described recently. A. I. Vvedensky (1941,1971) made taxonomical revision of Central Asian Iris, which treated *Juno* was treated as a separated genus. Also *Iris* has been revised in “Conspectus Florae Asiae Mediae” by O. Tscherneva (1971). 36 species of *Iris* are endemic for this area. R. Kamelin (1981) and later on T. Hall and A. Seisums (2011) made several new combinations from *Juno* restoring to *Iris*. Middle Asia can be treated no doubt as one of the largest centers of biodiversity of genus *Iris* L. Herbarium of the Komarov Botanical Institute (LE) is one of the biggest herbarium in the world. LE has specially the largest amount of specimens from Middle Asian area, such as Uzbekistan, Kazakhstan, Tajikistan, Kyrgyzstan, and Turkmenistan. Among the 88 taxa which were recorded in Flora of USSR, the 46 taxa are treated from Central Asia, which means Middle Asia and western part of Kazakhstan territory. Based on results of survey Herbarium of the Komarov Botanical Institute, specimens of 61 taxa were deposited in Middle Asia section. Some did not recorded as Middle Asian taxa in Flora of USSR, others which treated as Middle Asian taxa in Flora of USSR have no specimens in this section. The former included like as *I. sibirica* L., *I. setosa* Pall. ex Link, *I. laevigata* Fisch., *I. pseudacorus* L., *I. ludwigii* Maxim., *I. dichotoma* Pall., *I. pumila* L., *I. potaninii* Maxim., *I. tigridia* Bge in Ldb., *I. germanica* L. *etc.* The latter composed such as *I. sogdiana* Bge Beitr., *I. ewbankiana* Foster, *I. karategina* B.Fedtsch., *I. winkleri* Rgl., *I. maricoides* Rgl., *I. nicolai* Vved., *I. rosenbachiana* Rgl., *I. popovii* Vved., *I. parvula* Vved., *I. tadshikorum* Vved., *I. linifolia* O.Fedtsch., *I. vvedenskyi* Nevski, *I. narynensis* O.Fedtsch., *I. narbutii* O.Fedtsch., *I. kuschakewiczii* B.Fedtsch., *I. subdecolorata* Vved., *I. coerulea* B.Fedtsch., *I. vicaria* Vved., *I. warleyensis* Foster, *I. magnifica* Vved., *I. willmottiana* Foster, *I. orchioides* Carr., *I. maracandica* Vved., *I. tubergeniana* Foster, *I. kopetdagensis* Vved., *I. leptorrhiza* Vved. The other specimens are not treated in Flora of USSR but recorded in PlantList are 30 taxa. Based on taxonomical characters from Flora of USSR, these are redeterminated.

Maxent modelling of spiked pepper (*Piper aduncum* L.) in Mindanao, Philippines

Japitana Rowena
University of the Philippines Los Banos

Invasive alien species is the biggest threat to biodiversity next to habitat destruction. In Mindanao, *Piper aduncum* is considered as the most invasive alien plant species that affects forest ecosystem and agricultural areas. This study provides insights in identifying suitable areas for *Piper aduncum* in Mindanao using a novel modelling method known as Maxent. Two models were generated: Full Model which is based on the 25 environmental variables and Final Model which is based on the final set of variables maintained after a series of variable reduction method. The relative predictive performance of the two models were evaluated using Receiver Operating characteristic (ROC)-Area under curve (AUC). Result showed that the Final Model performed best with AUC score of 0.825 compared to the Full model (AUC = 0.749). The predicted suitable habitat of *Piper aduncum* was heavily influenced by these top five predictors: soil type, mean temp. of warmest quarter, mean diurnal range, max temp. of warmest month and precipitation of seasonality. We also assess the suitable area coverage in relation to administrative boundaries and protected areas in the study area. Overall, this study will contribute to natural resource managers especially in setting priority areas for current management of the species and predict its potential spread in the future.

Influences of wetland water factors on the photosynthetic fluorescence characteristics of submerged macrophyte

Minfei Jian, *Sicheng Wang, Houping Yu*
Jiangxi Provincial Key Lab of Protection and Utilization of Subtropical Plant Resources, College of Life Science, Jiangxi Normal University, Nanchang, Jiangxi, China

Submerged macrophyte is an important composition of a lake's wetland ecological system, and plays a crucial role in a lake's productivity and biogeochemical cycle. In this study, the wetland's submerged macrophyte, along with its water environment factors during the spring, summer, autumn, and winter seasons of Poyang Lake in Jiangxi Province were examined. Then we analyzed the characteristics of the temporal and spatial variations, as well as the chlorophyll fluorescence of the submerged macrophyte which grew under natural environmental conditions during the four seasons investigated. The results showed that the species diversity of the submerged macrophytes was higher in the wetland water during the spring and autumn, and the water depth changes were found to range from 25 to 70 cm and from 50 to 170 cm in the spring and autumn seasons, respectively. Also, the water transparency changes ranged from 25 to 65 cm and from 10 to 65 cm, respectively during these two seasons. The water changes ranged from 190 to 250 cm during the summer, with water transparency changes ranging from 45 to 140 cm. The superior species included *Hydrilla verticillata*, *Vallisneria natans*, *Najas minor*, and so on, which were determined to grow rapidly during the summer, with higher photosynthesis activity. The *QY*-max was 0.55 to 0.76, and 0.74 to 0.78, respectively. The photosynthesis activity of the *Vallisneria natans* was found to be higher in the spring, and the *QY*-max was between 0.34 and 0.62. The non-photochemical quenching (*NPQ*_Lss) of the submerged macrophyte, such as *Hydrilla verticillata*, *Vallisneria natans*, and *Najas minor*, which reflected the light protection capability parameters that plants use to avoid photosystem damage in the face of adversity, also showed significant spatial and temporal variations. They were found to reach the highest values during the winter, with mean values of 1.28,0.73, and 1.83, respectively. The wetland's water depth and transparency were determined to be the main factors which defined the diversity distributions and chlorophyll and photosynthetic fluorescence characteristics of the submerged macrophyte.

Predicting the potential distribution of *Polygala tenuifolia* Willd. under climate change in China

Hongjun Jiang[1,2], ***Jiancheng Zhao***[1]
1. Hebei Normal University, Shijiazhuang, China
2. Hebei Academy of Sciences, Shijiazhuang, China

Global warming has created opportunities and challenges for the survival and development of species. A great many shifts in the distribution and abundances of species occurred. Particularly, those species with high economic values face over-harvesting and environmental disruption. *Polygala tenuifolia* Willd. as an important original plant of Radix Polygalae, was one of them. Thus, determining how climate change may impact multiple ecosystem levels and lead to various species adaptations is necessary for both biodiversity conservation and sustainable biological resource utilization. To seek suitable habitats and evaluate the impact of climate change on *P. tenuifolia,* we employed MaxEnt to predict its changes in the habitat range and altitude under current and future climate scenarios in China. Four representative concentration pathways (RCP2.6, RCP4.5, RCP6.0, and RCP8.5) were modeled for two time periods (2050 and 2070). The model inputs included 732 presence points and nine sets of environmental variables (including ten, land cover, vegetation coverage, topographical variables, and bioclimatic variables) under the current conditions and the four RCPs in 2050 and 2070. The area under the receiver-operating characteristic (ROC) curve (AUC) was used to evaluate model performance. All of the AUCs were greater than 0.80, thereby placing these models in the "very good" category. Using a jackknife analysis, the precipitation in the warmest quarter, annual mean temperature, and altitude were found to be the top three variables that affect the range of *P. tenuifolia*. The total contribution of these three variables was 73.91%. The total contribution of climatic variables was 61.82%. The total contribution of three topographic variables was 19.96%. However, the total contribution of soil variables totaled 12.20%. This showed that climatic variables had a much greater impact than topography, soil, land cover and vegetation coverage on the habitat distribution of *P. tenuifolia.* The MaxEnt predictions showed that the highly suitable habitat of *P. tenuifolia* was mainly located in Heilongjiang, Jilin, Liaoning, Inner Mongolia, Hebei, Henan, Beijing, Shanxi, Shaanxi, Ningxia, Gansu, Qinghai, Sichuan, Hubei, Hunan, Shandong, Anhui, Zhejiang and Jiangxi. These regions were in reasonable agreement with its actual distribution. Our research also found 90% of the highly suitable habitat in the current scenario was below 1,700 m, and less than 10% of medium suitable habitat located above 2,000 m. Our research also revealed that the area of highly suitable habitat for *P. tenuifolia* in all eight future scenarios will decrease, and the medium suitable habitat will increase relative to the current area. In four scenarios (RCP2.6 2050, RCP6.0 2050, RCP8.5 2050 and RCP2.6 2070), the low and highly suitable habitat will decline, and the medium suitable habitat will increase. In the other four scenarios (RCP4.5 2050, RCP4.5 2070, RCP6.0 2070 and RCP8.5 2070), the low and medium suitable habitats will increase, and the highly suitable habitat will decline.

Plant resources of the transition zone between the Maowusu Desert and the Loess Plateau in China

Lin Jiang
1. Shenmu High School, Shaanxi Province, China.
2. School of Life Science, Yulin University, China

Yulin District in northern Shaanxi Province is located in the transition zone of the Maowusu Desert and the Loess Plateau. It has three different types of landforms: wind-sand region, loess hilly-gully region and river wetland region, retaining diverse vegetation types. Therefore, a systematic investigation of the plant resources across Yulin District is meaningful to understand the drought resistance and drought adaptability in plants. Since the beginning of the 1960s, we adopt the methods of field observation, collection of specimens and literature review to investigate the comprehensive plant resources. We collected ~10,000 wax leaf specimens and ~30,000 plant photos in the ecological environment across this desert-loess transition zone. Then, 101 families, 435 genera, 859 species seed plants were identified. The top four families were constituted of 35.9% of the total number of species, including 95 species from Compositae, 89 species from Leguminosae, 65 species from Rosaceae, 60 species from Poaceae. A scholarly monograph, “Yulin Seed Plants”, was published according to the long term investigation, detailed describing the morphological characteristics, distribution, usage and reproduction methods of 801 species across Yulin District, including 14 species with anti-cancer effects, 16 species with strong anti-drought ability, and 22 poisonous species. It indicated lots of different drought resistance mechanisms exist. This study fills the gaps of plant taxonomy in Yulin District and lays a theoretical foundation for the development and utilization of plant resources in the desert-loess transition zone.

Endangered categories evaluation of *Patis coreana* and *P. obtusa* (Poaceae) endemic to East Asia

Shanwen Jiang[1,2]*, Zhongshuai Zhang*[1]*, Linglu Li*[1]*, Wenli Chen*[1]
1. State Key Laboratory of Systematic and Evolutionary Botany, Institute of Botany, the Chinese Academy of Sciences, Beijing, P.R.China
2. University of Chinese Academy of Sciences, Beijing, P.R.China

The grass family is considered to receive less concern in biodiversity conservation due to the difficulty in identification and distribution information collection. Two east Asia endemic grasses, *Patis coreana* (Honda) Ohwi and *P. obtusa* (Stapf) Romasch., P.M. Peterson & Soreng (Stipeae, Poaceae) are such kind of poor known species, even their taxomomic status were recovered very recently (2011). They distributed in the partly closed habitat in temprate forest, which is quite different from the open grassland habitat in the most of Stipoid grasses. The two species were included in the Least Concern (LC) category in the Red List for Biodiversity in China-higher Plants in 2013. Based on distribution range, current population estimates and habitat status, we evaluated the endangered categories of *Patis coreana* and *P. obtusa* using the IUCN Red List Categories and Criteria (Version 3.1). The data from this study showed that the threatened levels of *P. coreana* and *P. obtusa* were both higher than LC. We also discussed the reason of underestimation and gave some suggestions on their protection.

Phylogenomics of Orchidaceae based on chloroplast genome

Xiaohua Jin
Institute of Botany, Chinese Academy of Sciences

Orchidaceae are among the largest families of angiosperm. Phylogenetics of Orchidaceae is not well understood. Phylogenomic analysis of relationships of Orchidaceae, based on 78 plastid genes from 85 species in 19 tribes and 5 subfamilies were presented. The backbone of Orchidaceae were well supported, and the interrelationships among tribes and subfamilies are well illustrated. The systematic position of several tribes, such as Codonorchideae, Nervilieae, Tropidieae, Thaieae, is different from previous results. Molecular dating, morphological character evolution and historical biogeography of Orchidaceae were also analyzed and discussed.

P0087
Rapid and simultaneous analysis of five alkaloids in four parts of Coptidis Rhizoma by Near-Infrared Spectroscopy

Jintao Xue
Xinxiang Medical University

Near-Infrared Spectroscopy (NIR) was used to develop a method for rapid and simultaneous determination of 5 active alkaloids (berberine, coptisine, palmatine, epiberberine and jatrorrhizine) in different parts (rhizome, fibrous root, stem and leaf) of Coptidis Rhizoma. A total of 100 samples from 4 main place of origin was collected and studied. With HPLC analysis values as calibration reference, the quantitative analysis of 5 marker components was performed by two different modeling methods, partial least-squares (PLS) regression as linear regression and artificial neural networks (ANN) as non-linear regression. The results indicated that the 2 types of models established are robust, accurate and repeatable for five active alkaloids, and the ANN model was more suitable for berberine, coptisine and palmatine while the PLS model was for epiberberine and jatrorrhizine. The performance of the optimal model was achieved as follows: the correlation coefficient (R) for berberine, coptisine, palmatine, epiberberine and jatrorrhizine was 0.9958,0.9956,0.9959,0.9963 and 0.9923, respectively; the root mean square error of validation (RMSEP) was 0.5093,0.0578,0.0443,0.0563 and 0.0090, respectively. Furthermore, the content of 5 active alkaloids in 4 parts of Coptidis Rhizoma and 4 main origin of place was analyzed and compared by the established NIR model for the comprehensive exploitation and utilization of plant resource of Coptidis Rhizoma. This work demonstrated that NIR spectroscopy may be a promising method as routine screening for off-line fast analysis or on-line quality assessment of traditional Chinese medicine (TCM).

The biogeography of the flora of arid central Australia: A preliminary study

Peter Jobson

Northern Territory Herbarium, Alice Springs

Contrary to what you would expect, the flora of central Australia is not poor in species number, but rather it consists of over 2300 species. This is due, in part, to the diverse landscape and soil types within this region. Sand dunes, claypans, salt lakes, gibber plains, river flood-outs, gorges-both deep and shallow, hills and mountain ranges all make up the landscape of central Australia. The most speciose part of central Australia is the MacDonnell Ranges region, housing well over 1300 species, with the highest level of endemism as well as providing a refuge to species more often associated with wetter climates. When looking at the floristics of the region, what is immediately obvious are the absences or poor representation of notable and iconic Australian genera. So, if the species one normally thinks of as iconically Australian are missing, but there are still large numbers of taxa present, what is the likely origin of the central Australian plants? The answer is a complex, three-pronged one. The three prongs are: temperate origin, tropical origin, and refugia from a wetter time. This presentation is a preliminary study leading to a more detailed analysis of the biogeography of the flora of arid central Australia.

Pollen viability of nipa (*Nypa fruticans* Wurmb.) under different storage conditions

Junaldo Mantiquilla*, Merlene Elumba, Jenny Adtoon, Salsabel Ladjahassan, Reynaldo Abad*

University of the Philippines Mindanao

Initial pollen collection of *Nypa fruticans* was conducted in the semi-wild stands of Carmen, Davao del Norte, the Philippines to determine viability levels and storage procedure. Collection of male spikes (staminate rachillae) was best at 5 to 6 AM using paper bags to maintain integrity of pollen samples. Viability levels were effectively determined using iodine potassium iodide (I_2KI) and acetocarmine stain since both clearly identified viable from non-viable pollen. Subjecting pollen at 40^{o}C at different duration (12,24,36 and 48 hours) did not affect general viability levels in spite considering the position of male spikes in the inflorescence (top, middle, bottom region). Percent viability was estimated at 97.80% as determined by acetocarmine method and 98.30% for I_2KI technique. Succeeding tests that included samples from Bago Aplaya, Davao City and Hagonoy, Davao del Sur, the Philippines revealed that oven-dried (40°C) pollen had significantly higher viability than deep frozen (-20°C) pollen using acetocarmine stain. Across storage duration in 75 days, 96.4% viability was recorded for oven-dried samples. The fresh pollen samples from Bago Aplaya produced low viability levels without proper drying. Hagonoy and Carmen samples had relatively higher % viability due to exposure in higher temperature during longer transit. Eventually, viability levels stabilized after 45 days during storage. Hence, nipa pollen requires sufficient drying to achieve higher viability without any signs of decline even after 75 days. *In vitro* germination also showed that pollen broke open by aperture when subjected to different levels of sucrose (2,4, 6,8 and 10%) at different duration (1,2, 3,4 hours) without significant differences among the treatments. In a separate study, 10% sucrose when combined with 0.01% boron and 15% sucrose combined with 0.005% boron achieved significantly higher *in vitro* germination at 60% and 69%, respectively. The latter combination measured the longest knob length at 10.7 µM. The content of the pollen was released during germination and thought to contain sperm nuclei necessary for fertilization instead of developing pollen tube as other plants do.

The citrus variety collection as a key resource for conserving citrus biodiversity in the USA.

Tracy Kahn

University of California, Riverside

The Citrus Variety Collection was initiated in 1910 as part of the University of California Citrus Experiment Station to establish a broad representation of citrus and related genera from all growing regions of the world. Today, with approximately 4,500 trees of over 1000 accessions of citrus and related genera, the University of California- Riverside Citrus Variety Collection (CVC) is one of the most extensive *ex-situ* collections of citrus diversity in the world. Currently the living collection encompasses approximately two field trees and two potted trees held in screened greenhouses as a backup protected collection cooperatively maintained by UCR and the USDA ARS National Clonal Germplasm Repository for Citrus and Dates. This collection encompasses both commercial citrus cultivars and other genera and species in the Aurantiodeae that is critical for research and extension activities that benefits the California Citrus Industry and is utilized by other researchers throughout the USA. There are accessions in the collection that are not duplicated anywhere else in North America making the CVC a key resource for maintaining citrus biodiversity in the USA.

EABCN: Research network for plant conservation in Northeast Asian Region

***Ho Sang Kang**[1], Miin Bang[1], Hyo Cheng Cheng[1], Jeong Ho Park[1], In Sik Kim[2], Hye Jin Kwon[2], Cheul Ho Lee[2]*

1. Seoul National University

2. Korea National Arboretum

Upon the background of globally initiated biodiversity conservation goals and strategies, such as the Goal 15 of Sustainable Development Goals and Global Strategy for Plant Conservation 2020, the East Asia Biodiversity Conservation Network (EABCN) was established for the regional cooperation initially in the Northeast Asian Region by six (6) organizations from five (5) countries (China, Republic of Korea, Japan, Mongolia, and Russia) in 2014. The EABCN is institutionalized based on working group (WG) conducting collaborative research and data sharing to establish a mid- and long-term regional plant conservation strategy in East Asia. Currently, four WGs under the EABCN are in operation. The WG on flora of Northeastern Asia (plant checklist) is reviewing plant list collected and re-arranging the scientific name and synonyms in response to the GSPC target of completion of World Flora, with preparation of web-based platform. Currently, it is completed to combine around 100,000 scientific names of plants in Korean peninsula and three provinces of China (Jilin, Liaoning, and Heilongjiang) through BRHAMS software, and it will be completed to combine the scientific names of plants in Mongolia and Russian Far East by the year of 2017. The WG on plant phenological monitoring is considering the common, rare and local endemic plants interacting through the website of East Asia Phenological Network, which is also linked with smart phone application. The WG on joint publication targets endemic plants in Northeast Asia which includes history, botany, ethnic use, cultural relation *etc.* for the public, which currently in preparation for the third volume titled "Important Plants of East Asia: Plants above Forest Limits" (the first volume is titled "Important Plants of East Asia: Plants Tell Stories", and the second volume is titled "Important Plants of East Asia: Endemic Plant Stories"). The objective of WG on vegetation monitoring is to understand the changes of vegetation and species composition in response to climate change. The collaborative researches on invasive, endangered and alpine plants will be developed in 2017.

New edible fungi from Southeast Asia: Discovery to production

Samantha Chandranath Karunarathna
World Agroforestry Centre, East Asia, Kunming 650201, China

The forests of Southeast Asia have the potential to be a rich source of cultivatable edible fungi. Although significant amounts of research on the taxonomy and phylogeny of edible mushrooms have been carried out, their domestication remains relatively little studied. Today, the most commonly cultivated strains are temperate species, but tropical and subtropical mushrooms are both abundant and highly diverse, with many species having long histories of human consumption. In addition, many new species have recently been introduced to science, including numerous species of high nutritional and medicinal value. The domestication and cultivation of tropical mushrooms therefore provides an enormous opportunity for Southeast Asian countries. Due to the difficulties of cultivating mycorrhizal species, we have concentrated on saprobic species. Most tropical and subtropical mushrooms, if provided with appropriate conditions, grow and produce fruiting bodies more quickly than temperate species. Tropical and subtropical mushrooms can be produced using readily available, cheap waste products such as sawdust, corn cobs, rice straw, sugarcane bagasse, and other forest and agricultural residues, making them an ideal crop for smallholder farmers. We have collected and isolated numerous strains of species of wild mushrooms from Southeast Asian forests, and have published some initial results documenting our progress in domesticating these species. Using a variety of steps including sample collection, isolation, spawn production and fruiting body production in sawdust and compost media, we showed for the first time that it is possible to domesticate *Pleurotus giganteus*; new Thai and French hybrid strain of *Agaricus subrufescens*; *A. flocculosipes*; *A. subtilipes*; *Auricularia thailandica*; *A. cornea* (white) and newly discovered *Ganoderma* species. These advances may create new opportunities for the mushroom growing industry and for smallholder farmers in Southeast Asia in particular.

P0093

The assessment and conservation of rare and threatened species of Boraginaceae Juss. in the Azerbaijan flora

Vugar Kerimov, *Valida Ali-Zade, Rashad Salimov*
Institute of Botany of Azerbaijan National Academy of Sciences

Azerbaijan is distinguished by the richness and diversity of its vegetation. Majority of vegetation types existed in the world is found in the area of our Republic. The main reason is the diversity of the physico-geographical as well as natural historical conditions that formed under the influence of distance and adjacent floristic region. *Boraginaceae* Juss. has a specific place and comprises 81 species belonging to 26 genera (Flora Azerbaijan 1957). Since 1998, as a result of the scientific research and dozens expeditions to the different botanical and geographical regions of Azerbaijan, the taxon number of this family increased up to 104 species belonging to 32 genera. The research works carried out on *Boraginaceae* Juss. over the years of 2000-2016 allowed us, to gather many valuable materials for justification to assess the current status of many species, particularly endemic, rare and threatened species through the long-term observations. In general each of 16 rare and threatened species of *Boraginaceae* Juss. were assessed separately according to IUCN categories. Herbarium materials of LE, TIB and BAK was analyzed, and literature, maps, the results of monitoring conducted by the various authors in nature were used. The comparative morphological, systematic, botanical, florogenic and other methods were used. Taking into account the species of the family, many of which are represented in the flora are endemics of Azerbaijan, and declining the number in nature, six of them were listed in the 2nd edition of the Red Book Azerbaijan (2013). These species are *Trigonocaryum involucratum* - VU A2c+3c; *Cynoglossum holoceryceum* - VU A2c + 3c; *Solenanthus brachistemon* - EN B1ab (iii)+2ab (iii); *Solenanthus circinnatus* - VU A2c+3c; *Rindera lanata* - EN B1ab (iii)+2ab (iii) and *Omphalodes rupestris* - VU B1b (i, iii). Two new species: *Nonea cyanocalix* Pop. ex V.Karimov and *Nonea bakuensis* Pop. ex V.Karimov were recorded for the science, and two: *Myosotis schistosa* Khokhr., and *Cerinthe alpina* Kit. for the Azerbaijan flora for the first time. In recent years, based on the detailed results, 11 species from the *Boraginaceae* Juss. should be listed to a new edition of "the Red

Book of the Azerbaijan" through assessing them according to the appropriate IUCN categories. These species are as followings: *Heliotropium szovitsii* (Stev.) Bunge; *Heliotropium tzvelevii* T.N.Popova; *Onosma gracilis* Trautv; *Cerinthe alpestris* Kit (C.*glabra* Mill.); *Symphytum peregrinum* Lebed.; *Anchusa officinalis* L.; *Nonea cyanocalix* Pop. ex V.Karimov; *Nonea daghestanica* Kusn.; *Nonea decurrens* (C.A.Mey) G.Don; *Myosotis schistosa* Khokhr.; *Solenanthus biebersteinii* DC.

Labellum micro-morphology of the *Nervilia plicata* (Orchidaceae) complex in Tropical Asia

Kanapol Ketjarun[1]*, Stephan W. Gale*[2]*, Paweena Traiperm*[1]*, Somran Suddee*[3]*, Santi Watthana*[4]

1. Department of Plant Science, Faculty of Science, Mahidol University, Rama 6 Road, Rachathewi, Bangkok

2. Kadoorie Farm & Botanic Garden, Lam Kam Road, Tai Po, New Territories

3. Forest Herbarium, Department of National Parks, Wildlife and Plant Conservation, Chatuchak, Bangkok

4. School of Biology, Institute of Science, Suranaree University of Technology, Nakhon Ratchasima

Nervilia plicata is a morphologically variable terrestrial orchid with a wide geographic distribution ranging from India and South China, through Southeast Asia to New Guinea, Australia and the Southwest Pacific Islands. Several forms have previously been recognised as distinct taxa within this complex, based on differences in the outline, size and colour of floral parts. Most notably, distinct purple and white colour morphs exist. Casual observations in various parts of the range suggest that this species is outcrossing, but the ecological significance of the variable floral morphology in attracting pollinators remains unknown. As a first step towards understanding the links between floral polymorphism, pollination ecology and speciation within the *N. plicata* complex, we undertook a micro-morphological investigation of labellum surface. In particular, we sought to ascertain whether the two distinct colour morphs exhibit any discrete micro-morphological differentiation. The labellum was harvested from flowers collected from 11 populations representing the two colour morphs in Thailand and Hong Kong, fixed in 70% ethanol, critical point dried, and examined under scanning electron microscope (SEM). The results revealed that osmophore cells in the secretary zone of labella from all localities are papillose with cutin sculpturing, but that they differ in cell shape and surface architecture. For example, most were polygonal or round, with a flat surface lacking reticulate ornamentation. However, the osmophore cells of some accessions possessed a papillose surface with a reticulate connective layer. These differences are not correlated with the two morphs and locations. Though these findings are still preliminary, there is therefore some evidence for discrete variation in micro-morphology among different *N. plicata* accessions. Further work, including observations of plant-pollinator interactions and analysis of genetic diversity, is ongoing to help provide taxonomic clarity within the *N. plicata* complex.

Collection and consumption of wild edible plants: With reference to tribal communities in Kalsubai-Harishchandragad Wildlife Sanctuary

Mahendra Khyade

Department of Botany, S.N. Arts, D.J.M. Commerce and B.N.S. Science College, Sangamner- 422605.Affiliated to Savitribai Phule Pune University, Pune (MS), India.

The present communication deals with the ethnobotanical exploration, identification and future potentialities of the wild edible plant species consumed by the tribal communities in Kalsubai-Harishchandragad Wildlife Sanctuary located in the northern Western Ghats. Data were collected by means of semi-structured open ended interviews with questionnaire in their local language through frequent field visits during 2013 and 2016. Data collected were structured with Use value reports (UV). A total of 52 plant species belonging to 27 families were reported from the study area. Out of 23 families 6 families were belongs to monocotyledon and remaining 21 families were dicotyledons. In dicot, the dominant families were Papilionaceae (6 species), Amaranthaceae, Asclepidaceae (5 species each), Boraginaceae, Cucurbitaceae (3 species each), whereas in monocots, Dioscoreaceae (3 species) Araceae, Liliaceae, Commelinaceae (2 species each) and remaining taxa belongs to one member of each families. Herbs are used more often (23 species), followed by climbers herbs (12 species), Tree (11 species) and shrubs (6species). Wild food plants were classified according to their uses such as salads, cooked vegetables, spices, raw snacks, teas, alcoholic drinks, *etc.*The leaves and fruits were the dominant parts used followed by tuber, flower and root. The most frequent usage was cooked as vegetables followed by raw, snacks and juices. This study provides indigenous knowledge regarding wild edible plants for future generation.

The state of endangered limestone plants in Peninsular Malaysia

Ruth Kiew

Forest Research Institute Malaysia

The limestone flora of Peninsular Malaysia is relatively well-known botanically. It is a hotspot for biodiversity with 1,300 species that represent 14% of the Peninsula's vascular flora crammed on 540 karst hills that occupy just 0.4% of land area. Not only is it biodiverse but a significant number of species are rare and endangered and they are increasingly threatened by quarrying, burning, cave temples, recreation and tourism. However, no karst hill conserves more than a fraction of the flora. Generally 200-300 species are found on a single hill. In addition, rare species are not concentrated on any particular hill. Of the critically endangered species, over a hundred species are found on a single karst hill and about eighty Endangered species are found on between two to four hills. This represents a challenge for conservation. Most karst hills are not protected because they lie outside State or National Parks. Will the status of the karst limestone as an environmentally sensitive area and individual hills as important plant areas because they harbour rare species carry sufficient weight to protect endangered species from extinction against commercial interests and the need for limestone products, like cement?

Diversity of economically important seaweeds from Tamil Nadu costs of India

Sahayaraj Kitherian
St. Xavier's College

India has a stretch of about 8,129 km coastline with nine maritime states *viz.,* Gujarat, Maharashtra, Goa, Karnataka, Kerala, Tamil Nadu, Andhra Pradesh, Odhissa, and West Bengal. Tamil Nadu coastline occupies about 13.08% contributing 13 districts namely Thiruvallur, Chennai, Kanchipuram, Villupuram, Cuddalore, Thiruvarur, Nagapattinam, Thanjavur, Pudukottai, Ramanathapuram, Thoothukudi, Tirunelveli and Kanyakumari. Marine algae or seaweeds having four classes namely Chlorophyceae or green algae; Phaeophyceae or brown algae; Rhodophyceae or red algae and Myxophyceae or Blue-green Algae, which are one among the easily as well as readily accessible and available natural resource in considerable quantity world-wide. The first three algae have been utilized as food, fodder, feed additives, green manure besides the sources of enormous compounds like agar, agaroids, algin, proteins, minerals, trace elements (Na, K, Ca, Mg, Chloride Nitrogen, Sulphate, Iron, Copper, Manganese, Boron, Zinc Phosphorus) and Vitamins (A, B12, C, D and E) with values in confectioneries, pharmaceuticals, and various industries. Out of 9,000 algal species reported from all over the world, nearly 12.81% seaweeds (1,153 species) were reported from India. Though Agarophytes and Alginophytes are considered as drifted seaweeds in India; we recorded more than 25 species as drifted seaweeds from Tamil Nadu cost. Porphyra spp. have been utilized for human consumption, whereas species of *Alaria, Laminaria* as animal feed; *Ulva, Porphyra* and *Centroceras* for food, fodder, feed additives. Gracilaria has been utilized for extracting agar, whereas *Hypnea, Spyridia, Sarconema, Acanthophora, Laurencia, Chondria, Gigartina* for algin; *Sargassum, Turbinaria, Cystophyllum, Hormophysa, Dictyota* and Padina used as agaroids sources. Algal proteins mainly obtained from *Ulva fasciata, Ulva rigida*, *Porphyra vietnamensis, Acanthophora muscoides* and *Centroceras clavulatum. Cymadocea, Diplanthera* and Halophila are utilized as green manure by the farmers. *Ulva fasciata, Codium fragile, Sargassum cinereum, Sargassum ilicifolium, Laminaria digita, Macrocystis pyrifera, Jania adhaerens* have been used by costal people for various medicinal (antioxidant, anticoagulant, antithrombotic, antitumour, immunomodulatory, antipeptic, antiadhesive, hepatoprotective, neuroprotective) uses. Toxic metals copper, nickel, lead, zinc and cadmium from industrial wastewater removing *Sargassum*, *Laminaria, Ecklonia, Ulva,* and *Enteromorpha* were recorded from Tamil nadu. Seven *Enteromorpha* spp. dwelled in intertidal zones of Tamil nadu coasts utilized for treatment of sewage and some agricultural wastes to reduce nitrogen and phosphorus containing compounds. More than 80 species were recorded from Tuticorin of Thoothukudi district. Rameshwarm of Ramanathapuram district is the hot spot where more than 200 species were observed. Arvee Biotech, Chidambaram; PL Agro Technologies Limited, Chennai; Aachreya Crop Care, ticel bio park, Chennai; Aadrika Organic Farms, Chennai; Anara Trading Company, Chennai; Manidharma Biotech Private Limited, Chennai are exploring available seaweeds for fertilizer manufacturing. BioNature, Salem engaged in seaweed gel production. Seaweed extracts have produced by International Chemicals, Thiruvanmiyur, Chennai; Unitech Chemicals, Ayanambakkam, Chennai; Reddy International, Nellore. Agar Agar (Cellulaids, Chennai), Carrageenan (Vaanan Global Traders, Chennai), Plat growth regulators (APS Biotech, Paranji, Arakkonam), Sea Weed Products, seaweed granules, and dried seaweeds have been produced by various small scale ad medium scale industries at Tamil Nadu. Various industrial activities directly or indirectly altered seaweeds pollutions will also discussed.

Spatial and seasonal distributional studies on herbaceous plants of lateritic Rocky outcrops of Chaukul (Amboli), Western Ghats, India

Rutuja Kolte, *Malapati Janarthanam*
Goa University

Western Ghats (WG) along with Sri Lanka is a biodiversity hotspot due to high number of endemic species it harbours. Varied types of habitats with their unique environmental conditions have enriched the flora of WG. But one of the neglected habitats among them is lateritic plateaus, which are mostly distributed in northern part of the WG. They are rich in herbaceous species with good proportion of endemics. Most of these endemics are habitat specific and distributed in very small area. In the recent past, sporadic attempts have been made to study the vegetation of these plateaus. However, as most of these endemic plants are ephemeral, intensive studies are needed to understand their composition on each lateritic plateau and their ecology. The present study is an attempt to understand systematic composition, distributional and phenological succession pattern of the herbaceous flora of lateritic Rocky outcrops of Chaukul (Amboli) from Sindhudurg district of Maharashtra. Periodic field visits (10-12 days of interval from June to November 2016 and once in a month in remaining period) were carried out from January 2016 to February 2017. During this period, 135 herbaceous plants belonging to 39 families have been documented from various microhabitats. Out of these, 60 are endemic to WG. It has been observed that as monsoon progresses, vegetation pattern also changes from dominance of tuberous plants to grasses. Family Poaceae top ranks with maximum number of genera and endemic species, which is dominant in post monsoon season. It is followed by family Orchidaceae which is present throughout the year and shows diverse habitat preferences by different members. Species such as *Indigofera dalzelii* and *Lepidagathis clavata* belonging to Fabaceae and Acanthaceae respectively are present throughout the year and show varied degrees of morphological variations. Duration of peak flowering of a given species is proportional to the length of the general flowering period. Overall peak flowering coincides with the receding of monsoon. Species of *Exacum*, *Senecio* and *Utricularia* occur on wide range of lateritic plateaus but species such as *Adenoon indicum*, *Ceropegia jainii*, *Lepidagathis clavata*, *Merremia rhynchorrhiza* are habitat specific. Few species are locally abundant and they are: *Eriocaulon stellulatum*, *Exacum lawii*, *Habenaria* spp., *Impatiens* spp., *Senecio belgaumensis* and *Utricularia purpurascens* while species like *Ceropegia jainii*, *Drosera burmanni*, *Iphigenia pallida*, *Sonerila scapigera* are found to be very rare. Ephemeral plants present unique adaptive traits such as epiphytic nature, underground perennating organs, carnivory, confining to cryptogamic mat *etc.* Based on rainfall and vegetation dominance four seasons can be recognized on plateaus. They are; pre monsoon period for tuberous plants, monsoon period for ephemeral plants, post monsoon period for grasses and dry period for sturdy plants. However microhabitat plays a very important role in occurrence and phenological succession of herbaceous plants on lateritic plateau. To understand full spectrum of herbaceous plants of lateritic plateaus and their dynamics more studies are required.

Preliminary investigation of bryophytes in Xizang, China

Jin Kou[1], *You-Fang Wang*[2], *Chao Feng*[3], *Shan-Shan Song*[1], *Li-Li Wang*[1], *Xiao-Tong Song*[1], *Xiao-Ming Shao**[1]
1. Beijing key Laboratory of Biodiversity and Organic Farming, College of Resources and Environmental Sciences, China Agricultural University
2. East China Normal University
3. Inner Mongolia Agricultural University

Xizang is the main part of Qinghai-Xizang Plateau and the representative with significant temperature increasing in China. It creates a special heterogeneous environment for bryophytes by its complex landforms, physiognomy, and climate. Meanwhile, both morphological characters and distribution of bryophytes can be used to reflect the environmental change. The early relevant researches are concentrated from 1970s – 1980s and the investigations were mainly in the Southeast of Xizang. Due to the traffic conditions, field investigations on bryophyte were conducted randomly along the ways. From 2007 to now, our fieldworks were carried out by two types: one was sampling with a size of 25 cm×25 cm or the other size of 50 cm×50 cm, the other one was random sampling. The investigation range is expanded, including Nagqu, the low altitude region of Motuo, and Ali unmanned area. Eight new species were described: *Bryoerythrophyllum pseudomarginatum* J. Kou, X.-M. Shao & C. Feng, *Bryoerythrophyllum zanderi* C. Feng, X.-M. Shao & J. Kou, *Didymodon epapillatus* J. Kou, X.-M. Shao & C. Feng, *Didymodon jimenezii* J. Kou, X.-M. Shao & C. Feng?*Didymodon liae* J. Kou, X.-M. Shao & C. Feng, *Didymodon mesopapillosus* J. Kou, X.-M. Shao & C. Feng, *Encalypta gyangzeana* C. Feng, X.-M. Shao & J. Kou, *Hilpertia tibetica* J. Kou, X.-M. Shao & C. Feng. Three species and one variant were new to China: *Bryoerythrophyllum latinervium* (Holmen) Fedosov & Ignatova, *Tortula brevissima* Schiffn., *Tortula transcaspica* Broth and *Stegonia latifolia* var. *pilifera* (Dicks.) Broth. In addition, *Grimmia indica* (Dixon & P. de la Varde) Goffinet & Greven was firstly discovered in Tibet. Besides, Pottiaceae samples collected from arid and semi-arid regions in 2007,2011 and 2012 were analyzed by GIF and SPSS software and diversity index analysis with climatic variables. The result shows that: 1) Pottiaceae species richness have obvious difference at different altitudes. But their evenness are similar; 2) there are remarkable negative between Pottiaceae diversity and elevation. Instead, Potteaceae diversity has obviously positive correlation with vegetation coverage. There are no significant correlation between it and soil water content; 3) elevation, vegetation type and temperature are the most key environmental factors to affect both Pottiaceae diversity and coverage. Vegetation cover is the second key factor. And there are no significant effect from human disturbance and substrate; 4) To spatial distribution of Pottiaceae and *Didymodon*, human disturbance is the most significant environmental variable. Both climate and vegetation take second place. The influence of topography is the least.

Taxonomy, ecology and *ex-situ* conservation of potential plant resources

Sanjay Kshirsagar
Shri Shivaji Vidya Prasarak Sanstha's Late Karmveer Dr. P.R.Ghogrey Science College, Dhule, Maharashtra

Present paper communicates potentially important plant resources with reference to their taxonomy, ecology, threats, precise locations, flowering and fruiting period, present status in the field, IUCN status and *ex-situ* conservation. Following plant species are collected from Khandesh regions (Dhule, Nandurbar and Jalgaon districts) and Sahyadri ranges of Western Ghats in Nashik District under UGC (University Grants Commission, New Delhi) PG Diploma in "conservation of medicinal, endemic and endangered plants" and conserved in botanical garden as an aid in education, for research, multiplication and transfer to other botanical gardens. For example, *Curcuma inodora*, *Dioscorea bellophylla*, *Sterculia urens*, *Ceropegia sahyadrica*, *C. bulbosa*, *C. hirsuta*, *Vigna khandalensis*, *Gloriosa superba*, *Rawolfia tetraphylla*, *Pterocapus marsupium*, *Radermachera xylocarpa*, *Entada pusaetha*, *Zingiber devakarianum*, *Michelia champaca*, *Costus picta*, *Costus speciosus*, *Bauhinia vahlii*, *Bauhinia tomentosa*, *Curculigo orchioides*, *Eulophia herbacea*, *Gymnema sylvestre*, *Enicostemma axillare*, *Caralluma adscendens* (Roxb.) R.Br. var. *fimbriata* (Wall.) Grav. & Mayur, *Cissus quadrangularis*, *Acorus calamus*, *Commiphora wightii*, *Amorphophallus bulbifer*, *Tylophora indica*, *Abrus precatorius*, *Notonia grandiflora*, *Terminalia tomentosa*, *Plumbago zeylanica*. *Pinda concanensis*, *Iphigenia magnifica*, *Neuracanthus sphaerostachys etc.*

The public trial run of PhycoBank - Registration of Nomenclatural Acts for Algae

Wolf-Henning Kusber, *Andreas Kohlbecker*, *Anton Güntsch*, *Walter G. Berendsohn*, *Regine Jahn*
Botanic Garden and Botanical Museum Berlin, Freie Universität Berlin

PhycoBank is to become the registration system for nomenclatural acts (new names, new combinations and types) of algae. Algae are a very diverse group of organisms and are covered by the International Code of Nomenclature for algae, fungi and plants (ICN). PhycoBank will provide a central registration service for the registration of new names and nomenclatural acts submitted either directly by nomenclatural authors or automatically via cooperating publishers. Each nomenclatural act will have globally unique PhycoBank http-based identifiers for new names and typifications, automatically redirecting to corresponding data and metadata in human- and machine-readable formats. Additionally, search functions for taxon names, registration date, category of nomenclatural act, and nomenclatural type specimen will be provided. Feedback mechanisms, annotations, and appropriate treatments of ambiregnal taxa will also be incorporated. Interoperability with the global names infrastructure will be achieved via standardized web services. The public trial run of PhycoBank started in March 2017. Curational data entry of nomenclatural acts is already in place. Data entry for nomenclatoral autors is under construction and an automatic workflow (from publishers) is in the planning phase. Upon registration, PhycoBank will feed evaluated name data into the Global Names Architecture via the Catalogue of Life. PhycoBank will meet all botanical community standards such as IPNI Authors, BPH-S, TL2. In addition, PhycoBank will also cover all specialties needed by the phycological community: treatment of ambiregnal taxa (e.g. bluegreen algae, dinoflagellates, euglenoids), algal group-specific provisions, later starting points, lecto- and epitypes, and figures of algae that cannot be preserved. Phycobank is supported by a DFG Grant (JA 874/8-1) and available at http://phycobank.org.

Useful plants diversity in Cop Village, Bac Huong Hoa Nature Reserve, Vietnam

Changyoung Lee[1,2], *Trung Thanh Nguyen*[2], *The Bach Tran*[3], *Sang Mi Eum*[1], *Soo-Yong Kim*[1], *Jin-Hyub Paik*[1], *Sang Woo Lee*[1], *Jeong Kwang Park*[1], *Yong-In Kim*[1], *Sangho Choi*[1]
1. Korea Research Institute of Bioscience and Biotechnology
2. VNU University of Science
3. Institute of Ecology & Biological Resources

A study was conducted in Cop Village, Bac Huong Hoa Nature Reserve (BHHNR), East Quang Tri Province to document and collect the useful plants used by local people. We found out 70 plant species distributed in 43 families. Of the total plant species 49% were trees, 24% shrubs, 17% herbs, and 10% vines. Among the collected plants, 57 species were used by local people as medicinal plant, 6 species categorized as food, 4 species categorized as fuelwood, 2 species categorized as dye and 1 species categorized as ornamental. Some of commonly used medicinal plants were *Areca catechu* L., *Litsea cubeba* (Lour.) Pers., *Passiflora foetida* L., *Piper sarmentosum* Roxb., *Schefflera heptaphylla* (L.) Frodin, *Tamarindus indica* L., *Trichosanthes tricuspidata* Lour. 20 different plant parts were used combined together by local people. These medicinal plants were mainly used for the cure of rheumatism, stomachache, dermatitis, cancer, backache, post-natal care, toothache, and wounds.

Introducing herbarium TUR

Samuli Lehtonen[1], *Seppo Huhtinen*[1], *Sanna Huttunen*[1], *Terttu Lempiäinen*[1], *Mia Lempiäinen-Avci*[1,2], *Nelly Llerena*[1], *Tarja Marsh*[1], *Arto Puolasmaa*[1], *Veli-Pekka Rautiainen*[3], *Mika Toivonen*[1], *Jukka Vauras*[3]
1. Biodiversity Unit, Herbarium, FI-20014 University of Turku
2. Museum of Archaeology, University of Stavanger
3. Biological collections of Åbo Akademi University, Herbarium, FI-20014 University of Turku

The University of Turku Herbarium (TUR) currently holds ca. 1 050 000 specimens, of which 600 000 represent vascular plants, 201 500 fungi, 120 000 bryophytes, 111 000 lichens, 6000 algae, and 15 000 subfossils, respectively. The most important collection is the E.A. Vainio's lichenological collection of over 35 000 specimens and with more than 4 000 types collected from all over the world. The herbarium TUR also incorporates the collections of ?bo Akademi (collection acronym TUR-A) and the two universities work together in maintaining and developing the collections. The collections are currently being databased and type specimens digitized using high-resolution scanning for vascular plants and high-resolution photo stacking for three dimensional specimens such as lichens. As well, the herbarium maintains a botanical library and laboratory facilities for molecular systematic and archaeobotanical studies, both of which are active research topics in the herbarium. The herbarium is internationally networked and actively serves researchers globally. The multidisciplinary University of Turku Amazon Research Team contributes thousands of plant specimens from Amazonia, making the neotropical collections one of the currently most actively studied parts of the collections. The herbarium has an active role in the societal development, for example, by running a citizen science project aiming to gather data on distribution and ecological preferences of Finnish fungi. These data are collected using a customised online database system allowing photo upload and thus, later verification of observations by specialists. Together with museum collections these data aid in the Red List evaluation of threatened Finnish flora, in which herbarium TUR contributes with other Finnish natural history collections. The herbarium also serves the public by providing identification services of plants and fungi, such as the construction damaging rot fungi.

The molecular identification of bulbous and perennial plants traded at Faraday "hawkers of health" medicinal market, South Africa using DNA barcoding.

Dorcas Lekganyane, *Ronny Kabongo*, *Michelle Van Der Bank*
African Centre for DNA Barcoding, Department of Botany & Plant Biotechnology, University of Johannesburg, PO BOX 524, Auckland Park, 2006, South Africa

The South African medicinal market generates approximately R2.9 billion per annum to the national economy, which provides a fundamental source of income but comes at an expense to the environment. Most plants traded at the market are harvested from wild resources resulting in noticeable levels of species depletion. Adulteration, trade using vernacular names and morphological similarities of plants or the lack thereof, makes identifying samples on a taxonomic level challenging. In this study, DNA barcoding was implemented to rapidly identify the plants, more specifically bulbous plants, traded at the Faraday market. Sixty samples were collected and sequenced for the core barcoding regions (*rbc*La and *mat*K). BLAST results were ambiguous for *rbc*La whereas *mat*K results were more specific, permitting samples to be identified to species level. Overall, 85% of the samples were identified to species level. Two additional approaches, the tree-based and character-based methods were followed to validate *mat*K samples to species level. Results from this study reveal a noticeable increase in the number of species traded with the majority of sought-after species of Least Concern. However, 10% of the species are Declining or Near Threatened in the wild posing a serious conservation issue. Prolonged unsustainable trade of these plants could lead to more Critically Endangered species in the future. An important outcome of the project is a new collaboration with the South African Department of Environmental Affairs to address these problems. Results and the consequences of illegal trade will be discussed.

Palm studies at Tirimbina Biological Reserve, Costa Rica

Juan Manuel Ley-López

Tirimbina Biological Reserve

Palms are an important component of a tropical forests. However, there has been only limited analysis of basic palm ecology and understorey species have also been neglected. During the last 3 years I have studied the phenology, germination patterns and seedling characteristics of the palm assemblage at Tirimbina Biological Reserve (TBR), located in one of the most diverse areas for palms in the Neotropics. Since October 2013 phenological censuses have been conducted twice a month for 174 individuals belonging to 13 species of understorey palm. Two subspecies of the polymorphic palm *Geonoma cuneata* host in their infrutescence the only gall report for Arecaceae. Phenological censuses regarding the success from every inflorescence in both subspecies was conducted for 138 consecutive weeks in 78 individuals. 5,172 mature fruits where collected and seeds from 220 individuals and 21 species were germinated within 48 hours after collection. Germination was checked weekly under nursery conditions for 57 weeks and the Kaplan-Meier estimate of survivorship was calculated. Finally, I created an identification key with detailed photos and descriptions for the seedlings of all native palms at TBR. While *Asterogyne martiana*, *Chamaedorea tepejilote* and *Prestoea decurrens* are seasonal, all species in the genus *Bactris* and most species in *Geonoma* bear fruit and flowers year round. *Reinhartia gracilis* is a supraannual species with no individuals flowering during the last 4 years. No difference was found with respect to the flowering season in both *Geonoma* subspecies. However, the number of abortions is much higher in *G. cuneata* subsp. *procumbens*. The percentage germination for the palm assemblage (%G) was 65.6%, whereas the mean length of germination and the number of weeks necessary to reach 50% of %G were 16.4 and 14, respectively. Ninety per cent of seeds germinated in 7-25 weeks and by week 40 most species had germinated. Main characteristics for the recognition of seedlings are seed form and size, leaflets arrangement on the rachis, presence of thorns, leaf margins, texture, and measurements of the leaf. The diagnostic characteristics in half of the species are easily recognized. In contrast, the other half require detailed measurements or the development of at least 4 to 8 leaves in order to distinguish them from other species. These studies show that at the community level understorey palms bear fruit and flowers year round and in contrast to the prevalent view that palms have low germination, germination was completed relatively quickly. Most palm seedlings are easily recognized at least at the genus level. Characterizing the phenological patterns, the temporal expression of germination and recognizing seedlings is critical for increasing our understanding of tropical palm ecology, their regeneration and their sustainable management.

P0106

Floristic analysis on the seed plants of Ordos Plateau, a biodiversity hotspot in arid and semi-arid areas of China

Engui Li, *Yongmei Huang, Huiying Chen*

Beijing Normal University, Beijing, China

Ordos Plateau is one of the biodiversity hotspots in arid and semi-arid areas of China. By integrating the document data and field survey data on Ordos Plateau, 792 species belonging to 346 genera in 85 families were recorded on Ordos Plateau. The area is characterized by herbaceous plants with a total of 607 species (77%), and there are 146 shrubs in this region. The flora of Ordos Plateau is a blend of several geographical elements, reflecting the ancient origin, temperate arid desert characteristic of the flora, and the relevance with broad-leaveas forest region in East Asia. At the generic level, 175 (79.52%) are primarily temperate elements, much higher than the level of China flora (30.95%), While 38 (13.3%) are tropical in nature, much less than the level of China flora (50.60%). The most genus-rich floristic distribution is north temperate (75 genera), contributing 35.49% to the flora. The percentage of Mediterranean, western to central Asia distribution is as much as 12.29% (28 genera), much greater than that of the national average (5.68%). At the species level, including temperate elements (38.64%), East Asia elements (23.86%), desert elements (18.18%), steppe elements (9.09%), and ancient Mediterranean elements (5.18%). Endemic phenomena is not obvious, 9 genera are endemic to China, 43 species are endemic to Alashan-Ordos. We also explored how the climate, geological substrate and the topography varied in this area to illustrate the prominent floristic characters. We discussed the conservation threats from the perspective of anthropogenic impacts, and recommend the endemic relic species be given to more conservation attention in this region. For biodiversity hotspot, we suggest that floristic composition may serve as an approaches to measure the biodiversity, and guide biodiversity conservation of the region.

How many species of seed plants in Tibetan sacred sites

Feifei Li[1,2]*, Bo Liu*[1]*, Jianqin Li*[1,3]*, Chunlin Long*[1,4]

1. College of Life and Environmental Sciences, Minzu University of China

2. State Key Laboratory of Environmental Criteria and Risk Assessment, Chinese Research Academy of Environmental Sciences

3. Faculty of Forestry, Southwest Forestry University

4. Kunming Institute of Botany, Chinese of Acamedy Sciences

Many researches indicated that religion was an important driving force for biodiversity conservation based on their special protection principle, law enforcement and sanctions regime. The value of sacred natural sites (SNS) was recognized by numerous scholars and international non-governmental organizations (NGOs) in the last decades. Because most SNS had long history and their traditional taboos were similar as some species protection guidelines. Tibetan region was a typical ethnic region that their traditional religion was closely related with natural environment. Tibetan sacred sites (TSS) have been existed for centuries which associated with deities, nature spirits, and spiritual leaders. Under the long-term protecting, TSSs were considered to be ecologically unique and important for conserving various scales of landscape, community, and species. However, the question that "how many species in TSS?" was still remained unanswered. A wider investigation of entire Tibetan region is required to enable a better understanding of the values of TSSs in species protection and nature conservation. We studied the seed plant species diversity of nine TSSs, and the value of TSS for conservation ecology and biotic richness of Tibetan areas. Our study discerned the number of seed plant species, endemic plant genera and endangered plant species in TSSs, as well as to examine whether these areas acted primarily as "plant museums", "plant refuge" or "gene pools". This study also analyzed the urgent conservation value of seed plant species and determined prior protection sacred natural sites, and provided suggestions for protecting these sacred natural sites. Results presented in this report can be summarized as follows: 1. The nine TSSs totally contained 7,630 seed plant species belonged to 200 families and 1,338 genera, in which 910 species are endangered, and 70 genera endemic to China. 2. The area of nine TSSs covered only 3.36% of the Tibetan areas, 0.77% of China's territory. However, they contained 79.83% species, and 80.18% endangered species; 23.00% species, 20.26% endangered species and 28.81% Chinese endemic genera of China. 3. Except the densities of species endemic to Tibetan areas, all of the densities of total species, endangered species and Chinese endemic genera in the nine TSSs were higher than that of the Tibetan areas. 4. Based on the urgent conservation value of seed plant species, the prior protection level of species were determined. Based on principle of complementarity, we proposed the prior TSSs for protection, which were Namcha Barwa Mountains, Baima Mountains and Bita Lake. 5. The human activities of other ethnic groups, ecotourism, changing belief system and management system were the main factors threatened biodiversity protection in TSSs. The key strategies for biodiversity conservation in TSSs were proposed, including action plans of completing surveys of TSSs, establishing protection network, information platform, and forming reasonable management mechanism of TSSs.

Microsatellite-based genetic diversity patterns in altitudinal gradient populations of *Cypripedium tibeticum*

Jing Li
School of Biological and Environmental Engineering, Xi'an University, Xi'an, China

Cypripedium tibeticum (Orchidaceae) is an unique orchid species with high ornamental and medicinal value. It is endemic to southwest China, including Tibet, Yunnan and Sichuan provinces. Due to habitat changes and human activities, *C. tibeticum* is threatened with extinction and is listed as national protected plant. In this study, we developed eight polymorphic microsatellite markers for *C. tibeticum*, and investigated the genetic diversity and structure of 21 altitudinal gradient populations collected in the distribution range of 3,150 to 3,400 meters above sea level in Huanglong Nature Reserve in Sichuan Province. From calculated values of number of effective alleles (NE), observed number of alleles (NA) and the average of Shannon index, we confirmed that the eight SSR loci we selected are suitable for genetic markers to analyze genetic diversity in the *C. tibeticum* populations. For further analysis, 21 populations we sampled were divided into four groups: Group 1 (G1) to Group 4 (G4) from low to high altitude. The disequilibrium test and Hardy-Weinberg equilibrium test was conducted for each microsatellite locus. The distribution of different alleles in each populations was calculated and the level of genetic diversity in populations of *C. tibeticum* was analyzed. Genetic parameters including *Fst, Gst* and *Nm* (effective gene flow) was calculated between pairwise populations in each altitude group. The results showed that the average *Fst* data display G4 > G3 > G2 > G1, while the average of *Nm* showed G1 > G2 > G3 > G4, which indicated that with increasing altitude the level of genetic differentiation among populations of *C. tibeticum* is increasing, and the level of gene flow is declining. Analysis of molecular variance analysis (AMOVA) was conducted to explore which is the main factors composed of genetic differentiation among *C. Tibeticum* populations. The results of AMOVA showed that proportion of variation component in descending order was "among populations within groups" > "within populations" > "among groups". The results of correlation analysis among pairwise populations between distribution altitude and genetic distance (*Fst*) showed that for small inner scale elevation within groups, there was a certain pattern of correlation. For large-scale distribution of elevation among all the populations tested in this study, there was no obvious (non-significant) correlation between genetic distance and altitude distribution of *C. tibeticum*. This study will help us to understand the genetic diversity patterns in natural environment and make applicable strategy to protect *C. tibeticum* in the future.

Research and application of landscape water conservation systems in the arid region of Loess Plateau

Ke-Ke Li, *De-Shun Zhang*
Tongji University

As China enter into the 21st century, issues including increased aridity and restoration are brought to the forefront of priorities. As a leading discipline, landscape architecture plays the role of transforming human settlement and sustaining the ecological environment. This research is of significant importance for Loess Plateau to accelerate xeriscape integration and explore native features. This thesis is divided into three parts. Firstly, with the background research of Loess Plateau, and theory literature reviews of ecological restoration, vegetation restoration, site types classification, evaluation system and landscape water conservation theory and practice of local and abroad, theory and analysis foundations are concluded and summarized. Second, the research objects of Loess Plateau arid districts, such as "vegetation", "soil" and "landscape" are defined, together with the relationships between these objects and "water" (e.g., water conservation landscape, vegetation water consumption and soil water content). Thirdly, in order to address the construction methods of landscape water conservation systems, the following principles are studied: "ecology and sustainability", "availability and universality", "quantity and quality", "practicality and operability", "scientificity and accuracy", methods of "vegetation quadrat sample surveys", "soil quadrat sample surveys", "Landscape Function Analysis" and "mathematics model derivation". In order to explore these individual properties, three groups of factors are taken on: "vegetation arrangements", "site types" and "landscape function", respectively. Regressions and clusters are analyzed jointly to study the water conservation system. In the system application portion of this study, the example of Huan County is studied. Local geography, geomorphology, land use, climate, soil and vegetation properties are identified. Based on the framework of part two, conclusions are stated regarding the landscape water conservation system of Huan County; vegetation arrangements affect soil water, site types restrict soil water, and landscape functions predict soil water. Finally, four levels of Huan County vegetation restoration sites are categorized and six restoration formulas are suggested for "recovery" and "reconstruction" in the next phase of restoration. Further research guidelines are provided following the summary of conclusions and innovations.

Water depth affects reproductive allocation and reproductive allometry in the submerged macrophyte *Vallisneria natans*

Lei Li[1,2], *Zhiping Song*[2]

1. Nanchang University

2. Fudan University

1. The relationship between size and reproductive output is a fundamental aspect of a plant's reproductive strategy: the conversion of growth into fitness. Differences among populations in the reproductive allometry have been attributed to environmental conditions. However, the causes of variation in reproductive allocation are still debated (i.e. due to fixed patterns of development, or plasticity in the developmental trajectory of vegetative and reproductive allocation). 2. Using a mesocosm experiment, we investigated variation in reproductive allocation of a semelparous submerged macrophyte *Vallisneria natans*, one of the dominant species in Poyang Lake (China). To test the hypothesis that allometric trajectories of reproductive allocation are highly plastic in *V. natans*, we grew plants at three levels (shallow, intermediate and deep) of water depth and measured them after 26 weeks of growth. The allometric relationships between reproductive (R) and vegetative (V) biomass among treatments were compared. 3. In deep water treatment, total plant biomass decreased, average height increased and individuals started flowering in smaller size when compared to the two shallower water treatments. Deep water affected the biomass and number of fruits produced per plant leading to less sexual reproduction. Plants in deep water (the more stressful treatment) had relatively high allocation to reproduction, though they were quite small. The log R vs. log V slope in deep water treatment was much lower than those in more favourable treatments, and shallow water plants exhibited a very different log R-log V relationship than intermediate water plants. A possible explanation is that the environmental limits on size in deep water should favour a relatively large reproductive allocation at smaller sizes and a smaller investment in reproduction per additional unit of biomass accumulated. 4. Our results demonstrated that water depth affects the observed pattern of reproductive allometry among experimental *V. natans* populations, and this has important implications for the fitness of macrophytes exposed to significant variations in water depth over time and space due to anthropogenic disturbance (e.g. dam building) and climate change (e.g. changes in local patterns of precipitation). Environmental stress in deep water tends to favor reproduction at relatively small sizes, associated with lower slopes of the log R-log V relationship, supporting that reproductive allometry can be interpreted as an adaptive strategy of plant growth and allocation, rather than as the product of fixed developmental constrains.

The academic discovery and current conservation status of *Metasequoia* in China

Minghe Li[1], *Shenhou Fan*[2]

1. Central China Agricultural University

2. Lichuan Forestry Institute

For many years, fossil cones and twigs similar to coast redwood were assigned as ancestors or relatives of *Sequoia* and considered to be extinct for over a million years. During World War II, in 1941, a Japanese scientist studied 'redwood' fossils carefully, found that some of those fossils were sufficiently different from *Sequoia,* and thus gave them a new genus name, *Metasequoia.* In July 1943, a Chinese forester collected specimens in Hubei Province from a large old unknown tree. After World War II, in 1946 a Chinese professor concluded that these trees should be assigned to a new taxon that had not been previously recorded. Then, another Chinese scientist examined the literature and found that the specimens closely matched the description of *Metasequoia* fossils. Thus, it was first realized that living members of the fossil genus *Metasequoia* had been found inChina. In 1947, Harvard's Arnold Arboretum sent US$250 to China for additional field work and seed collection. UC Berkeley also sent US$25 to China for seeds. Chinese grantees then sent many specimens and viable seeds to Harvard and Berkeley. American experts re-examined the large collections of 'redwood' fossils from various parts of the world, and concluded that most of them are actually of *Metasequoia*. In February 1948 a two-person American expedition, funded by the Save-the-Redwoods League and the San Francisco Chronicle, traveled to China. They observed the three living trees and the recently-discovered main population in Xiaohe Valley. Their reports confirmed that living members of the fossil genus *Metasequoia* had been found. The news created a stir in the worlds of science. Scientists at Harvard, Berkeley in U.S.and in China quickly sent *Metasequoia* seeds to interested scientists and institutions in at least 76 recorded localities around the world. In May 1948, Chinese scientists published *Metasequoia glyptostroboides* as the scientific name of what the local people had long called shui shan (‘water-fir’). It is also now commonly called ‘dawn redwood’, a name coined and popularized in the western world. The scientific and academic recognition, and then extensive planting of living *Metasequoia glyptostroboidesa* in the wider world had combined the efforts and intelligence of Japanese, Chinese, and American scientists during 1941 - 1948. Chinese governments have since attached great importance to conservation of the pre-1945 *Metasequoia* trees and populations, and added water-fir to the highest-priority list of its tree-species-protection project. Water-fir-protection stations are now established in Lichuan, Shizhu, and Longshan Counties. There are 5,693 old native water-fir trees at present known living in China. The *Metasequoia glyptostroboides* Type Tree in Mo-Tao-chi continues to grow well. Successful plantings of water-fir have been expanded to 26 provinces inChina, and ‘dawn-redwood’ plantings have now successfully occurred in more than 50 countries. Natural change and human activities have altered the recent native ecological environments of water-fir. Since 1984,84 old water-fir trees have died. This is a serious issue needing to be concerned about.

The genetic diversity and structure of the reintroduced population of *Cycas debaoensis* and its new offspring generation

Nan Li[1], *Yiqing Gong*[1], *Yanzhao Lu*[2], *Jinjia Gan*[3], *Yunhua Wang*[1], *Ting Chen*[1]
1. Fairy Lake Botanical Garden, Shenzhen, Guangdong
2. Mt. Huanglian Nature Reserve, Guangxi
3. Guangxi Institute of Botany

Cycas debaoensis Y.C. Zhong & C.J. Chen published in 1997 is endemic to China, sporadically distributing in a narrow area of Guangxi and Yunnan Provinces. It shapes like bamboo for the bipinnate leaf with dichotomous leaflets, and has significant scientific and horticultural value. Due to the habitat disturbance and stealing digging, the wild populations of the species were seriously destructed Therefore it is listed as the critically endangered species by IUCN (CR B2), and as the first grade protected plant species in China. The *Ex Situ* conservation of *C. debaoensis* has been launched since 2000 at ‘China National Cycad Germplasm Conservation Center’ at Fairy Lake Botanical Garden, Shenzhen, Guangdong Province, China. For the effective protection of the species with financial support from the China State Forestry Administration, the center reintroduced 500 seedlings of 5-7 years old, selected from the source population with ca. 700 individuals, to the Mt. Huanglian Nature Reserve, Guangxi Province in 2008, where is about eight kilometers away from the type locality of *C. debaoensis*. 440 individuals in the reintroduced population survived according to the survey data in late 2016. The survival rate was 88%. In 2011 eight male cones were found for the first time in the reintroduced population. In 2012 there were 19 individuals with female cones and 67 individuals with male cones in a proportion of 1:3.5, and 1200 seeds were mature in fall of the year. 30% seeds were left in site, while the other 70% seeds were collected for propagation, and 13 offspring were found in the reintroduction area. More female and male cones came into bloom since then. The beetle can implement the pollination during their life history. The natural seed setting rate of *C. debaoensis* was up to 70%, among which 60% can develop into seedlings. The rodents such as the rats and squirrels like to eat the outer seed coat, and carry the seeds into crannies in the limestone. The new generation of offspring in the reintroduction area were sprouted in succession since 2013, with some even 60-80 meters away from the reintroduction area, which indicates that the founder population has achieved self-renewal. By comparing the growth and reproduction of *C. debaoensis* among the *Ex Situ* conservation population at Fairy Lake Botanical Garden, the wild population at type locality in Fuping county and the reintroduced population, the effect of different conservation approaches was evaluated in this study. Meanwhile, 15 SSR molecular markers were used to detect the genetic diversity and structure of the reintroduced population and the new generation of offspring in the reintroduction area. The genetic coverage of the reintroduced population and the genetic background of the new offspring were calculated by comparing their genetic diversity with that of the wild population of *C. debaoensis*. The effective population size in the destination area for reintroduction was also calculated to infer the population dynamics. This study may provide scientific references for the management of reintroduced *C. debaoensis* and the reintroduction of other species.

Analysis of genetic diversity from different geographical populations in *Bauhinia varigata* with Sequence-Related Amplified Polymorphism (SRAP) markers

Jiuxiang Huang[1,2], *Miaokun He*[1,2, 3], *Qun Li*[1,2], *Xiaoxi Chen*[1,2], *Zhijiang Feng*[1,2], *Shaowei Huang*[1,2], *Tianyi Liu*[1,2], *Lincoln Fok* [4]
1. College of Forestry and Landscape Architecture, South China Agricultural University, Guangzhou, Guangdong 510642, China
2. Guangdong Key Laboratory for Innovative Development and Utilization of Forest Plant Germplasm, Guangzhou, Guangdong 510642, China
3. Heshan Shaping Experiment Middle School, Jiangmen, Guangdong, 529700, China
4. Department of Science and Environmental Studies, the Hong Kong Institute of Education, HK, China

Bauhinia variegata Linn is a common ornamental plant in South China, The genetic diversity and differentiation among 7 geographic populations of *Bauhinia varigata* were analyzed using sequence-related amplified polymorphism (SRAP) markers in this study. A total of 59 primers were screened and 13 primers were chosen for SRAP polymorphic analysis. The results showed that 112 bands, 66.67% of the total amplified bands were polymorphic. The genetic Nei’s distance among different *Bauhinia varigata* populations was 0.0470~0.2548. The general Nei’s genetic diversity index was 0.2265. The general Shannon’s information index was 0.3405. Our results indicate that the genetic variation was mainly from individuals within groups (54.20%), and the gene flow between populations (Nm) was 0.5917.

Ethnobotanical survey in multi used zone Antrema in Mada-

gascar

Tian Li[1], *Hasina Sandrah Rahantanirina*[3], *Edmond Roger*[3], *Claire Harpet*[2], *Marcel Hladik*[2], *Annette Hladik*[2], *Charlotte Pioch*[2], *Bernard Riera*[1]
1. UMR 7179. Mecadev, MNHN et CNRS. F 91800 Brunoy, France
2. UMR 7206. Éco-Anthropologie et Ethnobiologie, MNHN, CNRS et Université Paris-7. F 91800 Brunoy., France
3. Université d'Antananarivo, Département Biologie et Ecologie Végétale, Antananarivo, Madagascar

Antrema, as a multi-use protected area, is well-known for its Crowned Sifaka (*Propithecus coronatus*). The local ethnic group respect for this animal created a more in tune with nature and balanced way to utilize the region's resources, which can be a good example for the conservation and the development of traditional culture in local villages. The aim of this research is to clarify how local beliefs can influence people in responsible use of the forest, and how people take advantage of natural resources in their daily life. In this paper, 65 families in 8 villages were investigated in their utilization of plants, and a taxonomy database Xper2 of Antrema was built in order to facilitate the knowledge of local plants' characteristics. A strict hierarchy of divinity was found in Skalavas' religion, and the respect of their "ancestor" Sifaka endows their ability to protect their forest. Natural resources are extensively used in local people's daily life, like the petiole of *Bismarckia nobilis* Hildebrandt & H. Wendl. and *Hyphaene coriacea* Gaertn, used to do wicker-work, to wave baskets and cushions. The axes of *Ravenala madagascariensis*. Sonn., *Rhizophora mucronata* Lam. and *Ceriops tagal* (Perr.) C.B.Rob. and the petiole of *Raphia farinifera* (Gaertn.) Hyl. are frequently used when constructing homes. Thirty-eight medicinal plants were detected and among them, 23 plants are used for women and 9 plants are used for children. Thirteen plants are used to help delivering babies, like *Abrus aureus* R.Vig., *Anisocyclea grandidieri* Baill., 10 plants can help in curing fever, and the others can cure headaches, stomachaches, cholera and diarrhea. Furthermore, the database Xper2 includes all the information about the usage of these plants, including their medical effects and their morphological characteristics. This can be, in turn, used in websites and can be made available in cellphones, even offline, something that can help academics, scientists, locals or anyone interested in getting more information about local flora. This study identified a close relationship between the locals' interests in conserving the forest and the traditional beliefs of local people in which we can root future efforts of conservation of traditional culture in ethnic settlements, helping the preservation and survival of their way of life vis-à-vis the globalization trend.

Empowering practitioners to save South China's most threatened tree species

Xiaoya Li[1], *David Gill*[2], *Yanjing Geng*[1], *Margin Georgina*[2]
1. Fauna & Flora International China Programme
2. Fauna & Flora International

Trees have evolved over the last 360 million years into a wide range of shapes and sizes, adapted to a huge variety of habitats. Individual species play a myriad of economic, ecological, and cultural roles highly valued by today's society. However, over 9,600 tree species are threatened with extinction around the world. To safeguard the world's threatened tree species, the Fauna & Flora International (FFI) and Botanic Gardens Conservation International (BGCI) formed the only international programme called the Global Trees Campaign (GTC) in 1999. As part of GTC, FFI's China has been working on the conservation of threatened trees in southern China since 2006. The area is home to more than 200 threatened tree species, many of which are covered by nature reserves. FFI's work mainly focused on empowering the nature reserve staff to protect those threatened tree species to address the major gap that many practitioners lack the skill and experience for the plant conservation. From 2010-2016, FFI supplied six training courses to the chief techical staff of the nature reserve, covering status assessment/IUCN red listing, action plan, patrolling, monitoring, reintroduction, habitat management, awareness raising, communities engagement, conservation effectiveness assessment, involved more than 30 priority nature reserves (i.e. reserves with globally important populations of threatened tree species such as *Magnolia sinica, Abies yuanbaoshanensis, Pinus squamata, Firmiana major*). In the meantime FFI worked with local experts and stakeholders within four reserves and developed some pilot practices. Major results of this work include: (1) More than 60 nature reserves personnel supported to develop new conservation skills. (2) Staff from more than 20 nature reserves mentored to implement new conservation actions for 18 threatened tree species. (3) A plant conservation network established with more than 100 experts and practitioners participating, allowing continued exchange of information, experiences and technical support. (4) Fifteen nature reserves were supported to secure co-funding for threatened tree conservation from various sources including Yunnan and Guangxi Forestry Departments. The project is now attracting significant interest from the State Forestry Administration and several Provincial Forestry Departments who are keen to see the extension of this capacity building programme to a larger number of practitioners, sites and species.

A preview of mangroves' future when the sea level rises and coastal developments intensified

Xinnian Li[1], *Zixiao Guo*[1], *Renchao Zhou*[1], *Cairong Zhong*[2], *Wenqing Wang*[3], *Suhua Shi*[1]
1. Sun Yatsen University
2. Hainan Dongzhai Harbor National Nature Reserve
3. Xiamen University

Mangrove forests, which underpinned intertidal communities in tropics and subtropics, are increasingly threatened by the continuous sea level rising. More and more mangroves' dieback has been reported in recent years, and these events were reflected the vulnerability of mangrove forests to disturbances. The massive dieback of mangroves happened in unexpected ways regionally. Here we report a survey on a mangrove dieback event in Yalong Bay, Hainan, China between 2010 and 2012. Sea level in Yalong Bay rose as much as one meter and lasted for one week several times through a combination of unusual heavy rainfall, and narrowing of the outlet by coastal developments. More than half of mangrove trees died, and the numbers of species of mollusks declined by 77% in this event. A population genetics survey was conducted based on the samples collected before the dieback event. We found genetic diversity of many mangrove species were extreme low, and the diversity level is negatively correlated to the mortality in dieback event. A larger scale of population genetics analysis reveals a general pattern of low population diversity of major mangrove species in Southeast Asia, which implied that mangrove forests have suffered severe population reduction during the historical rapid sea level rising period. These species would be at risk to maintain the evolutionary potential. The combination of sea level rising and coastal developments in specific circumstances could significantly enlarged the threat to mangrove forests. Although the tragedy of the mangrove forest in Yalong Bay happened regionally, the global mangrove forests are under the same threats including sea level rising, low genetic diversity and coastal development intensified. The observation in Yalong Bay may be a rehearsal of the possible future for global mangrove forests. Therefore, urgent mangrove management for the challenge should be required.

Effects of cultivation management measures on the growth and flower of *Datura arborea*

Yan Li
Xi'an Botanical Garden of Shaanxi Province

The characteristics of *Datura arborea* L. was discussed with respect to its post-introduction. The growing and flowering habits of *Datura arborea* L. under different cultivation conditions was studied. The result can provide theoretical basis on production of *Datura arborea* in North China. With red flower and yellow flower varieties as experiment subject, the effects on the growth and flower of *Datura arborea* were studied under different of fertilization conditions, illumination intensity, medium and PH, temperature and humidity. At the same time, the plant type of *Datura arborea* was observed under different treatment of plant growth regulators. Leaf fresh weight and leaf area increased obviously under fertilizing Jiabao (N:12%, K2O:44%) and compound fertilizer (N:P:K=2:1:1), but the difference between two treatments is not obvious. The latter treatment has more flower buds. There is a good color appearance with 40% sunshade and 17280-25900Lx. Blosom quantity decreased by 8.41%, blossom diameter increased by 18.53%, corolla length increased by 22.02%. The plant performs slow growing at 0-15℃ and robust growing at 15-30℃ or higher than 30℃ . Significant difference between latter treatments is few. The promotion of temperature can enhance growth rate of ground diameter. The plant has a good type and ornamental value at at 15-30℃. Solution PP333 (0.5-1 g/L) can shorten internode length and increases flower buds. The result showed that the cultivation condition was favorable for the growth of *Datura arborea* L. with 40% sunshade, 17280-25900Lx of illumination, RH 60% and PH 6.5-7.5. The main fertilizer is N:P:K at 2:1:1, and were applied 3 to 4 times of Jiabao during growing period. Solution PP333 (0.5-1.0g/L) were applied three times from sprouting period to beginning of jointing stage to guarantee its ornamental value.

Research progress on germplasm resource and propagational technique of *Rhododendron* L.

Juyang Liao[1,2], *Chunliang Peng*[1,2]
1. Hunan Forest Botanical Garden
2. Hunan Engineering Research Center for Rhododendron L.

The largest genus of Ericaceae, *Rhododendron* L., consists of about 1000 morphologically diverse species. This genus is widely distributed in Asia, Europe, North America andAustralia (2 species). *Rhododendron* L. is the genus modeled on *R. ferrugineum* by Swedish botanist Carl Linnaeus in 1753, and recorded in the *Species Plantarum*. There are 573 species around China except Xinjiang and Ningxia, 409 endemic species are mainly found in the southwest and southern area. There are 58 species found in Hunan, including two new geographical distribution species, *Rhodedendron orbiculare* and *Rhododendron rupivalleculatum*, two new species, *Rhododendron zhangjiajieense* C. L. Peng et L. H. Yan and *Rhododendron tianmenshanense* C. L. Peng et L. H. Yan. *Rhododendron* is widely distributed in southwestern Hunan, the plant diversity of this genus is gradually increased with the increasing altitude. The vertical distribution center is at the altitude of 800-1500 m, the horizontal distribution center is between N 27°-25° and E 108°-114°, among which the subg. *Tsutsusi* has the largest spanning elevation of 50-2000 m.

Vascular flora research in wetland of Nanshui Lake in Guangdong Province

Weitong Lin, *Mingxuan Zheng, Yonbin Wu*
South China Agricultural University

According to the survey, there were 187 species of vascular plants in Ruyuan Nanshui Lake wetland, belong to 122 genera 67 families; Herbs occupied the largest proportion of all aquatic plants. Gramineae, Cyperaceae, Polypodiaceae, Thelypteridaceae, Urticaceae, Commelinaceae, Polygonaceae and Pteridaceae were dominant families; and Cyperus, Pteris, Polygonum, Selaginella, Hydrocotyle were dominant genus. There were 6 geographical distribution type and1variant in characteristic families, tropical elements also accounted for 83.33%. The geographical elements of all vascular plants were consisted of 13 distribution types and 7 variant, which tropical elements were dominant. Compared with other wetlands at similar latitude, flora of Nanshui Lake showed significant tropical characteristic than higher latitude region; Meanwhile, compared with other region at similar latitude, flora of Nanshui Lake showed more tropical characteristic than inland region. The result of clustering analysis showed that the flora composition of wetland plants from different region depended highly on location and latitude. By analysising the flora of vascular plants in Nanshui Lake wetland, we intended to provide some reliable information in wetland vascular plant resources protection, recovery and sustainable utilization in the future.

Using species distribution modelling to improve conservation of endangered plants in Southeast Asia

***Bo Liu**, Hongfeng Wang, Zheping Xu, Maofang Luo, Qinwen Lin, Keping Ma**

Institute of Botany, Chinese Academy of Sciences

Southeast Asia is generally defined as the area that includes the Brunei, Cambodia, East Timor, Indonesia, Laos, Malaysia, Myanmar, Philippines, Singapore, Thailand, and Vietnam. It is famous for its complex and diverse topography, and varying climates, provide a partial explanation for the high biodiversity, four global biodiversity hotspots: Sundaland, Wallacea. Philippines and Indo-Burma occur in this region.The natural vegetation and habitats of Southeast Asia are incredibly varied, ranging from the semi-arid scrub of East Nusa Tenggara, Indonesia, to the riverine forests of southern Borneo, (Kalimantan, Indonesia), the rainforests of Peninsular Malaysia, and the arid hills of Thailand. So far, the rich flora of Southeast Asia is under considerable conversion pressure with expanding human destructive exploration activities and economic development. Conservation strategies based on the geographic patterns of endangered plant species richness, including the identification of meaningful floristic regions and priority areas for conservation, could improve the effectiveness of policy and management of flora in this area. In this research, we produce distribution models at 10 km^2 resolution for all endangered plant species integrated by red list data for all Southeast Asia countries, using geo-referenced herbarium collections from this area, corrected for spatial bias using a null model, and detailed environmental variables, also using Bioclim model to predict the potential distribution areas for medicinal plants. As a results, we identified four important aspects of endangered plant species distribution in Southeast Asia: (1) the endangered species diversity hotspots; (2) major floristic rich regions by grid, using a cluster analysis of species presence/absence; (3) priority areas for plants conservation based on the concept of the 'irreplaceability' value of planning units; and (4) the estimated potential distribution for endangered species with the climate data combined with the specimen records under the global warming image. Our maps provide clear priorities for the development of a sustainable and feasible biodiversity conservation strategy for endangered plants in Southeast Asia.

The outline of taxonomic literatures and herbaria index of Southeastern Asian higher plants

***Bo Liu**, Hongfeng Wang, Zheping Xu, Maofang Luo, Qinwen Lin, Keping Ma**

Institute of Botany, Chinese Academy of Sciences

Plant taxonomy is the essential basis of all relevant disciplines of botany and horticulture. The very beginning for a taxonomical work is to locate the relevant taxonomical literature, and search for herbarium type and non-type specimens for future revision work. While, taxonomic literatures of Southeast Asia countries (Brunei, Cambodia, East Timor, Indonesia, Laos, Malaysia, Myanmar, Philippines, Singapore, Thailand, Vietnam) still remain incomplete and scattered. Many flora books written in local languages don't have an English name, which makes the young students and newcomers a pretty headache to start from volumes and volumes of books and journals from Linnaeus dated back almost 260 years ago.This research aims to serve as the most updated comprehensive guide dealing with the taxonomical literature of higher plants (covering bryophytes, pteridophytes, and seed plants) in Southeastern Asia, and with an thoroughly inventory of herbaria in this area. The first part introduces the basic information of literature, including classification of literature, grades of literature, literature retrieval, specialty of taxonomic literature, and book classification. The second part introduces different kinds of taxonomic books, including index, bibliography, abstracts, dictionaries, Florae, classification systems, collection history, International Code of Botanical Nomenclature, and Latin and types. The third part deals with journals, including local and foreign ones (arranged by different countries, totally 11 countries). The fourth part is appendices which include major herbaria in Southeast Asia.

The first garden ancient city is in China

***Fuhu Wu**, Haiyan Liu, Chuanrui Pan*

China Shenzhen Lvya Green Gardening Scientific Institute

Archaeological discovery of Sanxingdui site has been worked for 88 years, after the repeated investigation and study, the discovery of her west half city, the total dikes and strange water management facilities, the incomplete ancient city has been restored into the world's first perfect garden ancient city. In the city, we have found the 12 garden types, such as moon palace, Reevesia tree, feng shui garden, indoor garden and tree wall, dating back for 4087 years. It is different from the previous knowledge: the palace and the axis high-end are not in the small Moon Bay, and they are in the large Moon Bay and Qingguan Mountain, although the axis low-end is located between the two treasure pits of Sanxingdui, the axis is about 40 degrees from north to east. Axis is crooked as the city is crooked, the original palace with the neat symmetry and the proposed symmetric city have been split to the half nearly. As the study, the doll weir and the strange water management facilities in Sanxingdui are made for the hydroponic fire, non-defensive wall moat, the tools are fire, water, wood and bamboo. No prehistoric farmland, ancestors have created the "cited cutting", "sun burning" high-tech logging reclamation. The so-called "cited cutting" is to open water ditch, build lake embankment, introduce water, store water, and flood forest in the man-made lake; The so-called "sun burning" is to break up the lake embankment to deepen the drains 4-5 m and widen 40-50 m after flood and cut forest, make the drainage, dry the trees and roots, fire to burn forest, plant with the hard work, the human history has been put forward from the Stone Age into the great farming era. Inadvertently, it also leads to forest fires, melts the glacial and ice cover, raises the sea, floods farmland, settlement and forests, and brings the endless disaster. The land evidence are the strange channel embankment network, lake embankment or massive red burnt soil blocks many prehistoric sites, such as the Sanxingdui culture; the evidences submerged in the sea floor are the massive forests, temples, settlements and pyramids because of the long-term hydroponic fire and melting ice to raise the sea surface. As archaeological discoveries: England Dorgon waters and Norfolk North County with the equivalent of the European area are the forests and settlements thousands of years ago.

Influence of environmental factors on the active substance production and antioxidant activity in *Potentilla fruticosa* L. and its quality assessment

Wei Liu
Henan University of Science and Technology

Environmental factors may influence types and contents of active substances. This study investigated the influence of environmental factors on the active substance contents and antioxidant activity of Potentilla fruticosa L. from different regions of China. Also, HPLC fingerprint similarity analysis (SA) coupled with hierarchical cluster analysis (HCA) and discriminant analysis (DA) were further introduced for the accurate classification and quality assessment of P. fruticosa. The results showed that altitude was significantly and negatively correlated to the content of tannin ($P < 0.05$). Annual sunshine duration and altitude were significantly and positively correlated to the flavonoids content, rutin content and antioxidant activity ($P < 0.05$). Annual mean temperature was significantly and negatively correlated to the content of total phenolics, while altitude was significantly and positively correlated to the content of total phenolics ($P < 0.05$). Eight samples were unambiguously separated into three groups. Two types of discriminant functions with a 100% discrimination ratio were constructed. All data consistently supported the conclusion that P. fruticosa produced from Kangding, Sichuan Province had high quality among all samples, therefore, Kangding in Sichuan Province with favorable environmentalconditions is recommended as a preferable production location.

Geographic distribution of species strongly related to the limestone outcrops in Brazil

Pablo Hendrigo Alves De Melo, Tharso Rodrigues Peixoto, ***Julio Antonio Lombardi***
UNESP - State University of São Paulo

Limestone outcrops are places of great phytogeographic importance and are also relevant to research in archeology and paleontology. However, these sites are strongly threatened by mining activity, since limestone is used in the manufacture of fertilizers and in the production of cement and lime. The floristic composition of the limestone outcrops in Brazil is not well known, although occurring in all phytogeographical domains most of the studies are local in scope, are in the *cerrado* biome, and along the watersheds of the Rio São Francisco and Tocantins. Based in a floristic composition survey under way in ten areas at or near the extreme of ranges of the limestone outcrops formations in extra-amazonian Brazil, and distributed in the phytophysiognomies of *caatinga* (semi-arid scrub forests), *cerrado* (Brazilian savannas types; ranging from dense savanna forests to areas of open grass vegetation), and *Atlantic Forest* (humid evergreen to semideciduous rain forests), at the localities of Cafarnaum and Lajedinho (*caatinga*, Bahia State); Formosa (*cerrado*, Goiás State), Funilandia/Prudente de Morais (*cerrado*, Minas Gerais State), Matias Cardoso (*cerrado*, Minas Gerais State), Bela Vista (*cerrado*, Mato Grosso do Sul State), Nobres (*cerrado*, Mato Grosso State), Novo Jardim (*cerrado*, Tocantins State), Rio Branco do Sul (*Atlantic Forest*, Paraná State) and Apiaí/Iporanga (*Atlantic Forest*, São Paulo State), and search in digital databases (gbif.org; jabot.jbrj.gov.br and splink.org.br), we selected ten species strongly related to the limestone outcrops in Brazil to analyzes of geographic distribution: *Begonia exigua* Irmsch. (Begoniaceae), herb, in *cerrado* biome; *Encholirium longiflorum* Leme (Bromeliaceae), herb, in the transition between *cerrado* and *caatinga* biomes, *E. luxor* L.B.Sm. & R.W.Read, herb, in *cerrado* biome; *Cereus jamacaru* subsp. *calcirupicola* (F.Ritter) N.P.Taylor & Zappi (Cactaceae), arborescent shrub, in *cerrado* biome; *Chautemsia calcicola* A.O.Araujo & V.C.Souza (Gesneriaceae), herb, in *cerrado* biome; *Sinningia calcaria* (Dusén ex Malme) Chautems (Gesneriaceae), herb, in *Atlantic Forest*; *Ceiba rubriflora* Carv.-Sobr. & L.P.Queiroz (Malvaceae), tree, in the transition between *cerrado* and *caatinga*; *Ficus bonijesulapensis* R.M.Castro (Moraceae), tree, in the transition between *cerrado* and *caatinga*; *Priogymnanthus saxicolus* Lombardi (Oleaceae), tree, in *cerrado* biome; *Oxalis calcicola* Fiaschi (Oxalidaceae), herb, in *cerrado* biome; *Hemistylus brasiliensis* Wedd (Urticaceae), scrub, in *cerrado* biome. The species occurrences show distribution patterns restricted to small geographical ranges, indicating regionalization of the distribution of these species strongly related to the limestone outcrops in Brazil. (FAPESP #2015/13112-7 to PHAM and #2016/09444-7 to TRP).

Species richness and genetic diversity in *Dysopsis hirsuta* (Euphorbiaceae) and *Nothomyrcia fernandeziana* (Myrtaceae), endemic species of the Juan Fernández Archipelago, Chile.

Felipe Saéz[2], ***Patricio López-Sepúlveda***[1], *Glenda Fuentes*[1], *Hellen Montoya*[1], *Patricio Peñaillillo*[3], *Tod F. Stuessy*[4]
1. Depto. de Botánica, Universidad de Concepción
2. CONAF Juan Fernandez Archipelago
3. Inst. Ciencias Biológicas, Universidad de Talca
4. The Ohio State University

The Juan Fernández Archipelago is located 667 kilometers west of continental Chile and consists of three islands: Santa Clara, Robinson Crusoe, and Alejandro Selkirk, with a geological age estimated between 1-4 my. The Archipelago is a natural laboratory, characterized by a high percentage of specific endemism. Human activity, involving degradation of the forests as well as introduction of exotic animals and alien plants, has caused a significant reduction in population number and size, as well as genetic variation within endemic plant species. The objective of this contribution is to present information on genetic diversity in two endemic species from the Juan Fernández Archipelago, one an herb and another a tree, in conjunction with general species richness values to determine areas of greater interest for conservation. Samples of *Dysopsis hirsuta* (Mull. Arg.) Skottsb. and *Nothomyrcia fernandeziana* (Hook. et Arn.) Kausel in Robinson Crusoe Island were collected from 10 and 18 populations, respectively. After extraction of DNA, AFLPs were obtained for genetic analysis. Scoring was done with the program GeneMarker ver. 1.85, and a binary matrix was generated for each species. The data were analyzed using Genalex and the software Arc 9.3. In parallel, an analysis of richness of thirteen tree species was performed in Diva-Gis using a circular neighborhood method. In *Dysopsis hirsuta* the values of number of effective alleles (Ne = 1.078), percentage of polymorphism (% P = 50.6%), Shannon-Weaver Index (I = 0.237), and expected heterozygosity (He = 0.154) were lower in populations with less species richness (<7 species) and invaded sites. The highest values of genetic diversity (Ne = 1.3, %P = 65, I = 0.272, He = 0.170) were found in sites with high species richness (>9 species) and in fragments of native forest. *Nothomyrcia fernandeziana* does not evidence a relationship between genetic diversity and species richness, and it has high values of genetic diversity in invaded areas (%P invaded = 61.2%, %P native = 54.8%). We discuss the levels of genetic diversity in *D. hirsuta* in relation to forest fragmentation, isolation, low gene flow between populations, and mode of speciation. Homogeneous genetic diversity within *N. fernandeziana* may be associated, among other factors, with the continuous distribution of this species on Robinson Crusoe Island.

Resource sharing and facilitation of epiphytes in forest canopies

Hua-Zheng Lu[1,2], *Liang Song*[1], *Rob Brooker*[3], *Fei-Hai Yu*[4], *Lawren Sack*[5], *Wen-Yao Liu*[1]

1. Key Laboratory of Tropical Forest Ecology, Xishuangbanna Tropical Botanical Garden, Chinese Academy of Sciences, Menglun, Mengla
2. University of Chinese Academy of Sciences, Beijing
3. The James Hutton Institute, Craigiebuckler, Aberdeen
4. School of Nature Conservation, Beijing Forestry University, Beijing
5. Department of Ecology and Evolutionary Biology, University of California Los Angeles, Los Angeles

Forest canopies house ca.50% of terrestrial biodiversity. One important component of canopy biodiversity is the presence of epiphytes, but how epiphytes adapt to forest canopies remains one of the key questions in canopy ecological research. One notable pattern is that almost all non-vascular epiphytes and many vascular epiphytes are capable of clonal growth. However, how clonal traits such as physiological integration (resource sharing) affect the adaptation of epiphytes to forest canopies is virtually unknown. Epiphytic habitats are usually described as “harsh” because tree crowns are characterized by a limited storage capacity for available nutrients and water, sporadic and dilute nutrient inputs, low physical stability, extreme fluctuations in moisture and temperature, high wind speed, and severe and variable vapor pressure deficits. Significant variation in resource availability can occur at small spatial and temporal scales, and short-term drought can occur even in wet seasons of tropical rainforests. Although it was conceived that competition was the basic ecological process, stress-gradient hypothesis (SGH) implied that the role of competition decreased and facilitation increased with the rise of stresses. However, we know little about how epiphyte species interact with each other and what their effects on community assembly are. The experiments were carried on the clonal integration (with or without resource sharing) of several dominant vascular epiphytes and on its effects on interaction between vascular and non-vascular epiphytes (removed or intact) in a subtropical evergreen broad-leaved forest in Southwest China. Results were as follows, 1) preventing integration (without resource sharing) significantly reduced the ramet survival and biomass of epiphytes, but the magnitude of such integration effects did not vary significantly between species; 2) non-vascular epiphytes (bryophytes and lichens) facilitated the survival and growth of vascular epiphytes; 3) the effects of clonal integration on performance of vascular epiphytes without non-vascular epiphytes were higher than those with non-vascular epiphytes. We concluded that clonal integration (resource sharing) was a general strategy for clonal epiphytes to adapt to forest canopies where resources were limited and heterogeneously distributed in space and time. Meanwhile, our studies provided the first evidence of facilitation between vascular and non-vascular epiphytes and deepened our understanding of habitat adaptation of resource sharing and species interaction of epiphytes in the community assembly in forest canopies. It also shed light on the conservation of canopy biodiversity because of the facilitation cascades and domino effects.

Antibacterial activity, optimal culture conditions and first successful cultivation of *Ganoderma australe*, a new record to Thailand

Thatsanee Luangharn

Kunming Institute f Botany, Chinese Academy of Sciences, Kunming, China

Ganoderma is a well known genus of medicinal mushrooms that belongs to the order Polyporales. Many members of this genus are used extensively in traditional Asian medicines, and have wide potential for application in bioremediation. Even though 22 species of medicinal *Ganoderma* have been described worldwide, very few *Ganoderma* species have been domesticated. Herein we report a new strain of *Ganoderma australe* collected in Thailand and identified through phylogenetic analysis and an examination of its micro and macro morphological characteristics. We report for the first time in Thailand the antimicrobial activities of *G. australe* and the optimal conditions for mycelia and spawn production and cultivation. Ethyl acetate extracts of *G. australe* mycelia inhibited both Gram positive and negative bacteria including *Micrococcus luteus*, *Bacillus subtilis*, *Staphylococcus aureus* and *Salmonella typhimurium*, while it was not effective against *Escherichia coli* and *Pseudomonas aeruginosa*. The fungus mycelium was able to grow on PDA medium, 25–30^{o}C and pH 7–8, while sorghum and barley were found to be the best grain media for spawn production. Para rubber sawdust with organic and inorganic additives was used as a standard cultivation substrate. The mycelia were fully distributed throughout the sawdust substrate after being incubated at 30^{o}C, 60-75% relative, for 18 days. The first primordia were observed three days after the bags were opened. Three cycles of mushrooms were obtained, with the weight of mushrooms produced decreased each time due to the degradation of the substrate (115.04 ± 48.85 g kg^{-1},72.01 ± 6.00 g kg^{-1} and 36.47 ± 9.04 g kg^{-1}, respectively).

Wild growing Vacciniaceae in natural populations and prospects of cultivation

Ekaterina Luginina, *Tatyana Egoshina*
Russian Research Institute of Game Management and Fur Farming

Main wild growing species of *Vacciniaceae* family are cowberry (*Vaccinium vitis-idaea* L.), blueberry (*V. uliginosum* L.), cranberry (*Oxycoccus palustris* Pers.), and bilberry (*V. hirtum* Thunb., *V. ovalifolium* Smith, *V. myrtillus* L.). Biological stock (BS) of raw material of the studied *Vacciniaceae* species in Russia in average fruitful year is 4,733.9 thous. t. The most significant stock of these species is marked for Siberian (BS 1,818.9 thous. t), North-Western (BS 1,117.2 thous. t) and Far Eastern (BS 632.2 thous. t) Federal districts. The largest stocks among separate territories are in Krasnoyarsk Krai (BS 810.5 thous. t), Khanty-Mansiisk Autonomous District (BS 477.3 thous. t), Komi Republic (BS 473.8 thous. t), and Irkutsk region (BS 423.1 thous. t). In the structure of total BS bilberry fruits (40%) and blueberry fruits (27%) prevail. Exploitation rate of *Vacciniaceae* resources in different areas of the country varies from 20 to 98%, and the press on natural populations is increasing. The most significant anthropogenic load is marked for natural populations of berry plants near large cities in the central part of Russia and in boundary regions. In order to decrease exploitation load on natural populations in Russia the introduction, cultivation and selection projects are carried out. The experience of long-term (since 1987) introduction of wild growing berry plants in southern taiga subzone of Russia (Kirov region) allowed revealing the species and cultivars of plants that are highly productive, early ripening, and winter-hardy in conditions of the region with cold climate and short vegetation period. Out of 15 tested cultivars of *Oxycoccus мacrocarpus* Pers. only fruits of Bean Lear cultivar were able to get ripe annually before autumn frosts. Plants of Franklin, Early Black, Wilcox, McFarlin cultivars provided 0.3-1.8 t/ha yield in conditions of Kirov region. Flower productivity reached 40%. In 70% of years underripe fruits were damaged by early autumn frosts. Cultivars of *Oxycoccus palustris* Pers. of Russian selection (Krasa Severa, Dar Kostromy, Alaya Zapovednaya, Khotavetskaya, Severyanka, Sominskaya) gave high yields annually (about 3.6 t/ha), were early ripening (end of August - beginning of September) and had large fruits. Maximum weight of “Dar Kosrtomy” berries reached 3.3 g, “Krasa Severa” - 2.5 g. These cultivars proved to be winter-hardy: frost-killing was not marked during the period of studies. Cultivars of Estonian selection (“Tartu”, “Virusaare”) ripened in the end of September. Their productivity was about 2.8 t/ha. Fruit damage by autumn frosts was registered. These cultivars were the least winter-hardy among all European cranberry cultivars. Experimental plantings of *Oxycoccus palustris* Pers. were consistently fruitful; unfruitful year was registered once during the whole study period. Among 3 tested cultivars of *Vaccinium vitis-idaea* L. (“Coral”, “Rubin”, “Kostromskaya rosovaya”), “Coral” was the least winter-hardy in conditions of experimental ground. The cultivar also had active reflorescence which weakened main spring flowering and fruit setting. There were also trials on *Vaccinium canadense* Kalm. cultivation but in conditions of Kirov region the plants were annually frostbitten at the level of snow cover and never fruit. It was ascertained that only *V. angustifolium* Ait., which is a low shrub in regional conditions and reaches 0.27-0.6 m height on the third year (average 0.43 m), shows suitable winter-hardiness. The level of productivity of 3-year old plants varies from 18.2 to 406.0 g (average 177.5 g, which is about 407 kg/ha). During the latter years, the productivity increases reaching 4-6 t/ha at the age of 5 and more. Average berry weight varies from 0.9 to 5.3 g. It was evident that the least winter-hardy are cowberry “Coral”, American cranberry “Ben Lear”, European cranberry “Tartu” and “Virussaare”.

Pollen and stamen mimicry: The most speciose mimicry system of the world?

Klaus Lunau
Heinrich-Heine-University Duesseldorf

Many melittophilous flowers display yellow and UV-absorbing floral guides that resemble the most common colour of pollen and anthers. The yellow coloured anthers and pollen and the similarly coloured flower guides are described as protagonists of a pollen and stamen mimicry system. In this study, we investigated the entire angiosperm flora of the Alps, of Crete (Greece), and of Barro Colorado Island (Panama) in regard to visually displayed pollen and floral guides. All angiosperm species were checked by means of colour photos for the presence of pollen- and stamen-imitating structures. For some Flower UV-photos are used to confirm the ultraviolet absorbing properties of pollen and floral guides. More than 70% of the flowering plants of the Alps display yellow pollen, more than 65% of the species display yellow anthers and 28% of the species display pollen- or stamen-imitating structures. The percentage of species displaying pollen- or stamen-imitating structures on Crete is 24%, and on BCI 12%. The most frequent types of pollen and stamen imitations are yellow, UV-absorbing colour patches of petals, stamen-like pistils, and staminodes, and three-dimensional structures such as lower lips and filamental hairs. Dichogamous and diclinous species display pollen- and stamen-imitating structures more often. The visual similarity between the androecium and other floral organs is attributed to mimicry, i.e. deception caused by the flower visitor’s inability to discriminate between model and mimic, sensory exploitation, and signal standardisation among floral morphs, flowering phases and co-flowering species. We critically discuss the deviant pollen and stamen mimicry concepts and evaluate the frequent evolution of pollen-imitating structures in view of the conflicting use of pollen for pollination in flowering plants and pollen eating pollinators such as hoverflies as well as pollen collecting pollinators such as bees.

Disentangling community assembly mechanisms in distinct layers of plant communities along elevational gradient in subalpine forests

Yahuang Luo[1], *Jie Liu*[1], *Shaolin Tan*[1], *Dezhu Li*[2], *Lianming Gao*[1]
1. Key Laboratory for Plant Diversity and Biogeography of East Asia, Kunming Institute of Botany, Chinese Academy of Sciences, Kunming, China
2. Germplasm Bank of Wild Species in Southwest China, Kunming Institute of Botany, Chinese Academy of Sciences, Kunming, China

Determining how the relative strength of community assembly processes varies along elevational gradients is critical for understanding community responses to environmental change. However, little is known about the different forms of environmental variables that maintain the diversity of distinct vegetation layers. The community assembly processes of three growth forms were inferred by using functional traits and phylogenetic relatedness data in 15 0.1-ha plots across 1,200 m elevational gradients in Yulong Mountains, Yunnan Province, China. Abiotic conditions in terms of topography, soil nutrients, and climatic variables were also quantified. Null model was used to detect the importance of abiotic filtering and biotic interactions along elevational gradient. The effect of spatial and environmental variables on species, functional and phylogenetic diversity within community and across communities were also conducted. Our results revealed the assemblages of overstory tree species tended to be overdispersed at low elevation and clustered at high elevation, and the climatic variables (e.g. minimum temperature and mean annual precipitation) appears to be important factors to determine the species richness and phylogenetic structure. Whereas the understory woody species exhibited opposite trends with elevation, suggesting an important role for environmental filtering (e.g. aspect) in driving phylogenetic convergence at lower elevation. Overdispersion dominated in understory herbaceous assemblages, possibly due to limiting similarity. The functional diversity of leaf area and seed mass were associated with elevation among three vegetation layers. Species in different layers structured by stronger dispersal limitation showed faster species turnover than phylogenetic and functional turnover. The findings suggest the importance of abiotic stress or biotic interactions in shaping the diversity of different group communities at different elevations. Meanwhile, neutral processes may also be a predominant in structuring species composition along elevational gradient. Our study highlight the need for the combination of phylogenetic and trait-based approaches to better understand the species coexistence and community assembly in distinct layers of forests.

Mapping Asia plants

Keping Ma[1], *Bo Liu*[1], *Hongfeng Wang*[1], *Maofang Luo*[2], *Zheping Xu*[1], *Xuehong Xu*[2], *K Ganeshaiah*[3]
1. Institute of Botany, Chinese Academy of Sciences
2. Biodiversity Committee, Chinese Academy of Sciences
3. University of Agricultural Sciences, GKVK Bangalore

Because of the huge population and rapid growth of economy, biodiversity including plants are being seriously threatened in Asia. Both conservation and sustainable use of biodiversity need species distribution data. Asia is the continent with highest diversity of plants. However, the information of plant taxonomy and distribution in Asia are less available and more scattered, compared with other continents such as Europe and America. So, a better infrastructure for plant distribution in Asia is important. In 2015, Asia Biodiversity Conservation and Databases Network (ABCDNet) started a project entitled Mapping Asia Plants for cataloguing species of plants and collecting distribution data from the following aspects: 1) specimens, 2) observations, 3) species checklists, 4) expert maps, 5) inventories, 6) vegetation plots, 7) literatures and 8) on line datasets. Major achievements so far are as follows: 1) for China, national higher plant checklists including 35,835 species, 9 million records of occurrence; 2) for Southeast Asia, 120 thousands species names, 1.3 million records of occurrence; 3) for North Asia, 6,900 species of higher plants and their distribution in 13 sub-regions. Some of the data collected are shared with the websites of ABCDNet (www.abcdn.org).

Studies on sesquiterpenes from *Chenopodium album* Linn

Qinge Ma, *Rongrui Wei*
Nanyang Normal University

Chenopodium album Linn is a favorite vegetable in folk, which belongs to the Chenopodiaceae family. In this work, four sesquiterpenes (1-4) were isolated from *C. album* Linn for the first time. They were identified as arecolactone (1), 4α, 8β-dihydroxy-eudesm-7 (11)-en-12,8-olide (2), stereumin P (3), and lyophyllanetriol A (4) by their extensive spectroscopic data and the reported data in the references.

Ecological assessment and monitoring of biodiversity in terrestrial and aquatic ecosystems in Didipio Gold Copper Project, Nueva Vizcaya, Philippines

Pastor Jr. Malabrigo[1], *Nelson Pampolina*[1], *Juancho Balatibat*[1], *Crusty Tinio*[1], *Dianne Joy Aguilon*[1], *Keshia Tingson*[1], *Bonifacio Labatos*[2], *Arthur Glenn Umali*[1]
1. University of the Philippines Los Baños, College of Forestry and Natural Resources
2. Oceana Gold Philippines Inc.

The Didipio Gold-Copper Project (DGCP), owned by Oceana Gold Philippines Inc. (OGPI), is situated at the southern part of Palali-Mamparang mountain range, a known key biodiversity area in the region. As mineral reserve co-exists with biodiversity in DGCP site, it is important that mining activities are not affecting biodiversity and the ecological system. The government, hence, requires the conduct of environmental impact assessment and regular monitoring to ensure environmental compliance of the mining company. To comply with it's obligation, OGPI commissioned a group of biologists from the University of the Philippines Los Baños, College of Forestry and Natural Resources (UPLB-CFNR) to conduct the monitoring. In the past three (3) years, UPLB-CFNR diligently conducted the annual ecological assessment and monitoring of biodiversity in the terrestrial and aquatic ecosystems in DGCP. The monitoring conducted was one of the most complete and comprehensive, as it includes all the major groups of organisms (i.e. flora, vertebrate fauna, arthropods, fungi, and lichens). Nine sampling sites representing low, medium, and high impact zones were identified as monitoring stations for terrestrial ecosystems where a combination of transect and quadrat sampling techniques were used. For freshwater ecosystem, macrobenthos, periphyton, and fish assemblages were surveyed in 8 river stations within the mining area. For the three years of monitoring, UPLB-CFNR has accumulated biologically important information that are useful for the company to better conserve and manage the biodiversity in the surrounding area. A total of 484 morpho-species of plants were documented, 30% of which are new province records, 79 species were found to be Philippine endemics and twenty-three (23) species are threatened. More importantly, two undescribed species were discovered. The mountain ecosystem is also home to thirty-seven vertebrate wildlife species comprising of 24 species of birds, seven mammals, three reptiles and three species of frogs. About 51% of the species are Philippine endemics, including 5 threatened species. Beneath the forest ecosystem were terrestrial macrofungi comprising of 37 species, 34 genera and 33 families. Mostly were litter decomposers, some edible and medicinal, while a number were ectomycorrhizal that link roots of dipterocarps and other endangered non-dipterocarps for exchange of carbon and essential nutrients. Across the vertical forest stratum were lichens with 201 records belonging to 42 taxa, 32 genera, and 17 families. In aquatic ecosystem, periphyton assemblage comprised of 22 algal species from divisions of Bacillariophyta (diatoms), Chlorophyta (green algae) and Cyanophyta (Cyanobacteria). The macrobenthos communities list was 285 individuals under 10 taxonomic groups. The top three taxonomic orders were Ephemeroptera (mayflies), Trichoptera (caddisflies), and Hemiptera (water bugs). Trace metals from sampled tissue of freshwater crab were all below the maximum allowable limits set by various international standards. Overall, the three years of monitoring suggests that biodiversity and ecosystem were sustain at a level that allow their normal physiological and ecological processes to function and continue to provide goods and services in Didipio mountains from terrestrial down the river system. Their monitoring and assessment however warrant continued system as guiding parameters by the company and community.

EDC's ascendancy in the conservation of Philippine Ironwood trees

Xanthostemon Spp. Myrtaceae

Pastor Jr. Malabrigo[1], *Ronino Gibe*[2], *Ernesto Jr. De Guzman*[2]

1. Department of Forest Biological Sciences, College of Forestry and Natural Resources, University of the Philippines Los Ba?os
2. Energy Development Corporation

The genus *Xanthostemon* is globally recognized as the densest and strongest among the wood-producing trees. Members of the genus are collectively called Ironwood trees because of their exceptional hardness. The Philippines is blessed to have five unique species of Ironwood trees. All are endemic to the country with very narrow range of distribution. *Xanthostemon* spp. are almost exclusively found in ultramafic forests with soil rich in heavy metal elements. With the long history of mining in mineralized soil of the country, habitat of Ironwood trees became very much devastated putting the fate of these toughest trees into the brink of extinction. Recognizing the urgency to save the remaining populations of the world's hardest trees, Energy Development Corporation (EDC), the Philippines' leading industry in renewable energy production, launched a noble tree conservation program in 2008, called "BINHI" (Filipino term for seedling). Using science-based criteria based primarily on ecological and economic importance, EDC came up with 96 priority threatened trees for conservation including all the Philippine Ironwood species. For the past 8 years, with the partnership with the government agencies and academic institutions, EDC managed to discover and protect several new populations of ironwood species. The company's state of the art vegetative material recovery (VMR) facility has already developed protocols for the mass propagation of species through cuttings with survival rate ranging from 93-97%. Some of the planted seedlings among EDC's 133 partner institutions (mostly high schools and universities) are now source of seeds even at a very young age. Aside from species rescue and mass propagation, BINHI has a very virtuous advocacy and awareness component. EDC sponsors an annual BINHI Youth Conference participated by selected high school students from all over the country. The 3-day conference aims to deepen the level of awareness and appreciation by the young generation to the beauty and importance of the Philippine native trees. In all of the 133 arboreta established, seedlings were properly labeled including the name of the planters. EDC is maintaining a BINHI website wherein photos from regular bi-annual monitoring were continuously uploaded so that the planters can monitor the growth and status of the seedlings they planted even away from the arboretum. Lastly, all botanical information gathered for the 8-years of the project including new distributions, phenology, and propagation technology were recently published into a book "BINHI Tree for the Future" to disseminate the project learning and experiences to a larger public. With the efforts of EDC to mainstream threatened species in urban landscaping and the protection of their remaining natural populations, the Philippines is now assured that the precious ironwood trees are now far from being extinct.

P0135

Azerbaijan endem rare and endangered trees and shrubs

Tofig Mammadov

Institute of Dendrology of Azerbaijan National Academy of Sciences

Azerbaijan is the richest area in biodiversity in the Caucasus region due of a special plant cover distributed by geographical location, relief, soil and climate conditions. The diversity of flora and fauna species in Azerbaijan and classy endemism are associated with environmental conditions in the area due to the historical evolution. Despite of the country richness in flora and fauna in the past 30 years they are close to the destruction as a result of irrational, or various natural and human factors rapidly degradation a variety of plant species. Therefor by impacts of anthropogen factors many of precious trees and shrubs in forests areas *Quercus macranthera, Acer trautvetterii, Betula pendula, B.litvinovii, Paeonia mlokosewitschii, Laurocerasus officinalis, Taxus bacca-*

ta, Pinus eldarica, P. Kochiana, Punica granatum, Cotoneaster saxatilis, Juniperus foetidissima, Pistacia mutica, Rhus coriaria, Rosa spp*, Pyracantha coccinea* are extremely reduced. In addition there are created 9 National Parks, 11 State Nature Reserves and 20 State Nature Preserves in Azerbaijan. In created special protected natural reserves are conserved the majority of the flora and fauna species entered to "the Red Book". There arecarried out research works by ourselves to determine the protection of trees and shrub species in our republic, by accurate preparation of the records, the discovery of these plants belonging to rare plants category. There are researched processes by the distribution of plants, largenes of populations, an ecological resistance, physiological tolerance, reproductive biology, the next stages of developments. There are determined that in 1975 in Azerbaijan Dendroflora were existed 342 species, among them 24 rare and endangered species, in 1984 28 species, in 1989 45 rare and endangered woody trees and shrub species. Currently by the research works are determined that in Azerbaijan Dendroflora are found about 6000 plant species, among them 1600 species are trees and shrub species. They are forming approximately 37,5% of trees and shrubs of Azerbaijan flora. Recently are estimated the protection status of total flora, 300 plants (266 higher and 20 lower), 14 mushrooms are included to Azerbaijan "Red Book". By carried research woks are defined that plant species introduced in Azerbaijan flora are forming 68% species, 87%, genus, 95% families propagated in nature. 25% of trees and shrubs by specifications are relict in natural flora of Azerbaijan. There are determined by carried research works distributed the of rare and endangered trees and shrubs in Azerbaijan, studied results of the diminishing of distribution areas, endangered factors, defined the threat categories. By research works are used IUCN (2001) 3.1 versions categories and criterias, classification of taxas by APG III system. In addition there are comparative analized Azerbaijan Dendroflora and determined rare and endangered trees and shrubs number of species are 38 families, 63 genuses, 188 species. Among them 67 species are Caucasus endemic, 40 species are Azerbaijan endemic, 4 species are relict.

Medicinal plants among the Meranaos of Lanao, Philippines

Muhmin Michael Manting*, Norfaisah Razuman*

Mindanao State University-Iligan Institute of Technology

Medicinal plants are widely used all over the world to manage diseases and for health maintenance. This has played an important role in human's health for many centuries. Traditional medicinal knowledge, especially using medicinal plants in the developing countries has been in existence and use, and has been a part of therapeutic practices. The traditional use of medicinal plants is widely accepted in the Philippines. Plant species, cultures and practices on using the medicinal plants also vary in every island. Documentation of the indigenous knowledge on plants with ethnobotanical importance must be made. Thus, this study aimed to document and surveys the plants of the Meranaos of Lanao Provinces, Philippines using semi-structured questionnaires through Key Informant and Informal Interviews with a total of 160 respondent ages 60 years old and above. Seventy (70) medicinal plants in Lanao Del Sur and 43 medicinal plants in Lanao Del Norte were documented. Leaves were the most commonly used part in making traditional medicines and decoction method was the most used mode of preparation of medicines. Difference between the two provinces in the uses and the name of some plants varies such as local name of *Plectranthus scutellarioides* L. - "Paer" in Lanao Del Sur and "Mayana" in Lanao Del Norte. In terms of its plant parts and medicinal used, *Zea mays* L. in Lanao Del Sur leaves was used to treat as cure to abscess and cystitis while in Lanao Del Norte the root was used to cure problems in Urinary Tract Infection. The research on ethnobotanical plants can be a great help to a researcher that has ethnoparmaceutical studies and also it helps preserve traditional ethnobotanical knowledge of the Meranao people.

Trees of Dinagat Islands, Philippines: Basis for biodiversity conservation

May Angelie Paracale, Paul Alfonso Ondoy, Benjam Ray Maligro, Nikkimark Samoya, ***Muhmin Michael Manting***

Mindanao State University-Iligan Institute of Technology

The effect of anthropogenic activities on biodiversity is a global concern. Trees are bio indicators used primarily in the development and implementation of biodiversity conservation programs. Thus, a rapid floristic survey was conducted in Cuarenta Watershed, Municipality of San Jose and Panamaon Watershed, Municipality of Loreto to assess and document the tree species present in the area. The sites were chosen since the area is rich in mineral deposits, thus, mining and overexploitation are the major environmental threats. Data were obtained by means of transect walk on the trail used by the locals in traversing the watershed and photographic documentation. Identification of plant species was based on the given local names, comparison of specimen images with illustrated checklist of the philippineplant.org, the database of Co's Digital Flora of the Philippines, and other published scientific articles. As a result, 88 species were identified and recorded during the assessment period. Thirty percent of the taxa assessed in the study are on list of Threatened Tress Species. In contrast with the assessment of the threatened native flora of the Philippines released by the Department of Environment and Natural Resources, about 22% of the nationally threatened plants are locally threatened. The presence of nationally and globally threatened species calls for the strong development of conservation programs for the long-term protection of the forest ecosystems in the Island of Dinagat.

Gorilla food plants biomass distribution and variability adjacent to the Volcanoes National Park, Rwanda.

Olivier Jean Leonce Manzi[1,2], *Elias Bizuru*[1]

1. Dian Fossey Gorilla Fund International

2. University of Rwanda/College of Science and Technology

Gorillas ranging patterns are strongly influenced by their food plant distribution. From 2008, an increase of gorillas ranging outside the park in cultivated areas has been observed resulting in a rising conflict between gorilla and local people. This study aimed to determine gorilla food plants and their biomass distribution adjacent to the VNP which will help to determine whether there is a relationship between food availability and the frequency of gorilla visits outside park boundaries. We located about 93 transects perpendicular to the forest edge of 500 m length, each separated by 250 m. A total of 279 plots were established along transects in 250 m intervals. The plot size depended on the dominant plant life form. We identified all plants eaten by gorillas in each plot and calculated the gorilla food plant biomass using standardized methods. Results showed that there are 25 gorilla food plant species near the VNP boundaries. Dominant species were *Eucalyptus* sp., *Y. alpina* and *Rubus* sp. Three gorilla food plant species were found outside but not inside the park (*Eucalyptus* sp., *C. lusitanica,* and *A. glutinosa.)* Among the top 10 consumed plants inside the park, only 3 of them were not found outside the park (*L. alatipes, P.kerstenii*, and *D. erici-rosenii)*. For different life forms, *D. iners, C. nyassanus, Y. alpina*, and *Eucalyptus* sp. showed the highest biomass respectively. Gorilla food plant species diversity and biomass distribution outside the VNP were strongly influenced by both farming intensification and the distribution of Eucalyptus trees. This study shows that gorillas' ranging outside the park is due but not limited to the presence of their food outside the park. The failure to manage effectively the zones of interactions outside the park will result in continuous ranging outside the park and this will result in negative impacts for both gorillas and humans.

Classification and mapping of the woody vegetation of Gonarezhou National Park, Zimbabwe

Francesco Martini[1,2], *Robert Cunliffe*[1], *Alessio Farcomeni*[1], *Michele De Sanctis*[1], *Giacomo D'Ammando*[3,4], *Fabio Attorre*[1]
1. Sapienza University of Rome
2. Guangxi University
3. University of Liverpool
4. University of the Witwatersrand

Within the framework of the Great Limpopo Transfrontier Conservation Area (GLTFCA), the purpose of this study was to produce a classification of the woody vegetation of the Gonarezhou National Park, Zimbabwe, and a map of its potential distribution. Cover-abundance data of woody species were collected in 330 georeferenced relevés across the Park following a plotless approach with a sample area between 0.5-2 ha. These data were used to produce two matrices: the first one using the cover-abundance values as collected in five height layers and the second one based on merging the layers into a single cover value for each species. Automatic classifications were produced for both matrices to determine the optimal number of vegetation types. The two classification approaches both produced 14 types belonging to three macro-groups: mopane, miombo and alluvial woodlands. The results of the two classifications were compared looking at the constant, dominant and diagnostic species of each type. Based on these values and on expert knowledge the classification based on separate layers was considered more effective and retained. A map of the potential distribution of vegetation types for the whole study area was produced using Random Forest at a spatial resolution of 100 m. In the model, the relationship between bioclimatic and topographic variables, known to be correlated to vegetation types, and the classified relevés was used. A comparison with the only known previous assessment and description of the vegetation types of the Park was conducted. Moreover, identified vegetation types were compared with those of other national parks within the GLTFCA, and an evaluation of the main threats and pressures was developed. Vegetation classification and mapping are useful tools for multiple purposes including: surveying and monitoring plant and animal populations, communities and their habitats, and development of management and conservation strategies. Filling the knowledge gap for the Gonarezhou National Park provides a basis for standardised and homogeneous vegetation classification and mapping for the entire Great Limpopo Transfrontier Conservation Area.

Research of biological peculiarities and *ex situ* conservation of threatened georgian endemic species *Dianthus azkurensis Sosn*

Nina Melia, *Tinatin Barblishvili*
National Botanical Garden of Georgia, Department of Plant Conservation

We present the results of multilateral study of the endangered wild species of Georgia's flora *Dianthus azkurensis* Sosn. (EN) (Caryophyllaceae), included in the Red List of the Endemic Plants of the Caucasus and elaboration of effective measures for its protection. With this aim consecutive phases of ontogenesis- embryogenesis, seed productivity and viability, terms and rate of germination, age stages of seedlings development were studied in this species for the first time. *Dianthus azkurensis* Sosn. grows on rocks, in the middle mountain zone. The species is characterized by protandry. Study of embryonic structures revealed that at the initial stage generative sphere develops normally. The 80% of pollen grains is fertile. Pollen germination was optimal, attaining 15-20%, on artificial medium - 10% saccharose. Number of ovules in the ovary reaches 90, with 2 integuments, arranged in 4 rows on placenta. Embryo sac develops by Polygonum type and is situated on the chalasal end of ovule. Retardation occurs only in the process of fertilization and only small number of ovules finishes development. Number of fertilized ovules though is few, but all develop normally. In the adult seed dicotyledonous embryo occupies the whole seed perimeter. At an early stage endosperm is completely consumed by the embryo. On the next stage the embryo is surrounded by the perisperm. In order to determine seed viability, seed were tested on germination and sprouting capacity on different substrates under laboratory conditions. Spring sowing yields higher germination (91.6%) as compared to autumn sowing (60%), though in both cases germination starts on agar substrate in 3 days after sowing. Seeds were sown in pots to obtain *ex situ* collections of seedlings. While sowing in soil in spring germination starts in 4 days, while in autumn germination takes 2 weeks. On the stage of 5-6 storey of leaves seedlings are too week and auxiliary treatments are required to obtain robust planting material. Seeds of *Dianthus azkurensis*, banked in 2007 in the Caucasus Regional Seed Bank (CRSB) at -20°C were tested on viability. Seed storage behaviour is good and it retains high germination capacity – 70-75%. *Ex situ* conservation activities were carried out. Seed bank of this endangered species - *Dianthus azkurensis* - was created in the CRSB of the National Botanical Garden of Georgia and seed collections duplicated to the Millennium Seed Bank of the Royal Botanic Gardens, Kew, UK.

The caucasus regional seed bank development within the Millenium Seed Bank Partnership

Tsira Mikatadze-Pantsulaia, *Tinatin Barblishvili, Ana Gogoladze, Tolkha Shetekauri*
National Botanical Garden of Georgia, Department of Plant Conservation

Since 2005 staff of the Department of Plant Conservation of the National Botanical Garden of Georgia (NBGG), working in partnership with colleagues at Institute of Botany Georgia (Ilia State University) have been participating in the global Millennium Seed Bank Partnership, led by the Royal Botanic Gardens, Kew. Priority for the project was creation of the seed bank of endemic, rare, threatened, vulnerable and economically important plants. Seeds of target species are to be necessarily collected in the wild. For each species special data sheet is filled in, which along with geographic and botanical data contains comprehensive information about the sample, its habitat and the process of collecting. At least 500 seeds of each species are deposited at the CRSB and the corresponding labelled herbarium specimen kept at the Herbarium of Georgia (TBI). The duplicates of the seed collection and herbarium voucher are sent to the Millennium Seed Bank and Herbarium of the Royal Botanic Gardens, Kew (K). The Caucasus Regional Seed Banks is designed for the long-term storage of seeds. During the 2005-2016 period, within the scope of MSB-1 and MSB-2, seeds and herbarium samples of more than 1400 plant species and interspecific taxa, belonging to 106 families and 504 genera (more than 33% of Georgia's flora) -265 Endemics of Caucasus and 158 Endemics of Georgia, have been secured in the CRSB. Seed Bank Data are managed in BRAHMS, developed by the Department of Plant Sciences of Oxford University.

Digitisation and electronic access to19th century specimens from China housed in the National Herbarium of Victoria (MEL).

Josephine Milne, *Domenica Rita Macheda*
Royal Botanic Gardens Victoria

The collection in the National Herbarium of Victoria (NHV) at the Royal Botanic Gardens Victoria is estimated at approximately 1.5 million specimens. Approximately 400,000 of these specimens were collected overseas from various geographic areas including Africa, China, Europe and, South America and by many significant nineteenth century botanists and explorers including Odoardo Beccari, Robert Fortune, Joseph D. Hooker, Johann Georg Christian Lehmann, John Kirk (Livingstone Expedition), Franz Wilhelm Sieber, and Karl Zeyher. This significant foreign collection was acquired by Ferdinand von Mueller, appointed as the first government botanist in 1853, through his networking with the foremost herbaria and plant collectors worldwide. A substantial proportion of the foreign collection was also acquired by Mueller through the purchase of the Otto Wilhelm Sonder herbarium in 1883. The Australian collection at the NHV is digitized i.e. databased and accessible on Australia's Virtual Herbarium (AVH) http://avh.chah.org.au/, and type specimens are imaged and accessible on Global Plants on JSTOR https://plants.jstor.org/ . The NHV has now embarked on the Foreign Collection Project which focuses on databasing specimens from its foreign collection and also making the records accessible through AVH. In addition, known type specimens and any new types being discovered are being imaged and delivered to Global Plants on JSTOR. As the Foreign Collection Project progresses, the breadth of specimens collected from China is becoming apparent. The project is revealing specimens collected by a number of nineteenth century botanists and explorers, often described as 'plant-hunters' and material representing taxa from many vascular plant families. Collectors include: Henry Hance (explorer and plant collector) who collected in Guangdong Sheng, Augustine Henry (explorer and plant collector) whose specimens are mainly from Prov. Hupeh [=Hubei] Central China, Edouard Ernst Pere Maire (missionary and botanist) who collected in Yunnan Sheng and Alexander Gustav von Schrenk whose collections are all from Songarei [= Songaria, now Xinjiang Province]. The ongoing digitisation and electronic access to the foreign collection at the NHV will not only provide an invaluable resource for researchers globally, but access to this nineteenth century collection will fulfill, particularly for China, what has recently been described as 'virtual' repatriation of biodiversity records.

P0143

Cosmarium bahianum (Desmidiaceae, Streptophyta) a new desmid species from a phytotelm habitat in the Brazilian Restinga

Carlos Wallace Do Nascimento Moura[1], *Geraldo José Peixoto Ramos*[1], *Carlos Eduardo De Mattos Bicudo*[2]
1. Universidade Estadual de Feira de Santana
2. Instituto de Botanica de São Paulo

Cosmarium Corda ex Ralfs (Desmidiaceae, Streptophyta) includes the largest number of species among the desmids and so far encompasses more than 2,000 registered taxa, 1,100 of which are taxonomically accepted. The genus is characterized by solitary, biradiate cells with a more or less entire outline. Otherwise, *Cosmarium* is such a polymorphic genus that it should be considered to be highly artificial. Despite this, we presented a new desmid species, *Cosmarium bahianum* G.J.P. Ramos, C.E.M.Bicudo et C.W.N.Moura collected from a tank bromeliad (phytotelmata) in an urban area of "Restinga" in Salvador, Bahia State, Northeast Brazil. This species was collected during the rainy season (May 2015) from a *Hohenbergia littoralis* L.B.Smith tank, an endemic bromeliad from the Brazilian "restinga", by using a 50 mL syringe coupled with a polyethylene hose. Cell morphological features and dimensions as well as the generative reproductive stage were observed with a light and scanning electron microscope. *Cosmarium bahianum* is characterized by cells usually slightly longer than broad (20–29.3 x 16.9–23.3 µm), with a moderately deep median constriction. Sinus widely open, about rectangular at the apex. Semicells in frontal view elliptic-rhomboid, in apical view elliptic or subtriangular, in lateral view subcircular. Cell wall coarsely punctate. Chloroplast with 1 pyrenoid. Cells provided with a thick, sharply bounded mucilaginous envelope. Zygospore smooth-walled, globose to elliptical, measuring 16.1–20.7 µm diameter. Regarding morphology, *C. bahianum* is similar to *C. inconspicuum* West & G.S.West, however, this species is distinct from the first one by having smooth cell wall, zygospore irregularly ovoid and smaller cells dimensions (length 13,5–14,5 µm, breadth 9,5–11 µm, isthmus 4,8–5,7 µm, diameter zygospore 14,5–17 µm). The species was extremely abundant in the *H. littoralis* tank, and growth up the abiotic water conditions such as acidic pH (4.8), high temperature (29°C) and low electric conductivity (0.02 mS cm^{-1}), favorable for the development of desmids. *Hohenbergia littoralis* is endemic to Brazil, with the distribution restricted to the north coast of the Bahia State, in the “restingas” of Abaeté and Baixios. This is considered an endangered species due to the eradication of the natural vegetation for the planting of *Cocos nucifera* Linnaeus (coconut trees) near the beach line, together with the urban expansion and development of tourism in the region. If their natural habitat is threatened, *C. bahianum* will also be endangered. Therefore, preservation of *H. littoralis* and other bromeliads from “Restinga” is absolutely essential as potential habitat for certain groups of algae, especially the desmids.

P0144

Field studies on diversity of wetland flora of nanded district in eastern part of Marathwada region in Maharashtra, India

Ramjan Mulani

Department of Botany, DST-FIST, UGC-SAP sponsored School of Life Sciences, Swami Ramanand Teerth Marathwada University, Nanded-431606 (MS), India.

Wetlands are one of the important natural resources which either temporarily or permanently covered by water. This means that a wetland is neither truly aquatic nor terrestrial; it is possible that wetlands can be both at the same time depending on seasonal variability. Thus, wetlands exhibit enormous diversity according to their genesis, geographical location, water regime and chemistry, dominant plants and soil or sediment characteristics. Because of their transitional nature, the boundaries of wetlands are often difficult to define. Wetlands do, however, share a few attributes common to all forms. Wetlands are manly classified as: marine, estuarine, lacustarine, riverine and palustarine. Wetlands support a large variety of plant and animal species adapted to fluctuating water levels, making the wetlands of critical ecological significance. Directly and indirectly wetlands support millions of people in providing services such as food, fiber and raw materials, storm and flood control, clean water supply, natural beauty and educational and recreational benefits (National Wetland Atlas: Maharashtra (2010). According to MoEF report of National Wetland Atlas: Maharashtra (2010), Nanded has Total 1,072 wetlands are mapped including 440 small wetlands (< 2.25 ha) with 30,508 ha area. Rivers/streams occupy 57.21% area. There are 395 Tank/pond mapped with 25.22% area. There are 12 Reservoir/barrage mapped with 4,913 ha area (16.10%). Aquatic vegetation is slightly more during pre monsoon (2,673 ha) than during post monsoon (1,559 ha). Open water spread of the wetlands is significantly higher in post monsoon (26,935 ha) than during pre monsoon (8,311 ha), indicating the rainfall dependence of the wetlands in the state, particularly the dryness of rivers is very prominent. Turbidity of open water is mainly low during post monsoon, while ranged from low to moderate during pre monsoon. Present study deals with the field observations on wetland flora present in various natural and manmade wetlands occur in Nanded district. It is the eastern part of Marathwada where the rainfall is less and it has a forest area towards the border of Andhrapradesh on east and Vidarbha on north. In present work regularly the wetlands were visited and various species were recorded with their onset of various stages of life cycle. Special observations were made on the manmade wetlands with their change of occurrence of species of genera *Aponogeton, Bacopa, Cryptocorine*, *Ceratophyllum, Hydrilla*, *Hygrophila, Ipomea, Lemna, Lindenbergia, Lymnophila, Marsilea, Najas, Nelumbium, Nymphea, Nymphoides, Potamogeton, Spirodela, Typha*, *Utricularia, Vallisneria, Woffia*, *Zannichelia, etc.* The Government of Maharashtra played an important role in deciding the widening and deepening of both natural and manmade wetlands in 2014. According to this decision, the government has freely allowed removing the silted soil from the wetlands free of cost. This was even continued in 2015-16 also. This ultimately resulted in increase in ground water level as water level in wells. In addition wetland plant flora was also enhanced due to availability of new environment.

Evaluation of timber and fuel wood consumption and its impact on vegetation cover in northern parts of Pakistan.

Murad Ali Murad

University of Swat

The present study aims to investigate the deforestation and effects of floods on various plants in northern parts of Pakistan. Data was collected from the local people. The data shows that due to drastic and rapid cutting of trees is the major cause of deforestation. The data were recorded in the form of questioner after that, the recorded data were analyzed by SPSS (statistical programmed for social sciences) software. The trees are ruthlessly cut for burning, timber and furniture purposes. The highest ratio of cutting trees is for burning purposes. *Cedrus deodara*, *Querqus dialata*, *Betulla utillus*, *Juglans regia*, *Picea smithiana*, *Pinus willichaina*. Land sliding and floods are the second highest reason of deforestation. The deforestation also affects the growth of other plant species as its ground flora. The shade and moisture loving plants (sciophytes) disappear due to deforestation while the halophytes dominate the cleared area. Due to anthropogenic activity and rapid cutting of valuable species of the area affect the climatic condition of the site.

Herbaceous plant collections in botanical garden, Mongolia

Enkhtuya Luvsanbaldan, *Ochgerel Nanjidsuren*

Institute of Botany and Experimental Biology, Mongolian Academy of Sciences

Currently 70% of the territory across Mongolia is the subject to desertification and land degradation. Total 11% of species of flora in Mongolia is considered to be extinct and endemic while 26% is on the verge of extinction, yet 37% is considered to be on a high risk of extinction [1]. The Botanical Garden of any country aims to introduce or to transfer wild plants into ex-situ cultivation to conserve the species, to protect their gene pool, and to collect the representatives of various vegetation areas. Flora in Mongolia has a species 149 of endemic plants, 140 of interglacial vegetation, and about 100 of ice age period [2]. Whereas a Nature Reservation and Protection Law [3] officially notes the species 133 of endemic plants and 354 of rare plants. In order to introduce rare species such as perennial herbaceous plants, to evaluate their biological, ecological and adaptive capacity, and to learn the season rhythm from some medicinal and ornamental plants, we designed following tasks: To create an original seed sample collection from plants occurring in different geographic regions and ecosystems across Mongolia. To enrich the seed amounts and numbers from endangered plants of as many as 135 species listed in a Red Book of Mongolia by active plantation. The collections created by sampling of seeds, bulbs, rhizomes, and seedlings. The research and the following collections are started by formerly well used methods [3] Rare, endemic and ornamental herbaceous plants were cultivated in a Botanical Garden from the Institute of Botany and Experimental Biology, distributed in 16 flora-geographical regions of Mongolia. We selected 4,000 samples from 9 flora-geographical regions and have conducted studies on cultivation. The 60% were grown in the areas of original sites were plants were spotted and collected. We conclude that the selected plants from different flora-geographic regions can experience some positive results on introduction process. For 2016, 33048 individuals of 305 species, 141 genera, 59 families (tree, bush, herbaceous *etc.*) were cultivated and reserved in the Botanical Garden, including 70 species of rare and endangered plants and more than 10 sorts imported. We are successfully conducting the trials on introduction and acclimatization of plants from 22 families, 32 genera and 54 species of herbaceous included in the Red Book of Mongolia. As a result of research and introductory works, the endemic and rare species of *Allium altaicum* Pall., A. *sondensatum* Turcz., *A. obliquum* L., *Rhodiola rosea* L., *Adonis mongolica* Simon., *A. sibirica* Patrin, *Paeonia anomala* L., *P. lactiflora* Pall., *Convallaria keiskei* Miq., *Lilium buschianum* lodd., *L.dahuricum* Ker.-Gawl., *Tulipa uniflora* (L.) Besser ex Baker, *Lancea tibetica* Hook.f. et Thoms, *Iris oxypetala* Bunge, *Cypripedium macranthum* Sw., *Incarvillea potaninii* Batalin., *Dictamnus dasycarpus* Turcz. et al were introduced, propagated and taken into protection and moreover favorable conditions and possibilities for creating an experimental garden of rare species plant collection was identified and seed fund of these species was increased. Our conclusion is that the plants selected from different flora-geographical regions are at certain level influenced.

Altitudinal and temporal varition in mountain gorilla food plants biomass within Volcanoes National Park, Rwanda

Uwitonze Narcisse[1,2], *Bizuru Elias*[2], *Tuyisingize Deogratias*[1]
1. Dian Fossey Gorilla Fund International/Karisoke
2. University of Rwanda

The critically endangered mountain gorilla (*Gorilla beringei beringei*) is the only wild ape subspecies that is growing in number. Extreme long-term conservation efforts have nearly doubled the Virunga population since the 1980s, whereas their habitat remains a small isolated forest island. Improved forest protection is also likely to have resulted in growing buffalo and antelope populations, which share food plants with the gorillas. Higher re-visitation of gorilla groups and other herbivores at feeding sites may lead to a depletion of key gorilla food plants and cause a collapse of the gorilla population. The objective of this study, carried out in 2016, was to assess the altitudinal and temporal variation in biomass of six gorilla food plant species (add list of species here) in Volcanoes National Park. Systematic plant sampling techniques and established phytometric regression equations were used to calculate the biomass in 66 plots that were assessed previously in 1989 and 2010. Small herbs were collected, sun-dried and weighed, while stem length and leaf length were measured from tall herbs to assess biomass. We found that the biomass of five out of the six studied plant species was highest in mid-altitudes (2,900-3,250 m), possibly due to higher carbon sink generated by plant decomposition mainly in this zone. There was no change in *Galium*along the altitudinal range in contrast to the other plant species, which may reflect its current shift from lower to higher altitudes. Tall herbs, with the exception of *Peucedanum linderii*, clearlydecreased over time. Whether this decline in biomass is linked to overharvestingof feeding sites through frequent re-visitation by the growing gorilla population and other large herbivores (buffalo, antelope) who share these food plants needs to be investigated in future studies.

Testing the Wallace's riverine hypothesis for an autochorous plant species in the Amazon Basin

Alison G. Nazareno[1], *Christopher W. Dick*[2], *Lúcia G. Lohmann*[1]
1. Universidade de São Paulo
2. University of Michigan

The Amazon River and its tributaries have been the focus of several biogeographical studies due to their potential role in population isolation. As biogeographical barriers to gene dispersal and flow, the river and its tributaries may have prompted population differentiation and species diversification through vicariant processes, for a plethora of taxa in the Amazon River Basin. In fact, the main prediction of Wallace's riverine barrier hypothesis is that physical causes of population isolation are responsible for major biodiversity patterns in the Amazon. To test this hypothesis, we sampled a total of twenty-six *Amphirrhox longifolia* (Violaceae) populations in both banks of Rivers Branco and Negro, important waterways in the Brazilian Amazon Basin. We used a high-throughput methodology (i.e., double digest RADseq) to identify SNP markers from anonymous portions of the nuclear genome of 156 individuals. Based on 8,010 unliked SNPs, our data supports the hypothesis that the Negro River – a wide river in the Amazon Basin –

acted as a physical barrier, although a weak one, for *A. longifolia* gene flow. On the other hand, a lack of any significant genetic structure in populations of this plant species in the Branco River – a tributary of the Negro River – indicates that the Branco River did not serve as a barrier to gene flow, as shown by the high rates of migration between opposite river banks. While this study provides the first characterization of genetic differentiation and population structure for *A. longifolia* along two rivers in the Amazon Basin, future research testing Wallace's riverine barrier hypothesis for plant species with distinct biological histories could provide valuable clues for an improved understanding of the origin of the vast biological diversity currently found in the Amazon Basin.

The Amazonian Herbarium of Ecuador, ECUAMZ

Mercedes Asanza, *David Neill, Julio César Vargas Burgos, Diego Gutierrez Pozo*
Universidad Estatal Amazónica

Ecuador, a country in northwestern South America centered on the equator, is remarkable for its high diversity of plants despite its relatively small size. With a land area of 283,560 km^2 Ecuador covers just 0.2% of the land area of the globe, yet its vascular flora of 18,500 plant species includes about 7% of the world's flora. The Amazon region of Ecuador includes its six eastern provinces which contain the eastern slopes of the Andes mountains as well as the lowlands of the western Amazon basin. In this region, about one-third of the Ecuador' s land area, occur an estimated 10,000 native vascular plant species. The Amazonian Herbarium of Ecuador, with the acronym ECUAMZ, was established in 2012 and is the only herbarium in the Amazon region of the country. The herbarium is part of the research center of the Amazon State University (Universidad Estatal Amazónica); the main campus of the university is in Puyo, the capital of Pastaza province, but the research center, known by the acronym CIPCA, is located 44 km north of the main campus at the junction of the Anzu and Piatua rivers in Napo province. The research center comprises 2858 hectares including 2000 ha of primary forest at the eastern base of the Andes, 550-1200 m in elevation. The Herbarium was created with the intention of strengthening floristic studies and in general the development of the scientific and educational activities of the university and collaborating institutions, and to promote and carry out research and conservation of biological diversity in the Amazon region of Ecuador. The herbarium is currently conducting floristic inventories in several regions of Amazonian Ecuador including the buffer zone of Llanganates National Park on the eastern slopes of the Andes and the Cordillera del Cóndor in southeastern Ecuador. Adjacent to the ECUAMZ herbarium at the CIPCA research center is the Piatua Botanical Garden, covering 7 hectares, with living collections of native Amazonian plants including *ex situ* conservation of endemic and threatened species, as well as selected introduced plants with potential for cultivation in the region. The herbarium collection of ECUAMZ is curated according to international standards and currently contains 12,350 vascular plant specimens and 2850 specimens of non-vascular plants. The herbarium includes the type specimens of a number of recently published species that were described by the ECUAMZ herbarium staff and associates, including *Dacryodes uruts-kunchae* Daly, M.C. Martínez & D.A. Neill (Burseraceae) *Licania condoriensis* Prance (Chrysobalanaceae), *Clethra concordia* D.A. Neill, H. Beltrán & Quizhpe (Clethraceae), *Shuaria ecuadorica* D.A. Nell & J.L. Clark (Gesneriaceae), *Browneopsis puyensis* D.A. Neill & Asanza and *Inga yasuniana* T.D. Pennington (Fabaceae), *Pleurothyrium castaneum* van der Werff (Lauraceae), *Magnolia equatorialis* A. Vázquez, *Magnolia llanganatensis* A. Vázquez & D.A. Neill, and *Magnolia vargasiana* A. Vázquez & D.A. Neill (Magnoliaceae), *Calathea neillii* H. Kennedy (Marantaceae), *Palicourea neillii* C.M. Taylor (Rubiaceae). The symbol of the ECUAMZ Herbarium is the flower of *Meriania pastazana* Wurdack (Melastomataceae).

Primary result of empowering local communities to engage in conservation and management of Magnolia and conifer trees in Vietnam

Hieu Nguyen[1], ***Hiep Nguyen***[1], *Ngan Tu*[2], *Khang Nguyen*[3]
1. Center for Plant Conservation Vietnam
2. Vietnam National Museum of Nature
3. Institute of Ecology and Biological Resources

Since 2007, with support from Global Trees Campaign (GTC), Flagship Species Fund (FSF), Critical Ecosystem Partnership Fund (CEPF), Center for Plant Conservation Vietnam (CPCVN) and Fauna and Flora International (FFI- Vietnam program) have implemented botanical survey, raised awareness, *in situ* and empowered local communities to engage in conservation and management of *Magnoli*a and conifer threatened species in Vietnam. The aim of our conservation is to focus on taxonomy inventory, assess IUCN, identify and tag mother trees, collect seeds, trial train germination to local people, and bring plants back to their natural habitat. In the last ten years, we have implemented in ten locations in four provinces. We have involved local people in all of the activities as Community Tree-Conservation Teams. Throughout the country, we have established 3 satellite nurseries in North Vietnam (Hanoi, Ha Giang Province), 1 in Highland Plateau (Center Vietnam) and 1 in South Vietnam (Ho Chi Minh City). Up to now, they have produced over 12,000 seedlings of 8 *Magnolia* species, 3,745 seedlings and cutting of 4 conifer species. One of our main focus is *Magnolia* conservation. Fifty seven native magnolia species are recognized as indigenous to Vietnam. Throughout the project, 21 species of *Magnoli*a recorded in Ha Giang Province (Priority Corridor 1 - Sino-Vietnamese Limestone of CEPF) make up 35% in total and 13 species recorded in Lam Dong Province (Greater Mekong Area) make up 23% in total. Over the last five years, thirteen trees have been monitored by the Community Tree-Conservation Team (CTCT). Among those trees, there are two Critical Endangered (*Magnolia grandis, Magnolia sinica*) and three Endangered (*Magnolia coriacea, Magnolia hookeri* var. *longirostrata,* and *Magnolia citrata*). At the time of reporting, 1,005 *Magnolia grandis* seedlings, 134 *Magnolia foveolata*, 45 *Magnolia conifera*, 104 *Magnolia hookeri* var. *longirostrata*, 200 *Magnolia citrata* survive in the commune forest and natural habitat. In terms of the conifer conservation, 34 native conifer species are recognized as indigenous to Vietnam.

Throughout the project, four species identified as flagship species for conservation such as *Xanthocyparis vietnamensis*, *Cupressus tonkinensis*, *Calocedrus rupestris*, *Taiwania cryptomerioides*. At the time of reporting, 2,615 survive in the commune forest and natural habitat.

Impact of polycyclic aromatic hydrocarbons (PAHs) on physiological and biochemical responses of Coralline algae from Shenzhen, China

Lei Nie[1], *Evelin Peli*[2]
1. Shenzhen Institute of Information Technology
2. Szent István University

Coralline algae (Corallinales and Sporolithales, Corallinophycidae, Rhodophyta) are globally distributed benthic primary producers that secrete calcium carbonate skeletons. In the context of global change, they have received much recent attention due to the potential vulnerability of their calcite skeletons and their many important ecological roles in marine ecosystem establishment and global carbon cycle, especially geniculate corallines. Their important functional roles in ecological systems across latitudes and habitat types, including reef frameworks, carbonate production, larval settlement, fish nurseries, renewable natural resources and accurate paleoenvironmental recorders, thus providing a valuable mechanism for contextualizing global oceanic changes. However, little is known on the effects of human-induced persistent organic pollutants (POPs) on marine calcifying organisms to date. Polycyclic aromatic hydrocarbons (PAHs) are recognized globally as persistent, bio-accumulative and toxic. PAHs contamination can represent a serious threat to humans and ecosystems. Algal polysaccharides, especially extracellular polysaccharides (EPS), have been demonstrated to play an important role as free-radical scavengers in vitro and antioxidants for the prevention of oxidative damage in living organisms. For the purpose of understanding the coralline algae responding to persistent organic pollutants, we carried on an experimental study by exposing *Corallina officinalis* to different levels of typical organic pollutants, anthracene, in order to see the physiological and biochemical responses. The red calcareous alga was collected from the intertidal zone of Dapeng bay, Shenzhen, China (at 114°36'N and 22°25'E). The main results are as follows: Under the conditions of increased anthracene concentration, the relative growth rate (RGR) decreased significantly comparing with that under the control. PAHs treatment also reduced the contents of photosynthetic pigments (Chla, Carotenoid and PE). With the concentration of anthracene in seawater increasing, the permeability of cell membrane and the content of MDA were increased gradually, showed that the capacity of anti-oxidant was also inhibited. The content of extracellular polysaccharides increased at first and then decreased as concentration of anthracene increases, while the content of intracellular polysaccharides continuously going low. The changes of radical scavenging capacity, including superoxide radicals (O_2^-), hydroxyl radicals (-OH) and DPPH radical in extracellular polysaccharides showed a similar first increased-then decreased trend. This study suggests that PAHs pollution has significant negative impact on the physiological activity of Coralline algae. Looking ahead to the further research on coralline algae, particularly in the context of global change and increase of anthropogenic polluted activities, the areas of need including: Molecular studies of algal calcification; Role of multiple stressors on physiology, with an emphasis on integrating studies of pollutants; Mechanics and long-term repercussions of coralline algal bleaching; Importance of coralline algae to reef stabilization under future anthropogenic polluted scenarios.

Biodiversity conservation status and floristic revised lists of lycophytes and ferns of Myanmar

Thet Yu Nwe
Myanmar Floriculturist Association

Myanmar is a country in the north-western part of mainland South-East Asia. Being topographically highly diverse, Myanmar has species-rich different forest types. Although there is a number of researchers who have done taxonomic and floristic work in other plant groups, surveys on lycophytes and ferns of Myanmar are rather limited and incomplete. Ferns are rather important in Myanmar daily life as native people consume ferns as food and medicine as well as for ornamental and other purposes. The first floristic account of ferns of Myanmar was published by Dickason in 1937. He listed 379 species belonging to 105 genera. Since then several individual reports on ferns from different parts of Myanmar have been made. However, there is no complete assessment of all ferns from a floristic point of view. Therefore, a comprehensive list of native ferns is the basis for a future complete fern flora of Myanmar. In the present work, 622 taxa (51 specise in lycophytes and 572 species in ferns) are reported for new revised lists of Myanmar's lycophytes and ferns. According to the IUCN category, altogether 94 species are considered to be threatened or endangered in Myanmar.

Biodiversity of host plants of rust fungi (Pucciniales, Basidiomycota) of the island of Hispaniola

Omar Paino Perdomo[1], *Luis Rodriguez De Francisco*[1], ***Ivelisse Montero***[2]
1. Instituto Tecnologico de Santo Domingo
2. Dominican Society of Mycology

The Caribbean region, which is one of the 25 biodiversity hotspots in the world, possesses a unique phytogeographic region within the Neotropics, containing vascular flora plants containing of 58% endemism. Hispaniola is the second largest island in the Caribbean region comprised of several terrains which differ in their origin and geologic history. The landscape has mountainous ranges that are oriented from east to west, and intervening valleys and plains, leading to the highest diversity of climates and ecosystems of the Caribbean. The island has the highest peak of all the Antilles (Duarte Peak, reaching 3.175 m.s.n.m) and its lowest point, Lake Enriquillo, approximately 40 meters below sea level. The combination of these factors have favored a large diversity of plants. The vascular flora plants of Hispaniola have already been well studied and possess about 6,000 species, of which 2,000 are endemic (33% endemism). The flora has five phytogeographic elements: pantropical, Caribbean, endemic, continental and introduced. Currently, a total of 33 families of vascular plants are reported as rust hosts, with 134 genera and 230 species. The plant families with greater diversity of rust are: Asteraceae, Cyperaceae, Euphorbiaceae, Fabaceae, Lamiaceae, Malvaceae, Poaceae, Rubiaceae and Verbenaceae. This represents 3.83% of vascular plants infected by rust fungi. The Poaceae and Fabaceae families are the ones that possess more species of rust host plants. The microflora of the tropical region is still poorly known. Although the Pucciniales are the largest order of plant parasitic fungi among Basidiomycota, including about 9000 species, numerous unknown species supposedly exist, especially in the tropics. Rust specimens have been collected in protected, as well as wild areas of the island. The species of rust fungi collected during fieldwork in Hispaniola are apparently mostly autoecious, i. e. live on a single host-plant species, possible because many tropical plants exhibit green leaves all year. However, this apparent tendency may also be due to a lack of knowledge of the life history of tropical rust fungi. More studies on diversity and ecology, as well as extensive fieldwork regarding taxonomic, morphological, and phylogenetic research are required, necessary in all the chains of Caribbean island, in order to elucidate and understand host plants of rust fungi.

Onion essential oil induced markedly relaxation on the isolated rat *Corpus cavernosum*

Alev Önder
Faculty of Pharmacy, Ankara University

Introduction: Erectile dysfunction (ED) is a common problem which has become increasingly prevalent in societies. Approximately, 5-20% of the general population in men suffered from moderate or severe ED. It has been considered that many medicinal plants and secondary metabolites alleviate ED. The medieval Persian practitioners recommend some foods to help cure ED like *Allium cepa*. Onion (*Allium cepa* L.) belongs to genus *Allium* from the Amaryllidaceae family and is economically important as a vegetable. It includes sulfur containing active principles decomposed by allinase which are volatile and present in the onion essential oil (OEO) involving various important biological activities. It is also popular in cuisines of the world and has potential medicinal properties such as preventing cancer, reducing symptoms of diabetes, reducing coronary heart diseases, antibacterial activity and anti-inflammatory activity. The present study evaluated the relaxant effect of OEO on rat C*orpus cavernosum* (CC). Methods: Twenty-six adult male Sprague-Dawley rats were used in the experiments. Isolated rat CC strips were placed in organ baths containing Krebs solution, and functional experiments were performed. After preconstruction with phenylephrine (PE, 10^{-5} M), the relaxant response to OEO (25 - 400µL) was investigated in rat CC. The relaxant responses to OEO were repeated in the presence of nitric oxide synthase (NOS) inhibitor L-nitro-arginine methyl ester (L-NAME, 100µM) or soluble guanylate cyclase (sGC), [1H-1,2, 4] oxadiazolo [4,3-a]quinoxalin-1-one (ODQ, 30µM) inhibitor. Results: OEO caused relaxation of isolated CC strips in a concentration-dependent manner (maximum response: 98.0 ± 3.5%). The relaxant responses to OEO were not altered in the presence of L-NAME and ODQ in rat CC. Conclusion: OEO induced relaxation independent from NO/cGMP system in rat CC. We suggest that OEO may have a beneficial effect in ED patients who are non-responders to phosphodiesterase-5 inhibitors. In the future, we would like to investigate major components of onion essential oil and other extracts of the onion because of the health benefits.

T1
P0155
Effects of onion on functional responses of rat *Corpus Cavernosum*

Alev Önder
Faculty of Pharmacy, Ankara University

Erectile dysfunction (ED) is a common healthy problem, affecting more than half of men ages 40 to 70. It has been considered that many medicinal plants and secondary metabolites are used in the management of ED. Onion (*Allium cepa* L.) belongs to genus *Allium* from the Amaryllidaceae family and is economically important as a vegetable. The present study investigated the possible relaxant effect of OEO on rat corpus cavernosum (CC). Therefore, to investigate the relaxant effect, a total of twenty-six male Sprague-Dawley rats were used in this study. Isolated rat CC strips were placed in organ baths containing Krebs solution, and functional experiments were performed. After preconstruction with phenylephrine (PE, 10^{-5} M), the relaxant response to OEO (25 - 400µL) was investigated in rat CC. The relaxation responses to OEO were examined incubation with of nitric oxide synthase (NOS) inhibitor L-nitro-arginine methyl ester (L-NAME, 100µM) or soluble guanylate cyclase [1H-1,2, 4]oxadiazolo[4,3-a]quinoxalin-1-one (ODQ, 30µM) inhibitor. OEO showed relaxant effect on rat CC strips in a dose dependent manner (maximum response: 98.0 ± 3.5%). OEO caused relaxation of isolated CC strips independently of the NO/cGMP pathway. Further investigations are warranted to fully elucidate the mechanistic effects of OEO on ED.

The genus *Picea* A. Dietr. in Kyrgyzstan

Larisa V. Orlova[1], *Georgy Lazkov*[2]
1. Komarov Botanical Institute RAS
2. Institute for Biology and Soil NAS

The question of the taxonomic status and the origin of *Picea schrenkiana* Fisch. et C.A.Mey. and close related taxa (*P. tianschanica* Rupr., *P. robertii* Vipper and *P. prostrata* Isakov) is one of disputable in taxonomy of *Picea* A. Dietr. Most authors considers *P. schrenkiana* as independent species, close to *P. likiangensis* (Ran *et al.,* 2006), *P. wilsonii* (Lockwood *et al.,* 2013) or *P. smithiana* (Sun *et al.,* 2014; Ran *et al.,* 2015; Li *et al.,* 2015). Our field studies of the *P. schrenkiana* s.l. in different regions of Kyrgyzstan (Terskei range (Barskaun gorge), Kungei range, Susamyr range (Chichkan gorge), Chatkal range (Sary-Chelek Reserve) and comparative morphological studies of herbarium materials in LE, MW, NS, SVER, PE, FRU, K, E, BP, KRAM, *etc*., allowed to reveal some new diagnostic characters for the determination of *P. schrenkiana* and closely related taxa, and to clarify its geographic distribution. According our investigations, the closest taxa to *P. schrenkiana* are P. *asperata*, *P. crassifolia* and *P. meyeri*. *Picea schrenkiana* differented from *P. obovata* by larger (6-12 cm long and 2,5-3,5 cm wide) cones and seed scales (12-20 mm long, 13-18 mm wide), with a little black rim on the upper margin and slightly wrinkled longitudinally, and also longer (20-35 mm long) needles, bluish-green, with 5-8 stomatal lines abaxially and 3-6 – adaxially, with a little white wax coating only adaxially, and very slighly pubescent annual shoots. *Picea tianschanica* differs by seed scales, more prominent and thickened, appreciably longitudinally wrinkled, dark brown, often with a distinct reddish or purple-brown spots, in the inner part - orange; its terminal buds conical or broadly conical to almost globular, brown; needles on the shoots very crowded (in *P. schrenkiana* seed scales unprominent and more or less stright, almost smooth, brown, monochrome, in the inner part - brown; terminal buds ovoid, light brown; needles uncrowded). This taxon deserves by our view the status of separate species. In the eastern and northern Kyrgyzstan (Terskei and Kungei ranges) occurs *P. schrenkiana* with some characters of *P. tianschanica* (violet color of some seed scales). In Barskaun gorge we found the population of blue spruce intermediate in the characters between *P. schrenkiana* and *P. crassifolia*. The main differences concern the shape of the upper margin of the seed scales, its color, as well as some characters of vegetative organs. We can assume that this blue spruce is possibly result ancient hybridization of *P. crassifolia* with *P. schrenkiana* (which also occurs here, but in smaller amount). Possibility of occurrence of such hybrids in the Eastern Tien Shan pointed out by E.G. Bobrov (1978). Spruce, native to western Kyrgyzstan (Chichkan gorge, Sary-Chelek), is similar to *P. smithiana* by very large cones, wider seed scale, as well as morphology vegetative buds, profills and pulvini of annual shoots, but it possess much more variable characters of needles, as well as noticeably pubescent annual shoots, buds and pulvini, so we assume that they are ancient hybrids of *P. schrenkiana* x *P. smithiana,* and correspond to *P. robertii* Vipper. The geographical distribution of *P. schrenkiana* and close related taxa needs to be further investigation in nature.

Plants wealth: Power of planet (with specific reference to plant biodiversity, utilization, conservation and biodiversity–climate link)

Vashist N Pandey

DDU Gorakhpur University, Gorakhpur

Plant wealth is super natural power for the biological system on this planet i.e. they govern all biofunctions, distribution and climatic link of different habitat of this world. Biofunctional plants (BPs) are live telecast of our mother planet growing naturally and cultivated in different geographical regions of the world since ancient times. Plants are major component of our biological and Ecological system which deals direct relationship with Biodiversity of plants and Biological system. Plants have specific biofunctional role and growing in different Biospecific Regions (BRs) of the world, commonly known as Biospecific Region Plants (BRPs). In real sense Plants are the super natural wealth and power of our mother earth Planet. Food, Medicine, Health, conservation of Biodiversity, and Biodiversity –Climate link can be achieved by our plant wealth resources. Food security are major concern of our society which fulfilled by some our selected and well-known species of cereals, millets, pulses, vegetables and fruits. There are more 200 plants have been known to use by civilized society throughout world. Out of them approximately 15 plants have been used on large scale. Medicinal plants have been playing pivotal role in providing medical aid and promote positive health in mankind. In recent years there has been a tremendous expansion in the number of the institutions with provision for research and development of various branches of medical systems. The drug plants are collected and prepared in crude indigenous way. The medicinal value of drug plants is due to the presence of some chemical substances in the plant tissues which produce a definite physiological action on the human body. There are about more than 9000 thousand plants are known as medicinal plants but only a few are utilized on large scale by civil society. Health is a comprehensive term used for physical, biological and mental fitness on whole of humans and environmental system, directly or indirectly govern by plants. Considering all benefits derived by plants for human and ecological security, there is an urgent need of Conservation plants in natural state which is done either by *ex-situ* or *in-situ* methods. Fomeag (Fo=Food + Me=Medicine+ Ag=Agricultural/Arboretum/Aquatic Garden) Cafeteria would be a new mile-stone and vision to the nature's health, biodiversity-climate links, utilization and conservation of biodiversity especially for food, medicine and health plants which provides a new impetus in revolutionizing the sustainable and economically feasible development of the country and the whole world.

Diversity and distribution of ground herbs as indicator of fragmentation effect in tropical forest of Xishuangbanna, Southwest China

Bonifacio Pasion

Community Ecology and Conservation Group, Xishuangbanna Tropical Botanical Garden, Chinese Academy of Sciences, Mengla, China

The tropical forest of Xishuangbanna is one the most biodiverse region in China. However, this forest is being heavily fragmented due to rapid expansion of monoculture rubber plantations. In this study, ground herbs were sampled over the span of three years, which in contrast to trees are short-lived and may show an earlier compositional and diversity responses to the recent fragmentation (~30 years) in Xishuangbanna, Southwest China. Before analysis, herbs were classified into different herb groups (all herbs, monocot, dicot, and ferns), then composition, diversity (Shannon *H*), and species richness were used as response variable in determining fragmentation effect (fragment size, forest cover within 100,500, 1,000 meters around the plot, and plot distance to the forest edge). There were 232 identified herb species consisting of 82 dicots, 76 monocots, and 74 ferns. Non-metric multidimensional scale (NMDS) plot showed strong herb compositional differences between four community types (rainforest, oak forest, limestone forest, mixed forest over limestone). Diversity and species richness were higher in rainforest and lowest in the limestone forest. Fragment size is a poor predictor of herb communities but forest cover within 100,500, 1,000 meters around the plot explains herbs communities better at landscape level while plot distance to forest edge can be a better predictor at community scale. Monocots are most sensitive to fragmentation. Dicots are less sensitive to fragmentation at landscape scale, while ferns are less sensitive at community scale. Lastly, different communities has different responses to fragmentation effect especially for limestone and non-limestone communities, with effect differed among herb groups. This study showed that changes within forest fragments are already substantial after 30 years, calling concerns to protect the larger remaining forest fragments in Xishuangbanna, and initiate management aimed at buffering and, where possible, reconnecting them.

P0159

Solution for dozens of unresolved names regarding the genus *Photinia* (Rosaceae)

****Mitra Lal Pathak**, Yundong Gao, Xin Fen Gao*

Chengdu Institute of Biology, Chengdu, Post code 610041, Sichuan, China

Nomenclature can be complicated since the authors might have different opinion on species delimitation, as well as the limitation of communications in the past, which caused a lot of redundantnames applied in plant sciences. Accepted name, autonym, synonym, homonym, basionym, unresolved name, conserved name, rejected name, legitimate name, illegitimate name *etc.* are commonly used in taxonomy. Among them, unresolved names are those dubious names which are neither accepted nor synonym. Currently, the one of the widely used online site for nomenclature The Plant List (www.theplantlist.org) includes 1.25 million scientific plant names. Out of which, 33% are accepted names, 44.2% are synonym and about 23% names are "unresolved" since the contributing data sets do not contain sufficient evidence to decide whether they should be accepted names or synonyms. To solve about the seven dozen of unresolved names regarding the genus *Photinia*, the protologue and the type images from all around the world's herbarium were studied. Some herbarium specimens and the live images were also studied. Out of about seven dozens names, 16 names were found used as homonyms. Thirteen names were belongs to other genera. Some of the names were published locally and the description was not in Latin or English, thus made them illegal. Some names (e.g., *Photinia dulongensis* H. Li and *Photinia semiserrata* H.Li) were nomen nudum. The nomenclature and identification confusion was with other genera of family Rosaceae viz. *Eriobotrya, Stranvaesia, Aronia, Heteromeles, Sorbus, Cotoneaster, Malus, Pyrus, Rhaphiodes etc.*The name mentioned in a sheet *Photinia urdanetensis* Elmer was now identified as *Syzygium urdanetensis* of family Myrtaceae. Preliminarily, about fifteen names were now recommended to use as synonyms of the other *Photinia*species in present. Few are under describing as new names (The research is going on). After seriously examination on the protolugue and the type specimens, one of the interesting fact was that the twenty different taxon names (*Photinia blumei* Decne., *Ph. dasythyrsa* Miq., *Ph. flavidiflora* W.W. Sm., *Ph. Notoniana* Wall., *Ph. notoniana* W. & A., *Ph. notoniana* W. & A. var. *angustata* Bl. ex Koch in Miq., *Ph. notoniana* W. & A. var. *ceylanica* Hook. *f.*, *Ph. notoniana* W. & A. var. *macrophylla* Hook. *f.*, *Ph. notoniana* W. & A. forma *grandiflora* K. & V., *Ph. integrifolia* var. *notoniana* (W. & A.) J.E.Vidal, *Ph. integrifolia* Lindl. var. *subdenticulata* Miq., *Ph. integrifolia* Lindl.var. *sublanceolata* Miq., *Ph. dulogensis* H. Li., *Ph. eugeniifolia* Lindl., *Ph. lindeyana auct. non* W. & A.: Koch in Miq., *Ph. micrantha* Decne., *Ph. myriantha* Merr., *Ph. sambuciflora* W.W. Sm., *Ph. wardii* C.F.C.Fisch., and *Pyrus integerrima* (Wall.ex D.Don) N.P. Balakr.) described from different locations of the world were conformed as a single species *Photinia integrifolia* Lindl. (under publication). We feel that this kind of taxonomic work is very essential in all genera besides *Photinia*. Otherwise; it will be a great challenge to the taxonomist in the near future.

Study of native rice cultivars of Wayanad district of Kerala, India cultivated under upland conditions

***Surekha Y. Pawar**, V. V. Radhakrishnan, K.V. Mohanan*

Genetics and Plant Breeding Division, Department of Botany, University of Calicut, Kerala – 673635

Wayanad district, known as the land of paddy fields is in the southern tip of the picturesque Deccan plateau nested among the mountains of the Western Ghats on the Eastern portion of North Kerala, India. The culture of Wayanad is mainly tribal oriented and is very rich in flora and fauna. More than 35% of the area comes under forest cover. Rice is the most widely consumed staple food of the tribal people residing in Wayanad. Several native rice cultivars are phenotypically and genotypically diverse and can be categorized according to ecological and geographical variations. Native rice cultivars cultivated under upland conditions are very important under the present scenario of climate change and increasing rate of water scarcity in the area. It is notable that cultivars grown under upland conditions are water saving or drought resistant with a water requirement of only one third to one quarter of that of wetland rices. It is necessary that upland farming practices are popularized among the tribal farmers of Wayanad. The present paper is an effort to study the performance of some native rice cultivars of the area under upland conditions in terms of their morphological and agronomical characters. The seeds were collected from tribal farmers of Wayanad. The experiment was carried out in the experimental net house of the Genetics and Plant Breeding Division, Department of Botany, University of Calicut, Kerala, India in the first crop season of 2016 under upland conditions. For upland conditions, alternate drying and wetting method was used, but the soil was kept moist. Observations were made on 7 plant characters and 7 yield characters. The paper discusses the potential of some such rice cultivars under upland conditions.

Species identification among similar *Argyreia* spp. (Convolvulaceae) based on leaf anatomy and phenetic analyses

***Paweena Traiperm**[1], George Staples[2], Janene Chow[1], Possathorn*

Nopun[1], *Sasivimon Swangpol*[1]
1. Department of Plant Science, Faculty of Science, Mahidol University, Bangkok
2. HRA, Herbarium, Royal Botanic Gardens, Kew, Richmond, Surrey TW9 3AE

The genus *Argyreia* Lour. is one of the taxonomically difficult genera in the family Convolvulaceae. Several species complexes were recognized in which species delimitation was imprecise, especially when examining herbarium materials with scanty flowers. The main goal of this study is to investigate and describe leaf anatomy of some morphological similar species in *Argyreia* using epidermal peeling, leaf and petiole transverse sections, and scanning electron microscopy (SEM). The phenetic analyses including Cluster Analysis (CA) and Principal Component Analysis (PCA) were used to investigate the similarity of these taxa. Differences observed among the species include epidermal cell walls and the trichome types on the leaf epidermis, while the important characters of leaf and petiole transverse sections comprise are the epidermal cell shape of leaf blade, leaf margins and petiole transverse section outline. The phenogram from cluster analysis using UPGMA method represented four groups with an R-value of 0.87. Moreover, the important quantitative and qualitative leaf anatomical traits of the four groups were confirmed by the principal component analysis of the first two components. The results from phenetic analyses also confirmed the differentiation between the similar species. The leaf anatomical features regarded as particularly useful for species differentiation were used in constructing a key to species.

Modulating role of ROS in re-establishing desiccation tolerance in germinating seeds of *Caragana korshinskii* Kom

Long Peng
National Engineering Laboratory for Tree Breeding, College of Biological Sciences and Biotechnology, Beijing Forestry University, Beijing, China

In close coincidence with visible germination, orthodox seeds lose desiccation tolerance (DT). This trait can be regained under osmotic stress, but the mechanisms are poorly understood. In this study, germinating seeds of *Caragana korshinskii* Kom was investigated focusing on the potential modulating roles of reactive oxygen species (ROS) in DT re-establishment. Seeds with emerged radicles measuring 2 mm long can be rendered tolerant to desiccation by incubation in a polyethylene glycol (PEG) solution (-1.7 MPa). Upon PEG incubation, ROS accumulation was detected in the tip of radicles by nitroblue tetrazolium chloride (NBT) staining and further confirmed by confocal microscopy. The PEG-induced re-establishment of DT was repressed when ROS scavenger was added to the PEG solution. Moreover, ROS act downstream of ABA to modulate PEG-mediated DT re-establishment, and serve as a new inducer to re-establish DT independently. Transcriptomic analysis revealed that DT re-establishment by ROS involved the up-regulation of key genes in phenylpropanoid-flavonoid pathway, and total flavonoids content and key enzyme activity increased after ROS treatment. Furthermore, DT was repressed by phenylalanine ammonia lyase (PAL) inhibitor. Our data suggest ROS play a key role in DT re-establishment by regulating stress-related genes and phenylpropanoid-flavonoid pathway.

P0163
Functional characterization of BnHSFA4a as a heat-shock transcription factor in controlling the re-establishment of desiccation tolerance in seeds

Sirui Lang
Beijing Forestry University, Beijing, China

Desiccation tolerance (DT) is the crucial ability of seeds to resist desiccation. However, the regulatory mechanisms of seed DT are not fully understood. In this study, two heat shock cis-elements (HSE) were identified in the *Brassica napus galactinol synthase* (*BnGolS1*) promoter and shown to bind the heat shock transcription factor A4a (BnHSFA4a). Transcriptional expression of *BnHSFA4a* was induced at the early stage of DT acquisition, prior to increased *BnGolS1* activity and galactinol production. Ectopic overexpression of *BnHSFA4a* (*oxBnHSFA4a*) in *Arabidopsis* enhanced DT, particularly during DT re-establishment. *OxBnHSFA4a* up-regulated the expression of *GolS1*, *GolS*2 and *raffinose synthase 2* (*BnRS2*) in *Arabidopsis* and increased the enzymatic activity of *GolS* and RS and the concentration of raffinose family oligosaccharides (RFOs). Additionally, the overexpression lines exhibited increased antioxidant abilities. In contrast, the *Arabidopsis* mutant *athsfa4a* was more sensitive to dehydration, showing decreases in the efficiency of DT re-establishment, RFO contents and oxidation resistance. Complementation analysis indicated that DT was rescued in *athsfa4a*/*BnHSFA4a* seeds to similar levels compared with those of Col-0. Taken together, these results indicated that *BnHSFA4a* likely functions in the regulation of *GolS* expression and activity and activation of the antioxidative system and other stress response factors to improve DT.

Knowledge evaluation of characteristics and the state of conservation of three of medicinal plants in Córdoba, Argentina

Ana María Planchuelo, *María Laura Molinelli*
Centro de Relevamiento y Evaluación de Recursos Agrícolas y Naturales (CREAN-IMBIV-CONICET), Facultad de Ciencias Agropecuarias, Universidad Nacional de Córdoba, CC 509,5000 Córdoba, Argentina

Traditional medicinal plants have been used from ancient times for health care in Córdoba, Argentina, but recently it was observed an increased use of native's species as natural remedies The province of Córdoba has a rich medicinal flora and many of the species are sold in pharmacies and dietary or health shops. The vast majority of the commercialized herbs are not cultivated and are obtained directly from the natural environment where they grow, and this increases the risk of the number of potential endangered species. The objective of the present study was to evaluate the sellers' knowledge of medicinal plants in the city of Córdoba for species being commercialized under the names of "canchalagua" (*Scoparia montevidensis* (Spreng.) R.E.Fr.) "espinillo" (*Acacia caven* (Molina) Molina) and "pulmonaria" (*Croton subpannosus* Müll.

Arg. ex Griseb.) and to establish the sources, and the quality of the marketed product of those species. Surveys were carried out in 75 shops using a questioner to collect information about the uses and the origin of the target species. Samples of these medicinal plants were purchased. The total number of samples analyzed was 50 for “chanchalagua”, 23 for “espinillo” and 58 for “pulmonaria”. The results showed that the sellers do not have any kind of training in relation to the medicinal plants. The analysis of commercial samples showed two different species (*Scoparia montevidensis* and *Schkuhria pinnata* (Lam.) Kuntze ex Thell.) sold as ”canchalagua”; two species (*Acacia caven* and *Cercidium praecox (*Ruiz & Pav. ex Hook.) Harms) named as “espinillo” and three species (*Verbascum thapsus* (Lam.) Kuntze ex Thell.), *Croton subpanosus* and *Chersodoma argentina* Cabrera being sold as “pulmonaria”. This work verified the absence of government control in the stages of collection, storage and commercialization. It is also put in evidence that a comprehensive conservation plan should regulate the market and to engage all concerned parties in the implementation of sustainable management guidelines recommended by national and international agencies.

Ethnobotanical survey of *Okoubaka aubrevillei* (Pelleg et Norman) in Ameere Village of Osun State, Nigeria

Jacob Popoola[1], *Omolara Yakubu*[1], *Conrad Omonhinmin*[1], *Adegoke Adegbite*[2]
1. Covenant University
2. Ondo State University of Science and Technology

Okoubaka aubrevillei (Pellege *et* Norman) (Santalaceae) is a rare tree species traditionally considered sacred with enormous potential for medicine, pharmacology, building, construction, forestry products and tourism. The rarity/near extinction of the species prompted the ethnobotanical survey and search for the species in Osun and Oyo states, Southwest Nigeria, to gather indigenous knowledge use, traditional medicine practices and to enrich the existing traditional knowledge. Ethnobotanical data were collected using the participatory rural appraisals (PRA) method involving the village head, herbalists, traditional worshippers and artisans. Only two stands of the plant were located at Ameere Village of Osun State, while none was found in Oyo State. The two plants stands were considered ‘husband and wife’ and worshipped as gods, adored during traditional religion ceremonies and to ward off evil spirits. The whole plant parts (leaves, bark, fruits and seeds) are connected with various traditional beliefs and applications including taboos and healing potentials by the people in the studied area. The bark and seeds are the major parts used for traditional medicine. The medicinal potentials of the plant include the treatment of various health conditions such as insanity, convulsion, miscarriage, skin infections, food poisoning, stomach upset, snake bites, leprosy and veneral diseases. The fruit kernel mixed with powdered bark of *Milicia excelsa* in alcohol is employed in the treatment of chronic piles and weak erection. The dried bark of the plant in combination with other plants is also utilized to strengthen children’s bones thereby facilitating early walk. The taboos and fears created by conditions and special rituals for assessing and harvesting the plant parts contributed in a large extent to the low level of concerted research efforts to improve the cultivation, management of genetic resources, conservation and utilization of the species.

The type collection of I.P. Borodin Herbarium of St. Petersburg Forest-Technical University (KFTA), Russian Federation

Alexander F. Potokin[3], *Larisa V. Orlova* [1], *Vyacheslav V. Byalt*[1]
1. St. Petersburg Forest-Technical University
2. Komarov Botanical Institute RAS
3. St. Petersburg State University

Founded in 1865 by S.I. Karelshchikov, the I.P. Borodin Herbarium of St. Petersburg State Forest-Technical University (KFTA) is one of the oldest Herbaria in Russia, and includes about 200,000 specimens. During 2008-2016, we did a critical revision of the collections and as it turned out, the KFTA includes a large number of type specimens. It currently has about 6,000 authentic specimens of different categories. The collection of KFTA consists of two major sections: the General Herbarium and the Russian Herbarium. The General Herbarium (or that of the world flora) counted more than 70,000 specimens belonging to at least 15,000 species. The following exiccatae series were the richest in types: A.H. Curtiss and C.G. Pringle from the United States and Mexico (American Plants, Plantae Mexicanae and Plants of the Pacific Slope), von Eggers from the West Indies (Flora Indiae occidentalis exsiccatae and Flora exsiccatae Indiae occidentalis, ed. A. Toepffer), G.P. Lorentz and Otto Buchtien from South America (‘Herbarium Americanum’, ‘Flora Enteriana’), C. Baenitz (‘Herbarium Americanum’ and others), G. Zenker from Western Africa (‘Flora von Kamerun’), C. Holst from Eastern Africa (‘Flora von Usambara’), C. Wilms from South Africa (‘Flora Africae australis’), M. Holtze from northern Australia (Port Darwin), E.H. Wilson from China (‘Herbarium Veitch Expedition’) *etc.* Exsiccatae from Europe and the Mediterranean are especially rich in types. Among these, we shall name C. Magnier’s ‘Flora selecta exsiccata’, C. Baenitz’s ‘Herbarium Europaeum and Herbarium Dendrologicum’, M. Gandoger’s ‘Flora Gallica exiccata’, J. Bornmüller’s ‘Plantae Anatoliae orientalis’, P. Sintenis and J. Bornmüller’s ‘Iter Turcicum’ *etc.* A number of exsiccatae representing certain taxonomic groups also feature many type specimens, for example, M. Gandoger’s ‘Herbarium Generale. Rosarum Europearum Exsiccatum’—in the genus *Rosa* L.; G. Braun’s ‘Herbarium Ruborum germanicorum’— in *Rubus*; A. Kneucker’s ‘Gramineae Exsiccatae’, ‘*Carices* exsiccatae’, and ‘Cyperaceae’ (exclus. *Carices*) et Juncaceae exsiccatae—in the families Poaceae, Cyperaceae, and Juncaceae; *etc.* The Russian Section of Herbarium was started in 1885 and kept separately from the General Herbarium and included collections from various regions of the Former Russian Empire contributed by I.P. Borodin, Yu. F. Bosse, L. von Graff, K.F. Meinshausen, N. Puring, N.I. Bush, K. Golde, S.K. Fedoseev, F.N. Alekseenko, P. Vinogradov-Nikitin, F. Karo, A.N. Krasnov, A. Berg, A.A. Kushakevich, D.I. Litvinov, E. Regel, V.N. Sukachev, A.N. Petunnikov, and many others. Also of particular interest is the section ‘Dendrological herbarium’ created largely through the efforts of E.L. Wolf (1860-1931) and currently stored separately from the other parts of the Herbarium. The value of the collection of ‘Dendrological herbarium’ is in the presence of a large number of specimens collected by Wolf himself (historical value), and the presence in its structure of a large number of type specimens (around 500). In 2012–2014 the Borodin Herbarium joined the international ‘Global Plants Initiative’ for scanning type specimens and secured a grant from the Andrew W. Mellon Foundation intended for scanning and databasing some 3,500 type specimens. As a part of the grant, the Herbarium received a specialized inverted scanner Epson 10000 X producing large-resolution images (up to 200 Mb, with a 600 dpi resolution). During the next years, we scanned more than 5,600 specimens and partly forwarded the obtained images along with metadata to New York and Vienna for their further placement at the ‘Global Plants Initiative’ (hhtp://www.jstor.org and http://herbarium.univie.ac.at/database/search.php).

P0167

Cytotoxicity and hepatoprotective attributes of arborinine and total alkaloid fraction of *Glycosmis pentaphylla* (retz.) DC. leaves and callus on Hepg2 Cell Line

Pressy P Prakasia, *Ashalatha S Nair*
Department of Botany, University Of Kerala

Glycosmis pentaphylla (Orange Berry), belonging to the Rutaceae family is a shrub or small tree (1.5 – 5 m) widely distributed across India, Malaysia, Southern China and to the Philippine Islands where it occurs in tropical forests at low altitudes. Ethnomedicinally, *Glycosmis pentaphylla* is employed in the treatment of a wide range of ailments, including diarrhoea, cough, rheumatism, anaemia, jaundice *etc.* Leaves of *Glycosmis pentaphylla* is traditionally used for treatment of liver disorders. The current study is aimed at evaluating the cytotoxicity effects and hepatoprotective potential of total alkaloid fraction of *Glycosmis pentaphylla* leaf and callus and arborinine (isolated alkaloid) on human hepatoma HepG2 cell line. The cytotoxicity potential of the total alkaloid fraction and arborinine was assessed on HepG2 cell line and a normal 3T3-L1 mouse adipocyte by cell viability using 3- (4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide assay at the concentration of 12.5,25,50 and 100 µg/ml. Based on the cytotoxicity assay, total alkaloid fractions and the isolated arborinine at the above mentioned doses were assessed for its hepatoprotection potential against CCL_4 induced toxicity in HepG2 cell line by monitoring cell viability. Leaf total alkaloid fraction showed the most potent cytotoxic activity on HepG2 cell line ($p<0.001$) in concentration and time dependent manner with IC_{50} value of 102.40 µg/ml and 5.39 µg/ml after 48 and 72 h incubation respectively than the callus total alkaloid fraction and arborinine. Apoptotic morphological changes in HepG2 cells caused by treatment of total alkaloid fractions and arborinine were observed and showed chromatin condensation, cell shrinkage and apoptotic bodies following AO/EB staining. Toxicity in HepG2 cells was induced by treatment with CCL_4 for 12 h as manifested by a significant ($p<0.001$) decrease in cell viability. Pre-treatment with (prophylactic) with the total alkaloid fractions and arborinine effectively alleviated ($p<0.001$) the toxicity induced by CCL_4 in a concentration -dependent manner. The results evidenced that *Glycosmis pentaphylla,* the rich source of alkaloids has potent hepatoprotective effect on hepatocytes. Moreover, the well established callus cultures can be used as an alternative production system to overcome the limited availability of the medicinally valuable pharmaceuticals.

P0168

Simple and feasible approach to efficient callus establishment in *Glycosmis pentaphylla* (Retz.) DC.

Pressy P Prakasia, *Ashalatha S Nair*
Department of Botany, University of Kerala

Glycosmis pentaphylla (Retz.) DC. (Family: Rutaceae), commonly known as Orange Berry or Gin Berry, is a highly ethanomedicinally important plant widely used by rural and tribal communities in India. The plant is widely distributed across India, Malaysia, Southern China and to the Philippine Islands where it occurs in tropical forests at low altitudes. According to Kerala forest and wildlife department, *Glycosmis pentaphylla* is categorised as endemic plant in India. The plant has been continuously exploited due to its immense medicinal properties such as diarrhoea, cough, rheumatism, anaemia, jaundice *etc* and as well as for its rich source of secondary metabolites, mainly alkaloids. In this study, despite the meticulous efforts involved in callus induction from field grown plants, the success of the establishment of callus cultures was hampered by various obstacles such as bacterial and fungal contaminations, browning of the cultured tissues and the recalcitrant nature to most of the in vitro treatments experimented. In addition to it, the protocols that are dependable in terms of efficiency and repeatability is still rare to find in spite of a volume of work done on phytochemical and pharmacological area. A factorial experiment was conducted with four explants (radicle, hypocotyl, leaf and cotyledon), two light regimes (light and dark) and 4 levels of 2,4-D for callus induction from explants derived from a month-old-seedling grown on basal MS agar-solidified medium. Cotyledon explant gave a surpassing response and recorded the highest in terms of least days to visible callus induction, percentage explants forming callus, callus biomass than the other explants with the treatment of 22.6 µg/ml M 2,4-D augmented MS medium. Furthermore, the quantity of calli produced on a medium under dark condition was higher than that on media under light condition. Averaging the results from all hormone concentrations and light regimes together, highly efficient callus was induced from cotyledon (70.92%) followed by hypocotyl (50.44%). The response from the leaf was lower, 37.39% and the radicle response being the poorest with only 11%. Among the concentrations of 2,4-D taken into account, regardless of other factors, 22.6 µM proved to be the best for callus induction for all the explants. Successful proliferation of callus was achieved when the callus obtained from cotyledon was shifted to proliferation medium consisting of a hormone combination of 2,4-D +NAA and 2,4-D +BAP. Presently optimized callus production protocol holds a promising route for continuous production of plant biomass in laboratory controlled environment, independent of seasonal, climatic and geographical limitations and be considered a bright hope towards conservation and thereby providing a sustainable source for the extraction of therapeutically important chemicals and for the genetic improvement of this pharmaceutically important plant.

Alkaloid profiling of *Glycosmis pentaphylla* by GCMS and its anticholinestaerase activity

Pressy P Prakasia, *Ashalatha S Nair*
Department of Botany, University of Kerala

Glycosmis pentaphylla (Orange Berry), belonging to the Rutaceae family is a shrub or small (1.5–5 m) tree widely distributed across India, Malaysia, Southern China and to the Philippine Islands where it occurs in tropical forests at low altitudes. Ethnomedicinally, *Glycosmis pentaphylla* is employed in the treatment of a wide range of ailments, including diarrhoea, cough, rheumatism, anaemia, jaundice *etc.* Juice of leaves used against fever, liver complaints, vermifuge *etc.* Paste of leaves used to cater against eczema, skin affections, snake bites, wounds and finally decoction of roots for bilious attacks, intestinal trouble and ascaris. The plant is known for the high diversity of their secondary metabolites which include many groups that represent a rich source of structural diversity and are good candidates as sources of alkaloids that could be useful in pharmacology. The chemical composition of alkaloids from leaves of *Glycosmis pentaphylla* was analyzed by GC/MS revealing the presence of three compounds, belonging to acridone and quinozoline group of alkaloids. Arborinine (acridone group) was isolated using alkaloid acid base protocol and the chemical structure was elucidated by mass-spectrometry and NMR spectroscopic experiments. Dose dependent inhibition of acetylcholinesterase (AChE) was determined by acetylcholinesterase enzyme kit. The results showed a marked inhibition of AChE with an IC50 value of 77.90 µg/ml. The study showed evidence for neuroprotective action of arborinine against stress induced toxicity on SHSY5Y cell lines. Molecular docking revealed the structural insights behind its significant inhibitory activity on AChE. The treatment of neurological disorders and neurodegenerative diseases is related to the levels of acetylcholine (ACh) through the inhibition of acetylcholinesterase (AChE). In this sense, many alkaloids isolated from natural sources such as donepezil, galanthamine, tacrine and rivastigmine have long been recognized as acetylcholinesterase inhibitors. The study indicated promising potential of arborinine as an acetylcholinesterase inhibitor which needs to be further developed and explore its potential lead for Alzheimer's disease.

Aquatic plants as bioindicator in the wetlands of Mekong Basin and Thailand

Chavalit Vidthayanon
1. Dependent researcher, Bangkok
2. Department of Biology, Faculty of Science, Naresuan University

Wetlands in the Mekong Basin and Thailand are one of the global aquatic plants hotspots. Over 500 species of 32 families have been occurred but less than half were assessed (252 species) and five are reported as threatened taxa. Most wetlands in the Mekong and Thailand region are degraded and disturbed by human activity including habitat alteration, agro-chemical, water extraction, invasive alien species and climate change. Several aquatic plants are disappearing or replaced by tolerance taxa or exotic taxa. The species composition and occurrence in the wetland can indicate the water and habitat integrity. More *In situ* inventory monitoring as well as local market survey are needed approach for assesses wetland habitat indicators in the region.

Pollination biology of *Hemiboea ovalifolia* (Gesneriaceae), an endangered herb from Guangxi, China

Gaozhong Pu
Guangxi Institue of Botany, Guangxi Zhuang Autonomous Region and Chinese Academy of Sciences

Although information on the reproductive biology of the endangered plant family Gesneriaceae is well known, the pollination mechanisms of these plants in karst regions are poorly understood. To determine the pollination ecology of *Hemiboea ovalifolia*, a rare and highly geographically restricted endemic species in karst regions, flowering phenology, pollinator observations, and pollination manipulations were conducted *in situ*. Findings revealed that the anthesis of *H. ovalifolia* often occurred late, during sunset, or early morning, with a duration of 2–4 days. The most effective pollinators were *Bombus ignitus* and *Anthophora zonata*. The co-existence of spontaneous self-pollination, protandry and herkogamy in *H. ovalifolia* suggested that this species outcrosses with partial self-compatibility, and exhibits late-acting inbreeding depression in seed sets. Controlled pollination indicated that these plants were pollen limited resulting from the seed set. However, despite the co-existence of large numbers of fruit and seed sets, and vegetative propagation in *H. ovalifolia*, a failure in seedling survival and long duration to establishment of first-year seedlings in natural populations suggests that the species does not easily recover from damage.

Conservation and reintroduction of *Bentinckia nicobarica* in Nicobar Islands- a case study

Pushpa Kumari, *Paramjit Singh, Reshma Lakra*
Botanical Survey of India

Bentinckia, a palm genus is restricted to Indian subcontinent with *B. nicobarica* restricted in distribution to Nicobar Islands. Usually, Island species are quite frequently within their limited area of distribution not having any chance of migration, so that destruction of even a small forest area may render the endemic species high threat over their existence. The Andaman and Nicobar Islands represent 86% of forest coverage including tropical rain forests, tropical moist deciduous forests, lowland forests *etc.* with a total geographical area of 8249 sq.km, while the Nicobar group of Islands cover an area of 1841 sq.km. *B. nicobarica* belonging to the family Arecaceae is one of the hardest, tall palms growing up to ±50 m height with small globose, blackish fruits (when ripen) in big bunches. It specifically grows in moist hills, valleys, plains and slopes of lowland forests of Nicobar Group of Islands mainly in Great Nicobar, Kachal, Nancowry group, Teressa, Chowra and Car Nicobar Islands. In the year 1988, "The IUCN Red List of Threatened Species" assigned this species endangered category. *B. nicobarica* is used in the Islands for housing, furniture, boat making, *etc.* by the tribal of Nicobarese and Shompen. The emerging shoots are eaten by the local people as vegetable and the fallen fruits are eaten by pigs. Due to all these activities over the time the species population has declined very much in these islands. Considering the importance of the species the present study has been taken to investigate its population, multiplication and reintroduction. The method of Ecological Niche Modelling (ENM) map is applied by using the modeling algorithms of DIVA-GIS and MAXENT. Nineteen bioclimatic variables are used as environmental variables for modeling, which includes Annual Mean Temperature, Mean Diurnal Range, Isothermality, Temperature Seasonality, Maximum Temperature of Warmest Month, Minimum Temperature of Coldest Month, Temperature Annual Range, Mean Temperature of Wettest Quarter, Mean Temperature of Driest Quarter, Mean Temperature of Warmest Quarter, Mean Temperature of Coldest Quarter, Annual Precipitation, Precipitation of Wettest Month, Precipitation of Driest Month, Precipitation of Seasonality, Precipitation of Wettest Quarter, Precipitation of Driest Quarter, Precipitation of Warmest Quarter, Precipitation of Coldest Quarter *etc.* Through this modeling, we could predict the potential area of occurrences the species and their reintroduction for the population study and the limiting factors. More than four thousand seedlings of *B. nicobarica* are raised so far in controlled condition in polyhouse of Dhanikhari Experimental Garden Cum-Arboretum, Botanical Survey of India, Andaman and Nicobar Regional Centre and being reintroduced in the identified habitat for improving their conservation status.

Species diversity of pteridophytes in Ton Nga Chang Wildlife Sanctuary, Southern Thailand

Nutdanai Putthisawong[1], *Chayanin Kraithep*[2], *Sahut Chantanaorrapint*[1]
1. Prince of Songkla University, Songkhla, Thailand.
2. Chulalongkorn University, Bangkok, Thailand.

A survey of pteridophytes at Ton Nga Chang Wildlife Sanctuary was conducted from September 2015 to March 2016. One hundred and twenty five specimens were collected and 97 species were identified, belonging to 50 genera and 19 families. Among these 6 species were lycophytes, and 91 species were monilophytes. Common families are is Polypodiaceae, Pteridaceae, and Thelypteridaceae, with 16,10, and 8 species, respectively. Of these, 56 species are terrestrials, 30 species are epiphytes, and 28 species are lithophytes. Regarding distribution of pteridophytes in the study area, 61 species forest along the stream are the most abundant, followed by 38 species in lower mountain forest, 28 species are in lowland evergreen forest, whilst 14 species are in dry evergreen forest and only 9 species are on rock platform forest. Among them, 37 species can be found in more than one forest types. In addition, an examination of type specimens and several collections of *Bolbitis malaccensis* (C. Chr.) Ching and *B. sinuata* (C. Presl) Hennipman, however, confirm that *B. malaccensis* should be reinstated as a separate species.

Land-use changes cause rapid loss of seagrass resources: Case in Guangxi Province, China

Guanglong Qiu[1], *Zhinan Su*[2], *Hangqing Fan*[1], *Meiqiu Wei*[2], *Meng Li*[3]
1. Guangxi Key Lab of Mangrove Conservation and Utilization, Guangxi Mangrove Research Center, Guangxi Academy of Sciences
2. Forestry College, Guangxi University
3. School of Geography and Planning, Guangxi Teachers Education University

Seagrasses are the flowering plants which have adapted to exist fully submersed in the sea. They play significant roles in providing nurseries and shelters for marine lives, sequestrating carbon, stabilizing sediments, improving water quality, *etc.* Globally, seagrasses are declining at a accelerating rate mainly due to anthropogenic activities. Here, we present our comprehensive investigation results of seagrass resource in Guangxi, China in 2016. We also accessed the primary causes which induced the losses of Guangxi seagrass resources in the past ~10 years. We used field surveys, combing with Google satellite images interpretations to investigation the area of Guangxi form April to Oct, 2016. Our results show that, total 617.2 hm^2 of seagrasses were found along the coast of Guangxi, of which 20.1 hm^2 were newly found in 2016. Specifically, seagrasses in Beilunhe Esturary, Western Fangchenggang Bay, Eastern Western Fangchenggang Bay, Lianzhou Bay, Inner Yingluo Bay, *etc.*, were all recorded for the first time. In the comprehensive survey of 2016, four seagrass species were found, namely *Halophila ovalis*, *Zostera japonica*, *Halophila beccarii* and *Ruppia brevipedunculata*. Tieshangang and Pearl Bay (Zhenzhugang) were the major seagrass distribution areas in Guangxi, dominated by *Halophila ovalis* and *Zostera japonica*, respectively. Total 354 hm^2 of seagrasses, accounting for 37.6% of seagrasses area in 2008, were lost as a result of coastal land-use practices, like sea reclamations. This leads to -5.5% of annual loss of seagrasses in Guangxi from 2008 to 2016. Besides, the seagrasses *Halodule uninervis*, *Halodule pinifolia* and *Halophila minor* which have been recorded in 2008 in Guangxi, couldn't be found any longer in 2016.

Ecosystem services of aridlands of District Khushab (Thal Desert), Punjab, Pakistan

Rahmatullah Qureshi
Pir Mehr Ali Shah Arid Agriculture University, Rawalpindi

The aim of this study was to record ethnobotanical information in order to compute ecosystem services of the aridlands of Khushab (Thal Desert), Punjab, Pakistan. For this purpose, field trips were arranged and the study area was surveyed during 2010 to 2013 by using a semi-structured questionnaire to record the uses of plants by the local peoples of this area. A total of 157 plant species belonging to 118 genera and 52 families that served to the natives for fulfilling different needs from them. The use value index (UVI) of species indicated that two species viz., *Acacia nilotica* and *Aza-*

dirachta indica are first in rank which is utilized in fulfilling eight use categories. Since the area is rangeland therefore there is very common of native plants as fodder/forage was very common in the area (25.82%), followed by fuel, medicinal (16.76%), vegetable (7.71%), *etc*. The area sustains high proportion of highly palatable species (81 spp.), followed by medium palatable (44 spp.) and less palatable (19 spp.). With reference to medicinal use, 87 plant species were used in treating 69 different ailments/diseases by the natives. Based on the reults, it can be concluded that the area is rich in plant diversity along with rich heritage of utilization. There is need to promote the customary use of plants by expansion of plant based products obtained from this area. Such efforst not only preseve the tradional lore as well as sustainable development of the area. So efforts are required to conserve/maintain some of the areas depicting diversity of medicinal/valueable plants for their sustainable utilization by the future generation.

Floristic diversity, threats and conservation isssues: A case of Tharparkar Desert, Pakistan

Rahmatullah Qureshi
Pir Mehr Ali Shah Arid Agriculture University, Rawalpindi, Pakistan

Thar Desert is located in the Sindh Province, Pakistan. This is a hot sandy desert with small hillocks. The aridity is the characteristics of desert with erratic rainfall taking place in clusters. This aridland provides some ecosystem services to human being such as food, feed, shelter and medicine. The plant diversity of this area includes 331 species belonged to 198 genera and 60 families. The vegetation is typified by xerophytic species composed on *Acacia senegal, Aerva javanica, Aristida adscensionis*, *Calligonum polygonoides, Dipterygium glaucum, Crotalaria burhia, Capparis decidua, Euphorbia caducifolia, Indigofera argentea, Limeum indicum, Leptadenia pyrotechnica, Prosopis cineraria, Salvadora oleoides, Tamarix aphylla, Tecomella undulata* and *Stipagrostis plumosa* mostly found inhabiting on majority of the area. *Abutilon bidentatum, A. pakistanicum, Alysicarpus monilifer, A. tetragonolobus, Caralluma edulis, Cenchrus prieurii, Commiphora wightii*, *Convolvulus scindicus, Gisekia pharnacioides, Ephedra ciliata, Gynandropsis gynandra, Monsonia heliotropioides, Rhynchosia schimperi* and *Tecomella undulata* are some of the threatened species which are socio-economically used by the inhabitants to meet their various needs. The rising incidence of prolonged drought, desertification, overharvesting of woody species and soil erosion are serious threats to the typical this desert habitat. The pragmatic conservation measures are required to protect such habitat, since it represents threatened/rare and endemic species which are economically and unsustainably used by the local communities of this area.

P0177

The impact of *Lantana camara* and *Chromolaena odorata* on native species diversity in some parts of vhembe district municipality.

Tsumbedzo Leonard Ramalevha, *Maanda Hadzhi Ligavha-Mbelengwa*
UNIVERSITY OF VENDA

Species diversity indirectly increases the productivity of ecosystem and understanding the impact cause by invasive alien plant species at different parts of the municipality is essential in predicting their impact on ecosystem productivity in different localities. Previous studies attributed the impact of invasive alien plant species to their competitive ability, high growth rate, effective reproductive mechanism and other characteristics. Significant progresses have been achieved over the years in accepting and eradicating the alien plant species from new habitats. However, the degree of impact and association of invading plants with the native flora vary from region to region. Rectangular quadrat method will be used for data collection; analysis of variance and multiple regressions will be used to analyze data collected. Impact of alien invasive plant species will be revealed by checking the response of native plant species following the non-removal and removal of alien invasive species in some areas of study.

Antioxidant, anti-inflammatory and anticancer activities in selected Philippine ferns and lycopods

Reggie Dela Cruz[1], *Aileen Mae Ang*[1], ***Glenda Z. Doblas***[1], *Victor Amoroso*[2], *Heidi Porquis*[1]
1. Central Mindanao University
2. Center for Biodiversity Research and Extension in Mindanao

Ferns and lycopods, collectively called as pteridophytes, are among those neglected plant resources whose medicinal potentials are very high. This study explored the antioxidant, anti-inflammatory and anticancer potentials of selected pteridophyte species. Ethnopharmacological surveys were initially carried out in three ethnic tribes, Talaandig tribe in Mt. Kitanglad, Bukidnon; Higaonon tribe in Mt. Caburakanan, Bukidnon as well as the Mandaya tribe in San Isidro, Davao Oriental. Ten species of pteridophytes were found to be used by these tribes for a total of 13 illnesses which include arthritis and inflammation. A total of fifty-seven methanolic extracts were produced from the fronds and rhizomes of 25 species of ferns and three species of lycopods collected from eight locations in Mindanao. These were studied in terms of their DPPH radical scavenging activity, cytotoxicity against human epidermal keratinocytes, cyclooxygenase inhibition and anticancer activity against lung cancer A549 cell line. The selected species were also identified using morphology and barcoded using the chloroplast *rbc*L gene with an average length of 561 bp. The sequences were compared with the GenBank and BOLD databases to confirm initial identification and phylogenetic analysis was carried out using neighbor joining method. Qualitative phytochemical screening revealed 19 extracts positive to alkaloids, 41 extracts positive to anthraquinones, 46 extracts positive to phenolics, 54 extracts positive to saponins, 22 extracts positive to tannins and 45 extracts positive to terpenoids. Highest total phenolic content was 302.19 ± 28.83 mg gallic acid equivalent/g sample and flavonoid content of 36.74 ± 2.17 µg quercetin equivalent/g sample. The results further showed that crude rhizome extracts from all collected fern samples generally had higher values of total phenolic and total flavonoid contents compared to crude frond extracts.

Antioxidant values of more than 50% radical scavenging activity relative to ascorbic acid were observed in 5 rhizome and 1 frond extracts. All 57 extracts were found to be nontoxic based on MTT cell viability assay using neonatal human epidermal keratinocytes at two doses of 20 and 200 ppm. Assays were conducted to measure inhibition of the two forms of the enzyme cyclooxygenase, *COX*-1 and *COX*-2. Twenty-four crude extracts exhibited more than 50% *COX*-2 inhibition. Moreover, ten extracts gave *COX*-2: *COX*-1 selectivity indices of ≥ 1.2. The highest value was that of extract 20F with 2.64 followed by 21R with 2.34. Moreover, two extracts, 5R and 20F were active against lung A549 cancer cell line. It is interesting that 20F has both anti-inflammatory and anticancer activities. Isolation of the bioactive compounds as well as mechanistic and cell-based assays will be done to provide more conclusive data for the reported bioactivities.

Efficacy of botanicals derived from indigenous plants to wheat aphid under the field conditions

Hafiz Mahmmod Ur Rehman, *Muhammad Sajjad, Shafiq U Rehman, Javed Akhter, Asif Sajjad, Intazar Ali*
Department of Entomology, University College of Agriculture and Environmental Sciences, the Islamia University of Bahawalpur, Bahawalpur-Pakistan

Aphid damages wheat, *Triticum aestivum* L. by rolling of wheat flag and trapping of emerging heads and awns which results in poor pollination and thus reduction in yield. Present study aimed at to test the efficacy of botanicals derived from some indigenous herbs to wheat aphid under field conditions. The extracts (5% solution) of neem, *Azadirachta indica* (leaves and seed), garlic, *Allium sativum*, eucalyptus, *Eucalyptus globulus* and tobacco, *Nicotiana tabacum* were applied when population of aphid exceeded the economic threshold level (ETL). There was a significant difference in the populations of wheat aphid and its natural enemy (coccinellid beetles) among five treatments after the application of extracts. The population of aphid was significantly lower on neem leaf extract and tobacco. Higher numbers of the aphids were recorded in control where no extract was applied. A significant difference was observed in the population of coccinellid beetle among the different treatments of extracts. Neem (leaf) and tobacco extracts received least while eucalyptus, garlic, neem (seed) and control had significantly higher numbers of beetles. There was a significant difference in numbers of grains per spike. Neem (seed) had comparatively higher numbers than control. No significant difference was observed weight of grain per spike.

Impcats of REE'S Enrichment on growth and anatomy of eight common mosses from Baiyun Obo

Yeqing Gao, *Caiqin Ding, Dongmei Ren, Xueliang Bai*
College of Life Science, Inner Mongolia University, China

Selecting *Jaffueliobryum wrightii* (Sull.) Ther., *Didymodon constrictus* (Broth.) Saito, *Bryum argenteum* Hedw, *Didymodon tectorum* (C.Muell.)Saito, *Syntrichia sinensis* (C.Müll.) Ochyra, *Didymodon nigrescens* (Mitt.) Saito, *Pterygoneurum kozlovii* Lazarenko and *Tortula atrovirens* (Smith) Lindb from Baiyun Obo mine, the morphological and anatomical characteristics were studied by comparing with the same species from Helan mountain and SangGenDalai. Its main characteristics were taken microscopic pictures and made plates and the specifically important characteristics were measured. Three mosses from different mining area in Baiyun Obo were compared, using statistical analysis methods to explore the variation and variation amplitude of their morphological structure resulted by three different growth environment. the results showed that: (1) the differences between two regions are significant in these index: plant height, stem width, leaf length and leaf width. But non-significant in leaf length-width ratio and leaf cells length-width ratio. (2) three mining area mosses in leaf length and leaf width indicated differences: West mine>Main mine>East mine; and irregular in stem width. (3) the main factor to the mosses growth was the rare earth elements content and influenced mainly through the leaf. A preliminary discussion about the mosses growth influenced by the rare earth elements was made, meanwhile it enriches the content of the moss plant anatomy.

Red and invisible? Evolution of flower characters in the genus *Fritillaria* L. (Liliaceae) in response to the pollinator shift

Katarzyna Roguz, *Marcin Zych*
University of Warsaw Botanic Garden

Majority of *Fritillaria* species have insect pollinators, however some North American and Asian species are bird-pollinated. The switch from entomophily (insect pollination) to ornitophily (bird pollination) happened at least once in the history of the genus. Such pollinator shifts should be accompanied by a divergence in some floral characters - morphological, phenotypical and/or physiological. New character states should be a response to preferences of the most common and the most effective pollinators. These features may also act as phenotypic filters when flowers become repelling, invisible or discouraging to illegitimate flower visitors. Such characters might be of great significance in case of the ornitophilous *Fritillaria* species where bees can act as the least efficient pollinators. Moreover, flowers characters favouring bird pollination can differ depending on biogeographic context since ornitophilous Fritillaries grow in different continents and their pollinators belong to different taxonomical groups (hummingbirds vs. passerines). The present paper discusses the evolutionary shift from entomo- to ornitophily in *Fritillaria*, illustrating different combination of character states associated with various pollination systems in the genus.

Plant diversity, management status and research opportunities in the different botanic gardens of Ecuador

Hugo Romero-Saltos
Jardín Botánico Yachay (Yachay Tech & Yachay EP)

Ecuador (in South America) is one of the smallest of the “megadiverse” countries. With a land area of just 0.2% of Earth’s terrestrial surface, it is home to approximately 18,400 native vascular plant species—about 7% of global plant diversity—from which 5,400–5,700 species are endemic. In this country, the responsibility for the *ex situ*, at times *quasi in situ*, conservation of the native wild species belongs to the different botanical gardens active in the country, while the responsibility for *ex situ* conservation of agricultural species (crops) is shared with the Instituto Nacional de Investigaciones Agropecuarias (INIAP). At this conference, I will provide general information about the different botanic gardens in Ecuador and will summarize the diversity and management status of their live plant collections. It will become evident that we need to better systematize and use our collections for research and educational purposes.
(Full list of co-authors of this conference is pending for their approval. Given the deadline, I am submitting this abstract with just the first author only).

Soil substrate constraints the suitable niche of rare plants in Labrador, Canada

Natalia De La Torre-Rodriguez[1], *Sean Bennett*[2], *Shelley Pardy*[3], *Claudia Hanel*[3], ***Julissa Roncal***[1]
1. Memorial University of Newfoundland
2. STANTEC
3. Newfoundland and Labrador Department of Environment and Climate Change

Information regarding rare plant species distribution and their habitat requirements in remote areas of northern Canada is typically lacking. This represents a major challenge to government agencies, environmental consultancies, and indeed all stakeholders when conducting baseline studies under the federal Environmental Impact Assessment (EIA) review process; and to support accurate conservation decision-making on the part of the agencies and project proponents alike. This is particularly true of those rare plant species considered as having both narrow geographical ranges and specialized habitat requirements. According to the Newfoundland and Labrador Department of Environment and Climate Change (NLDECC) there are more than 200 species of flowering plants in Labrador considered “rare”, and subsequently of management concern to the Province. The aim of this project was to model the distribution of rare plant species habitats (i.e. realized niche) across Labrador identifying areas where these species could potentially occur based on a set of known environmental attributes. We tested the hypothesis that if the realized niche is sufficiently widespread, then plant rarity is due to other factors like dispersal limitation, or reproductive challenges. This initiative was a collaborative effort between Memorial University of Newfoundland (MUN), in partnership with local government agencies (NL DECC - Wildlife Division) and environmental consultancies. Using locality coordinates acquired from herbarium records, ecological niche models were developed applying the Maximum Entropy (MAXENT) approach to a subset of uncorrelated climatic variables (Worldclim), land cover, altitude and geology (Newfoundland and Labrador Nature Atlas website). Of the 200 plant taxa, five were selected as case studies for niche modelling: *Calla palustris*, *Eleocharis palustris*, *Maianthemum stellatum*, *Potamogetum alpinus* and Viola *renifolia*. The ecological niche models presented here indicate that suitable habitat may exist for rare plant species outside that of their known locations. Overall, the environmental attribute contributing most to the distribution of these five species was bedrock geology (as indicated by current soil substrate), followed closely by temperature. Suitable habitat was widespread for *Calla palustris*, *Potamogeton alpinus* and *Viola renifolia,* suggesting that rarity on the basis of habitat availability is unlikely. Alternatively, suitable habitat for *Eleocharis palustris* and *Maianthemum stellatum* was deemed limited, fragmented, and may pose a challenge to species dispersal and recruitment. Our results contribute to a better understanding of the ecology of rare species, notably their ecological niche, may be an effective tool for new population discovery of rare plant species in Labrador, and has the potential to inform the conservation status assessment and management of these plant taxa in the future. The potential also exists for stakeholders, including our project partners to use these distribution models to guide future fieldwork, make appropriate management recommendations, and prescribe suitable mitigation actions, where feasible.

Spekboom planting in degraded areas improves soil properties and native species diversity in Eastern Cape, South Africa

Sheunesu Ruwanza
University of Venda

We assessed whether *Portulacaria afra* (spekboom) planting improves both soil physico-chemical properties and native species diversity in the Saltaire Karroid Thicket. We collected topsoil samples from a spekboom planted site and compared them to adjacent natural and degraded sites and quantified soil physico-chemical properties. We further conducted vegetation surveys in plots measuring 10 x 10 m. Results show significant increase in soil P, total C, total N, Ca and soil moisture in the natural and spekboom planted sites compared to the degraded site. Soil compaction and water repellency were significantly high in the degraded site compared to the natural and spekboom planted sites. Species richness and diversity were significantly high in the natural and spekboom planted site compared to the degraded site. We conclude that the planting of spekboom in degraded areas improve some soil properties and native species diversity.

Vascular plant biodiversity and floristics of the Canadian Arctic

Jeffery Saarela*, Lynn Gillespie, Paul Sokoloff, Roger Bull*
Canadian Museum of Nature

Despite nearly 200 years of exploration, substantial gaps remain in our understanding of the diversity and distribution of the vascular plant flora of the Canadian Arctic, which comprises over one third of the global Arctic ecozone. Detailed information on the diversity and distribution of Arctic plants is urgently needed to understand the potential impacts of climate change on the region's flora. Since 2008 we have been conducting detailed floristic surveys in botanically-understudied regions of the Canadian Arctic. The comprehensive baseline data of our >8000 new collections, all housed in the National Herbarium of Canada and other herbaria in Canada and internationally, adds important knowledge to our understanding of Arctic plant biodiversity. Many of our collections represent first records for specific areas, others represent the second or third collections of poorly-known species at the edge of their ranges in the Canadian Arctic, and many fill in gaps in the known distributions of Arctic species. We will summarize our floristic work to date in the context of current understanding of the Canadian Arctic flora, with a focus on the many particularly noteworthy discoveries we have made in this rapidly changing ecozone.

The Arctic Flora of Canada and Alaska project

Jeffery Saarela*, Lynn Gillespie, Paul Sokoloff*
Canadian Museum of Nature

The Arctic Flora of Canada and Alaska project aims to produce a new flora treating all vascular plants (ca. 800 species) in the Arctic ecozone in Canada and northern Alaska. Our research team includes botanists from Canada, Norway, and the United States, and is being led by researchers at the Canadian Museum of Nature. We are using a web platform to move the Flora beyond traditional standards, and to produce a treatment that is digital and interactive, taking full advantage of current web and database technologies. The flora will include parallel taxon descriptions, dichotomous keys, detailed nomenclatural data, common names, information on traditional uses, taxonomic comments, and will be richly illustrated with photographs taken in the field and of herbarium specimens showing characters important for accurate identification. Tracking specimens examined will allow future verification of distributional and descriptive data, and will facilitate production of dynamic distribution maps. The Arctic Flora of Canada and Alaska website (http://arcticplants.myspecies.info) will be updated with content on an ongoing basis. The Flora will eventually serve as the key source of information for anybody who requires accurate and up-to-date information on the Arctic flora, including those involved in Arctic terrestrial monitoring, students in the north and elsewhere, and the international botanical community. It will also serve as an up-to-date source of baseline information on plant biodiversity in one of the worlds' most climate-threatened ecosystems.

The vegetable oils like the Amazon cosmetics basic and development of alternative socioeconomic community

Terezinha De Jesus Soares Santos
Instituto de Pesquisas Científicas e Tecnológica do Estado do Amapá

The Amazon has been a source of inspiration for the latest releases in the cosmetic market due to the richness of its biodiversity, the exoticism of its products and the stimulation factor for sustainable development of local communities. By the year 2010 the main species found on the market were andiroba (*Carapa guianensis*) and the Brazil nut (*Bertholletia excelsa*), from the same year, new species were discovered as excellent raw materials for cosmetics, mostly. But the traditional knowledge holders fail to develop their communities or even their lives from the sustainable use of plant raw materials in abundance in the Amazon rainforest. This work will show some vegetable oils, few popular, but are in favor as a raw material for cosmetic and with the use of machines and low-cost equipment, promoting industrial innovation regarding the quality of raw materials and improvement product quality, can drive, so the input production base for cosmetic in traditional communities in the Amazon.

Taxonomic inflation caused by philosophical disparities in *species concepts* and peccadilloes in the methodology followed for delimiting new species and recommendation for an International Standard Plant Species Numbering (ISPSN) system

Satheesh George
St. Joseph's College (Autonomous), Devagiri

Organic diversity is divided into different groups of various sizes separated by discontinuity of relationships. These groups are assigned to different categories in a taxonomic hierarchy according to their phylogenetic relationships. The most important category is that of species, the basic unit in taxonomy. But the existence of species in plants is a matter of theory. The judgment of characters may vary between individuals. Usually each taxonomist will have a different opinion on what represents a discontinuous character, what level of variation equals to the species rank and what equals to the ranks below species *etc.* It is the discretion of the taxonomist to fix the individual with discontinuous variation to appropriate category. Hence the criteria for demarcating species is crucial as different methods for diagnosing a species can arrive at different entities. False description of new species/varieties, due to lack of detailed study on intraspecific variations is discussed. Publication of nomenclatural novelties without consultation with authorities and /or publication in ephemeral journals resulted in the increased numbers of species in the checklist of a group. At present there is no proper compiled document on the novelties being published world wide. We propose to introduce the International Standard Plant Species Number (ISPSN) system for ensuring species stability in plant nomenclature. Recommendation for a universal system for delineating new species/sub specific categories is proposed.

Phylogenetic analysis of resurrection plants on Inselbergs of Madagascar

Juliane Schmiel, *Stefan Porembski*
University of Rostock

Malagasy Inselbergs are geomorphological old isolated rock outcrops whose microclimate differs from the surrounding area. On Inselbergs extreme conditions for plant growth are caused by water deficiency, high light irradiation and temperature variation between day and night and between seasons. A number of plant species have evolved specific adaptations that allow their survival on Inselbergs. These specialists include carnivorous plants, succulents and desiccation-tolerant species. Dominant representatives of desiccation-tolerant plants are mat-forming monocotyledons, which occur in large populations on outcrops. Our model species is *Coleochloa setifera* (Cyperaceae- sedge family), which belongs to these mat-forming specialists. Morphologically there are hardly any differences between populations. Nevertheless, we are assuming that differentiation processes occur between geographically isolated populations of *C. setifera*, since the gene flow is limited beyond the populations. Currently, 19 Inselbergs from different regions of Madagascar have been sampled. From each Inselberg 20 plant leaves samples were taken randomly, dried and stored in silica gel. The aim of the study is the phylogenetic analysis of *Coleochloa setifera* at population level. Due to no detectable morphological differences, genotyping should determine whether a population consists of one single species or varieties. Furthermore, we aim to investigate whether there is any indication of differentiation processes (emergence of new species/ varieties) between Inselbergs of varying geographical distances and isolation levels. We assume that *C. setifera* reproduces clonally within a population. In addition, due to differing microclimatic conditions on each Inselberg, we expect changes in the DNA sequences. Since no genetic sequence information is available, the populations are to be analyzed by genotyping. An economically new method is double digest RAD-Seq (ddRADSeq). DdRADSeq is an inexpensive method for SNP (Single Nucleotide Polymorphism) discovery and genotyping in model and non-model species. Our study has the potential to provide novel taxonomical information on this species. The research findings could serve as powerful tool in terms of conservation issues of the generally threatened Inselbergs and their unique vegetation.

Collection of naturalized *Helianthus* species from Australia

Gerald Seiler[1], *Gary Kong*[2], *Sue Thompson*[3]
1. U. S. Department of Agriculture, Agricultural Research Service
2. University of Canberra
3. The University of Southern Queensland

Genetic resources are the biological basis of global food security. Collection and preservation of crop wild relatives of important crop species such as sunflower provide the basic foundation to improve and sustain the crop. Acquisition through exploration is the initial step in the germplasm conservation process. Sunflower *(Helianthus annuus L.)* is native to North America and is grown on 20 million ha in 60 different countries. Due to domestication, cultivated sunflower has a very narrow genetic base that has been broadened by the infusion of genes from the crop wild relatives, which have provided a continued source of agronomic traits for crop improvement. The genus *Helianthus* comprises 53 species (14 annual and 39 perennial), all native to North America. However, wild sunflowers have been inadvertently and intentionally introduced into several countries where they have become naturalized, most notably in Australia, Argentina, and southern Europe. The distribution of the wild naturalized sunflower species in Australia occurs primarily within the states of Queensland (QLD), New South Wales (NSW), Victoria (VIC), South Australia (SA), and West Australia (WA). Since these species have been naturalized in Australia, the possibility exists that they may have traits distinct from their North American progenitors due to the different environments and disease and insect pest complexes. Prior to the exploration, there were no populations of wild sunflower from Australia in the USDA-ARS National Plant Germplasm System (NPGS) wild sunflower germplasm collection. This germplasm would greatly increase the available genetic diversity for these species from outside of North America. The objective of this exploration was to collect achenes from as many populations as possible of *H. annuus* and *H. debilis*, and make them available for future research and improvement of cultivated sunflower and *in situ* preservation for the future. The Australian exploration took place from February 22 through March 14,2007. It covered 10,000 km in the states of QLD, NSW, VIC, SA, and WA. Five days were spent exploring WA. In spite of the extreme drought, 14 populations of naturalized *H. annuus* were collected. Six days were spent exploring SA, SW and VIC. These states were especially hard hit with drought, but 21 populations of naturalized wild *H. annuus* were collected. An exploration to Queensland, also suffering from extreme drought, resulted in the collection of two populations of wild naturalized *H. annuus* and two populations of *H. debilis* ssp. *cucumerifolius*. The germplasm collected will be evaluated for oil concentration and fatty acid composition, as well as screened for various diseases and insects as a potential source of genes for the improvement of cultivated sunflower. The origin of the naturalized populations of wild sunflower in Australia is still open for discussion. The species found there are commonly grown in gardens as ornamental flowers and escapes. It is also possible that the seed was inadvertently introduced in imported forages, or possibly mixed in bird seed. Currently, the time of the introduction of the wild species into Australia is not known. Future population studies will help to answer that question.

Conservation of *Ainsliaea fragrans* in Kochi, Japan

Akihiro Seo[1], *Maeda Ayako*[1], *Yabe Kota*[1], *Hayashida Taishi*[1],

Sugimoto Sayako[2], *Ishikawa Shingo*[2]
1. Makino Botanical Garden
2. Kochi University

Biodiversity in Kochi prefecture has been decreasing predominantly due to human activity and presumably climate change. The protection of plant diversity in the prefecture has been a key priority for The Makino Botanical Garden of Kochi Prefecture (MBK), one of many local botanical gardens in Japan. The garden has initiated several conservation projects, one of which is the conservation of the endangered understory herb *Ainsliaea fragrans* Champ. (Compositae). This plant species is distributed in southern China, and southwestern Japan. In Japan, its easternmost geographical distribution is Kochi Prefecture where it occurs at a single locality and is listed as an endangered species. However, the ecological requirements of *A. fragrans* are poorly known and with the hope of conserving this species, its population dynamics and habitat were observed and analyzed. The habitat of Japanese populations of *Ainsliaea fragrans* is in the understory of forests. Our observations of the habitat at the Kochi study site have shown the vegetation here to be a mosaic of secondary mixed forests dominated by *Castanopsis sieboldii* and deciduous forest dominated by *Vernicia cordata*. The habitat of *A. fragrans* at the study site occurred only under the deciduous forest where seasonal change in light intensity during autumn and winter was higher than in summer. The niche for *A. fragrans* seems to be the relatively bright areas of the forest floor that received higher autumn and winter light. The increase in light during winter seems to be an important factor for the growth of *A. fragrans*. At MBK an *ex-situ* population sourced from the wild population in 1989 was established in the nursery and subsequently provided a source of plants for this study. We initiated two experiments to test our hypothesis; the first started in July 2016 and investigated the effects of different levels of light on plants grown in the nursery. The second involved translocating 100 plants from the *ex-situ* population back to the original wild population at locations under both a deciduous and evergreen canopy in October 2016. Data from the wild population has been collected here since July 2016 and air temperature, humidity, soil moisture and light intensity at the study site were measured and recorded using data loggers. The survival rate of these plants and response to differing light levels *in-situ* was also observed and recorded. Results from the *ex-situ* investigation have shown a higher mortality rate during summer under brighter conditions than under shaded conditions. On the other hand, the mortality during autumn was not clearly different between these conditions. These results did not conflict the hypothesis. The translocated population of *A. fragrans* has not fluctuated under either a deciduous or evergreen canopy, although the observation period was short. Ongoing observations of both the tranlocated population and wild population of *A. fragrans* are required to analyze the correlation between environmental conditions and the survival rate of *A. fragrans*.

Dendroclimatological investigation of the relict chestnut-leaved oak *(Quercus castaneifolia)* in azerbaijan

Farid Seyfullayev, *Vahid Farzaliyev*
Central Botanical Garden of Azerbaijan National Academy of Sciences

The chestnut-leaved oak (Quercus castaneifolia) is a species of oak in the turkey oak section Quercus sect. Cerris. It is naturally distributed in Azerbaijan and Alborz mountains of Iran, It is a deciduous tree growing up to 35 m tall, with a trunk up to 2.5 m diameter. Tree ring widths were measured in Lintab measuring stage with TsapWin program. Anatomical features were measured under microscope. Investigations were carried out by using dendroclimatological, anatomical methods. Response function results showed that current year May and June precipitation positively, current year June and July temperature negatively influenced annual radial growth. According mean radial growth deviation analysis, during droughts growth was 30-40% less; in wet years were 40-60% more than mean. Calculated Pimm indices showed that even 1-2 years after drought tree didn’t reach normal growth level. All these analysis showed that this species is very sensitive to local climate change, depending on the changing precipitation and temperature radial growth strongly changing. As a result of global climate change, there are forming new microclimates which affect radial growth in the natural distribution area of the oak. These new extreme conditions forming frost scars in the wood. In Europe these kinds of scars forming one time in a century. But in our case in samples which were collected from high limit (1450 m) of the distribution oak in Lenkoran region, were observed 7 frost rings during last 60 years. Interesting point that 5 frost rings were formed last 30 year. It means last times local climate changed extremely and that is why oak is not adapted to it. Our investigation showed that effects of the climate change are clear in high limit. If it will continue by this way, during next decades’ effect of changes will be visible in the low elevation and will negatively affect growth.

Biogeography, ethnobotany and conservation status of *Pinus gerardiana* from Pakistan

Amin Ullah Shah, *Sarvat Rahim, Arif Muhammad Khan*
University of Sargodha

Pinus gerardiana Wall. ex D. Don (Chilgoza pine) is regarded as a unique, highly specialized and marvelously improbable gymnosperm belonging to family Pinaceae. It has attained the greatest economical value because of its delicious edible nuts (rich in carbohydrates, proteins and fats) throughout the world. Chilgoza pine tree is also unique because of its endemism as it is only restricted to Asia in the world and is native of Afghanistan, India, Pakistan and some parts of China. The distribution of *P. gerardiana* in Pakistan is limited to Zhob, Chilas, Astor, Swat, Chitral, GilgIt, Kurram Valley, Tangir Valley and Kashmir mostly. This species contributes a lot to the economy by providing valuable nuts that find a very briskly market both in the country as well abroad. Reckless cone extraction and almost complete lack of natural regeneration (mostly people pick all the cones from a tree for nuts and the fallen nuts are wiped out by rodents and birds) have led this valuable tree on the verge of extinction which deserves immediate attention for genetic conservation and improvement. Genetic variation is one of the most important components in maintaining population viability and resilience to environmental stress. The basic pre-requisite for genetic improvement and protection of genetic resource is the study of genetic variability. Biogeography and conservation status studies of *P. gerardiana* are urgently needed to properly manage conservation strategies on scientific ground and yet to preserve the species as an industrial plant as well as landscape tree.

Ethnobotany and floristic diversity in Eastern Ghats of India

Mahammad Khasim Shaik
Acharya Nagarjuna University

The ethnobotanical and floristic diversity studies were carried out in some sacred groves (protected forest patches) of Eastern Ghats of India, from 2011-2015. The ethnomedicinal knowledge was gathered through interviews of tribal physicians. Data collected were processed using Microsoft Excel spreadsheet. The data was analyzed using the fidelity level (FL) of each species determined. Floristic diversity studies of sacred groves were conducted by using random quadrate method (1m × 1m for herbs, 5m × 5m for shrubs and 10m × 10m for trees) for vegetation analysis. Ethnobotanical study revealed that therapeutic applications of 87 plant species belonging to 76 genera and 45 families. These plants are used to cure various ailments such as malaria, jaundice, diabetes, bronchitis, fevers *etc.* The majority of remedies were taken orally in the form of juice extracted from freshly collected plant parts harvested from the wild. Plants that have the highest FL values are *Gymnema sylvestre* (100%) and *Andrographis paniculata* (100%), followed by *Phyllanthus amarus* (91%). The lowest is *Woodfordia fruticosa* (46%). The most used plant parts are leaves. Floristic diversity analysis revealed that a total of 344 species belonging to 101 families were observed in the sacred groves. The total number of species encountered in four sacred groves was 222,139,195, and 186 species in Dummakonda, Korukonda, Peddakonda and Rampa sacred groves respectively. Total density of tree species ranged from 33.2 to $56.1m^2/ha^{-1}$ and total basal area of all species between $8.61\text{-}18.59m^{-2}/ha^{-1}$. The Shannon-weiver index of herbs ranged from 2.914 to 3.368, for shrubs 2.617 to 3.154 and for tree species 2.803 to 3.534 respectively. These diversity indices reduced on more disturbed sacred grove (Korukonda) than undisturbed sacred grove (Dummakonda). Over-exploitation, deforestation and Podu-cultivation are main threats for medicinal plant vulnerability. The anthropogenic pressures such as more urbanization, encroachment and modernization of the temple are main cause for loss of sacred grove biodiversity. With the above findings it is concluded that documentation of ethnomedicinal knowledge provides basic data for further studies on pharmacology and conservation practices are immediately needed and recommended for the local community participation for successful conservation.

A non-destructive DNA sampling technique for herbarium specimens

Lara Shepherd
Museum of New Zealand Te Papa Tongarewa

Herbarium specimens are becoming increasingly popular as a source of DNA for plant research. They provide a ready source of material for rare, extinct and difficult to obtain taxa and can provide historical perspective. However, sampling herbarium specimens for DNA is not without its drawbacks. Herbarium specimens are a finite resource and the removal of part of a specimen for DNA extraction may limit its future use by both geneticists and other researchers. Non-destructive DNA extraction methods have been developed for other museum specimens including teeth, bones and invertebrates. Here I describe a nondestructive method to isolate DNA from the leaves of robust herbarium samples. The sampling for this method is cheap, straightforward and requires no special equipment. Using this method DNA was successfully obtained and PCR amplified from herbarium specimens up to 50 years old.

Flora and vegetation of the Meskheti and Javakheti (Lesser Caucasus)

Shamil Shetekauri[1], *Davit Chelidze*[2], *Nana Barnaveli*[1], *Tolkha Shetekauri*[1,2]
1. Ivane Javakhishvili Tbilisi State University
2. National Botanical Garden of Georgia

The study area represents provinces of south Georgia and is divided into three floristic provinces: Euxine, Armeno-Iranian and Caucasian (Grossheim, Sosnowski, 1928; Takhtajan, 1986). The flora and vegetation is more or less different from plant species of Mediterranean, Iran-Turkish and northern hemispheric geographical areas. The vascular plants of study area consist of 1,652 species, 561 genera and 131 families. The following vegetation types are represented in Meskheti and Javakheti: riparian, middle and high mountain forests, xerophilic shrublands, halophilous vegetation with *Nitraria schoberi*, vegetation of high mountain meadows and steppes, wetlands, petrophyton and subnival belt vegetation. Phytocoenological composition of wetland vegetation of the Javakheti lakes (Tabatskuri, Paravani, Kartsakhi, Sagamo, Madatafa) and their surroundings is mainly defined by Eurasian, West Asian-Caucasian and European-Mediterranean species including *Carex juncella (=C. wiluica), C. panicea*, *C. irrigua, C. vesicaria, Calamagrostis canescens, Sagittaria sagittifolia, Menyanthes trifoliata, Utricularia vulgaris etc.* Surroundings of Tetrobi-Chobareti limestone area are distinguished by special botanical-geographic diversity on the Lesser Caucasus. A significant portion of the calcephilous flora is represented by species of Lesser Caucasian-Anatolian geographic type: *Arenaria steveniana, Asphodeline taurica, Scorzonera ketzkhovelii, Cerastium sosnowskyi, Silene dianthoides*, *etc.* Such diversity of the Tetrobi flora is related to the location of the area on the floristic intersection of the Lesser Caucasus, Armenia and Iran as well as isolation of the Tetrobi limestone massif, which is in turn connected with the history of geodynamic processes on the Javakheti. Subnival zone on the Javakheti vulcanogenic plateau is present only on Mts. Abuli (3,304 m) and Samsari (3,284 m). During the florogenesis of subnival belt of the Lesser Caucasus a decisive role was played by the floristic centre of Anterior Asia and a minor role by the floristic center of the Greater Caucasus and arcto-alpine floristic centres.

The Poales Order in the state of Aguascalientes, Mexico

José Carlos Sierra Muñoz[1], *María Elena Siqueiros Delgado*[1], *Rosa Cerros Tlatilpa*[2], *Joaquín Sosa Ramírez*[1]
1. Universidad Autónoma de Aguascalientes
2. Universidad Autónoma del estado de Morelos

The order Poales is one of the groups of plants with greater importance for the human being, currently includes 16 families and presents a cosmopolitan distribution. Mexico is recognized as one of the most biodiverse countries on the planet, however, knowledge of the plant species that inhabit its territory is still limited. In order to contribute to the knowledge of the flora of the state of Aguascalientes, a taxonomic study of the species of the order Poales that are distributed in its territory is carried out. To date, a total of 56 sites have been sampled throughout the State and 1012 samples have been obtained that were properly herborized for taxonomic determination. Also, a total of 2,322 herbarium specimens deposited in the HUAA herbarium. Currently the Poales order in the state of Aguascalientes includes 275 species: 204 of the family Poaceae, 49 of Cyperaceae, 10 of Juncaceae, 9 of Bromeliaceae, 2 of Eriocaulaceae and one of Typhaceae. 26 species have turned out to be new records for the state. It has a preliminary floristic list and a preliminary distribution map that allows to conclude that the order Poales presents cosmopolitan distribution throughout the territory of the State, the families Bromeliaceae, Cyperaceae and Poaceae are those that present the most generalized distribution; Eriocaulaceae, Juncaceae and Typhaceae are characteristic of wetlands and bodies of water throughout the State. Up to now none of the species is in any of the categories of Official Mexican Standard (NOM-059-SEMARNAT-2010) and is not considered vulnerability in their populations.

Ethno-ecological survey of underutilized plant diversity of Hamirpur District, Himachal Pradesh, India: An edibility assessment

Anand Narain Singh, *Ramchand Bhatti*
Panjab University Chandigarh

The present study was conducted to explore diversity and status of underutilized wild edible plants of Hamirpur district, Himachal Pradesh, India. Total 85 plant species of 66 genera belonging to 39 families under various life forms and origins were recorded; in which, 30 species as trees (25 native and 5 exotic), 11 shrubs (6 native and 5 exotic), 28 herbs (10 native and 18 exotic) and remaining 16 were creepers (12 native and 4 exotic). Edibility index (EI) showed 100% score of edibility by two species, while 80% was shown by 11 species, 40% by 3 species and remaining 69 species showed 10 to 30% only. Across family, maximum utilization efficiency (10 score) was found only in 2 families (Apiaceae and Violaceae), while 5 families (Chenopodiaceae, Commelinaceae, Liliaceae, Oxalidaceae and Portulaceae) have shown 8 and one family (Amaranthaceae) exhibited 5.8 score followed by 31 other families. In this study, it was observed that consumption mode of various plant parts were either fresh or cooked. In conclusion, present study may help in alleviating food scarcity, malnutrition and can be employed further as commercial crop plants for the welfare of human in developing countries.

Reintroduction of *Bentinckia nicobarica* in Nicobar Islands- A case study

Pushpa Kumari, *Paramjit Singh*, *Reshma Lakra*
Botanical Survey of India

Bentinckia, a palm genus is restricted to Indian subcontinent with *B. nicobarica* reported from Nicobar Islands. Usually, Island species are within their limited area of distribution not having any chance of migration. The Andaman and Nicobar Islands represents

86% of forest coverage including tropical rain forests, tropical moist deciduous forests, lowland forests *etc.* with a total geographical area of 8,249 sq. km while the Nicobar group of Islands covers an area of 1,841 sq. km. *Bentinckia nicobarica*, belonging to the family Arecaceae is one of the tall palms growing up to ±50 m height with small globose, blackish fruits (when ripen) in big bunches. An endemic to the Nicobar Islands, it specifically grows in moist hills, valleys, plains and slopes of lowland forests of Nicobar group of Islands mainly in Great Nicobar, Kachal, Nancowry group, Teressa, Chowra and Car Nicobar Islands. In the year 1988, "The IUCN Red List of Threatened Species" assigned this species endangered category. *Bentinchia nicobarica* is used in the Islands for housing, furniture, boat making *etc.* by the tribal of Nicobarese and Shompen. The emerging shoots are eaten by the local people as vegetable and the fallen fruits are eaten by pigs. Due to all these activities over the time the species population has declined very much in these islands. Considering the importance of the species the present study has been taken to investigate its population, multiplication and reintroduction. The method of ecological niche modelling (ENM) map is applied by using the modeling algorithms of DIVA-GIS and MAXENT. Nineteen bioclimatic variables are used as environmental variables for modeling, which includes Annual Mean Temperature, Mean Diurnal Range, Isothermality, Temperature Seasonality, Maximum Temperature of Warmest Month, Minimum Temperature of Coldest Month, Temperature Annual Range, Mean Temperature of Wettest Quarter, Mean Temperature of Driest Quarter, Mean Temperature of Warmest Quarter, Mean Temperature of Coldest Quarter, Annual Precipitation, Precipitation of Wettest Month, Precipitation of Driest Month, Precipitation of Seasonality, Precipitation of Wettest Quarter, Precipitation of Driest Quarter, Precipitation of Warmest Quarter, Precipitation of Coldest Quarter *etc.* Through this modeling, we could predict the potential area of occurrences the species and their reintroduction for the population study and the limiting factors. More than four thousand seedlings of *B. nicobarica* are raised so far in controlled condition in polyhouse of Dhanikhari Experimental Garden Cum-Arboretum, Botanical Survey of India, Andaman and Nicobar Regional Centre and being reintroduced in the identified habitat for improving their conservation status.

Moss genera *Leratia, Lewinskya, Nyholmiella* and *Orthotrichum* in China

Zuzana Skoupa[1], *Guo Shuiliang*[2], *Mamtimin Sulayman*[3], *Lucie Fialova*[1], *Vitezslav Plasek*[1]
1. University of ostrava
2. Shanghai Normal University
3. Xinjiang University

In total, the traditionally conceived genus *Orthotrichum* s.l., it currently consists of 45 species in China, including one species of the genus *Leratia*, 15 of the genus *Lewinskya*, one of *Nyholmiella* and 28 of *Orthotrichum* s.str. This study provides new data on the distribution of species based on a critical revision of material from Europaean herbarium, including PC, B, H, W, C and LE, and from four largest Chinese herbaria, namely KUN, PE, IFP (formerly IFSBH) and XJU and field survey of 7 Chinese provinces. One species of the genus *Lewinskya* and two of *Orthotrichum* were recently recorded for the first time in China and moreover 20 species are newly reported by authors from various provinces in China, including Gansu, Heilongjiang, Hubei, Hunan, Inner Mongolia, Jiangxi, Jilin, Qinghai, Shaanxi, Shanxi, Shandong, Sichuan, Xinjiang, Xizang, Yunnan and Zhejiang. Detail distribution and ecological requirements of the species are discussed. Although, species richness of the Orthotrichalean mosses is relatively high in China, it is largely unbalanced in different parts of this country. Species diversity is perceptibly decreasing from the west to the east. Surprisingly, no species within the moss group have been recorded until now in four Chinese provinces (Guangdong, Guangxi, Henan and Ningxia).

Historical biogeography in Fouquieriaceae (Ericales) with special focus in succulence, and chromosome evolution

Fabiola Soto-Trejo[1], *Susana Magallón*[2], *Ken Oyama*[1]
1. Escuela Nacional de Estudios Superiores Unidad Morelia, UNAM
2. Departamento de Botánica, Instituto de Biología, UNAM

We estimated the biogeographical history of Fouquieriaceae, a small family from arid and semiarid regions of Mexico and southwestern USA, and evaluated hypotheses concerning its biogeographical origin and evolutionary history. We used modern likelihood-based models and methods of statistical model comparison as implemented in BioGeoBEARS for biogeographical inference. The best-fitting biogeographical model showed that the crown node of Fouquieriaceae may have originated in the upper Miocene, around 6.6 Mya in either Baja California desert, the Sonoran desert, or the Tehuacán-Cuicatlán area. This high uncertainty at deeper nodes in the phylogeny could be due to the fact that the split between extant Fouquieriaceae and its sister family Polemoniaceae occurred around 86 Mya, which preclude the inclusion of Fouquieriaceae's relatives that would yield more support in ancestral range estimation. Additionally, the family is a small clade (10 species), some of the species are relatively widespread, and sister species tend to have different geographic ranges, which could affect biogeographic inference. However, we tested if other sources of information such as the succulence and chromosome evolution within Fouquieriaceae could contribute to the identification of the biogeographic origins in this family.

The plant diversity of the coastal tropical bog, an endangered habitat of South-East Asia Mainland: A case study in the Peninsular Thailand

Kitichate Sridith
Department of Biology, Faculty of Science, Prince of Songkla University

The surveys of plant diversity have been achieved in the tropical bog along the coast in the Peninsular Thailand, which is the part of South -East Asia mainland as a case study of plant diversity in such endangered habitat on the sandbars along the coast of the

Tropical Asia. These coastal sandbars, created by the sea current in the pass, have performed various high ridge dunes as well as lower flat deposition areas between dunes. The ground water permeating in these lower areas between such dunes caused the swampy condition in the place where the water level is higher than the ground, while in the place where the ground water level is about the same as the ground between dunes which comprised of fine silt, it has turned such sandy ground to become permeated areas or "bog". The water of those swamp and permeated areas is weak acidic, due to the peat depositing condition of the developed peat swamp vegetation in the swamp between the dunes. This special acidic condition is allowed only very low nitrate and less microorganism available. This is so called "tropical bog". In which, a special plant community has adapted. The selected groups of plants in such plant community have got Nitrogen from an animal protein in this low Nitrogen condition of soil i.e. the carnivorous plants e.g. genera *Nepenthes* spp., *Utricularia* spp., *Drosera* spp. *etc*. And there is a possibility that this plant community might play some important role in maintaining the balance between nutrient cycling in the coastal dune system which, on the other hand, is not have some impacts to the required plant nutrient level and physical environment conditions among the coastal dunes system only, but to the nearby inland habitats next to the coastal dune system as well as the marine habitats along the coast where the dunes occurred.

The relation between green tea consumption and CVD (cardiovascular disease) development as action plan for the prevention and control: A systematic review

Fairuza Syarfina, *Aprillia Hardiyani Tanto, Safira Adilla, Fahmi Dimas Abdul Azis, Prima Alifian Hergaputra*
Airlangga University

Background: Tea (*Camellia sinensis*) is one of the most popular beverage in Asia.Tea products can be divided into three categories based on the degree of fermentations, one of them is green tea (unfermented tea). Many researchers have reported antioxidant activity of green tea to prevent chronic diseases. Daily consumption of green tea can reduce the development of atherosclerotic complication related to stroke, myocardial infarction, coronary heart disease, and CVD (cardiovascular diseases). Every year there is increasing number on people die annually from CVD than from any other causes. CVD is the number one cause of death in the world and over three quarters of CVD deaths take place in low and middle income countries. The use of dietary substances in healthy lifestyle takes important role for preventing individuals who have risk factors for developing atherosclerotic complication. There are evidences from clinical studies which prove that green tea can play protective role in the development of CVD. Various components of green tea, especially polyphenol, have antioxidant and antidyslipidemic activity. The utilization of green tea are considered to be potentials in preventing the development of atherosclerotic and CVD. Green tea is also reported with its ability to recover the metabolic abnormalities by various mechanisms. Objectives: The aim of this study was to review the relation between green tea consumption and CVD development. Methods: Published observational studies and meta-analysis (2013-2017) addressing green tea or green tea polyphenol and CVD were identified based on searches of on-line database (Elsevier, Science Direct, PubMed). Results: The number of clinical studies in this field is still limited. Eight research articles met inclusion criteria have been conducted and summarized. The results in clinical studies showed the significant reduction in total and low-density lipoprotein (LDL) cholesterol in subjects who received green tea group compared to the control group. Green tea consumption has found to be inversely associated with the development of CVD. The group received 2-3 cup green tea/ day had less incidence of myocardial infarction, hyperlipidemia risk, and stroke risk compared to the <1 cup/ day group. Taking green tea is effective in reducing atherosclerosis risk associated oxidative stress. Conclusions: Behavioural risk factors such as unhealthy diet affected the development of CVD. The utilization of dietary substances such as green tea have promising potential to prevent the development of CVD complications. In general, green tea consumption is recommended for maintaining human health.

Biodiversity and ecosystem services in Morocco: Current state, threats and conservation strategies

Mohammed Sghir Taleb
Institut Scientifique, Mohammed 5 University in Rabat

Located at the northwest corner of the African continent between 21° and 36° north latitude and between the 1st and the 17th degree of west longitude, Morocco with a total area of 715,000 km^2 enjoys a privileged position with a coastline of 3,446 km long opening to the Mediterranean and the Atlantic Ocean. Morocco is characterized by an important genetic diversity represented by a rich and varied flora with 5211 species and subspecies and many natural ecosystems. This biodiversity is currently subject to many pressures: overgrazing and deforestation, climate change, including increased drought, urbanization and forest fire. Conscious of the risks that weigh on biodiversity, Morocco set a strategy of management of biodiversity that focus on programs of *in situ* and *ex situ* conservation. This presentation will be focused on the current state of biodiversity, on the different pressures (grazing, timber harvest, harvesting of medicinal and aromatic plants, charcoal making..) and the efforts constructed by Morocco to conserve and sustainably manage biodiversity.

Plant inventory research in Myanmar: Materials towards the Flora of Myanmar

Nobuyuki Tanaka[1], *Mu Mu Aung*[2], *Shuichiro Tagane*[3], *Akiyo Naiki*[4], *Norio Tanaka*[1], *Hidetoshi Nagamasu*[5], *Thaung Naing Oo*[2], *Tsukasa Iwashina*[1]
1. National Museum of Nature and Science
2. Forest Research Institute, Ministry of Natural Resources and Environmental Conservation
3. Center for Asian Conservation Ecology, Kyushu University
4. Tropical Biosphere Research Center, University of the Ryukyus
5. he Kyoto University Museum

Myanmar (Burma) is located south of the Himalayan region, spans from the mangrove forests and coral reefs of the Andaman Islands in the south, to the snow-capped peaks of Mt. Kakaboradzi (5,881 m) in the north, and Myanmar embraces incredible floral diversity. However, more than half a century has elapsed since botanists previously botanized in the country until 1960's. Due to political situation, there have been nearly 50 years blank of the floristic investigation. Further expeditions were carried out in 2000's, however most of the regions have still not been botanized. Therefore much still remains to be learnt of its flora as well as of its floristic relations with neighboring regions of Asia. National Museum of Nature and Science, Japan (NMNS) and Forest Research Institute (FRI), Ministry of Natural Resources and Environmental Conservation embarked the international joint inventory research project to collect the materials towards the "Flora of Myanmar" under the MoU (Memorandum of Understanding) covering whole regions in Myanmar. Although this memorandum covers not only for the plants, but also fungi, lichens, insects *etc.*, in the whole regions in Myanmar. We are focusing on the hitherto-unexplored areas in Myanmar; especially peninsular part, such as Tanintharyi (Tenasserim), Lenya and Lampi Marin National Park in the Mergui Archipelago. Our inventory research activity is introduced here focusing on the results of vascular plants. In 2016 we performed the Japan-Myanmar joint inventory research in Tanintharyi, Indawgyi Lake Wildlife Sanctuary (Kachin State), Htamanthyi Wildlife Sanctuary (Sagaing Region) and also other regions. Besides dried and pressed herbarium specimens, alcohol preserved specimens, and leaf materials for DNA analyses were collected. The herbarium specimens are deposited in TNS (NMNS) and RAF (FRI), the only one Myanmar herbarium registered in the Index Herbariorum. As the results of the inventory research in 2016, ca. 7,200 vascular plant specimens including duplicates were made. In Annonaceae, Ebenaceae, Euphorbiaceae, Lauraceae, Melastomataceae, Zingiberaceae *etc.*, many taxa were considered to be new or newly recorded from Myanmar. These results will be published as a series paper such as "Contributions towards the Flora of Myanmar". Furthermore the data from our intensive inventory works in the unexplored areas would provide the significant materials for compiling a full flora of Myanmar. In order to further efforts in floristic research, as well as to contribute to the development of human resources in Myanmar in general, it is necessary to provide international assistance in this respect. Part of our project in Myanmar involves cooperation with our partner institutes to help promote the development of human resources.

An early Oligocene palynoflora from Yunnan, Southwest China

He Tang[1,3], *Shu-Feng Li*[1], *Tao Su*[1], *Zhe-Kun Zhou*[1,2]

1. Key Laboratory of Tropical Forest Ecology, Xishuangbanna Tropical Botanical Garden, Chinese Academy of Sciences, Mengla, Yunnan 666303

2. Key Laboratory for Plant Diversity and Biogeography East Asia, Kunming Institute of Botany, Chinese Academy of Sciences, Kunming 650201

3. University of Chinese Academy of Sciences, Beijing 100049

Following the Eocene-Oligocene transition (~33.9Ma), the Oligocene is an important period marks the establishment of modern vegetation. Until now, fossil-bearing Oligocene sediments with absolute geological dating are relatively rare in China, especially in Southwest China, a biodiversity hotspot worldwide. Recently, a plant fossil-bearing outcrop with several volcanic tuff layers was discovered from Lühe Basin, in central Yunnan Province, Southwest China. The U-Pb dating results show an unequivocal early Oligocene age of this section (33-32 Ma). To better understand the plant diversity of Oligocene flora in this region, we did a combined LM/SEM investigation for the palynomorphs extracted from the outcrop. The early Oligocene palynological assemblage of Lühe was composed of 46 palynomorphs, belonging to 39 genus, covering angiosperms (13%), gymnosperms (73.9%), ferns (8.7%) and other elements (Fungi and Alge, 4.3%). Our result shows that the palynoflora of Lühe was dominated by gymnosperms (41%, such as *Piceapollenites, Pinuspollenites, Tsugapollenites, Ephededripites*), the angiosperm taxa were dominated by (*Alnipollenites, Betulaepollenites, Betulacepollenites, Carpinites, Ulmipollenites, Quercoidites*). Generally, this palynoflora indicate a needle- and deciduous broad-leaved mixed forest with warm and humid subtropical elements in the early Oligocene of central Yunnan. This vegetation type suggest a temperate to subtropical humid climate in this region during the early Oligocene.

Tackling indonesia's diabetes challenge with Indonesian traditional herbs as dietary therapies to reduce development of cardiovascular complications: Promotion the use of natural product

Aprillia Tanto, *Fairuza Syarfina, Fahmi Dimas Abdul Azis, Safira Adilla*

Airlangga University

Objectives: Indonesia's biggest challenge in the next 10-15 years is non-communicable diseases (NCD) like cardiovascular and diabetes with its complication which are accounted for nearly 50 percent of deaths in the country. As of 2014, Indonesia's diabetes population was the fifth largest in the world, International Diabetes Federation (IDF) predicted more than 14 million Indonesians will suffer diabetes in 2035. Dietary therapy can reduce the risk of diabetes development and its cardiovascular complication. Indonesia as a country that is rich in natural sources has the opportunity to maximize the utilization and benefits of its natural products. Indonesian traditional herbs have been used to treat disease and nowadays they are being scientifically developed for therapies. These natural products are considered to have potentials in delaying the development of diabetes and its complications and to be able to cure the metabolic abnormalities using a variety of mechanism. Methods: Comprehensive literatures were used to review Indonesian traditional herbs used in the management of diabetes. An online database research from Elsevier, Science Direct, and PubMed was conducted to find literature on herbs growth in Indonesia that improves health outcomes in the development of diabetes and its cardiovascular complication. All of the data were analysed with descriptive technique. Results: Indonesian traditional herbs such as *Momordica chatarantia*, *Trigonella foenum-grae-*

cum, *Zingiber officinale*, *Curcuma domestica*, *Allium sativum*, *etc.* have been proven to produce significant improvement of blood glucose, 2 hour post load glucose, A1C, LDL-C, blood pressure level as compared with control intervention which have antidiabetic and cardioprotective activity with different mechanism of action. Conclusions: Indonesian scientifically proven traditional herbs have potentials to be used as dietary therapies to reduce the development of diabetes and its complication. It can be the investment to tackle global challenge for reducing deaths caused by diabetes and its cardiovascular complication.

Diversity and pharmacology study of selected Zingiberaceae from Peninsular Malaysia

Yannick Tatin
Tropimundo - Erasmus Mundus Master Program

The Zingiberaceae diversity of a restricted area of Kenyir Lake (Terengganu, Malaysia) was characterised using different richness indices. A high diversity was found (α-diversity value H' = 2.04) with sixteen species belonging to five genera. Besides, potential medicinal properties (antimicrobial and cytotoxicity assays) of four *Etlingera* species (*E. megalocheilos, E. metriocheilos, E. punicea, E. pauciflora*) found in the study site were tested using rhizome crude extracts. In vitro antimicrobial assay was performed with the agar disc diffusion method against eight bacteria strains *Vibrio algninolyticus, Vibrio cholera, Eschercia coli, Klebsiella pneumonia, Pseudomonas aeruginosa, Salmonella* sp., *Staphylococcus aureus, Bacillus cereus, Streptococcus uberis* and *Micrococcus* sp. The crude extract of *E. punicea* exhibited the best antimicrobial activity against *S. aureus, S. uberis* and *K. pneumoniae* (inhibition zone of 11.5 mm, 13 mm and 18.75 mm respectively at 100 mg.ml^{-1} of crude extract) whereas *E. pauciflora* was the most efficient against *Microccocus* sp. (inhibition zone of 36mm at 100 mg.ml^{-1} of crude extract). No activity was exhibited against the four other strains of bacteria by any plant. The cytotoxicity against MCF7 cancer cells was tested using the MTT assay method. The crude extract of *E. punicea* exhibited the best cytotoxicity (LC_{50} = 18 g.ml^{-1}) followed by *E. metriocheilos* (LC_{50} = 29.2 g.ml^{-1}), *E. megalocheilos* (LC_{50} = 33.4 g.ml^{-1}) and *E. pauciflora* (LC_{50} > 100 g.ml^{-1}).

International germplasm conservation, database construction and cultivar registration of *Nelumbo*

Daike Tian[1,2], *Fengluan Liu*[1,2], *Dasheng Zhang*[1,2], *Qingqing Liu*[1,2], *Qing Chen*[1,2, 3], *Jie Min*[1,2, 4]
1. Shanghai Chenshan Plant Science Research Center of Chinese Academy of Sciences, Shanghai Chenshan Botanical Garden, Shanghai, China
2. Shanghai Key Laboratory of Plant Functional Genomics and Resources, Shanghai, China
3. Fujian Agriculture and Forestry University, Fuzhou, China
4. Hunan University of Science and Technology, Xiangtan, China

Lotus (*Nelumbo*) has over 2,500 years of history in cultivation, and it is the national flower of India, as well as one of the traditional Chinese flowers due to its medicinal, edible, ornamental and cultural values. There are only two living species (*N. nucifera and N. lutea*) but nearly 2,000 cultivars in *Nelumbo*. For the purpose of promoting germplasm conservation, scientific research, industry, and public education of lotus, an integrative project is developing at Shanghai Chenshan Botanical Garden of China, China. So far, more than 700 genotypes (species, varieties and cultivars) of lotus has been globally collected and *ex situ* conserved in this garden. The International *Nelumbo* Database or Website is also constructed, from which, the information extensively covered on lotus is available, including literature, database of species and cultivars, scientific research, industry, culture, international lotus cultivar registration, lotus forum, important links, and so on. In addition, the projects are undergoing on lotus cultivar identification, population diversity, mechanisms of double-flower development and petal coloration through the integrated morphological, physiological and molecular methods.

Privileged-account herbarium plant specimen archival management system

Kun-Chan Tsai[1], *Jenn-Che Wang*[2], ***Chin-Shan Tien***[1]
1. Microtek
2. National Taiwan Normal University

The digitization of herbarium specimen collection consists of two time-consuming processes, one is specimen label recognition and the other is verification of metadata prior to uploading for public access. The latter part is especially vital and usually determined by experienced taxonomists to guarantee the explicit information and image quality (focus, brightness, and contrast *etc.*) of each plant specimen. Given increasing budget vulnerability and limited time availability, the metadata digest rate of herbarium curators and managers can hardly match that of label recognition, further delaying expected digitization progress. The aim of this study is to introduce an image archival management system, which is characterized by (1) assigning privileged-account lists specific to distinct digitization steps, (2) maximizing metadata confirmation efficiency through joint global academic effort, (3) releasing specimen (metadata and image) for public access after professional verification, and (4) intuitive user-interface for a quick-start manipulation. The file structure follows default JSTOR standard, adding significant convenience between global herbaria for metadata sharing and exchanging. By coordinating with the implementation volunteer recruiting-and-training system specialized on specimen digitization and label recognition, herbaria curators and managers can fully devote to backstage management through this system to ensure specimen collection in corrected digitized format.

Promoting the conservation and creation of wetlands in Mexico through a Low Impact Design Demonstration Project

Cruz Elisa Torrecillas Nuñez[1], *Antonio Jose Miguel-Rodriguez*[2]
1. Universidad Autónoma de Sinaloa
2. SAMI Ltd

Low Impact Design (LID), also known as Green Infrastructure or Sustainable Drainage Urban Systems, is a technology that has been applied in developed countries for more than twenty years but its use is hardly known in Mexico. In Mexico there are 142 Wetlands of International Importance known as Ramsar sites, but there are practically no wetlands in modified environments as they have been destroyed by urban and agricultural land use. Society at large does not appreciate the value of wetlands, hence the need to demonstrate their benefits in cooperation with governmental and non- governmental agencies (NGO) such as CONAGUA, SEMARNAT, CONANP and Fabricas del Agua (a NGO that promotes reforestation in watersheds). This paper presents the results of a project being carried out at the Autonomous University of Sinaloa as part of its Green Campus Strategy with the purpose of demonstrating the feasibility of LID in the arid to semi-arid conditions found in the country. LID is used to control the impacts of deforestation and loss of wetlands and vegetative cover due to changes in land use which affect the balance of the water cycle by altering surface runoff, surface and underground storage and groundwater flows. As a result of the hydrological alternations, there are increases in peak flows and a decrease in the ecological flow, which leads to greater amplitude of flooding and the reduction of the recharge of the aquifers. Another consequence of land development is the generation of silt which smothers plant habitats and the discharge of contaminants which affect ecosystems. Additionally the loss of wetlands due to development leads to the alteration of natural habitats and the removal of wetland-dependent plants. Therefore there is a pressing need to develop and implement strategies to reduce these impacts. LID is a systematic process that begins by protecting ecologically important areas such as wetlands as part of development proposals. LID offers an optimal solution to mitigate the impacts as it addresses the causes by managing the impacts at their source, maintaining wetlands and the natural stream channels, and recovering the capacity of infiltration and storage present in the natural basin. Some of techniques used include: retention and detention ponds, artificial wetlands, rain gardens, bioretention systems, dry wells, permeable pavement, and vegetated swales. Plants play a critical role in LID through evapotranspiration, capturing and treating stormwater; the interaction of soil and plants helps to capture rainfall, reduce flooding and remove contaminants. The inclusion of native vegetation as part of LID ensures that plants are drought resistant and promotes biodiversity. It is expected that this project will have a significant impact as the Autonomous University of Sinaloa is the leading academic institution in Sinaloa State (Mexico), thereby being in a position where it can influence the attitude towards wetlands of the 2,966,321 persons who live in the state.

P0216

Population genotyping of a wild botanical species with the use of SNP TaqMan assays

Sonia Trujillo-Argueta, *Yesenia Pacheco Hernández, Rafael Felipe Del Castillo*
CIIDIR Oaxaca - Instituto Politécnico Nacional

Wild plant species DNA nucleotide sequences are less reported on genebanks, in comparison to economic plant species, so that studies on genetic diversity based on DNA, are more limited. Most nucleotide sequences reported on gene banks of native botanical species, come from phylogenetic relationships studies. We looked for these sequences in order to find SNPs and genotype *Malacomeles denticulata*, a native rosacea that grows from south USA to Central America. We searched for nucleotide sequences on this rosacea on NCBI gene bank. We found 19 sequences and only two transition mutation SNPs, which states for a base change from T to C. We also look for nucleotide sequences on genera closely related to *Malacomeles* and found another transition mutation SNP from *Amelanchier bartramiana*. The three sequences obtained holding an SNP were reported on nucleotide sequences of 5.8S ribosomal gen and internal transcribed spaces 1 and 2. All these sequences were analyzed with Repeat Masker software and Basic Local Alignment Search Tool (BLAST) so that a SNP TaqMan assay could be designed. Genomic DNA was obtained from leaves of *M. denticulate* that grew in seven different localities, in the state of Oaxaca, México, from soil eroded places to pine oak forests. After a PCR-RT, DNA samples could successfully amplified with each designed SNP assay and homozygous and heterozygous individuals, were registered. Since all three SNPs found, were in nucleotide sequences of 5.8S ribosomal gen and internal transcribed spaces 1 and 2, a linkage disequilibrium test was performed. No significant evidence ($P \leq 0.05$) was found that these three SNPs were linked. Genetic diversity analysis performed were percent polymorphic loci (P), mean number of alleles (A), effective number of alleles (Ae), Shannon index (S), genotype frequency, allelic frequency, observed heterozygosity (Ho) and expected heterozygosity (He). Genetic structure was calculated with the coefficient of endogamy (F). Higher values of P were observed on Teotitlán del Valle y Paraje Xía de San Juan Chicomezúchil populations (50% each). Teotitlán del Valle population, was the one that showed the higher mean value of observed heterozygosity (Ho = 0.306), followed by Ixtlán de Juárez (Ho = 0.253), Paraje Xía (Ho = 0.253) and Santo Domingo Yanhuitlán (Ho = 0.066) populations. San Pablo Huitzo, Díaz Ordaz and Santo Domingo Yanhuitlán gulls, hold homozygous populations for the three SNP assays analyzed. Estimates of genetic structure showed that all seven populations studied are genetically different (F_{ST} = 0.337) and, that there is an excess of heterozygotes inside each population (F_{IS}= -0.510). We could successfully genotype seven populations of a native rosaceae, with three SNPs found in the few nucleotide sequences reported on genebank on 5.8S ribosomal RNA gene and internal transcribed spaces 1 and 2.

P0217

Gender variation and sexual system diversity of *Elatostema* (Urticaceae) in Taiwan

Yu-Hsin Tseng[1], *Jer-Ming Hu*[2]
1. Biodiversity Research Centre, Academia Sinica
2. Institute of Ecology and Evolutionary Biology, National Taiwan University

Sexual systems are varied and complex in angiosperms, which has diversified at the level of the individual flower, inflorescence, plant individual, and within or between populations. The diverse sexual expression system in Elatostema provides a special case to study the evolution of sexual system. To investigate the gender expression of Elatostema in Taiwan, we closely scrutinized herbarium specimens for determining the sexual system. Among 15 Elatostema species in Taiwan, sexual systems can be categorized into four types: monoecious, dioecious, both monoecious and dioecious in same species, and female-only/female-biased species. In 52 individuals of five populations monitored over two years, six flower-opening patterns have been recorded in *E. lineolatum* var. *majus*, including pure male, pure female male→stop→male, male→female, male→female→stop→male, and male→stop→female. Additionally, based on the bagging experiment, molecular phylogeny and chromosome observation, three of female-only/female-biased species in Taiwan, *E. cyrtandrifolium*, *E. oblongifolium* and *E. rivulare*, were confirmed to be apomictic plants with polyploidy and evolved independently in different lineages. The results of flow cytometric seed screen and embryogenesis further demonstrated that these species should belong to an infrequent case of obligate autonomous apomixis.

Patterns of genetic isolation and diversification in limestone karst area: A case study of widespread *Begonia* (Begoniaceae)

Yu-Hsin Tseng[1], *Han-Yau Huang*[1,2], *Ching-I Peng*[2], *Kuo-Fang Chung*[1,2]
1. Biodiversity Research Centre, Academia Sinica
2. School of Forestry and Resource Conservation, National Taiwan University

Begonia sect. *Coelocentrum* is one of the most characteristic plant groups that can serve as a model system of limestone plant speciation. To test the hypothesis of allopatric speciation via isolation-by-distance triggered by extensive karstification, population genetics and phylogeography of a widely distributed limestone *Begonia*, *B. luzhaiensis*, were investigated by using EST-SSR markers and one chloroplast DNA sequence (*trnC-ycf6*), representing 171 individuals in 17 populations. Using next-generation sequencing (NGS) technique, 44,368 contigs were assembled, revealing 5,602 EST-SSR loci and resulting in 16 polymorphic EST-SSR markers for *B. luzhaiensis*. The *F*st analysis and Bayesian clustering approach implemented in Structure revealed a high level of population differentiation and a strong phylogeographical structure. Moreover, Mantel Tests indicated a significant positive correlation between genetic differentiation and geographic distances, concurring to geographic speciation via isolation-by-distance. Haplotype network reconstructed using *trnC-ycf6* sequences showed a highly geographic-correlated phylogeographic pattern, also supporting the hypothesis of population differentiation via geographic isolation. Our data support strongly the importance of extensive karstification in shaping the species diversity on the Sino-Vietnamese limestone karsts. The fragmented karst landscapes and the low dispersal ability of *Begonia* could have been the major driving forces that promoted genetic isolation among populations and resulted in allopatric speciation.

Biogeography and threatened categories of some Caucasian *Pyrus* L. (Rosaceae) species

Zübeyde Uğurlu Aydın[1], *Ali A. Dönmez*[2]
1. Hacettepe University
2. Hacettepe University

The geographical distribution of pears is concentrated in western Eurasia, especially Caucasia, and eastern Asia. In the study eight Caucasian *Pyrus* taxa, namely *P. caucasica*, *P. georgica*, *P. salicifolia*, *P. oxyprion*, *P. demetrii*, *P. cordata*, *P. elaeagrifolia*, and *P. taochia* were evaluated to show present biogeography and threatened category according to collected specimens from the region, herbarium samples and the relevant literature. Taking into account the collected samples from Turkey, it is clear that *P. georgica* and *P. demetrii* naturally grows further west part than currently known distribution in Caucasia. Turkey plays critical role for this dispersal manner because geographically it is located between Caucasia and Europe and it includes probable mountains as habitat for the genus. Georgia is the most important region of diversity for examined taxa except *P. elaegrifolia* because this species has great morphological variations only in Turkey. However *P. salicifolia* is very similar to *P. elaeagrifolia* morphologically and also they prefer similar habitats, but they are not sympatric. *P. salicifolia* is diversified mostly in Azerbaijan while it was collected from only two close locations in Turkey despite detailed field research. As a result, threatened categories were assigned for *P. georgica*, *P. salicifolia, P. demetrii*, and *P. cordata* at first time based on new collections of these taxa. Present distributions were also marked on maps and discussed for IUCN criteria.

The diversity and commercial potential of the African flora

Ben-Erik Van Wyk
University of Johannesburg

Africa is a continent of exceptional biological and cultural diversity, much of which remains scientifically poorly explored. The continental plant diversity is conservatively estimated at 71,486 species of flowering plants (North Africa: ca. 10,000; sub-Saharan Africa: 50,136; Madagascar: 11,350). The African angiosperm flora therefore represents nearly 20% of the global diversity, recently estimated to be about 391,000 species, of which 369,400 are angiosperms. Valuable and ongoing contributions towards an inventory of the flora have been made since the colonial era. A special highlight was the publication of a flora checklist for sub-Saharan Africa, based on the combined data sets from the Conservatoire et Jardin Botaniques de la Ville de Genève, Switzerland and the South African National Biodiversity Institute. In terms of useful plants, the Plant Resources of Tropical Africa project (PROTA) has provided a valuable collection of detailed monographs on hundreds of tropical African plants. Ongoing ethnobotanical studies are continuously revealing new records of useful plants with commercial potential. Plants have a multitude of direct and indirect uses, and provide a wide range of ecosystem services related to agriculture, horticulture, conservation, education, ecotourism, scientific research, literature, art, designs and symbols. Novelty is an important component of product development and it is likely that many more African plants will reach international markets in one form or another. Perhaps the greatest gift to the world has been coffee, estimated to be second only to petroleum as the most valuable natural product in international trade. African plant species have also contributed to commercial food (119 species out of the global top 900), functional food (10 of the top 56), commercial medicine (83 of the top 900), phytomedicine (eight of the top 43), and pure phytochemical compounds (13 of the top 135 valuable chemical entities extracted from plants). The African flora represents a rich source of inspiration for scientific, cultural and commercial innovations.

The botanical garden of M.V. Lomonosov Moscow State University and its role in conservation of rare and threatened plants

Tatiana Varlygina*, Sergey Efimov, Galina Degtjareva, Elena Terentieva*
M.V.Lomonosov Moscow State University

The Botanical garden of MSU founded in 1705 by Peter I is one of the oldest in Russia. Since 1977 the Garden studies the questions of natural plant conservation. The researches are conducted in different ways, which are complemented each other and allow to collaborate with other institutes. First of all, there is investigation of native flora of Russia. As a consequence of it, the creation of more than 100 natural plant reserves (important plant areas) was proposed and the composition of Plant Red Lists of the Russia and some its regions was specified. Together with the Ministry of Nature Resources of RF the preparation of the Red Data Book of Russian Federation (2008) was organized and descriptions for some plant species were made. Now it includes 514 rare and threatened species of vascular plants (474 Angiospermae, 14 Gymnospermae, 23 Pteridophyta, 3 Lycopodiophyta), as well as 61 mosses, 35 algae, 42 lichens and 24 fungi species. Among them, 135 species are endemics of Russia and 99 species are near-endemics, growing both in Russia and one of the neighboring countries. Many endemic species belong to the families Fabaceae (16 and 24 relatively) and Asteraceae (10 and 10). 277 (58%) species of Angiosperms from Red Data Book of RF are under protection in zapovedniks. However, the majority of them grow only in one or in just several of them, 14% species grow in national parks and reserves, and 131 species (28%) do not have territorial protection. Cultivation of many rare and endangered species in the Botanical Garden of MSU serves to educational and scientific programs. In our collection there are 115 (22. 4%) species of vascular plants from Red Data Book of Russia and 90 (44%) rare species from Red Data Book of the Moscow region. In addition, investigations of state of population (ecology, age structure, reproductive biology and so on) of rare species in natural conditions are also carried out. Special attention was paid to the Russian orchids. As a result, two books were published. There are Vakhrameeva M.G. *et al.,* Orchids of Russia and Adjacent Countries (within the borders of the former USSR) (2008) and Vakhrameeva M.G., Varlygina T.I., Tatarenko I.V. Orchids of Russia (biology, ecology and protection) (2014). The books include information about species area, ecology, morphology, ontogenesis, seasonal rhythm, and protection. In 2015 together with the Russian Research Institute of Nature Protection methodic recommendations for restoration and translocation of rare plants populations were prepared.

P0222

Polymorthism of chalcone synthase genes as factor of hop breeding

Andrii Venger
Plant Breeding and Genetic Institute

Hop (*Humulus lupulus* L.) is a dioecious plant from Cannabaceae family. One of most important genes in hop's genome are genes *chs*_H1, *chs*2, *chs*3, *chs*4 and *vps* (*chs*5), which encode chalcone synthase 1, chalcone synthase 3, chalcone synthase 3, chalcone synthase 4 and valerophenone synthase (chalcone synthase 5) enzymes, which catalyze biosynthesis of secondary metabolites (some of which impart the bitter taste and aroma to beer), such as bitter acids (alpha-acids humulone and cohumulone, beta-acids lupulone and colupulone) and prenylflavonoids (xanthohumol) accumulated in the lupulin glands. Depending on content of aroma and bitter subtracts hop varieties are derived in aroma and bitter samples. Many hop varieties from the world collection were studied by polymorphism of some of those genes, but there are no varieties studied by polymorphism of all of indicated genes. We have studied polymorphic and non-polymorphic regions of chalcone synthase encoded genes by PCR in Ukrainian hop varieties. There were detected new alleles of polymorphic regions and polymorphism in regions, which were described as non-polymorphic. Data of analysis was processed by Unweighted Pair Group Method with Arithmetic Mean and Maximum Likelihood; Distance Methods. In result there was built dendrogram with two groups one of which contained only aroma varieties whereas the other had only bitter varieties. The use of molecular markers in detection of aroma and bitter type of hop variety is cheaper than usually applied methods and needs lest time than using biochemical methods. Producing of hop genome database is important in studying of hop diversity, evolution and determination of type of varieties, members of population and individual samples of hop.

Aquatic plant as bioindicator in the wetlands of Mekong Basin and Thailand

Chavalit Vidthayanon
IUCN SSC-Freshwater Fish Specialist Group, Mekong and Southeast Asia Regional Co-Chair

Wetlands in the Mekong Basin and Thailand are one of the global aquatic plants hotspots. Over 500 species of 32 families have been occurred but less than half were assessed (252 species) and five are reported as threatened taxa. Most wetlands in the Mekong and Thailand region are degraded and disturbed by human activity including habitat alteration, agro-chemical, water extraction, invasive alien species and climate change. Several aquatic plants are disappearing or replaced by tolerance taxa or exotic taxa. The species composition and occurrence in the wetland can indicate the water and habitat integrity. More *In situ* inventory monitoring as well as local market survey are needed approach for assesses wetland habitat indicators in the region.

Vegetation structure and dynamics of tree species along the altitudinal gradient of Ilong Peak, Halcon Range, Mindoro, Philippines

Elaine Loreen Villanueva[1], *Inocencio Jr. Buot*[1,2]
1. University of the Philippines Los Baños
2. University of the Philippines Open University

The vegetation of Mt. Halcon is diverse, unique, and culturally important, but there is a very limited information on its vertical distribution and structure the along the gradient of the Halcon range. This research study analyzed the vegetation structure and dynamics of the tree species distribution along the altitudinal gradient of Ilong Peak, Halcon Range, Mindoro, Philippines. Fourteen plots of 10 m x 10 m were established along the slope from 100-1,400 m elevation. The tree species that were sampled from the plots were subjected to classification and ordination analyses. The cluster analysis identified five zones: Zone I (agroecosystem zone), *Lansium-Nephelium-Mangifera* zone; Zone II (agroecosystem zone), *Artocarpus* zone; Zone III (abandoned swidden zone), *Cratoxylum-Cyathea-Pterocarpus-Saurauia-Litsea* zone; Zone IV (forest zone), *Cyathea-Astronia-Syzygium-Garcinia-Ficus-Psydrax-Diplodiscus-Litsea-Ardisia-Garcinia-Actinodaphne* zone; and Zone V (forest zone), *Agathis*-Suli*-*Ardisia*-Alitugba* zone. The canonical correspondence analysis (CCA) showed that the elevation and the nitrogen level are the environmental variables that have strongly influenced the species distribution in the area, a characteristic that is similar to other tropical mountains.

New findings and conservation status of the family Magnoliaceae in Vietnam over the past five years

Quang Nam Vu
Vietnam National University of Forestry

The report is a summary and statistics on the family Magnoliaceae's species which have been new findings for the Flora of Vietnam over the past 5 years with some remarkable notes on conservation. Of the total 22 species, belonging to 5 genera added for the Flora of Vietnam, 7 taxa are new species, including: Magnolia *bidoupensis* Q.N. Vu, *M. cattienensis* Q.N. Vu, *M. tiepii* V.T. Tien, N.V. Duy & V.D. Luong, *M. lamdongensis* V.T. Tran, N.V. Duy & N.H. Xia; Manglietia *sapaensis* N.H. Xia & Q.N. Vu, *M. crassifolia* Q.N. Vu, N.H. Xia & Sima; and Michelia *xianianhei* Q.N. Vu. 15 taxa are new records, consisting of Magnolia *championii* Benth.; Manglietia *forrestii* W.W. Smith ex Dandy, *M. lucida* B.L. Chen & S.C. Yang, *M. ventii* Tiep, *M. grandis* Hu & W. C. Cheng, *M. hongheensis* Y. M. Shui & W. H. Chen, *M. longirostrata* (D.X. Li & R. Z. Zhou) Q.N. Vu; Michelia *citrata* (Noot. & Chalermglin) Q.N.Vu & N.H.Xia, *M. flaviflora* Y.W. Law & Y.F. Wu, *M. fulva* Hung T. Chang & B.L. Chen, *M. macclurei* Dandy, *M. mannii* King, *M. coreana* Hung T. Chang & B. L. Chen; Kmeria *septentrionalis* Dandy; and Parakmeria *robusta* (B.L. Chen & Noot.) Q.N. Vu & N.H. Xia. The condensed information on nomenclature, vernacular name, distribution & ecology, remarkable characters is also given for each species. Based on IUCN (2001), 10 species – CR, 10 species – EN and 2 species - VU of the family Magnoliaceae from Vietnam are proposed for conservation.

Ethnobotanical uses of some plants of family Apocynaceae and Asclepidaceae from north-western region of Ahmedngar district, Maharashtra

Mohan Waman
Dr. D.Y. Patil Arts, Commerce and Science College, Akurdi, Pune. Affiliated to Savitribai Phule Pune University, Pune (MS), India.

Ahmednagar is one of the largest districts in Maharashtra in terms of area and population. The north-west region of this district includes Sangamner and Akole Tehsil, fall in the Sahyadri ranges of Western Ghats which is one of the 34 Global Hotspot. It has diversified topographic and climatic conditions, gives rise to a wide range of flora and fauna along with different ethnic communities. The study was taken up for documentation and analysis of traditional knowledge regarding the use of plants in medicine and food belongs to family apocynaceae and asclepidaceae. Frequent field visits were carried out during 2014–2016 to different villages situated in the hilly regions and the 'key informants' were identified based on their reputation and experience regarding applications of plants for different purposes. The information was collected through semi-structured open ended interviews with questionnaire in their local language. All plants recorded for their use in different ailments and in the food were photographed in the field; voucher specimens were made subsequently and are deposited in the Herbarium, Nature Information Centre, Wildlife Department, Shendi. The information such as botanical name, family, vernacular name, habit and habitat, analysis like parts used, Use value (UV) and Informants Consensus Factor (ICF) are provided. In the present study, a total of 31 plant species belonged to both families used to treat different types of ailments and for food were provided by 47 key informants. Among the 31 plants recorded, 14 species used in medicine, 11 species in food and remaining 06 species used in both food and medicine. The highest number of species belonged to Asclepidaceae (25 species each) followed by Apocynaceae (06 species each). Climbers are used more often (16 species), followed by herbs (09 species), shrubs (3 species) and tree (3 species). The leaves were the dominant parts used followed by tuber, root, flower and fruits. The documentation and data analysis of such traditional knowledge of plants may provide novel compounds from the plants for the treatment of different ailments and new food species for coming generation.

Community ecology of a 300 mys tropical flora in Inner Mongolia

Jun Wang[1], *Weiming Zhou*[2]
1. Nanjing Institute of Geology and Palaeontology, Chinese Acad-

emy of Sciences, Nanjing, China
2. Nanjing University, Nanjing, China

The peat forming vegetation from the earliest Permian (*ca*. 298 Ma) of Wuda Coalfield in Inner Mongolia buried by ash fall has been called as a Chinese “vegetational Pompeii”. Such a T^0 deposits allows palaeoecologists to examine the Late Palaeozoic coal forest ecology in much the same way as neoecologists appraise modern environments. Seven major plant groups consist of the flora, including lycopsids, sphenopsids, noeggerathialeans, ferns and seed ferns, primitive cycadophytes and coniferophytes. Lycopsids are represented by *Sigillaria* cf. *ichthyolepis*, tall pole-like trees. Two sphenopsids were encountered, *Sphenophyllum*, and *Asterophyllites*. Most abundant were the marattialean tree ferns represented by *Pecopteris*. Herbaceous ferns include *Nemejcopteris feminaeformis*, *Cladophlebis*, and *Sphenopteris*. Noeggerathiales, an extinct spore-bearing group of uncertain systematic position, are small trees represented by species of *Tingia* and *Paratingia*. Gymnosperms include possible early representatives of the cycads, *Taeniopteris* and *Pterophyllum*, and tall trees of *Cordaites* that were early coniferophytes, and seed ferns including species of *Sphenopteris* and *Alethopteris*. In addition to the proportional taxonomic composition and individual plant growth habit, landscape heterogeneity (species-area curve), forest structure (ecological assembly, density of individuals) and vegetational recovery are evaluated. This flora growing on peat is also taxonomically distinct from those growing on clastic soils in the same area and during the same time interval. More significant is that a preliminary investigation of ontogeny of the individual taxa of the forest reveals reproductive biological strategy of this tropical swampy vegetation.

Classification of disturbance regimes of subtropical forest by using forest canopy structure metircs calculated from airborne LiDAR data

***Ningning Wang**, Xiangcheng Mi, Haibao Ren, Tianyu Hu, Qinghua Guo, Keping Ma*
State Key Laboratory of Vegetation and Environmental Change, Institute of Botany, Chinese Academy of Sciences

Disturbance is an important factor for shaping forest community pattern and canopy structure. Forest canopy structure provides the physical environment that generates, supports, and maintains forest biodiversity and is considered as important biodiversity indicator. Airborne LiDAR systems (light detection and ranging) could measure three-dimensional forest canopy structure accurately, and have been widely used in wildlife habitat mapping and species distribution modeling. Classification of disturbance regimes using LiDAR-derived variables would be helpful for guiding biodiversity monitoring and conservation assessments of species at regional level. This study conducted an investigation on the effect of different human disturbance regimes on subtropical forest canopy structure. The monitered evergreen, broad- leaved subtropical forest is locate in the Gutianshan Nature Reserve, Kaihua, China (29°15′N, 118°07′E). Nine 1-ha forest plots suffered three disturbance regimes (logged-selective: Logged-clearcut 50 years ago, and logged-selective 20 years ago; Logged-clearcut: Logged-clearcut 50 years ago; undisturbed: Undisturbed more than 100 years) were analyzed. Nine LiDAR-derived variables (Canopy height: 95th percentile height of all returns; SD of height: Standard deviation of canopy height; CV of height: Coefficient Variation of canopy height; Canopy cover: % of total returns above 2 m; Canopy height density-2-5 m: % of total returns between 2 and 5 m; Canopy height density-5-10 m: % of total returns between 5 and 10 m; Canopy height density-10-20 m: % of total returns between 10 and 20 m; LAI and Gap fraction) were calculated and used to classify forest structure. Cluster analysis was applied on the 9 variables grouping the 9 plots into three classes: logged-selective forest charactered as very short and low height variation, high canopy cover and gap fraction; Logged-clearcut charactered as very tall and high height variation, high canopy cover, LAI and low gap fraction forest; Undisturbed forest is tall and with high height variation, low canopy cover and high gap fraction and LAI. This result can be used together with species distribution data for conservation planning.

Investigation on the effective cmponents of the flowers of *Trollius chinensis* Bunge from the perspective of intestinal bacterial transformation and intestinal absorption

*Lina Guo, Shanshan Qiao, Deli Li, Duozhi Shi, **Rufeng Wang***
School of Life Sciences, Beijing University of Chinese Medicine, Beijing 100102, China

The flowers of *Trollius chinensis* have been used in traditional Chinese medicine for respiratory tract infection due to their antibacterial, antiviral and anti-inflammatory activities. These flowers mainly contain flavonoids, phenolic acids and alkaloids; however, their effective components are debatable because the *in vivo* processes of these compounds are unclear. This study is to investigate the main effective components of these flowers from the perspective of intestinal bacterial transformation and intestinal absorption. The intestinal bacterial transformation model was applied to investigate the biotransformation of aqueous extract of the flowers of *T. chinensis* (AEOF). Both human colon adenocarcinoma cell line (Caco-2) monolayers and everted gut sacs were employed to evaluate the intestinal absorption of the intestinal bacterial transformed AEOF. The results showed 2^2-*O*-b-L-galactopyranosylorientin, orientin, vitexin, quercetin, veratric acid, proglobeflowery acid, and trolline were not transformed by intestinal bacteria while isoquercetin and trollioside were completely transformed by these bacteria to quercetin and proglobeflowery acid. The ratio of flavonoids to phenolic acids to alkaloids changed from 16:10:7 to 9:12:8 before and after absorption. Only glycosides such as isoquercetin and trollioside are transformed into their aglycones by intestinal bacteria, and the dominant position of the flavonioids was replaced by phenolic acids after intestinal absorption. The results of this study improve our understanding of the effective components of the flowers of *T. chinensis.* In addition to flavonoids which used to be considered as the dominant effective ones, phenolic acids and alkaloids are also very important to the efficacy of these flowers.

Shanghai digital metroflora: Botanical gardens and metroflora

***Yuan Wang**, Huiru Li, Jinshuang Ma, Jianping Chen*

Shanghai Chenshan Botanical Garden, Shanghai Chenshan Plant Science Research Center

Shanghai is China's most important economic, financial and trade center. Due to the narrow land, the simple habitat, the huge population, the native plant species is very rare, only recorded more than 800 species. However, Shanghai horticulture industry is very developed, the introduction of plant species up to thousands of species (including varieties), a variety of cultivated plants is very strong demand. Shanghai Chenshan Botanical Garden, as one of the most abundant botanical gardens in China, it also leads the development of horticulture industry and the conservation of rare and endangered plants in Shanghai and East China. In Shanghai, a special place to compile local flora, however it has a very different needs from other provinces in China. We divided the Shanghai area into three hundred areas by 5 × 5 km^2. The native plants and cultivated plants in each area were investigated in detail, including the introduction of two botanical gardens in Shanghai. For cultivated plants, we rely on the botanical garden's rich data and living plants, most of the detailed identification to the variety, and to solve a lot of long-standing, large-scale use of the names by misuse. According to the survey data, historical specimens and literature, we have established the first provincial digital flora website (http://shflora.ibiodiversity.net) in China, which will show the results of the survey over the years, including the publication of the "Checklist of Shanghai Vascular Plants", " Key of Shanghai Vascular Plants" and "Illustrated Flora of Shanghai" in series of 3 volumes. The site is rich in pictures and information to help the relevant practitioners and ordinary people understand the status of Shanghai plants, rare and endangered plant conservation and plant information, solve the traditional flora by the lack of plant cultivation, stop the confusion names in the Chinese horticultural industry, and promote the health development of horticulture.

Exploring the evolution of a megadiverse genus on a megadiverse island; herbarium genomics of New Guinean *Begonia*

Hannah Wilson

Royal Botanic Garden Edinburgh/ University of Glasgow

The megadiverse genus *Begonia* L. is one of the world's largest plant genera, comprising over 1,800 species. Globally, *Begonia* species richness mimics angiosperm species richness, so the genus may be used to infer general truths about tropical evolution. With a wide distribution and an estimated 400 endemic species on New Guinea, *Begonia* is an ideal subject for the study of evolution and biogeography in the region. Additionally, *Begonia* displays a preponderance for narrow-range endemism, making it a natural choice for studying species radiation on New Guinea, an island where endemism is remarkably high. The island of New Guinea is one of the last great tropical wildernesses; least explored and poorly understood. New taxa from the region are being published at a rapid rate, yet current knowledge of the flora of New Guinea is still very limited as the region is comparatively under-collected and under-researched. This project aims to understand the evolution of *Begonia* on New Guinea from the arrival of the first ancestor around five million years ago. Initial estimates indicate that the diversification of *Begonia* in New Guinea is possibly the fastest angiosperm radiation on record. To investigate this, firstly we will reconstruct the evolution of these species by using hybrid bait capture on DNA from herbarium specimens, to sequence a representative sample of New Guinea *Begonia* and place them in a time calibrated phylogeny. To further understand the radiation we need to know how many species there are and where they are distributed. Utilising over 1,000 herbarium specimens collected over the past 150 years, complemented by further field exploration, we will document and map the *Begonia* species diversity on New Guinea, then use this data to conduct species distribution modelling. Finally we will use the distribution data and phylogeny to obtain species diversification rates, and see if any rate shifts detected on the phylogeny are correlated with other factors, such as the formation of topographical heterogeneity and promotion of microallopatry by rapid orogenesis in the Pliocene and Pleistocene, or cyclic vicariance linked to frequent fragmentations and reformations of habitat caused by climate and sea-level fluctuations in the Pleistocene. Other areas such as the tropical Andes have long been feted for their massive and recently evolved biodiversity. However, it seems likely that New Guinea more than rivals this diversity and further studies of the region are likely to teach us some general truths about tropical evolution.

Diversity and human perceptions of insects in tropical East Asian megacities

***John James Wilson**[1], Kong Wah Sing[2], Hui Dong[3]*

1. China Agricultural University
2. Chinese Academy of Agricultural Sciences
3. Fairy Lake Botanical Garden Shenzhen

The East-Southeast Asia region, currently rich in biodiversity, has experienced rapid urbanisation and improved socioeconomic conditions, but has suffered the greatest loss in species diversity compared to any tropical region over the last 50 years. As urban development replaces native or remnant habitat, resources in the surrounding areas are depleted to support urban economies causing biodiversity loss. However, in urban environments, insects such as bees and butterflies, continue to offer important benefits to humans, especially pollination of plants which contributes to improved well-being and productivity. Studies of urban ecology have suggested city parks can be effective beneficial insect refuges in temperate regions, but their effectiveness as refuges for beneficial insects in East-Southeast Asia regions is unknown. Management schemes and techniques for conserving beneficial insects in urban parks are well- established in temperate countries but are currently lacking for tropical countries. Moreover, it remains to be seen which planting schemes that can be effective in improving the ability of urban parks to sustain populations of beneficial insects in East-Southeast Asia cities.

Plant ecology and conservation of Desert Ciénegas

Dustin Wolkis[1,2], Juliet C. Stromberg[2]
1. National Tropical Botanical Garden, Department of Science & Conservation
2. Arizona State University, School of Life Sciences

Landscape-wide investigations are essential to inform conservation and restoration efforts of rare vegetation types including groundwater-dependent ciénega wetlands of the American Southwest. We asked: How regionally distinct are ciénega floras? How similar are their plant communities? What factors influence species richness and composition? At six study ciénegas, spanning a 1,000-m elevation gradient within the Santa Cruz watershed of Arizona, we sampled vegetation and soils in 30 quadrats, three times. Our results show that ciénegas have a distinct regional floristic signature, with one fourth of species restricted to American Southwest. All were dominated by clonal herbaceous perennials, but floristic overlap was low. Each ciénega supported a distinct suite of rare species. Species richness per site was influenced by salinity (negative) and wetland area (positive); quadrat-level influences included elevation (positive) and moisture (negative). Composition was influenced by water availability, salinity, and canopy cover. *Eryngium sparganophyllum* grew in moderately saline soils (which occurred at sites with high temperatures and negligible flooding), of importance for efforts to restore this imperiled species. Berming has influenced ciénegas, with drought effects apparent only at an unbermed ciénega. The high variability of ciénega wetlands and the rare species they harbor make these vanishing communities high priority for conservation.

Biologically Agarwood-inducing technique formed Agarwood column in *Aquilaria sinensis*: A novel technique for high-quality and quantity Agarwood producing

Zeqing Wu
Xinxiang Medicial university

Agarwood, a precious resinous trunks or branches derived from wounded trees of *Aquilaria* species. Agarwood had been widely used throughout the world as medicine and fragrances since ancient times. Nowadays artificial agarwood-inducing techniques providing low quality and quantity agarwood had limited the international agarwood supply. Therefore, novel methods on agarwood production are in dire need to provide high-quality and yield agarwood with less time and labor cost. Our study established a novel agarwood-inducing technique in cultivated *Aquilaria sinensis* trees, biologically agarwood-inducing technique. A complete Agarwood column can be taken from the trunk without rotten wood. The whole trunk was divided into 8 parts according to color and length for analysis. Compared with agarwood from natural and Burning-chisel-drilling induced methods, 8 parts were analyzed by HPLC, GC-MS to determine chemical compounds. Other quality characteristics like TLC and alcohol soluble extraction content were also determined. Results showed that three chromones in 8 parts were detected in 6 month after treatment. The compounds from essential oil detected by GC-MS in some parts by Agar-Bit were similar to that of natural agarwood, so were the results of TLC and alcohol soluble extraction content. In conclusion Agar-Bit can significantly produce high-quality and quantity agarwood with much lower cost.

Alien plants and their diffusion trend in the wetlands of Yunnan Plateau, Southwest China

Zhaoulu Wu, Xixi Xiang, Yuan Lei
Institute of Ecology and Geobotany, Yunnan University, Kunming 650500, China

Wetland plants, being important biological resources for ecological stability and social economic development, are facing the simplification and degradation recently. One of the causes is that the rapid decreasing of native species and increasing of alien species. We conducted an investigation of alien plants in 25 wetlands all over Yunnan Plateau, aiming at finding the alien plants and their dispersion. We have three findings: (1) There were 212 alien species belonging to 74 families and 167 genera, of which, 62 were included in the List of Chinese Invasion Plants, and 80 species from America; (2) Almost all of the aquatic alien plants were main artificial introduced to purify polluted water and beautify wetland landscape but some of them escaped and became invasive species, while most of terrestrial alien plants within 100 m around the wetlands were the spread of themselves; (3) The number of alien species decreased as altitude increasing and human disturbance decreasing. Our study indicates that a large number of alien plants (including invasions) appeared at present in the wetlands of the Central Yunnan Plateau, they may spread to the surrounding areas in the nearly future.

In vitro antioxidant and antidiabetic activities and phytochemical quantification of some apomictic ferns from China

Baskaran Xavier Ravi[1,2], Zhang Shouzhou[1], Liao Wenbo[2]
1. Fairy Lake Botanical Garden, Shenzhen & Chinese Academy of Sciences, Shenzhen
2. Sun Yat-sen University, Guangzhou

We compared pseudo-viviparous ferns from six genus namely, *Tectaria, Woodwardia, Asplenium, Polystichum, Adiantum, Bolbitis* to compare their *in vitro* antioxidant, antidiabetic activities and phytochemical quantification. We quantified the total phenolics, total flavonoids, tannins and total protein using standard protocols. Several *in vitro* antioxidant methods namely DPPH radical scavenging, metal chelating, phosphomolybdenum, hydrogen peroxide assay, ABTS, superoxide and hydroxyl radical scavenging activities of matured, young leaves, vivipary and rhizome extracts were studied. *In vitro* antidiabetic activity was analysed using α-amylase inhibition assay. Higher amount of total phenolics (320.71 mg GAE/g extract), total flavonoids (49.27 mg RE/g extract), tannins (289.52 mg GAE/g extract), and total proteins (13.41 g BSAE/100 g) were observed in vivipary buds of *W.orientalis.* On the other hand, lower amount of total phenolics (289.76 and 85 mg GAE/

g extract), total flavonoids (28.86 and 2.56 mg RE/g extract), tannins (236.66 and 21.90 mg GAE/g extract) and total proteins (12.12 and 3.97 g BSAE/100 g) were observed in matured and young leaves, respectively. In rhizome of *W.orientalis*, significant amount of total phenolics (278.81 mg GAE/g extract), and total flavonoids (73.95 mg RE/g extract) were exhibited whereas, highest amount of total phenolics (471.90 mg GAE/g extract), total flavonoids (71.92 mg RE/g extract) in rhizome extract of *W.japonica*. Higher amount of total flavonoids (88.75 mg RE/g extract) and tannins (590 mg GAE/g extract) were identified in rhizome of non-viviparous fern, *T.decurrens* while, lower amount of total flavonoids (77.59 mg RE/g extract) and tannins (418.09 mg GAE/ g extract) were identified in rhizome of viviparous fern, *T.fauriei*. Higher amount of total flavonoids was observed in vivipary buds (10.11 mg RE/g extract) of *A.bulbiferum* while, 9.67 and 5.70 mg RE/g extract were obtained from matured and young leaves. The vivipary buds of *A.ailaoshanense* showed total phenolics (52.85 mg GAE/g extract), total flavonoids (10.11 mg RE/g extract) and total proteins (12.06 g BSAE/100 g) whereas, 61.90 and 53.80 mg GAE/g extract of total phenolics, 2.16 and 2.38 mg RE/g extract of flavonoids, and 4.13 and 4.42 g BSAE/100 g of total proteins were attained in matured and young leaves, correspondingly. In antioxidant activities, significant metal chelating (17.29 mg EDTAE/g extract) and phosphomolybdenum (193.68 mg AAE/g extract) activities were observed in vivipary buds of *W.orientalis*. Significant superoxide (52.83%) and hydroxyl radical scavenging (46.78%) activities were observed in vivipary buds of *A.bulbiferum*. Higher amount of metal chelating (17.43 mg EDTAE/ g extract), phosphomolybdenum (603.51 mg AAE/ g extract) and hydroxyl radical scavenging (36.84%) activities were observed in vivipary buds of *A.ailaoshanense*. Significant activity of DPPH inhibition (34.86 IC_{50}), metal chelating (17.71 mg EDTAE/ g extract), phosphomolybdenum (1221.05 mg AAE/g extract), superoxide (89.57%) and hydroxyl radical scavenging (70.76%) activities were obtained in mature leaf of *Tectaria fauriei* while lower amount of DPPH inhibition (38.16 IC_{50}), metal chelating (17.44 mg EDTAE/g extract), phosphomolybdenum (670.87 mg AAE/g extract), superoxide (82.74%) and hydroxyl radical scavenging (42.69%) activities observed in young leaves, respectively. In conclusion, pharmacological validation using *in vivo* methods, mode of action and their mechanism of the vivipary buds should be studied.

Medicinal uses of ferns and fern allies

Baskaran Xavier Ravi[1,2], *Zhang Shouzhou*[1], *Liao Wenbo*[2]

1. Fairy Lake Botanical Garden, Shenzhen & Chinese Academy of Sciences, Shenzhen

2. Sun Yat-sen University, Guangzhou

Our present aim was to explore the medicinal uses of fern and fern allies. Pteridophytes (*aka*, ferns and fern allies) are an ancient lineage, and human beings have been utilizing fern taxa for over 2,000 years. Even though more than 12,000 species of pteridophytes distributed all over the world, fewer of them only evaluated for their phytochemicals and its pharmacological studies. We documented several medicinal pteridophytes which belong to following thirty families: Davalliaceae, Equisetaceae, Lygodiaceae, Ophioglossaceae, Polypodiaceae, Psilotaceae, Pteridaceae, Salviniaceae, Selaginellaceae, Tectariaceae, Woodsiaceae, Aspleniaceae, Athyriaceae, Blechnaceae, Cyatheaceae, Dennstaedtiaceae, Dicksoniaceae, Dryopteridaceae, Hymenophyllaceae, Lindsaeaceae, Thelypteridaceae, Marsileaceae, Nephrolepidaceae, Onocleaceae, Marattiaceae, Oleandraceae, Osmundaceae, Cystopteridaceae, Gleicheniaceae, and Huperziaceae. The lycophyte, *Selaginella* sp was exhibited multiple pharmacological activities such as, antioxidant, anti-inflammatory, anti-cancer, antidiabetic, antiviral, antimicrobial and anti-Alzheimer properties. Among all the pteridophytes examined, taxa from Pteridaceae, Polypodiaceae, and Adiantaceae exhibited significant medicinal activities. Many pteridophytes have bioactive principles that could be used in alternative medicine for various human illnesses. Even though several studies reported the medicinal uses of ferns, the possible bioactive compounds were not identified for several pteridophytes. The presence of caffeic acid, chlorogenic acid, rutin and quercetin were reported in many pteridophytes namely, *Pteris multifida*, *P.vittata*, *Pteridium aquilinum, Polypodium leucotomos, Cyathea phalerata, Selaginella tamariscina, Onoclea sensibilis*, *Matteuccia struthiopteris*, *Dicranopteris linearis*, *Psilotum nudum*, *Equisetum arvense*, and *Adiantum capillus-veneris*. In addition to biological activities, pharmacokinetics, toxicological profile, multidrug therapies should be developed from early tracheophytes and pteridophytes. Furthermore, their optimal dosage level and treatment strategies still need to be assessed. Moreover, the pteridophyte group of plants should be analysed for their genetic relationship on the basis of secondary metabolites synthesis.

The conservation of Bromeliaceae germplasm and application in Shanghai Botanical Garden

Meiling Xiu

Shanghai Botanical Garde

We have introduced the Bromeliaceae family plantssince 1998.We have collected more than 1100 species, including horticultural varieties.It is one of the most collection amount in Chinese botanical gardens. We attempted to grow Bromeliaceae plants outdoor and designed the theme garden in flower shows since 2010. We bundle the epiphytes on other plants or rocks in order to show their special characteristics and living habits. We will continue the application for local usage of Bromeliaceae family plants in Shanghai, and select the plants which are suitable for local climate.

3. State Key Laboratory of Paleobiology and Stratigraphy, Nanjing Institute of Geology and Paleontology, Chinese Academy of Sciences, Nanjing 210008, China
4. University of the Chinese Academy of Sciences, Beijing 100049, China

Fossil records of Cenozoic ferns are quite rare in Tibet. In this study, a megafossil record of *Cyclosorus nervosus* J. R. Tao is described from the Upper Paleocene sediment of Liuqu Conglomerate, southern Tibet, China, based on well-preserved leaf pinnae with *in situ* sori imprint. The frond fossils have typical characters, e.g., at least 2-pinnate-pinnatifid, catadromous fronds, lanceolate pinnae, ovoid segments with attenuate or obtuse apex and entire margin, relatively thick midveins of segment extending to the apex. The pattern of segment venation is goniopterid, veinlets located in the segments are simple, straight. Some upper lateral veins are curved toward the segment apex, while the lower 6 - 8 pair of lateral veins are connected to each other, forming the 1/2 or less than 1/2 pinnatified. One or two pair of the lowest lateral veinlets of segment and primary vein of the pinna connected forming triangular areolae, occasionally pinnatified connecting vein goes down into triangular areola. Two lines of ovoid sori (~9 sori) are located in the middle of the lateral veins along the midvein of segment from the sori compressions. All these morphological characters confirm the assignment of this species to the genus *Cyclosorus*, which is now distributed mainly in the pan-tropics, with the diversity center in Asia. The discovery of *Cyclosorus nervosus* suggests that *Cyclosorus* occurred in southern Tibet no later than the latest Paleocene. Moreover, according to the floristic composition of the Liuqu flora, it suggests that a warm and humid climate occurred in southern Tibet in the latest Paleocene. Furthermore, proto-Himalaya was at much lower elevation in the latest Paleocene as previously suggested.

The biological and ecological potential of the genus *Spiraea* (*spiraea* l.) For introduction and cultivation in a garden

Gerelchuluun Yadamsuren
Institute of General and Experimental Biology, Mongolian Academy of Science

Seven species of spirea (*Spiraea* L.) introduced into botanical gardens and evaluate their biological and ecological potential. We determined seedling's developmental periods based on development of the spirea ontogeny stages during the introduction study. Seed germination period – after seed is planted, it continues 7-10 days until sprouting and emergence of seminal roots. Stem emerging period after the germination, stem node emerges with seed cover and extends to the soil surface within 5-10 days. Coleoptile (leaf like structure) emergence period as stem emerges; coleoptile which encloses primary leaves emerges within 6 to 10 days. Bud break and the primary leaf emergence period the first true leaf emerges from the coleoptile tips within 8-12 days. Vegetative organ emergence period seedlings are capable to grow as vegetative organs. Bud growth period after growth of apical buds the plant growth rate decreases to get ready for winter dormancy. Three year old seedlings of spirea met the standard criteria MNS 6255 : 2011 (mean height was 45-50cm with 6-8 branches of twigs, flower shoot emerged, root system well developed, the primary root 25-30cm, and apical bud is grown) and provided required seedlings for the year for city garden development. After planted by seed, *Spiraea aquilegifolia*, *S. media* flowered in the third year, produced seeds in the fourth year, self-reproduced by root, its seeds matured and disseminated in the sixth year and its potential for introduction and cultivation was evaluated by 100 points. Also, *S. alpina*, *S. dahurica*, *S. flexuosa*, *S. salicifolia* were successfully cultivated in the botanical garden and was evaluated between 95-97. Introduction and cultivation of the indigenous species *S. Chamaedrifolia* was evaluated at 90 points. It flowered within three years and matured in 4-5 years after its seeds were planted. The standard of introduction and cultivation of spirea species was issued in 2011 as result of this study. As well as, scientific experimental research based cultivation methodology of spirea species were developed for use of gardening, mining restoration. Invention patent of Mongolia was given for cultivation methodology of elm-leaved spirea S. aquilegifolia Pall. By seeds in 2016 year. There is several advantages cultivation by seeds than vegetative organs including well development of root system, high branching with good shape and flowering evenly but due to minute seeds germination rate is low for cultivation by seeds. It is needed to collect seeds from the nature with same climate condition and geographical region. We collected seeds of *Spiraea aquilegifolia, S. flexuosa, S. hypericifolia S.media, S. alpina S. salicifolia, S. sericea, S. pubescens* from the forest steppe and mountain forest steppe of Mongol-dogar vegetation district of Mongolia. Planting date is crucial for further growth and development of seed and seedlings. According to some researchers, planting late falls or late spring when soils get warm is more productive for spirea. As result of this study, seedling prepared in a greenhouse and transplanting in June was effective way to cultivate spirea. Spirea planted by seeds had well developed root system, highly branched canopy and at the third year seedlings got ready to transplant in a botanical garden.

Co-administration of Artemisinin and *Ricinodendron heudelotii* leaf extract: Effects on certain antioxidants and Liver Parameters in male wistar rats

Omolara Yakubu[1,2]*, Abiodun Adebayo*[1]*, Jacob Popoola*[1]*, Emeka Okechukwu*[1]*, Oladipupo Adeyemi*[1]*, Emeka Iweala*[1]*, Ying-Jun Zhangyj*[2]
1. Covenant University
2. Kunming Instiutute of Botany

Startling rate of malaria parasite resistance to Artemisinin and its derivatives has led to possible herb-drug antimalarial combination therapy. This study assessed the effect of coadministration of artemisinin and *Ricinodendron heudelotii* (Euphorbiaceae) leaf extract on certain antioxidant and liver parameters in rats and also phytochemical analysis of different fractions of the extract. Forty male rats were randomly grouped into four and administered: distilled water (Group A), artemisinin only (Group B), artemisinin with extract (Group C) and extract only (Group D). Alanine aminotransferase (ALT), aspartate aminotransferase, alkaline phosphatase (ALP), total protein were determined using standard methods. Reduced glutathione (GSH), catalase and malondialdehyde (MDA) were determined spectrophotometrically while the qualitative and quantitative phytochemical analysis was also carried out. Phytochemical screening revealed the presence of saponin, tannin, flavonoids, alkaloids, terpenoids and steroids. Biochemical analysis revealed total protein increased significantly in the combined and extract only groups (C and D). The activities of ALT and AST were significantly increased ($p \leq 0.05$) in artemisinin only group (B) while their activities were regulated to control level both in the combined and extract only groups (C and D). The antioxidant parameters analyzed in this study reveals that the liver GSH concentration decreased in the artemisinin only group (B) compared to the other treatment groups. Similarly, artemisinin administered singly significantly increase ($p \leq 0.05$) the MDA concentrations in the liver while the extract both in the combined treatment group and when administered alone decrease the MDA and catalase concentration. Histology showed few of the hepatocytes were necrotic in the artemsinin only group while the combined and extract only showed mild to moderate central venous congestion and periportal cellular infiltration. The study indicates that the bioactive constituents in the extract might have a regulatory effect on artemisinin toxicity or collaboratively enhance its activity. Such bioactive constituents can further be isolated and characterized for drug development to tackle *Plasmodium falciparum* resistance.

Invasive flora of China: Introduction and information

Xiaoling Yan, *Zhanghua Wang, Jing Yan, Huiru Li, Jinshuang Ma*
Shanghai Chenshan Botanical Garden

Invasive species cause serious environmental and economic harm and threaten global biodiversity, so compiling a complete inventory and flora of invasive species is necessary for predicting and hence preventing plants invasion. However, nationwide information on invasive plants in China is still lacking. We set out to investigate how many invasive plant species are currently spreading in China and how their distributed patterns were formed. Based on the literature, field investigations, specimen records and taxonomic research, we compiled a nationwide flora of the invasive plant species of China. Data of taxa, origin, pathway, and environmental impact of invasive plants were analyzed. The flora comprised a total of 515 invasive plant species from 72 families and 285 genera reported from China. The three most dominant families were Compositae, Poaceae, and Leguminosae, accounting for 18%, 14% and 11% of invasive plants, respectively. *Amaranthus, Euphorbia, and Solanum* were the three dominant genera. Over half of all invasive plants were of American origin (56%), followed by those with European (16%) and Asian (15%) origins. Annuals and perennial herbs were prevalent among invasive species. According to their biological and ecological characters, extent of spread within China, and amount of damage caused, each species was put into one of 5 categories: noxious invasion (34 species), serious invasion (69 species), local invasion (85 species), general invasion (80 species), and species requiring further observation (247 species). Most noxious invasive plants were with a perennial life cycle, clonal growth ability and from the American continent. According to our analyses of geographic distributional patterns, Chinese invasive plants were highly concentrated in the southwestern and eastern coastal provinces of China, and were rapidly spreading to inland China. Furthermore, the warm regions, which are the hot spots of local biodiversity, and relatively developed areas of China, require immediate attentions. These categories and distributional patterns of invasive plants could help to assess and control their invasive risk. Our results provide baseline information on Chinese invasive plants; and, at the same time, we put forward preliminary suggestions for further study, public education and the management of the important invasive plants in China.

7. China National GeneBank
8. Guangxi University
9. Universiti Brunei Darussalam

Gametophytic and sporophytic physiology and unique aspects of photobiology make ground ferns and lycophytes thrive as ground flora in low-light tropical forest understories. Although these understory plants comprise a major component of tropical forest diversity, they have been relatively little studied. This study examines the ground fern and lycophyte diversity and composition in rainforest (RF), karst forest (KF) and rubber plantation (RU) habitats in Xishuangbanna, Southwest China. We documented species abundance and incidence in four appox. 250 m transects in each habitat using 2.5 m × 1 m plots placed 10 m apart and compared 11 abundance, diversity, rarity and shared species indices for the three habitats. A total of 36 ground fern species and four lycophytes (*Seleginella* species) were observed; 28 species in RF, 20 species in KF and 11 species in RU. *Tectaria subtriphylla* was the most abundant species and was found in all three habitats. The effect of habitat on species accumulation was a significant for 10 indices (all $P < 0.01$), except for number of species represented by only one individual. Rainforest habitats had greater values for all species abundance, diversity, rarity and shared species indices, compared to KF and RU habitats (all $P < 0.01$). The difference between KF and RU habitats were only seen for species abundance, number of species that were only found in two plots and Shannon diversity index (all $P < 0.01$). Permutational Multivariate Analysis of Variance and Analysis of Similarities both showed that species composition measured by abundance and incidence were significantly different among habitats ($F_{2,261} > 22.263$, $P > 0.001$

and $R = 0.2581$, $P > 0.001$, respectively). A common core set of species (*Tectaria subtriphylla*, *Cyclosorus parasiticus*, *Pronephrium gymnopteridifrons*, *Cyclosorus acuminatus*, and *Lygodium flexuosum*) were shared between all three habitats with RU and KF habits containing a subset of the RF species (C-score = 65.79, $P > 0.01$ and C-score = 106.55, $P > 0.05$, respectively). Indicator species analysis with both abundance and incidence data revealed that there were 13,4 and 2 species as indicators of RF, KF and RU habitats, respectively (IV > 0.0481, $P < 0.05$). The top two indicator species for each habitat are: RF: *Tectaria decurrens* and *Archangiopteris henryi*; KF: *Tectaria simaoensis* and *Adiantum soboliferum*; RU: *Microlepia marginata* and *Pronephrium gymnopteridifrons*. Of the 40 species studied here there were four species that were only found in the RU habitat: *Microlepia marginata*, *Pteris semipinnata*, *Pteris fauriei*, and *Schizoloma ensifolium*. Our findings convey that the rainforest habitats maintain a high species diversity of ground ferns and lycophytes while karst forests and rubber habitats also contribute to promoting diversity. Therefore, we conclude that the diversity in habitat types contribute to maintaining a larger group of ground fern and lycophyte species across landscapes and although monocultures, rubber plantations act as refugia for a subset of rainforest fern species while karst species are least likely to be maintained in the rubber understory.

Biodiversity of the micro-morphologies of the epidermal cells of petals of angiosperms

Shaoyong Yang[1], *Hua Wang*[2], *Hong Hu*[2], *Dixin Wu*[3]
1. Southwest Forestry University
2. Kunming Insitute of Botany, Chinese Academy of Sciences
3. Beijing Forestry University

According to anatomy and microscope photography techniques, the micro-morphologies of the upper and lower epidermals of petals of fresh flowers of different species or cultivars have been researched, a new phenomenon has been discovered: there is a biodiversity among the micro-morphologies of the pigmented cells of the epidermals of petals. The result shows these much-varied pigmented cells appear a lot of different quasi-geometry forms, genus specific and artistic beauty with vivid colors. Such that a brand new research field of a real “Cell Taxonomy” should be established instead of the current “Chromosome Taxonomy” widely used in phytosystematics nowadays. Our preliminary research about 64 species or cultivars is very important to the following three aspects: firstly, plant micro-biodiversity; secondly, a new criteria to taxonomy; and thirdly, a whole new epoch of art history and art creation has been born-these diversified colorful micro-morphologies of the pigmented cells by microscope appear fatastic natural beauties or asethetics, just the so called “Scientific Aesthetics” or “Scientific Beauty” which has been searched long time by Prof. Zhengdao LI, the first Chinese American Nobel Laureate, and many achieved artists such as Shana Chang, the former Principal of Central Academy of Fine Arts, the current Art College of Qinghua University-we successfully build a bridge between science and art. And at last, the cells we studied are quite different from pollens by electroscope, some of them are similar to the cells of the epidermal of leaves, however they are much diversified and prettier than that of the leaves, and such that another necessity to carry on a widespread research to the entomophilous pollination groups and ornithophilous pollenation groups of Angiosperms, of course, a set of terminologies should be worked out to describe these diversified, precious and beautiful colorful cells (We call someone with an “art cell” if he or she is talented on art, no wonder, cell is really artistic. And in Bible Jsus said: Even the King Solomon in his richest time wore is not as magnificent as a lily flower in the wild! Now our result reveals the two secrets!). Besides micro-biodiversity, taxonomy and scientific aesthetics, it is also a new compensation to anatomy.

On finding potential distributions of threatened plant species using machine learning on specimen data

Yu-Chang Yang[1,2], *Li-Na Zhao*[1,2], *Hui-Yuan Liu*[1], *Hai-Ning Qin*[1]
1. Institute of Botany, Chinese Academy of Sciences
2. University of Chinese Academy of Sciences

A herbarium is not only a treasure house for plant classification specialists, but also an enormous data set which provides valuable information for wild plant conservation - every specimen witnesses the bygone existence of a certain plant species at a certain location, especially those with exact coordinates. Some places recorded on the labels are designated as type localities, where the most typical plant individuals of that species can be discovered. Given longitude and latitude, with some external geographic and climatic data serving as calibration standards, one can estimate the altitude, topography, illumination and precipitation there, which determine temperature, light, water and other environmental factors. As people know, plant species are likely to reoccur at spots environmentally resembling the type localities, which really matters for those thought to be endangered already. To search for these potential distributions, we are now doing a study on a new model based on machine learning, which is designed to train the model itself recursively to better extract features corresponding to environmental indices significant to plant survival, growth and development, from the big data we feed the computers with. We aim to find actual shelters for threatened species which remain unknown to the researchers by using this artificial intelligent model, and acquire new related knowledge necessary to conserve our nature more effectively.

Red-list assessment for larger fungi based on a database of check-list of fungi in China

Yi-Jian Yao
Institute of Microbiology, Chinese Academy of Sciences, Beijing, China

After the compilation of red-lists of plants and vertebrates in China, the assessment for larger fungi was also carried out from 2016. Although much work has been do for plants and animals, it was the first attempt to assess the threat status of larger fungi in a large scale in China, evolving all the relevant researchers national wide. In order to complete the assessment of about 10 thousands species of lager fungi, including lichens, ascomycetes and basidiomycetes, recorded in China in a limited time, methods had been developed to conduct the task largely based on a database of the Check-List of Fungi in China benefited from the information technology. The database contained the information extracted from publications related to records of non-lichenised fungi from 1970 and of lichenised fungi from 1990 up to 2013 overlaping the literature coverage of pre-1973 for Sylloge Fungorum Sinicorum (Tai, 1979) and pre-1990 for An Enumeration of Lichens in China (Wei, 1991), respectively. Around 2,400 lichen, near 1,000 ascomycetes and around 5,600 basidiomycetes species were determined as larger fungi in China for assessment. All the species were classified as widespread or endemic species with either dispersed or concentrated distribution based on the records in the check-list database. Species of well-recorded as dispersed distribution, no matter of widespread or endemic, were generally considered as Low Concerned. With concentrated distribution, widespread species were assessed as Data Deficient, while endemic species needed further investigation to see if they were threaten or not. However, those widespread species, even if with dispersed distribution in China, needed further attention for assessment if they suffered by human exploitation or by environmental changes. In this way, the large number of larger fungi recorded in China were scanned quickly so that the evaluators were allowed to concentrate on a few hundred species which require close examination. More than 130 Chinese mycologists took parts in the process of assessment. A special website for the project of the Red-list Assessment of Larger Fungi in China have been set up to facilitate the review of initial assessment and two meetings of consultation had been held, each with 60-70 participants from all over the country. Consensus had been reached for almost all the species evaluated. Different opinions for a few dozens of species were recorded in the final report and might become useful in the future assessment. The Red-list of Larger Fungi in China might be officially made public in May 2017.

Macro-fungi substrate utilization pattern in Greater Mekong Sub-region

Lei Ye
World Agroforestry, CAS Kunming Plant Research

This study aims to raise the following question: (1) Do fungal species have special substrate preferences? (2) What are the differences in substrate utilization patterns in different sites in the GMS region? (3) Can fungal substrate specifically explain fungal diversity pattern? Base on the preciously studies, we hypothesis that: (1) most of the fungal species have their own substrate, less species have diverse substrate; (2) soil, wood, litter and plant-root are the most common substrate for macro-fungi; (3) fungal diversity pattern is correlated to their substrate diversity.

Assessment and indicator species analysis of Ornamental plant species grown in home gardens of Rustum, District Mardan, Pakistan

Shahab Ali[1], *Shujaul Mulk Khan*[2], ***Zeeshan Ahmad***[2]
1. Department of Botany, Hazara University Mansehra, Pakistan
2. Department of plant science, Quaid-i-Azam University Islamabad, Pakistan

Home gardens are one of the old cultural practices all over the world. It is a system in which variety of foods, vegetables, fruits and medicinal plants are grown in comparatively smaller areas. It is important in terms of biodiversity and thus far their importance is often unrecognized and described as man managed ecosystem with high energy complex structure and multiple functions. Present study was conducted on Ornamentals plant species composition, abundance, distribution pattern and formation of various ornamentals plant communities in the area of Rustum, District Mardan. Special biological (Quadrates) methods were used to assess ornamental plant species distribution in the home gardens of targeted study area. Different stations were recognized at random intervals. Density, frequency, relative density, relative frequency and Importance Values of plant species were measured at each home garden. Preliminary results showed that a total of 43 ornamental plant species belong to 30 families were grown by the people of an area. Presence absence data of 43 Ornamental plant species and 50 home gardens were analyzed using Cluster and Two Way Cluster Analyses via PC-ORD version-5 that resulted four major ornamental plant communities. CANOCO software version 4.5 was used to evaluate the environmental and cultural gradient of ornamental plant through Canonical Correspondence Analyses (CCA). Based on present results it is concluded that further study should be conducted to examine, conserve and manage the ornamental plant species diversity and their contribution towards livelihood in projected area.

Endangered new genera and species from Wuling Mountains of central China

Dai-Gui Zhang, *Dan Xie, Cheng Zhang, Ze-Long Nie*
Jishou University, Jishou, Hunan

Wuling Mountains is a mountain range located in Central China, running from Chongqing and east Guizhou to West Hunan and southwestern Hubei. Unique climate and geographical location make this area extremely rich in plant diversity with both old and endemic elements in eastern Asia. Here, alist ofrecent published genera and species from this region is collected to serve as a stimulus to further investigations of plant diversity and protection in this special and rare area. To date, two new genera and 17 new species from 12 family and 14 genera were reported from Wuling Mountains. *Zhengyia* T. Deng, D. G Zhang & H. Sun is new genus of Urtiaceae found recently from Shennongjia. It is monotypic with *Z. shennongensis* Deng, D. G Zhang & H. Sun, an endemic and endangered species only distributed in Wushanhu of Shennongjia. *Changiostyrax* Chen is the other new genus (Styraceae) found from Shimen of Hunan. Its corresponding single species *C. dolichocarpus* (C. J. Qi) C. T. Chen is endemic to China narrowly distributed in Sangzhi and Shimen of Hunan province and is considered as an endangered species according to the IUCN criterion. There are six new species from two genera of Asteraceae: *Sinosenecio baojingensis* Y. Liu & Q. E. Yang, *S. jishouensis* D.

G. Zhang, Y. Liu & Q. E. Yang, *S. hupingshanensis* Y. Liu & Q. E. Yang, *S. albonervius* Y. Liu & Q. E. Yang, *Aster tianmenshanensis* G. J. Zhang & T. G. Gao, and *A. jishouensis* W. P. Li et S. X. Liu. Two new species were reported from Brassicaceae, including *Cardamine hupingshanensis* K. M. Liu, L. B. Chen, H. F. Bai & L. H. Liu and *Eutrema bulbiferum* Y. Xiao & D. K. Tian. Other new species includes *Primula hunanensis* G. Hao, C. M. Hu & X. L. Yu (Primulaceae), *Astragaluswulingensis* Jia X. Li & X. L. Yu (Fabaceae), *Pinellia hunanensis* C. L. Long & X. J. Wu (Araceae), *Epimedium tianmenshanensis* T. Deng, D. G. Zhang & H. Sun (Berberidaceae), *Oxalis wulingensis* T. Deng, D. G. Zhang & Z. L. Nie (Oxalidaceae), *Corybas fanjingshanensis* Y. X. Xiong (Orchidaceae), *Sedum fanjingshanensis* C. D. Yang et X. Y. Wang (Crassulaceae), *Chrysosplenium zhangjiajie* X. L. Yu, Hui Zhou & D. S. Zhou (Saxifragaceae), and *Aspidistra fenghuangensis* K. Y. Lang (Asparagaceae). All the new species are endemic and endangered with a high restricted habitat with a narrow distribution in Wuling Mountains. Moreover, most of them are listed as CR or EN level according to IUCN criterion. It is critical to pay much attention from both scientists and government to protect these endangered species and genera in the Wuling Mountains.

Molecular evidence for maternal origin of *Sorbus* with pink fruits in North China

Wei Tang, *Xue-Dan Yu, Chuan-Hong Zhang, Xue-Min Ye, Qi-Di Fu*

Research Institute of Forestry, Chinese Academy of Forestry; Key Laboratory of Tree Breeding and Cultivation, State Forestry Administration, Beijing, China

Numerous hybrids in genus *Sorbus* have been documented between different species in England and other countries. Within the genus, there are a number of species, morphologically intermediate between species in overlapped areas which often interpreted as a result of a hybridization event. *Sorbus* individuals with striking pink fruits, which were morphological intermediately between *S. pohuashanenesis* and *S. discolor* in their sympatric area and haven't documented in the flora, were found by members of our research group during their investigation in Mount Tuoliang?Heibei province of North China. The origin of *Sorbus* with pink fruits and its relationship with *S. pohuashanensis* and *S. discolor* are uncertain. Therefore, the altidude distribution pattern of *S. pohuashanenesis*, *S. discolor* and *Sorbus* with pink fruits investigation and molecular biological analysis based on the sequences of four non-coding regions of choloplast DNA were carried out to explore the origin of *Sorbus* with pink fruits found in Beijing Municipality and Hebei Province. The main conclusions are as follows: In addition to Mt. Tuoliang, Sorbus with pink fruits were also found in Mt. Baihua, and Mt. Xiling. *S. discolor* was distributed at an altitude of 1300-2000 m. *S. pohuashanenesis* had an altitude of 1500-2200 m. The minimum altitude and the maximium altitude of *S. pohuashanenesis* were both higher than those of *S. discolor. Sorbus* with pink fruits grow within the overlapping areas were between 1500-2000 m of *S. pohuashanenesis* and S. discolor, with a discontinuous distribution. There were 50 mutation sites in cpDNA sequences including mutation, insertion and deletion of bases. There were 23 cpDNA haplotypes. *S. discolor* had 4 haplotypes (H1, H21, H22 and H23). *S. pohuashanenesis* had 12 haplotypes (H6, H7 and H11-H20). *Sorbus* with pink fruits had 8 haplotypes (H1, H6, H7, H13, H17, H18, H19 and H21), they shared haplotypes H1 with S. discolor, and shared haplotypes H6, H7, H13, H17, H18 and H19 with S. pohuashanenesis. 70% haplotype of individuals with pink fruits shared with S. discolor and 10% with *S. pohuashanensis*, the other is the specific. The cpDNA data provided the first convincing evidence that *S. pohuashanensis* or *S. discolor* may serve as maternal parent of individuals with pink fruits. It is inferred that the *Sorbus* individuals with pink fruits originate from interspecific hybridization between *S. pohuashanensis* and *S. discolor*, and they have multiple origins and might belong to a new species in natural taxa system. Directional hybridization events were responsible for the origin of the individuals with pink fruits. Extensive gene flow was detected between *S. pohuashanensis* and *S. Discolor* in this study, suggesting an important role of reticulate evolution in subgenus. It was concluded that hybridization plays an important role in the evolution of *Sorbus* species.

Rare and threatened plants of Dawei Mountain National Nature Reserve in Yunnan

Guiliang Zhang[1], ***Jie Cai***[2]

1. Administration Bureau of Yunnan Dawei Mountain National Nature Reserve, Hekou Branch

2. Kunming Institute of Botany, Chinese Academy of Sciences

Dawei Mountain National Nature Reserve, located at Honghe Prefecture in southeastern Yunnan, is a 43,993 hectare of protected area. It extends from Gejiu, Mengzi, Pingbian to Hekou county near the border between China and Vietnam. The reserve's altitude ranges from 100 meters in the valley of Xiaonanxi river to 2,363 meters above sea level at the peak of Dajian mountain. Vegetation of Dawei Mountain is mainly composed of montane rain forest, monsoon evergreen broadleaf forest and montane mossy evergreen broadleaf forest. According to latest statistics, it is estimated that 5,859 species of higher plants belongs to 1,714 genus and 367 families in Dawei mountain, among them there are 538 species, 207 genus, 75 families of bryophyte; 528 species, 151 genus, 55 families of pteridophyte and 4,793 species, 1 356 genus, 237 families of seed plant. Dawei Mountain provides a refuge for many "ancient" plant species, including 9 species of tree ferns (Cyatheaceae), 6 species of Cycads and 35 species of Magnolias, representing as much as 67%, 25% and 31% those of native to China respectively. Monotypic families of seed plant, such as Crypteroniaceae, Bretschneideraceae and Rhoipteleaceae also could be found in this region, which provides invaluable materials for the study of paleogeography and climate changes in the past. Moreover, Dawei Mountain is home to China's rare and endangered plants, there are 122 species endemic to Dawei Mountain and about a quarter of China's national key protected wild plant species (70 species) flourish in this area, many of them are traditional medicinal plants including *Panax stipuleanatus* and *Psammosilene tunicoides*, crop wild relatives such as *Fagopyrum dibotrys*, *Sorghum propinquum* and important timber species like *Garcinia paucinervis*, *Burretiodendron hsienmu, Madhuca pasquieri.* In the past two decades, there are 47 new species were discovered and reported from this region. To better understand the plant diversity and its current conservation status, local forestry authority conducted field surveys on rare and threatened plant species in Dawei Mountain. Thirteen rare and threatened species are confirmed new to Dawei Mountain, including 3 of them belong to national key protected species. Another dozen of species collected are potential new to science. Most rare and threatened plants in Dawei Mountain are pictorially documented, which conveyed visual and detailed information to forest rangers and villagers for community-based biodiversity monitoring and conservation, as well as to researchers who are working on the biodiversity of China-Vietnam border area for further investigation.

Herblabel: An R package for making labels for herbarium specimens

***Jinlong Zhang**, Huiling Zhu, Jingang Liu, Gunter Fischer*

Kadoorie Farm and Botanic Garden

Specimens are the basis of plant taxonomy, molecular systematics, ecology and conservation. Labels for herbarium specimens are of great importance as they include field observations and subsequent annotations. With the help of label printing programs, collectors are able to prepare elegant labels for herbarium specimens more efficiently. However, checking the spelling and validity of scientific names, finding out the family for a specific species, as well as manually reformatting the date of collection could be time-consuming and error-prone. Meanwhile, templates adopted by different label printing programs are often not consistent, and data entry in some programs could be troublesome. Here we describe herblabel, an R package to overcome these challenges. herblabel uses an Excel template derived from Darwin Core (http://rs.tdwg.org/dwc/) and CVH5.0 (www.cvh.ac.cn) data exchange standards, thus data entry is straightforward and easy to manipulate. With (1) modern family-genera database, (2) accepted names from The Plant List website V1.1 (http://www.theplantlist.org/), (3) accepted names from Flora of China (http://www.efloras.org/flora_page.aspx?flora_id=2) (4) accepted names from Flora Republicae Popularis Sinicae, and (5) Checklist of Latin words being embedded, the information for creating herbarium labels undergoes thorough evaluation to avoid potential errors. herblabel produces both herbarium labels and the annotation labels in RTF (Rich Text Format) format, which is suitable to be viewed and edited in MS Word. At present, herblabel (version 0.5.6) provides 4 themes for herbarium labels (i.e. PE, KUN, HU and KFBG) and one theme for annotation labels. However users can create their own themes since this package is open source, and is under the GNU GPL-2 license. herblabel is written purely in R, and runs on Windows, MacOS as well as Unix-like systems. Since the template is based on Darwin Core standards, it is not only convenient for generating reports, but also makes data sharing much easier. This package will increase the efficiency and accuracy for data entry, herbarium management, and should play important roles in cataloging plant diversity. herblabel is freely available at https://github.com/helixcn/herblabel.

Chemical constituents of several *Phyllanthus* spp. and their bioactivities

***Ying-Jun Zhang**, Xiao-Hong Zheng, Hong-Tao Zhu, Dong Wang, Chong-Ren Yang*

Kunming Institute of Botany, Chinese Academy of Sciences

The genus *Phyllanthus*, comprising about 600 species, belongs to the family Euphorbiaceae, with most species widely distributed throughout the tropical and subtropical countries of the world. In addition to the edible fruits of some species, most *Phyllanthus* plants have been used medicinally for the treatment of various diseases. Flavonoids, alkaloids, terpenoids, lignans, and tannins were reported from the genus *Phyllanthus*. Some of them showed potent antiinflammatory, antioxidant, antivirus, and antitumor activities. In our continuing efforts to search for the structurally and biologically significant metabolites from genus *Phyllanthus*, more than 200 compounds referring to monoterpenoid, sesquiterpenoid, norsesquiterpenoid, diterpenoids, phenylpropanoids, limonoids, sucrose benzoyl esters, lignan, and simple phenolics were identified from *P. acidus, P. cochinchinensis, P. emblica*, *P. flexuosus*, and *P. glaucus*. Ninety-five of them are new compounds. Their structures were determined on the basis of detailed spectroscopic analysis and chemical methods. Determination of absolute configurations of these compounds was facilitated by theoretical calculations of electronic circular dichroism (ECD) spectra using time-dependent density functional theory (TDDFT) for the aglycone components, and pre-column derivative/chiral HPLC analysis for the monosaccharides. Most of the isolates were also evaluated for their effects on antivirus against enterovirus 71 (EV71) for hand, foot and mouth disease, influenza A virus strain H3N2, hepatitis B virus (HBV), herpes simplex virus (HSV-1), and Coxsackie virus B3 (CVB3), antifeedant against the larvae of a generalist insect (*Spodoptera exigua*), and cytotoxicity against five human cancer cell lines (breast cancerMCF-7, hepatocellular carcinoma SMMC-7721, human myeloid leukemia HL-60, colon cancer SW480, and lung cancer A-549).

Development of polymorphic microsatellite loci and study on fine-scale spatial genetic structure of *Pteroceltis tatarinowii*, an endangered plant endemic to China

Yunyan Zhang

Nanjing University

Pteroceltis tatarinowii, the sole representative of the genus Pteroceltis, is an endangered deciduous tree endemic to China. It not only serves as food, medicine and timber, but also is the best source for the manufacture of Xuan paper. Due to the extensive deforestation, the distribution and size of the P. tatarinowii population have been decreasing for years, which makes it a national class III endangered plant in China. With wide distribution in the genome, the microsatellite markers relied on expressed sequence tags (EST) can be linked to genetic traits and applied broadly in population genetics, molecular marker assisted breeding and molecular marker screening of target traits. In this paper, we used

Illumina high-throughput sequencing technique to sequence the P. tatarinowii leaf transcriptome, based on which polymorphic microsatellite loci is developed. The main results were as follows: we obtained a total of 42,477 Unigenes with an average length of 815bp. After aligning with NR, SwissProt, GO, COG and KEGG databases, 23,688 unigenes were assigned. These Among the unigenes, a total of 6,543 EST-SSRs were identified. 130 EST-SSRs were selected for validation as EST-SSR markers by PCR amplification. Of these, 48 EST-SSRs were amplified successfully and 32 EST-SSRs were polymorphic among 47 P. tatarinowii individuals. Additionally, cross-amplifications of EST-SSR were detected in Ulmus gaussenii and Ulmus chenmoui, and the versatility and polymorphism were 25% and 87.5%, respectively. The development of P. tatarinowii microsatellite markers provided the molecular basis for the study of P.tatarinowii and other plants in family Ulmaceae. We also investigate the fine-scale spatial genetic structure of this population. Significant fine-scale SGS was found in the whole population within 28 m, and the Sp was 0.0140. The Sp of class I, II, III, IV and V were 0.0142,0.0158,0.0008,0.0026 and 0.0018, respectively. As a result, P. tatarinowii population was under growing pattern and exhibited high genetic diversity. However, saplings were clumped around adult and aged trees because of limited seed dispersal, resulting in heterozygous deficiency. Furthermore, significant fine-scale SGS was found in class I and II. These results indicated that it was threatened by limited gene flow, increased inbreeding and the risk of inbreeding depression. Therefore, for in situ conservation, artificial promotion of gene flow should be encouraged, while inbreeding depression should be monitored. For *ex situ* conservation, individuals should be sampled at apart to 28 m to reduce genetic similarity.

Compositions, *in vitro* antioxidant and antibacterial activities of ethanol extracts of *Opisthopappus taihangensis* (Ling) Shih leaves from China

*Jinyong Huang, **Yuqian Zhang**, Junfeng Liu*
Zhengzhou University

Major flavonoids components, as well as the antibacterial and antioxidant activities of ethanolic extracts of leaves (transplanting seedling from tissue culture) from the endemic genus of China-*Opisthopappus taihangensis*, were investigated in this paper. The results were shown as follows: 1. The content of total flavonoids from the 70% ethanol extracts sample was 82.705±3.725 mg Rutin/g dried weight (DW) by sodium nitrite-aluminum nitrate-sodium hydroxide colorimetric method, which was lower (around 33.245 mg Rutin/g DW) than that of wild type detected in the previous study. 2. Three main flavonoids components were analyzed qualitatively and quantitatively by HPLC with the results of chlorogenic acid accounting for 1.18% rutin accounting for 2.07% and quercetin accounting for 0.48%, respectively. It also performed differently compared with each content of the wild type, which were 0.84%, 0.54% and 1.48%, correspondingly. 3. The respective average diameters of inhibition zone of sample extracts to *Escherichia coli* and *Staphlococcus aureus* were 1.245 cm and 1.164 cm, with the corresponding MIC to be 5 mg/ml and 10 mg/ml. It revealed a more significant antibacterial potential to the Gram-negative. 4. The antioxidant potential of *O.taihangensis* was evaluated using three different assays in vitro, they were total antioxidant capacity (T-AOC) kit assay, superoxide anion radical scavenging kit assay and 2,2-Diphenyl-1-picryl hydrazyl (DPPH) radical scavenging assay. The results showed a positive dose-responses relationship between the concentration and bio-activities: the scavenging capabilities were strengthened along with the increasing concentration of ethanolic extracts. It revealed the sample extracts had a remarkable scavenging capacity, especially against DPPH, of which the IC50 calculated by SPSS was 0.101mg/ml. O.*taihangensis* was proved rich in flavonoids components in this study, which is consistent with the previous reports, and it also maintained a favorable antibacterial and antioxidant potential. We made the primary speculation that there may be some close correlation between the components and its bio-activity. Moreover, we analyzed that though the overall content performed to be high, the living environment, cultivating conditions and illumination intensity could be the possible factors contribute to the content differences between the transplanting seedling and the wild type, as the former material was planted in the experimental green house while the latter one was obtained from the cliffs of Taihang Mountain. Hence, *O.taihangensis* can serve as a promising source applied in natural preservatives of food industry and medical care field, *etc.* The study lays a foundation on the further research and applying of this new medicinal plant.

Mycobiota from karst caves in China

***Zhifeng Zhang**, Lei Cai*
Institute of Microbiology, Chinese Academy of Sciences, Beijing, China

Karst caves, formed from limestone erosion by underground water, have several striking characteristics, such as darkness, constantly low temperature, high humidity and scarcity of organic matters. Studies on cave fungi have a history of more than 50 years, which revealed a high fungal diversity. This is the first time to systematically study fungal resources from caves in China. In the past two years, more than 510 samples were collected from 15 karst caves from five provinces of Southwest China, and 3,763 fungal strains were obtained. They belong to three phyla, 294 genera and 881 species. Based on their characters of phylogeny and morphology, 20 new species were identified and described, and a lot more potential new species awaited further works for naming. This study suggested that karst caves encompass a high fungal diversity, including a number of previously unknown species. Nine of the 15 caves were chosen for metagenomic analysis and four kinds of substrate (air, carbonate, soil, water) were collected. After data processing and annotation, 64.2% OTUs were assigned to the fungal kingdom, while 35.7% OTUs failed to be assigned to any known kingdom. Among the six phyla we observed, Ascomycota is most abundant (53% of the fungal OTUs); followed by Basidiomycota (12%), while about 31% are unculturable fungi. The α-diversity showed that the fungal diversity from water samples is the highest, while that from air is the lowest. Through comparisons of the OTU compositions from different materials, we concluded that fungal diversity from different substrates are generally similar, but large number of habitat-specific species are also identified. The sample cluster analysis and PCA analysis showed that most of the compositions from same sample type clustered very well, and the soil and rock samples outside of cave clustered with samples inside of cave, suggesting that the diversity and distribution of karst cave fungi are highly influenced by the substrate and the fugal flora from the outside environments.

Research progress on the secondary metabolites of *Vaccinium dunalianum*

*Xu-Lu Luo[1], Na Li[2], Ji-Ting Yin[1], Dong-Yang Zhu[1], Wei Du[1], Jian Song[1], Xia Zhang[1], He Zhang[1], Wei-Lin Zeng[1], Yong Ding[1], Jun-Rong Tang[1], Yun Liu[1], Chong-Ren Yang[2], Ying-Jun Zhang[2], **Ping Zhao**[1]*
1. Key Laboratory for Forest Resources Conservation and Utilization in the Southwest Mountains of China, Ministry of Education, Southwest Forestry University, Kunming 650224
2. State Key Laboratory of Phytochemistry and Plant Resources in West China, Kunming Institute of Botany, Chinese Academy of Sciences, Kunming 650201

Vaccinium dunalianum Wight (Ericaceae) is an evergreen shrub mainly distributed in the Southwest of China, with leaves used as folk medicine for treating articular rheumatism and the dried leaf buds as herbal tea. Previous phytochemical study led to the identification of 36 compounds including 12 new ones from the leaf buds, leaves and fruits of the plant, referring to acylated arbutin derivatives, flavone glycosides, iridoid glycosides, pyrone glycosides, sucrose benzoyl esters, and simple phenolics. Among them, arbutin, chlorogenic acid and 6'-*O*-caffeoylarbutin (CA) were rich in the leaf buds. CA was also found in our recent study to suppress the melanogenesis, and have hypolipidemic and anti-inflammatory activities in a live zebrafish model. Interestingly, the unusual accumulation of CA, up to 31.76% by yield from the dried leaf buds, suggested that CA and its related biosynthetic key enzymes may possess important biological functions in the titled plant. In order to clarify the high yield mechnism and biological significance of CA in *V. dunalianum*, the potential biosynthetic pathways assocoated with CA was investigated by de novo transcriptome sequencing, and the full-length cDNAs of two glycosyltransferase genes and three acyltransferase genes were cloned by RACE-PCR. The tissue cultures, suspension culture cells, and adventitious root cultures were also established. Meanwhile, investigation on the diversity and secondary metabolites of endophytes in *V. dunalianum*, and the metabolic interactions with host are in progress.

P0258

Duckweeds biodiversity around Hongze Lake and molecular structure of rDNA intergentic spacer

***Yuzhen Zhou**, Guiming Chen, Borisjuk Nikolai*
Huaiyin Normal University

Duckweed is a group of aquatic plants which can efficiently remediate different types of waste water and is also known as the smallest known flowering plants with accelerated growth rate. The accumulated biomass rich in cellulose, starch and protein can be used for biofuel, bio-fertilizer, animal feed and human food. Systematic characterization of natural biodiversity of duckweed species is essential for the germplasm preservation and various practical applications. We have systematically collected samples of duckweed in Jiangsu province of China, around Hongze Lake and characterized species biodiversity by genotyping using chloroplast (atpF-atpH and psbK-psbI spacers) and nuclear DNA (ribosomal DNA ITS and ETS regions) barcodes. *Spirodela polyrhiza* was revealed as a clear dominant species in all locations of the area with occasional presence *Wolfia globosa* and *Lemna aequinoctialis*. The recent whole genome survey of *Spirodela polyrhiza*, revealed that: 1) duckweed genome has a lowest copy number of rDNA genes coding for ribosomal RNAs, which are essential components for biogenesis of ribosomes, among all the examined plants; 2) the spacer between rDNA genes, which contains the gene promoter, is profoundly undermethylated. Taking into account that ribosome biogenesis is essential for supporting active protein synthesis and organism's growth, we speculated that the transcription of individual rDNA copies in duckweed, an extremely fast growing plant, has to be much more efficient compared to other plants where rRNA supply relies on higher rDNA copies. In order to get insights into rDNA transcription in duckweed, we have cloned and sequenced the rDNA intergenic spacer regions (IGS) from representatives of three duckweed genera: *Spirodela*, *Lemna* and *Wolfia*. The revealed unique features of the duckweed IGS, especially the unusual molecular structure of the rRNA transcription initiation site (TIS), will be discussed in relation to evolution of plant Polymerase I transcription machinery.

Dynamic changes of photosynthetic properties and chemical compositions of *Eucommia ulmoides* Oliver under two planting models

***Ming-Qiang Zhu**[1,2], Wei-Zhou Xu[1,3], Jia-Long Wen[2], Ya-Hong Zhu[1], Yi Li[1], Yin-Quan Su[1], Qiang Zhang[1], Run-Cang Sun[2]*
1. College of Forestry, Northwest A&F University, Yangling, China.
2. Beijing Key Laboratory of Lignocellulosic Chemistry, Beijing Forestry University, Beijing, China.
3. College of Life Science, Yulin University, Yulin, China.

Photosynthesis is a fundamental and complex physiological process for the biosynthesis of secondary metabolites in the green plant species. In this study, the dynamic changes of photosynthetic properties, chemical compositions and cumulative production between the traditional arbor forest model of *Eucommia* planting (AFMEP) and using leaf model of *Eucommia* planting (ULMEP) were systematically investigated. The photosynthetic properties were plotted using a portable photosynthesis system. Chemical composition and structural characterization of the EUO wood were comparatively investigated by a combination of HPAEC, Raman images, Elemental analysis, and 2D-HSQC NMR. Meanwhile, the composition and content of secondary metabolites in EUO leaves from different planting models were determined by the HPLC. Besides, the water content in leaves, barks and wood were calculated by the gravimetric method. Results showed that the light-saturated net photosynthetic rate in ULMEP was significantly higher

than that in AFMEP. The content of lignin in AFMEP wood was higher than that of ULMEP wood, while the amounts of β-O-4 linkages were abundant in lignin from ULMEP wood, which was beneficial to utilize the ULMEP wood. By contrast, the content of carbohydrates in ULMEP was slightly higher than that of AFMEP wood. Besides, the contents of various secondary metabolites (chlorogenic acid, geniposidic acid, eucommiol and gutta percha) in the leaves from AFMEP and ULMEP varied with the seasonal change, respectively. Moreover, the cumulative production of dry biomasses in wood, leaves and barks of EUO at the same periods (10 years) were all significantly higher in ULMEP than those in AFMEP, which indicated that the ULMEP was a promising planting model to solve the source of the EUO resources in industrial scenario.

SpeciesgeocodeR: Automatic cleaning of geographic coordinates for biodiversity analyses

Alexander Zizka[1,2], *Alexandre Antonelli*[1,2, 3]

1. Univeristy of Gothenburg, department of Biological and Environmental Sciences, Gothenburg

2. Gothenburg Global Biodiversity Centre, Gothenburg

3. Gothenburg Botanical Garden, Gothenburg

The public availability of large-scale species distribution data has increased dramatically over the last ten years. In particular, the digitalization of collections from museums and herbaria and the aggregation of information in public databases, such as the Global Biodiversity Information Facility (GBIF) have contributed significantly to this development. However, the use of these data for ecological and biogeographic research as well as conservation planning is often hampered by issues regarding data quality. A major issue are erroneous geographical information due to wrong or imprecise or erroneous geographic coordinates. Here we present a new software tools: *speciesgeocodeR* to automatically identify and clean potentially errors in geographic coordinates common to biological collections. Furthermore, we illustrate the use of these tools on GBIF data. *speciesgeocodeR* is available as R-package or shiny app from https://github.com/azizka and www. antonelli-lab.net.

Ethnobotanical and taxonomical studies of Chamla valley district Buner KPK Pakistan

Anjum Perveen, *Shaukat Ali*

Centre foe Plant Conservation University of LKarachi

Ethnobotany is the direct study of plant interaction of a known area with the local population through its culture. Chamla valley of district Buner is a remote area of Khyber Pakhton Khwa Pakistan. The dependency on scare Hakeems (herbalists) in the valley is reduced by the introduction of allopathic medicines, but still there are many areas where the plants are still used by the locals as medicines. During the study a total of 183 species were collected from the valley. Taxonomic description of all the studies taxa has been also done. Based on ethnobotany medicinal is the largest class represented by 45.3% followed by fodder class 20.5% while the third dominated class is edible and vegetable represented by 14.8% of the total species, the least represented classes were sedative, aromatic and parasitic, the former 2 classes shared 1.41% each while the later one had 0.70% only.

Study on the variation of spina *Gleditsia* and its grafting products

Tiejie Wang, ***Chang Su***, *Xiaoying Guan, Qiaoji Guo, Xiaoxiao Song, Yaoxuan Xie, Jing Li, Shuhong Wang*

Shenzhen Institute for Drug Control

Spina Gleditsia is the thorns of *Gleditsia sinensis*, which is widely used in clinic for anti-tumor purposes. In commercial herbal market, some closely related species such as *Gleditsia japonica* and *Gleditsia microphylla* are commonly used as counterfeits and adulterant of Spina Gleditsiae. Throughout history till today, morphological feature of the thorns is the traditional and reliable method to differentiate the official Spina Gleditsia and its adulterant. But recently, grafting *Gleditsia sinensis* on *Gleditsia microphylla* or *Gleditsia japonica* is gradually popularized, and this planting behavior may cause variation on morphological feature, chemical composition and DNA sequence. In this study we present comprehensive analysis on Spina Gleditsiae by the method of the original planting investigation, morphological identification, microscopic identification, DNA barcoding molecular identification and chromatography identification. The results show that grafting products of *Gleditsia sinensis* do not have significant differences in microscopic features, psbA-trnH DNA barcode, TLC and HPLC chromatography with *Gleditsia sinensis*, but presents morphological variation on thorns and leaves, which is familiar with the feature of the closely related species as the grafting stock. At the same time, *Gleditsia sinensis* as well as its grafting products have significant differences in microscopic features, TLC and HPLC chromatography and psbA-trnH DNA barcode with its closely related species. That means grafting products reserves most of the characteristics of *Gleditsia sinensis*. The results of our work can solve the difficulties in the identification confusion caused by the grafting of Spina Gleditsiae. This study also provides the essential basis for future study to clarify the mechanisms of inheritable variation caused by grafting and the rationality of this cultivated usage in TCM plants.

Study of rare and endangered plants of Pachmarhi Biosphere Reserve, India

Pramod Patil[1], *Moni Mathur*[2]

1. Institute for Excellence in Higher Education, (IEHE) Bhopal, India

2. Govt. SNGPG College Bhopal, India

India is one of the 17 countries designated as mega biodiversity centers among the 196 countries of the world and geologically has elements of the Palearctic and Indo Malayan Realm. Situated in Central India are the lofty hills and plateaus of Satpura Ranges made up of multilayered sandstone dating from Permian to Cretaceous. Amidst these ranges, at 22° 11' to 22°50'N and 77°47' to 78°52' E meridian is located Pachmarhi, a UNESCO declared Biosphere Reserve over an area of 4928.25 sq. km at an elevation of 1100 meters above mean sea level. Pachmarhi is endowed with moderate tropical summer and up to 200 mm rainfall which foster dense forest. The medicinal plants of Pachmarhi were studied with a view to understand the biodiversity, habitat, availability and their status. Large trees form the upper canopy of the forest with one of the finest timber yielding species of *Tectona grandis* and *Shorea robusta.* The midsized tree, shrubs and climbers together with undercover herbs lodge a treasure trove of medicinal plants. The study revealed more than 600 species of Angiosperms are medicinal; some species which were once common but now rare and threatened are *Aristolochia indica, Berberis aristata, Balanites aegyptiaca, Boswellia serrata, Chlorophytum tuberosum, Gardenia gummifera, Gloriosa superba, Pterocarpus marsupium, Rouvolfia serpentina, Eulophia nuda, Pueraria tuberosa, Mallotus philippensis, Oroxylum indicum, Litsea glutinosa, Terminalia bellerica, T. chebula, Uraria picta.* With the unsustainable harvesting by local inhabitant and over exploitation by profiteers for commercial purposes, their availability has subsequently declined to the extent that many species have become endangered up to critical levels. To salvage this dwindling treasure immediate attention is required for their *in-situ* and *ex-situ* conservation.

Documentation of medicinal plants in Sabah, Malaysia

Ying Fah Lee, *Doris Jauris Salegin*
Forest Research Centre, Sabah Forestry Department

A project to document the known medicinal plants in Sabah was initiated in 2014. Medicinal plants used by different ethnic groups and various communities are described. Previously uses of medicinal plants have been recorded but not widely publicized. This project aims to collate information on medicinal plants found in Sabah and publish a series of manuals. For each species of medicinal plant, the following information is provided: Group (Pteridophyte, Gymnosperm, Monocotyledon or Dicotyledon), Family, Scientific name, Vernacular name, Habit & occurrence, Taste (Acrid, sweet, sour, bitter or salty), Energy & characteristics (Cold, cool, warm, hot or neutral; toxicity), Function (The role of herb in the healing process), Uses (List of ailments for which the herb is used), Parts used, Folk prescription (Selected traditional uses), Family and vernacular names in Chinese. The objective of thef manuals is to document the known medicinal plants in Sabah to serve as a reference for further research and for information and not to be used to diagnose, treat or cure any disease. Readers are advised to consult qualified health care practitioners for treatment of any ailment. So far two volumes of the series “ Medicinal Plants in Sabah” have been published, respectively in 2015 and 2016. Each volume covers 100 species of plants.

Saving rare wild flora: Lessons from Azerbaijan

Valida Ali-Zade[1], *Gulnara Osmanova*[2], *Naiba Mehdiyeva*[1], *Sevda Ibrahimova*[3], *Rena Abdiyeva*[1], *Rashad Salimov*[1], *Aida Dadashova*[1]
1. Institute of Botany of Azerbaijan National Academy of Sciences
2. Mari State University
3. National Aviation Academy

The flora of the Azerbaijan is estimated to include more than 4,500 species of higher plants of which around 950 are Caucasian and 200 national endemics. Along with its faunal diversity, this botanical wealth makes Azerbaijan as a valuable floristic center within the Caucasus region, which is one of the Biodiversity Hotspots of the world, and of critical conservation concern. No less than 10% of the species are regarded as rare or endangered and are subject to protection. 6% of the flora of Azerbaijan constitutes rare species included in the Red Book of Azerbaijan (II-nd edition, 2013), and listed by IUCN categories as follows: CR - 30, VU - 156, DD - 9, EN- 53, NT – 52. Taking into account continuing negative impact of anthropogenic factors and other drivers on the status of plant populations, in 2015 a new multidisciplinary projectwas initiated at the Institute of Botany of Azerbaijan National Academy of Sciences, to developadynamicintegrateddatabasewith mathematical and computer models for rare species. This ongoing project aims to implement the Targets 1 and 3 of the GSPC that are most closely linked to Aichi Target 19: “by 2020, knowledge, the science base and technologies relating to biodiversity, its values, functioning, status and trends, and the consequences of its loss, are improved, widely shared and transferred, and applied”. Database covers indicators such as, taxonomy, life forms and ecological groups of rare species, distribution species according to botanical-geographic regions and altitudinal zonation, rarity status endemic and threatened species, ontogenic status and structure of populations, as well as online-map, photos and their useful properties. By January 2017, database contains data on 180 populations of 41 species.Mathematical model that allows assessing the risk of extinction of species on the basis of population-ontogenetic features is used for the preparation of prognostic scenarios. In addition, since 2013 MSBP, Kew launched the project in Azerbaijan with the Institute of Botany to develop an *ex situ* conservation programme for the saving the wild flora of the Azerbaijan. A key focus of the project was the contribution of seed banking to progress towards GSPC Target 8 and Aichi Target 12, and Azerbaijan’s National Biodiversity Strategy in Azerbaijan. Currently, over 193 live seed collections from the 121 Azerbaijan 3E (endemic, endangered and economic) wild species had been seed banked within the framework of the project. The taxonomic diversity of seed collections comprising 46 families and 103 genera. Along with this ongoing project a new RE Garfield Weston Global Tree Seed Bank Project (Azerbaijan) was initiated in 2016 in collaboration with the MSBP, Kew for the most threatened tree species.

Impacts of domestication on population genetics of a traditional Chinese medicine, *Atractylodes macrocephala* (Asteraceae)

Chuan Chen[1], *Li Zheng*[3], *Chengxin Fu*[2]
1. Hangzhou Botanical Garden
2. Key Laboratory of Conservation Biology for Endangered Wildlife of the Ministry of Education, and College of Life Sciences,

Zhejiang University
3. Key laboratory of Jiaxing Second Hospital

As a medicinal herb, *Atractylodes macrocaphala* experienced centuries of cultivation in China, and *Atractylodes macrocaphala* Rhizoma in the market is generally from cultivated *A. macrocaphala* at present. However, the germplasm resources of all cultivated populations of *A. macrocephala*have degraded over time as a consequence of the domestication processes. This study provided an in-depth analysis by two cpDNA regions and eight microsatellites on genetic and evolutionary consequences of domestication in a broad range of current *A. macrocaphala* germplasm resources. The results revealed that cultivated *A. macrocephala* (except 'Pingzhu' cultivar) exhibited higher genetic diversity (average HE = 0.682) than its wild progenitors (average HE = 0.663) and low level of genetic differentiation occurred between cultivated and wild groups. Both STRUCTURE analysis and UPGMA tree indicated four main genotypic clusters of *A.macrocephala*. We inferred that wild germplasm in Central China (Shanxi and Hunan Province) which is also the main distribution area for natural populations has most likely been involved in the origin of cultivated *A. macrocephala*. Moreover, the wild population from Qimen, Anhui Province and the cultivated 'Pingzhu' variety harbor unique gene pools and rare alleles that could be useful in future breeding efforts. This study represents the first large-scale analysis of population genetics of *A. macrocephala* which has a centuries-long history of human-mediated selection as a medicinal crop and the results will facilitate utilization and conservation of the valuable genetic resources of this species.

The Genus *Henckelia* Spreng. (Gesneriaceae) in Southern Western Ghats

Janeesha A P, *Santhosh Nampy*
Department of Botany, University of Calicut, Kerala

The genus *Henckelia* was re-established by Weber & Burtt in 1997 to accommodate the species of *Didymocarpus* sect. *Orthoboea* from South India and Sri Lanka, *Didymocarpus* sect. *Didymocarpus* and sect. *Elati* from Malesia and included 180 species. Weber *et al.,* in 2011 re-defined the genus based on molecular data and included species of *Henckelia* sect. *Henckelia*, *Chirita* sect. *Chirita* (excluding the species under *Damrongia* Kerr *ex* Craib), the monotypic genus *Hemiboeopsis* W.T.Wang and exclude the species of *Henckelia* sect. *Loxocarpus*, *Didymanthus*, *Heteroboea* and *Glossadenia*. At present the genus has approximately 60 species world wide, with distribution in North-East and South India, Sri Lanka, the Himalayas and continental South-East Asia excluding Peninsular Thailand and Malaysia. The genus is represented by 30 species inIndia, of which 15 are distributed in southern Western Ghats. Except for *H. humboldtiana* (Gardner) A.Weber & B.L.Burtt (which also occur inSri Lanka) all the others are endemic. The Indian Henckelia's fall under two groups: (1) plants predominantly caulescent, with internodes and leaves in whorls of 2 or 3 andorthocarpic capsules dehiscing along both upper and lower suture. The other group is predominantly acaulescent, with leaves in basal rosette and plagiocarpic capsules opening along the upper suture only. The former occurs in North-East India and Sri Lanka (*Chirita* sect. *Chirita*) while the latter is found in southern Western Ghats (*Henckelia* sect.*Henckelia*). The present paper discusses the taxonomy, ecology, distribution and endemism of *Henckelia* in southern Western Ghats. An artificial key for the identification of species is provided. A phylogenetic tree is also constructed using sequence data from ITS and trn loci.

Phylogeny and pollination observations of *Amorphophallus* (Araceae) on Borneo

Nor Fathiah Abd Rahim, *Sin Yeng Wong*
Department of Plant Science and Environmental Ecology, Faculty of Resource Science and Technology, Universiti Malaysia Sarawak (UNIMAS)

Amorphophallus Blume ex Decne with *ca* 200 species, belongs to the family Araceae (aroid family). The genus is spread mainly in the tropics from West Africa eastward into Polynesia. On Borneo, there are at least 18 indigenous *Amorphophallus* species, all endemic. This project served to address two main questions. Firstly, to infer the biogeographic history of the entire genus on Borneo whether the dispersal events to Borneo, is more than one event (s). Secondly, to focus on the pollination biology of two unrelated taxa, *Amorphophallus hewittii* Alderw. and *A. eburneus* Bogner. The phylogenetic analyses were carried out by using a plastid region and two nuclear regions: *mat*K, ITS and PhyC. A total of 96 accessions representing 69 species of *Amorphophallus* were included with 36 accessions representing 16 species from Borneo and 60 accessions representing 53 species from other regions. The study showed that the Bornean taxa were placed in three separate clades. *Amorphophallus hewittii sensu lato* is closely related to *A. titanum* (Becc.) Becc. ex Arcangeli. The white-flowered *Amorphophallus* species in Sarawak is related to *A. declinatus* Hett. and *A. dactylifer* Hett. from the Philippines. *Amorphophallus angulatus* Hett. & A. Vogel is not closely related to any of the Bornean taxa. Flowering mechanism and pollination strategy of *A. eburneus* and *A. hewittii* were also presented in this study.

P0263

Phylogenetic analyses of *Shorea* (Dipterocarpaceae) on Borneo

Nur Aina Afiqah Abdul Halid, *Sin Yeng Wong*
Department of Plant Science and Environmental Ecology, Faculty of Resource Science and Technology, Universiti Malaysia Sarawak

Dipterocarpaceae is a key family, both ecologically and commercially, in the forests of Southeast Asia. The distribution is pantropical, confined to Asian tropics between the Seychelles Island and Southeast Asia to New Guinea with the greatest diversity and abundance in western Malesia. Members of the family are predominantly distributed in tropical lowland and hill forests within this region. The family consists of 17 genera with about 680 species in three subfamilies and shows a high rate of endemicity. *Shorea* Roxb. ex C.F.Gaertn. is the largest genus in the family, consisting of 360 species. So far, 138 species are known in

Borneo, of which 91 species are endemic and 130 species occur in Sabah and Sarawak. Previously, the phylogeny of *Shorea* focused on Southeast Asia, but none of these studies were specifically focused on Borneo. Former studies showed that *Shorea* is probably paraphyletic with the genus *Hopea* Roxb., probably belonging within the genus *Shorea*. Therefore, this project is conducted to investigate the phylogeny of the genus *Shorea* on Borneo broadly focusing on the issue of their intrageneric delimitation. There are three objectives in this project: (1) To resolve the phylogeny of *Shorea* species on Borneo with the emphasis on species from Sarawak; (2) To determine the paraphyly of *Shorea* species; (3) To revise *Shorea* species based on the outcome of objective (1). Thirty four accessions are included in this study which comprised of six sections from the tribe Shoreae. Phylogenetic analyses of *Shorea* were carried out in this study by using two gene regions: Internal Transcribed Spacer (nrITS) and Megakaryocyte-associated tyrosine kinase (*mat*K).

P0264

Speciation of the sect. *Camellia* based on pollinator shift - focusing on Japanese *Camellia*

Harue Abe[1], *Hiroki Miura*[2], *Yoshitaka Motonaga*[1], *Yu Matsuki*[5], *Yoshihisa Suyama*[3], *Saneyoshi Ueno*[4]
1. Niigata University
2. Aomori Prefectural Asamushi Aquarium
3. Tohoku University
4. Forestry and Forest Products Research Institute
5. DNAform

Organisms have the ability to adapt to specific conditions within their environments, resulting in morphological diversification and speciation. It is thought that speciation is more likely to occur as a result of premating isolation rather than premating isolation. Therefore, to elucidate the speciation of plants, it is important to identify the factors that cause premating isolation. In Japan, *Camellia japonica* and *Camellia rusticana* belonging to the sect. *Camellia* are naturally distributed. Despite differences in their habitats and morphologies, they have been classified as variants, subspecies, or species depending on the researchers. Thus, their taxonomic positioning remains unclear, because they are known to hybridize if their habitats are adjacent to each other. *C. rusticana* grows in snowy places, whereas *C. japonica* does not. While *C. japonica* adopts ornithophily, *C. rusticana* adopts entomophily. Both species have adapted to different growing environments and pollinators. Thus, they may have been speciated by premating isolation, which causes morphological mutations in flowers and leaves. Hence, this study aims to examine the degree of speciation of two species by comparing the floral and leaf morphologies and the genetic differentiations. In the results, it was possible to distinguish between these species by the presence or absence of hypodermis in leaf morphology. In flower morphology, PCA analysis clearly distinguished between these species, and both petal and filament colors were also statistically different between these species. The genetic structures based on eight cpSSR loci and 151 SNPs are divided into 3; southern and northern *C. japonica*, and *C. rusticana*. The haplotype diversities are 3.13 in *C. japonica* and 30.8 in *C. rusticana*. These results suggest that morphological and genetic differences between these species are clear. Furthermore we investigated the candidate pollinators quantitatively. They are birds for *C. japonica* and small insects for *C. rusticana,* which means the gene flow between two species might be rare. In conclusion, it is reasonable to think that *C. japonica* and *C. rusticana* are different species and are not closely-related because the difference on morphology is not consecutive and there is no difference in the genetic diversity. It also suggested that premating isolation caused by differences in environments is one of the factors that promote speciation of sect. *Camallia*. It could cause the pollinator shift between birds and insects. The main pollinators of *C. japonica* are birds because it blooms in winter when the availability of fruits and insects is limited in the temperate forests. On the other hand, *C. rusticana* are pollinated by small insects in the early spring season when insect begin to come out. Then the adaptation to different environments might result in the different pollination systems.

Phylogeny and ancestral state reconstruction of the cool season grasses (Poaceae subfamily Pooideae)

Carmen Acedo[1], *Félix Llamas*[1], *Manuel Pimentel*[2], *Elvira Sahuquillo*[2], *Alicia Alonso*[1], *Ana Molina*[1], *Pilar Catalan*[3]
1. University of Leon
2. University of Coruña
3. University of Zaragoza

The cool season Poacaeae subfamily Pooideae consists of 4234 species belonging to 197 genera and 14 tribes, as recognized current classification, showing great diversity in habit and morphology. In this study, we investigate the phylogeny of main lineages and reconstruct the ancestral character states of ten traits commonly used to build its taxonomy, to better understand their evolution, and compare them with the evolution and diversity of major clades. In grasses, inflorescence architecture can be one of the reasons of the success of some lineages, determining how many flowers and seeds are produced in a single inflorescence. We sequenced two nuclear and five plastid markers of some 170 species representing 120 genera, thirteen of the fourteen tribes, and all the included subtribes. Phylogeny was inferred by maximum parsimony (MP) and bayesian inference (BI). Ancestral states, for traits playing a main role in the taxonomy of the lineages, were reconstructed using MESQUITE by means of parsimony and maximum likelihood (ML) and, full bayesian method in BayesTraits. Differences between topologies obtained by MP and BI of the combined matrices were minimal. The monophyly of the subfamily and the mayor clades were strongly supported. Most of our results agree with previous hypothesis about the phylogeny and, find the same conflictive cases suggesting a more recent diversification of the monophyletic Phaenospermatae after Meliceae and before Stipeae with strong support for all main clades. A perennial habit for the MRCA of subfamily and major clades (the only exception is Ammochloinae and relatives) is not surprising, but a bidirectional origin with reversions is showing. Some traits evolved consistently with adaptive radiation: The branching inflorescence and multi-flowered spikelet are common in genera diversify rapidly. Different ancestral state reconstruction methods do not yield conflicts. As expected, reconstruction found support, for an ancestor of the subfamily and its main lineages, having a branched inflorescence, spikelet with two glumes not enclosing the flowers, and spikelet 1-flowered in the MRCA of the subfamily and early lineages, but multiflowered in the most recent divergent lineages. Our results for the attachment of the central awn, extensively used in to circumscribe lineages, have no certainty about which is the ancestral state suggesting an ambiguous MRCA. The results are clear reconstructing the presence-absence of dorsal awn: MRCA lacks dorsal awns -presence being derived- but results are bidirectional. The reconstruction of geniculate awns is similar. Finally, for dispersion it is suggested a MRCA with diaspore formed by separate florets. In conclusion, our study suggests different relationships among some early Pooideae lineages and corroborates the controversial relationship between traditional subtribes Agrostidinae and Brizinae. It has resolved the morphology of subfamily MRCA and provided information helping us to understand the evolution and success of the main lineages. Branching inflorescence and multi-flowered spikelet reconstruction supports the high diversification of the most specialized annual representatives: A more effective dispersal supports an evolution consistent with the adaptive radiation.

P0267

Tetraploid induction of *Vigna unguiculata*

Olagorite Adetula

National Horticultural Research Institute.P.M.B5432, Idi-Ishin, Ibadan

Cowpea (*Vigna unguiculata* (L.) Walp.) is most important grain legume crop because of its high protein content and economic uses. With increasing economic importance attempts were made to develop tetraploid plants for crosscompatibity breeding between cultivated and wild relatives of Cowpea. Tetraploid plants *Vigna unguiculata* were obtained from both culturing the seed in MS media with different concentration of colchicines (invitro colchicine treatment) and from application of colchicine to the shoot tips. The frequency of tetraploid using 0.05% and 0.1% was 30% and 20% respectively. The survival rate was 90% for 0.05col. and 55% for 0.1col. treatments. Morphological data were collected from both induced tetraploid and diploid plants. Remarkable differences were observed in morphological attributes which are useful traits for breeding work. Effects of colchicine treatment was more pronunced in the plant habit and height ranging between 10-65 cm. Cytogenetic analysis showed the frequency of 80% of the cell of the tetraploid plants with 2n=44. Shoot tips colchicine treatment and invitro colchicne treatment were both effective for producing tetraploid in Cowpea.

P0268

Phenetic analysis of three populations of *Dendropanax arboreus* (L.) Decne. & Planch. (Araliaceae) in the Tuxtlas region, Mexico

Andrés-Hernández Agustina Rosa, *Tamanis-Coatl Sandra Ivet, Rivas-Arancibia Sombra P., Carrillo-Ruiz Hortensia, Martínez-Moreno David*

Benemérita Universidad Autónoma de Puebla

The species *Dendropanax arboreus* is widely distributed, but there is phylogenetic evidence, based on molecular data, that some studied specimens do not form a monophyletic group. In Mexico, all morphotypes have been labeled with the name *D. arboreus*. Three morphologically different populations have been recognized in different types of vegetation in the Tuxtlas region. This work compares and evaluates the similarities and differences between these populations regarding wood anatomy, and leaf architecture and anatomy of leaf. Anatomical sections of the wood, petioles and laminae were obtained from specimens of *D. arboreus* collected in different locations with different vegetation types: a) high evergreen forest, b) mangrove, c) cloud forest (Populations 1,2 and 3, respectively). The leaves were also diaphanized. Qualitative and quantitative characteristics were analyzed by Principal Component Analysis (PCA), and a dendrogram was constructed. It was found that the specimens from all three locations showed typical characteristics of the Araliaceae family such as diffuse porosity, presence of solitary vessels and in multiples of 2 to 5 with scalariform perforation plates, brochidodromous venation, bifacial leaves and resin canals. The characteristics that allowed us to differentiate the specimens from the three locations were vessel wall thickness, the length of vessel elements and fibers, the type of venation, presence of tracheoblasts and arrangement of the vascular bundles in the petiole. Interestingly, population number 2, collected in a location with mangrove vegetation, has a frequency of vessels of 347 mm^2, which is different than the values reported for other species of the family. PCA results showed that the three populations are separated, and the dendrogram showed that there is a greater similarity between the specimens from mangrove and cloud forest, while the specimens from evergreen forest showed greater dissimilarity. We conclude that there are three different populations based on the anatomy of wood, and suggest that it could be possible to propose two new species.

P0269

Modelling distribution of *Cinchona capuli* L.Andersson: A new report for Peru

Joaquina Alban[1], *Lizeth Huaman*[1], *Miguel Durand*[1], *Eder Chilquillo*[2]

1. Museo de Historia Natural San Marcos
2. Campinas University

The genus *Cinchona* L. is distributed in the neo tropical region, along the slopes of the Andean region from Venezuela to Bolivia. Currently recognized 23 species, of which 17 are reported for Peruvian territory. *Cinchona capuli* L.Andersson is an endemic species of Ecuador, but it was registered in 2006 for Peru (Cusco and Pasco regions). Due this precedent, we developed the present research which main aim is to verify if the species could have a wider distribution.The methodological design was based in examining approximately 700 specimens of herbariums (AAU, AMAZ, CUZ, F, HOXA, HUT, K, LOJA, MO, MOL, NY, QCNE, US and USM). This information was complemented with collection records for Ecuador and expeditions done by the authors between the years 2004-2016. Furthermore, the ecological niche model analysis was conducted in order to identify potentially suitable habitat areas for *C. capuli*. We used the predictive software MAXENT version 3.3.3e and bioclimatic data (WorldClim).The result shows that the specimens of Cusco and Pasco do not correspond to *Cinchona capuli*. However, it was registered in Ayabaca, Piura region. On the other hand, the analyses of the potential niche modelling confirm this; widen the distribution area to northern Peru, based on the mean area under the curve (AUC = 0.987) which indicate an optical performance. It should be mentioned that the predicted model was supporte by 4 of the 19 bioclimatic variables (Isothermality, Precipitation of Coldest Quarter, Temperature Seasonality and Precipitation of Wettest Month).We conclude that *Cinchona capulí* has a distribution up to northern Peru, being not limited to Ecuador as previously believed. Additionally, according to the predictive model, montane forest of San Ignacio, Jaen and Huancabamba could present suitable habitats for the species. To wind up it assumes the presence of 18 species of Cinchona in Peru and reconfirms that Peruvian territory constitutes and the centre of distribution of the genus.

A diverse Miocene megaflora from the Hattiesburg Formation, Mississippi, U.S.A.

Daniel Mcnair[1,3], *Debra Stults*[2], *James Starnes*[4], ***Mac Alford***[3], *Brian Axsmith*[2]
1. University of California, Davis
2. University of South Alabama
3. University of Southern Mississippi
4. Mississippi Department of Environmental Quality

Our understanding of Miocene plant evolution in the southeastern United States is hampered by the rarity of productive sites with well-preserved fossils. Berry (1916) briefly described a poorly preserved palm (*Sabalites apalachicolensis*) and leaves of *Ulmus floridana* from the Miocene Hattiesburg Formation in southeastern Mississippi. In 1944, a few plant fossils from the Hattiesburg Formation were identified by Roland Brown as a probable *Taxodium* (possibly *T. distichum)*, *Salix*, either *Morus* or *Celtis,* and fragments of some type of monocot. None of these fossils were described in detail or figured. Recently, an extensive megaflora has been recovered from the upper part of the Hattiesburg Formation along the Bowie River in Hattiesburg, Mississippi. The Bowie River locale is typical of the non-marine fine-grained sediments of the Grand Gulf Section. The locale consists of pyritic, gray-green colored, laminated to finely-bedded sediments with alternating clays, silts, and fine-grained sands. This strongly fissile and repetitive sequence is slightly carbonaceous to highly lignitic, with well-preserved fossil leaves and leaf hash along partings and large, imbedded, lignitized logs. The depositional setting is likely an interfluvial over-bank deposit in the lower distributary portion of a coastal river. Ferns are represented by specimens of *Salvinia* with attached sporocarps, a probable *Woodwardia* s.l. based on a pinnatifid frond, and a possible *Osmunda* cf. *regalis* pinna. Conifers are represented by branchlets of *Taxodium* with preserved cuticles. Angiosperms include leaves attributable to the Lauraceae based on venation pattern, oil bodies in the mesophyll, and paracytic stomata. *Platanus* (Platanaceae) is commonly associated with palms and recognized from leaves, fruits, and large logs. Leaflets of *Sambucus* (Adoxaceae) are common. *Cercis* (Fabaceae) is recognized from leaves with palmate venation and pulvini. Leaves of *Quercus* (Fagaceae) sections *Lobatae* and *Quercus* have been recovered. The Juglandaceae include fruits of *Juglans* section *Rhysocaryon* and two species of *Carya* section *Apocarya*. *Morus* (Moraceae) is known from leaves, as are *Populus* and *Salix* (Salicaceae). Of particular interest is an endocarp of *Sargentodoxa* (Lardizabalaceae), being the first record of this Chinese endemic from the coastal plain of the southeastern U.S. and only the third occurrence in North America. Monocots include *Cyperus* (Cyperaceae) based on spikelets with achenes and two types of palm (Arecaceae). One type of palm is costapalmate, the other palmate. Two palmate specimens have robust, recurved spines on the petiole, the first record of this type of fossil palm from North America. The Hattiesburg Formation megaflora is now one of the most extensive in eastern North America, and along with the Brandon Lignite of Vermont, the Alum Bluff flora of Florida, the Brandywine flora of Maryland, and the Gray Fossil site of Tennessee, helps to fill a major temporal and biogeographic gap in our understating of Miocene plant evolution in eastern North America.

Transatlantic crossing: Revisiting relationships between Neotropics and African-Madagascan ferns and lycophytes

Thais Elias Almeida[1], *Alexandre Salino*[2], *Sabine Hennequin*[3,4], *Jean-Yves Dubuisson*[3,4]
1. Universidade Federal do Oeste do Para
2. Universidade Federal de Minas Gerais
3. nstitut Systématique Evolution Biodiversité (ISYEB), Sorbonne Universités, UPMC Univ Paris 06, MNHN, CNRS, EPHE
4. Centre de Recherche en Paléobodiversité et Paléoenvironnements (CR2P)

Floristic relationships between Neotropics and Africa-Madagascar region (continental Africa, Madagascar and Ocean Indian Islands) are well known in several groups of vascular plants. Compared to seed plants, ferns and lycophytes have a greater capacity of migration (dispersal and establishment) and are less limited by geographical barriers, being more dependent on microhabitats and microclimate for establishment. In this group, a considerable number of disjunct geographic distribution hypotheses have been proposed in the last decades. These usually are represented as species pairs or taxa with morphological affinities occurring in both areas. Given the current available data on phylogenetic relationships for several groups of fern and lycophytes, we revisited some of these hypotheses of phytogeographic relationships. We evaluated species pairs proposed by Moran and Smith (Moran RC, Smith AR. 2001. Phytogeographic Relationships between Neotropical and African-Madagascan Pteridophytes. Brittonia 53,304–351) for which phylogenetic evidence was available. We assessed, in the light of available phylogenetic inference, if these morphological affinities reflect a shared evolutionary history, or simply convergence. In the case of taxa derived from common ancestors we examined the biogeographical history and events that might have led to their current geographic distribution. Among the “species pairs”, several represent taxa that are not closely related, as their morphological similarity reflects convergence to similar environments and habitats in both continents. Examples of taxa representing same lineages with disjunct distribution are, indeed, found among the investigated groups. Explanations on how this biogeographic pattern might have emerged include the boreotropics hypothesis, vicariance, and long-distance dispersal. The subjacent biogeographic history of these transatlantic ferns and lycophytes is a complex and composite one, and distinct explanations are required to explain patterns among different families and genera. It involves more commonly migration events through long-distance dispersal, with vicariance playing a subsequent role in radiation following the emergence of local barriers due to geological and climatic changes.

P0272

DNA barcoding and conservation of timber species from Ghana

Phyllis Akua Amamoo, *Gabriel Ameka*
Department of Plant and Environmental Biology, University of Ghana

The Forestry Commission-Ghana estimates that about 50 timber tree species are in commercial trade in Ghana. Of these 31 species were identified and sampled from three biodiversity hotspots and protected areas (Ankasa Resource Reserve, Bia Biosphere Reserve, and Kakum National Park), in the country in the present investigation. The purpose is to provide DNA barcodes for the timber species in the country to enable their accurate identification. Total genomic DNA was extracted from silica-dried leaf samples of each timber species, obtained randomly from the three sampling localities, using the modified CTAB method, and sequenced using standard procedures. To verify the authenticity of the data in the molecular identification of timber species from Ghana, DNA sequences were retrieved from reference database in GenBank for comparison. The results indicate that the combination of the *matK* and *rbcL* gene regions can identify the timber species accurately, thus enabling the tracing of illegal logged timber. Illegal logging is known to be one of the main causes of deforestation and biodiversity loss, and trade with illegal timber and wood products creates market disadvantages for products from sustainable forestry. Sustainable forestry conserves and protects biodiversity and prevents biodiversity loss, by controlling the rates of harvesting timber species. The authors recommend a large scale DNA barcoding of all tree species in Ghana to facilitate and enable the use of DNA barcoding in tracing illegally logged timber and trade with illegal timber and wood products in the country.

P0273

DNA barcoding and conservation of medicinal plants from Ghana

Gabriel Ameka, *Phyllis Akua Amamoo*
Plant and Environmental Biology, University of Ghana

The purpose of this project is to DNA barcode all medicinal plants in Ghana; providing DNA barcode sequences from the *matK* and *rbcL* gene regions. In a preliminary investigation ca. 150 medicinal tree species from protected areas in southern Ghana were sampled. Total genomic DNA was extracted from silica-dried leaf material, and sequenced using standard procedures. The trees are mainly used in the treatment of malaria, general fevers and in post-partum nourishment (nutraceuticals). The DNA barcode sequences will be linked to herbarium voucher specimens, digital images/photos, locality, literature, medicinal uses, will enable the verification and authentication of herbal medicines. The data generated will be available, as a public reference library of DNA barcode sequences of tree species, and associated data in international genomic and DNA barcoding databases, including Barcode of Life data (BOLD) Systems, and EBI/GenBank. This will ensure that substitutes are not used, intentionally or unintentionally, and delivering safer herbal medicines to local and international markets, thus increasing the confidence of the general public in herbal medicines. This will also ensure sustainable harvesting of medicinal trees; and thereby promoting sustainable forestry and thus conserving and protecting biodiversity and biodiversity loss.

Divergence dates of *Astragalus* L. section *Incani* (Fabaceae) based on nrDNA ITS and plastid *rpl32-trnL* $_{\mathrm{(UAG)}}$ sequences

Elham Amini[1], *Shahrokh Kazempour Osaloo*[1], *Aliasghar Maasumi*[2]
1. university
2. Research Institute

Section *Incani* DC. was established with 12 species by De Candolle. Linnaeus introduced the first species of *Incani* as *A. incanus* (exclusion Southern Europe in Spain and France) and Podlech placed this species, as the lectotype of section, for *Astragalus* group with perennial habit, acaulescent, bifurcate hairs and mostly leaves imparipinnate but in a few species tri- or unifoliolate. This section with about 140 species worldwide is one of the richest and the most important sections of *Astragalus*. Section *Incani* distributed throughout Southern Europe, North Africa, Anatolia, Central Asia and the Caucasus. Its main centre of diversity
seems to be in Iran and Turkey with about 120 species. In this study, Bayesian inference (BI) analysis was conducted in BEAST v1.8.3 [Bayesian Evolutionary Analysis Sampling Trees] using the substitution model selected by the AIC for each gene and a Relaxed Clock. Bayesian and Maximum Likelihood phylogenetics analyses applied to nrDNA ITS and *rpl32-trnL* $_{\mathrm{(UAG)}}$ sequences for 82 species of section. A. frigidus, A. stocksii and A. aegobromus were selected as outgroup. The present study indicated that sect. Incani forms a monophyletic group. In the divergence time studies that included rates of nucleotide substitutions using *matK* sequences, Wojciechowski provided the estimated *Astragalus* diverged from its sister group, *Oxytropis*, 12–16 Ma, the middle Miocene, with divergence of Neo-*Astragalus* beginning ca. 4.4 Ma. BEAST chronogram is congruent with those resulting from Bayesian analyses. The timing of diversification events is illustrated by a chronogram derived from the all-compatible Bayesian consensus tree with dates for selected nodes constrained to the mean of penalized likelihood estimates obtained from sub-sampling of 1000 trees from the posterior distribution of the Bayesian MCMC tree search. The crown node age of the section *Incani*, is estimated to be 4.1 Mya. The posterior probability distribution of this dating supports a Pliocene origin for sect. *Incani*.

GCMS Analysis, phytochemical screening, antioxidant and radical scavenging capacities by novel and contemporary methods of different extracts of *Typha domigenesis*

Anjum Perveen[1], *Andleeb Anwar Sardar*[2], *Zaheeruddin Khan*[2]
1. Centre for Plant Conservation, University of Karachi
2. GC University Lahore, Department of Botany

Two innovative, rapid and cost-effective approaches for evaluation of antioxidant potential are developed. N, N- Diphenyl Para Phenylene Diamine (DPPD) decolorization assay and Diamino Naphthalene Decolorization assay are developed for the screening of antioxidant activity. Both of these assays evaluate the free radical scavenging activity of analytes. A chromogenic reaction takes place between DPPD and DAN with potassium persulfate at selective pH produces two distinct radical cations with maximum absorption at 700 nm and 575 nm in its first-order derivative spectrum. A linear inhibition of color production was observed with linearly increasing amounts of antioxidants, with correlation coefficients (R^2) ranging from 0.999 to 0.982. The antioxidant capacity of standard solutions of different hydrophilic and hydrophobic antioxidants was evaluated. Comparison of antioxidant capacity determined with these newly developed DPPD assay and DAN assay with the well-known 2,2'- azinobis-[3-ethylbenzthiazoline-6-sulfonic acid] (ABTS)-persulfate decolorization assay indicated the efficacy and sensitivity of the procedure. The proposed assays are less expensive (costs about US$5 per 100 assays) and require very short time for preparation of radical cation solution in comparison with ABTS assay. These novel assays are also applied for evaluation of antioxidant potential of *Typha domigenesis* and the results obtained are very much in accordance with other contemporary methods. DAN decolorization assay is applied to plasma samples to evaluate the antioxidant activity of plasma or the oxidative stress level of plasma. The results of phytochemical screening and Gas chromatographic analysis reveals that *Typha domigenesis* are enriched with Flavonoids, alkaloids, polyphenols, Terpenoids and other important classes of phytochemicals.

From Eurasia to the Americas and back: Biogeographic patterns in *Zanthoxylum* (Rutaceae)

Marc Appelhans[1,2], *Niklas Reichelt*[1], *Jun Wen*[2]
1. University of Goettingen
2. Smithsonian Institution

The genus *Zanthoxylum* is the second largest genus within the *Citrus* family (Rutaceae) and its 220+ species are distributed throughout the tropics of the New and the Old World with several species in temperate regions in Asia and eastern North America. Several species are used in traditional medicine and as a spice (`Sichuan pepper`) and the genus is usually easily distinguishable by its prickles on trunks and branches ('knobthorns') and sometimes on the leaf rhachis. The genus had been largely neglected by plant sytematists and we are presenting the first molecular phylogeny with a worldwide taxon sampling. Our results based on the markers ETS, ITS, *rps16* and *trnL-trnF* suggest that the Asian genera *Phellodendron* and *Tetradium* as well as the African and Malagasy *Fagaropsis* are the closest relatives of *Zanthoxylum*. *Toddalia*, a monotypic and widespread genus that occurs from Africa to eastern Asia, is not a separate genus but is part of the *Zanthoxylum* clade and is sister to the African and Malagasy species. *Zanthoxylum* was formerly split into the genera *Zanthoxylum* (small flowers with tepals) and *Fagara* (sepals and tepals). Our results show that a distinction between these two taxa is artificial. Four sections used to be recognized within *Fagara*. Out of these, the monotypic section *Mayu* and the American section *Tobinia* are monophyletic. The Australian and Pacific section *Blackburnia* is resolved as monophyletic in the plastid trees, but as paraphyletic in the ETS/ITS trees due to the phylogenetic position of the Hawaiian species. An ILD test revealed that the alignments of the different markers were only congruent after the Hawaiian species had been excluded. A hybridization event prior to the colonization of Hawaii is the most likely explanation for this incongruence. The most species rich section *Macqueria* is largely polyphyletic. Due to the rich fossil record of *Zanthoxylum*, *Tetradium* and *Phellodendron*, this group is well-suited for biogeographic studies. The oldest fossils have been found in the Early Eocene in Europe. The results of our molecular dating and ancestral area reconstructions suggest a Eurasian origin of *Zanthoxylum* in the Early Eocene. From there, one migration to Africa and Madagascar and several migrations to eastern Asia were inferred. One lineage migrated to the Americas and colonized both the northern and southern continent. This lineage also gave rise to a small Asian lineage with tepalous flowers, so that *Zanthoxylum* first crossed the Atlantic Ocean from Eurasia to North America and migrated back to Asia via the Pacific or across the Bering Strait.

Revised infrageneric classification of *Homalium* (Salicaceae) and taxonomic revisionary studies of Malagasy sections.

Wendy Applequist
Missouri Botanical Garden

The pantropical woody genus *Homalium* (Salicaceae, formerly Flacourtiaceae) includes slightly over 150 currently recognized species. The genus is characterized by two perianth whorls, semi-inferior ovaries, and single large glands at the base of each sepal. It encompasses considerable floral diversity and has previously been divided into two subgenera (characterized by having stamens one per petal or fasciculate) and ten sections. Based on floral morphology, it is possible to conclude with considerable confidence that the subgenera are not monophyletic. Therefore, only sections should be recognized. This author has proposed that all fasciculate-stamened Asian, Malesian and Pacific species formerly included in sect. *Eumyriantheia* should be transferred to sect. *Polyanthera*. The primary center of diversity is Madagascar, where six sections are present, of which five are endemic. The previous taxonomic treatment of *Homalium* in Madagascar, dating to 1973, recognized 36 species. With the much larger volume of material now available, revisionary studies recently completed or now in progress reveal that at least 54 species are present. Underdescription may occur in other regions as well.

Canalization and modularity of “fit” vs. advertisement traits of triggerplant flowers (Stylidiaceae)

W. Scott Armbruster[1], *Juliet A. Wege*[2]
1. University of Portsmouth
2. Western Australia Department of Parks and Wildlife

In 1960 Raissa Berg suggested that plants with flowers involved in specialized pollination should experience pollinator-mediated canalizing selection, and that such plants should evolve floral modularity, i.e., phenotypic independence of floral traits from variation in plant stature, leaf size, *etc*. She found support for this hypothesis in the correlation patterns within and among floral and vegetative traits. However, the strength of stabilizing and canalizing selection can be expected also to vary among floral traits. For example, one could predict that traits related to floral fit with pollinators will be under stronger canalizing selection than advertisement traits. In addition, modularity is also a possible outcome of genetic-developmental organization rather than selected by pollination function. We might thus expect all floral parts to be similarly integrated into a floral module, with non-floral parts forming a separate module or modules. We used several approaches to test these ideas in 9 species of triggerplant, *Stylidium* (Stylidiaceae), a genus with flowers that transfer pollen via a motile, protandrous columns formed by the fusion of staminate and pistillate tissues. Exploratory factor analyses of 15 traits suggested that traits related to pollination precision and pollinator fit (e.g., column length, corolla-tube length) generally form a module separate from those traits related to advertisement (e.g. petal length and width). Both sets of traits were largely decoupled from variation in a module comprising vegetative traits. We also examined the allometric relationships between size parameters and specific floral traits, with emphasis on contrasting floral traits that can be expected to be under strong (precision and fit) vs. weak canalizing selection (advertisement). We found that, as predicted, traits important in determining floral fit with pollinators (and where anthers and stigmas contact pollinators) varied less and were generally more negatively allometric in relation to variation in non-floral traits than those floral traits involved purely in attraction. Finally we assessed and compared the adaptive accuracies of pollen deposition (column exertion, male phase) and retrieval (column exertion, female phase) to evaluate within- and among-species relationships. Extremely high fundamental pollination accuracy was observed in all 9 species, although realized accuracies are much lower in some.

The phylogenomic study on mainland Southeast Asian Andropogoneae (Poaceae)

Watchara Arthan[1,2], *Michael R. Mckain*[3], *Paweena Traiperm*[1], *Cassiano A. D. Welker*[4], *Jordan K. Teisher*[3,5], *Elizabeth A. Kellogg*[3]
1. Department of Plant Science, Faculty of Science, Mahidol University, King Rama VI Road, Ratchathewi, Bangkok 10400, Thailand
2. Department of Pharmaceutical Botany, Faculty of Pharmacy, Mahidol University, Si Ayutthaya Road, Ratchathewi, Bangkok 10400, Thailand
3. Donald Danforth Plant Science Center, 975 North Warson Road, St. Louis, Missouri 63132 USA
4. Universidade Federal de Uberlândia, Instituto de Biologia, Rua Ceará s/n, Uberlândia, Minas Gerais 38400-902, Brazil
5. Academy of Natural Sciences of Drexel University, 1900 Benjamin Franklin Parkway, Philadelphia, PA 19103 USA

Andropogoneae evolution has been investigated extensively because of the economic and ecological importance of the tribe and wide native distributions in Africa, America, and Asia. Within these ranges, Southeast Asian Andropogoneae represents extensive and novel diversity from widespread genera, such as *Andropogon* and *Schizachyrium*, to several minor genera such as *Coix*, *Hemisorghum*, *Kerriochloa*, and *Pseudosorghum*, which are characterized by various and unique forms of inflorescences and spikelet structures. However, evolutionary relationships with other Andropogoneae need to be resolved and the taxonomic status of the Southeast Asian taxa needs to be re-evaluated. Full plastomes of Southeast Asian Andropogoneae were analyzed with Maximum Likelihood (ML) and Bayesian Inference. To understand morphological trends, four characters of inflorescences and spikelets were optimized by ML. *Coix*, *Hemisorghum*, *Kerriochloa*, *Pseudosorghum*, and *Andropogon burmanicus* were discovered to diverge outside core Andropogoneae. In core Andropogoneae, *Andropogon* and *Schizachyrium* are polyphyletic genera. *Schizachyrium sanguineum* populations divided into two clades, implying that its populations are being driven by cryptic species differentiation, hybridization, or introgression. However, other species with multiple accessions were monophyletic. In morphological evolution, convergent evolution and reversal are common throughout Andropogoneae, especially in the traits of inflorescence and spikelet. Striking diversity in reproductive parts is evident among minor genera of Southeast Asian grasses. In *Andropogon* and *Schizachyrium*, the traits are so variable that both genera cannot be distinguished from each other using traditional characters.

Resolving the *Coccineum* complex in *Hedychium* J. Koenig (Zingiberaceae) using molecular and morphometric data

Ajith Ashokan, *Vinita Gowda*
Indian Institute of Science Education and Research- Bhopal

The true species and taxonomic identifications are confusing within *Hedychium* due to the occurrence of intermediate forms (hybrids and polyploids) and clinal variations. Taxa that are not accepted as unique species are considered to be part of a species complex and several complexes have now been identified within the genus *Hedychium*. In Indian subcontinent, *Coccineum* (7 taxa) and *Coronarium* (8 taxa) are the two main species complexes among *Hedychium* that contain species that are undistinguishable based on morphology alone. *Coccineum* complex consists of at least seven species- *Hedychium angustifolium* Roxb., *H. aurantiacum* Roscoe, *H. carneum* G. Lodd., *H. coccineum* Buch.-Ham. ex Sm., *H. longifolium* Roscoe, *H. roscoei* Wall. and *H. squarrosum* Buch.-Ham. ex Wall. All taxa included in this complex are distributed in the Himalayan and/or Indo-Myanmar ecoregions. Of the seven species, six of them are native to the Indian state of Meghalaya (collection location is unknown for *H. roscoei*). Previous treatments of this complex have resulted in lumping all species under one name, *H. coccineum* Buch.-Ham. ex Sm. However, *H. coccineum* has much broader distribution and phenology ranges compared to other members in the complex and we strongly suggest that this group cannot be accommodated under a single name. We believe that many of the species within the *Coccineum* complex show overlaps in their distributional ranges and thus similar ecological conditions might have shaped their morphologies in a more homoplasious manner, and further resulted in the cryptic species status of *H. coccineum* and its allies. During our sampling surveys in the NE Indian states, especially in Meghalaya we observed and collected many of the *Coccineum* and its allies. The phenology data for these species were obtained from the available herbarium specimens, regional floras and last two years field observations. The flowering periods of five *Coccineum* complex species coincide with the monsoon season (June to September) and they overlap at least for a month. Phenology data for *H. roscoei* and *H. squarrosum* are not available since we could not locate any individuals of these species in the field and the protologues were silent about their phenology. Morphological characters were coded in the field and herbaria to understand the variability within and among species. PCA revealed that the morphological characters overlap among different taxa within the *Coccineum* complex. Using field observations we have now identified eight key floral characters (out of 152 original characters) which are believed to vary within and among populations. Many of these characters are not retained in herbarium specimens. This is a huge improvement in our understanding of morphological variations since all of the 8 characters have a potential to be selected by ecological factors such as pollinators, and dispersers and they may contribute significantly towards the plants reproductive success. Earlier confusions generated by the morphological characters had forced the recent studies to focus on the molecular tools for clearly resolving the species boundaries. Interestingly, no representative taxa other than *H. coccineum* were included in any molecular investigations which demands further analysis using molecular tools.

P0281

Studies on morphological variations and evolutionary trends of the genus *Murdannia* Royle (Commelinaceae)

Anna Ancy Antony Attullil[1], *Santhosh Nampy*[2]
1. St. Albert's College, Ernakulam
2. Calicut University

Murdannia Royle (Commelinaceae), with about 52 species worldwide, is represented by 26 species in India. It is the largest genus of Commelinaceae in Asia and has more species in India (50% of the total) than in any other country in the world. The genus is studied in India based on field and herbaria data and the characters are recorded. Entire morphological variations within the genus are considered. Morphometric analysis of the species occurring in India is performed with NTSYS software. Twenty six species occurring in India are selected as Operational Taxonomic Units (OTU's) and a data matrix is prepared on vegetative, floral and seed characters. Sixty one characters are used for the cluster analysis and a dendrogram is prepared. The study shows that the Indian species falls under 6 distinct sub-clades in 3 different homogeneous clades portraying the inter relationships among the species. Variations in morphology including reduction and modification of vegetative and floral parts prove helpful in resolving evolutionary relationships within the genus.

Phylogenetics of the *Bouteloua gracilis* complex (Poaceae)

Marcela Avendaño-González[1], *Maria Elena Siqueiros-Delgado*[1], *Travis Columbus*[2], *Francisco Morales-Dominguez*[1]
1. Universidad Autónoma de Aguascalientes
2. Rancho Santana Botanic Garden

B. gracilis (Kunth) Lag. ex Griffiths is the most common specie in the north american semiarid grassland. The species is distributed natively from southern Canada through the central and western USA to Mexico, and throughout this wide range populations vary appreciably in morphology and chromosome number ($2n$ = 20–84). The basis of morphological differences between populations– genetic and/or environmental– of this species remain unclear and genetic variation among *B. gracilis* populations throughout its distribution is unknown. Nuclear and chloroplast markers sequenced (ITS, *rpL32-trnL* and *rps16-trnK*) resulted invariant in this species populations from throughout the geographic range of the species, indicating that a different approach is needed to understand diversification within *B. gracilis*. Additionally, based on the same data, conflicting topologies, and low clade support, it remains doubtful which of four closely related species is sister to *B. gracilis*. Restriction site-associated next-generation DNA sequencing (RADseq) is going to be employed to reveal relationships among populations of *B. gracilis* and its sisters. Our objective is to resolve relationships in the *B. gracilis* complex, test the monophyly of each currently recognized species and determine if populations within the morphological highly variable *B. gracilis* justify separate species or subspecies recognition as well as examine this species morphology in a phylogenetic context. All potential sister species of *B. gracilis* have been sampled from throughout their distributions in Mexico. Thirty-three populations of *B. gracilis* were sampled, and USA populations will be sampled this summer. Genomic DNA is extracted and RNA purified in order to obtain good DNA quality and quantity. Samples (96) will be sequenced using one lane for RADseq, 87 samples of *B. gracilis*, two samples from each of the four candidate sister species, and one sample of *B. ramosa* (outgroup) will be included. Phylogenetic inference (maximum likelihood and Bayesian) will be carried out after processing the sequences. To evaluate the morphological variation in *B. gracilis* throughout its range, a morphometric analysis will be carried out using specimens from Mexico and USA, including those included in the molecular study. Many vegetative and reproductive traits will be measured and then subjected to various analyses (e.g., ordination and statistical analysis).

P0283

Phylogenomics and spatio-temporal evolution of the Neotropical genus *Amphilophium* (Bignonieae, Bignoniaceae)

Veronica Thode[1], *Isabel Sanmartin*[2], *Lúcia G. Lohmann*[1]

1. Universidade de São Paulo
2. Real Jardín Botánico, RJB-CSIC

The Neotropics represent one of the most biodiverse areas on Earth. Yet, the processes that have shaped such high levels of diversity remain poorly understood. Detailed information on the geographic distribution of taxa combined with time-calibrated phylogenies are key for an improved understanding of the Neotropical history. While previous attempts to reconstruct the spatio-temporal history of Neotropical plants have been based on a few molecular markers, there is growing consensus that phylogenomic approaches based on multiple markers are needed to solve problems of species tree/gene tree incongruence and lack of resolution due to rapid diversification. *Amphilophium* (Bignonieae, Bignoniaceae) includes 47 species with diverse morphology and distribution patterns, representing an excellent model to study the origin and assembly of the Neotropical Biota. In this study, we use 36 newly generated plastid genomes to reconstruct phylogenetic relationships, estimate divergence times and reconstruct temporal and spatial patterns of evolution within the genus. Our dataset consists on alignments with ca. 140 kilobases (Kb), including 78 protein-coding regions that concatenated resulted in a matrix with ca. 62 Kb or 20,600 amino acids when translated. Phylogenetic relationships were estimated using Maximum likelihood (RAxML) and Bayesian inference (MrBayes 3.2.6) as well as site-heterogeneous models in PhyloBayes MPI 1.7. Divergence times were estimated using Bayesian relaxed clock methods implemented in BEAST 1.8.3 and PhyloBayes MPI 1.7, while ancestral ranges and rates of geographic range shifts were inferred using the ML Dispersal-Extinction-Cladogenesis model (DEC) in Lagrange. Our molecular phylogenetic analyses corroborate the monophyly of *Amphilophium* and reconstructs strongly supported clades within the genus that are also well characterized by morphological synapomophies. The spatiotemporal evolution of *Amphilophium* indicates that the genus diversified during the Neogene (23-2.6 My), a period characterized by intense geological activity and climatic changes in the Neotropics. Interestingly, diversification in the Atlantic forest started ca. 21 My, while the Amazonian radiation occurred much more recently, at around 4.6 My. This study shows one of the first phylogenomic studies of a Neotropical plant group. The well-sampled and strongly supported plastid phylogeny of *Amphilophium* provides a solid basis to explore the mechanisms associated with the assembly and evolution of the Neotropical Biota.

Diversity of pollen types in Apiales – a phylogenetic approach

Jakub Baczyński, *Aleksandra Miłobędzka, Krzysztof Spalik, Łukasz Banasiak*
University of Warsaw Biological and Chemical Research Centre, Department of Molecular Phylogenetics and Evolution

Angiosperm order Apiales comprises almost 5500 species classified in seven families. The largest of them, Apiaceae (umbellifers) and Araliaceae, have long been treated as closely related. The other families - Pittosporaceae, Griseliniaceae, Torricelliaceae, Pennantiaceae, and Myodocarpaceae - have been recognized or reclassified quite recently based on molecular data. Our knowledge on morphological evolution in this group is therefore limited due to the lack of comparative studies conducted within the framework of modern phylogeny. In this study we have analyzed evolution of pollen morphology in Apiales. The results are based upon comprehensive phylogenetic sampling of c. 150 taxa including representatives of all major lineages recognized in the order with particular emphasis on Araliaceae and Apiaceae. For each species included in the study we have defined a set of 17 discrete and 11 continuous traits and subsequently ancestral morphology was reconstructed on a molecular phylogenetic tree. We conclude that most families share a rather uniform (plesiomorphic) morphology characterized by prolate/oblate spheroidal shape, relatively thin wall, long ectocolpus and broad, elongated ora. The advanced morphology resulting from shortening of equatorial axis and gradual reduction of compound aperture is generally apomorphic for umbellifers.

P0285
Genetic variation of Ulleung Island endemic *Saxifraga fortunei* var. *pilosissima* Nakai and its alliance

Sang-Hun Baek[1], *Jin Suk Youn*[1], *Jung Sung Kim*[2], *Jae-Hong Pak*[1,2]
1. Depart of Biology, Kyungpook National University
2. Research Institute for Dokdo and Ulleung-do Island, Kyungpook National University

Saxifraga fortune, a perennial herb species, is widely distributed in Eastern Asia and two varieties have been reported from Korea. One is *Saxifraga fortunei* var. *incisolobata* (Engl. & Irmsch.) Nakai which found in high and humid mountain are of South Korea, the other is *Saxifraga fortunei* var. *pilosissima* Nakai which is morphologically similar to S. *fortunei* var. *incisolobata* (Engl. & Irmsch.) Nakai. The latter one is well-known endemic taxa of Ulleung-island, an eastern volcanic island of Korea. Even though some taxonomist had described the morphological difference of them, it is too difficult to recognize each other due to the overlapped variation between them and it has been still argued the relationship and their taxonomical circumscription. To clear their relationship and understand their evolutionary history, we tried to analyze genetic diversity of them in this study. We collected two population of *Saxifraga fortunei* var. *pilosissima* from Ulleung Island and five populations of *Saxifraga fortunei* var. *incisolobata* from inland of Korea peninsular. We analyzed and compared the sequences of two cpDNA non-coding regions (*trnL-F, psbA-trnH*) and nrITS. Based on sequence variation among them, we found three different haplotypes from each region. Both of Ulleung Island populations of *Saxifraga fortunei* var. *pilosissima* were genetically identical and shared the haplotype against to inland populations of S. *fortunei* var. *incisolobata* which have two different haplotypes. It meant that *S. fortunei var. pilosissima* have genetically diverged from *S. fortunei var. incisolobata* in spite of high morphological similarity. Besides, finding of intermediate type between both taxa suggested the probability of more dynamic relationship among them.

Do males and females in Pleurocarpous mosses differ in their environmental niches?

Irene Bisang[1], *Johan Ehrlén*[2], *Lars Hedenäs*[1]
1. Swedish Museum of Natural History
2. Stockholm University

Biased adult sex ratios (SR), usually inferred from counts of sexually mature plants, are commonly observed in unisexual bryophyte species. For sex-expressing bryophytes, there is evidence of spatial variation of reproductive traits, including SRs, related to environmental conditions. However, how sexes in rarely fertile or non-fertile species are distributed with regard to environmental factors is largely unknown. We determined genetic sex ratio (GSR), irrespective of sex expression, in natural populations of two pleurocarpous mosses, using a specifically designed female-targeting molecular marker. We measured environmental conditions and assessed whether sexual niche partitioning may contribute to spatial variation in GSR. *Drepanocladus trifarius* and *D. lycopodioides*, two wetland mosses with a documented female bias in overall European GSR, differ from each other in the levels of realized sexual reproduction both at the European scale, and in the study areas (sporophytes absent vs. present). We sampled 214 individual shoots of *D. trifarius* in a completely random design in a population in Central Sweden, and 660 individual shoots of D. *lycopodioides* stratified randomly in 11 local populations in each of three regions in the Swedish Baltic. We confirmed that GSR is female-biased in local and regional populations in both species. In *D. trifarius*, spatial distributions of genetically male and female shoots were not more clustered than expected under random distribution, and environmental factors did not differ between locations with females and males, indicating lack of sexual niche partitioning. In *D. lycopodioides*, GSR varied among local populations and differed among the three study regions. Habitat patch size and Habitat wetness strongly affected GSR and the occurrence of genetically male plants, genetically male plants not occurring in the wettest habitats. We suggest that this is due to higher energy requirements of females due to sporophyte maturation, indicating sexual niche partitioning. We hypothesize that the evolution of sexual niche partitioning between genetic sexes is unlikely in species without or very rare sexual reproduction.

P0288
Phylogenomics of *Ephedra*

Ruben Blokzijl[1], *Niklas Wikström*[2], *Catarina Rydin*[1,2]
1. Stockholm University
2. Bergius Botanic Garden

Relationships among species within *Ephedra* are partly poorly understood, despite previous efforts. *Ephedra* comprises 50-60 species native to arid regions of the Northern Hemisphere and South America. Classification of *Ephedra* based upon morphological characteristics is hard, due to limited character variation and parallel evolution of characters. Besides, results based on molecular data show incongruence with the morphological classifications. The long evolutionary distance to outgroups and the low amount of variation in molecular markers have hampered the inference of *Ephedra*. Previous studies using dense taxon sampling and several molecular markers indicate geographical groupings of species but results are partly weakly supported. We address the phylogeny of *Ephedra* using Next Generation Sequencing data, thus a substantially larger amount of characters, but reduced taxon sampling compared with previous studies.

T2
P0289
Pollen and pollination of *Ephedra* (Gnetales)

Kristina Bolinder, *Catarina Rydin*
Stockholm University

Most gymnosperms are, in contrast to angiosperms, pollinated solely by wind. The pollination biology of the enigmatic gymnosperm group *Ephedra* (Gnetales) is understudied and partly misunderstood. In a series of studies we have therefore investigated pollination biology and reproductive morphology of the group. Through extensive field work in northeastern Greece we found that the sister species to the remaining genus, *E. foeminea*, is insect-pollinated. The pollination system is of a generalist nature but nocturnal moths are among important pollinators. The moths navigate using the moon and interestingly enough the secretion of the pollination drops is correlated with the lunar cycle. Insect pollination is the ancestral state in *Ephedra* and during the long evolutionary history of the genus there has been a shift in pollination mechanism, from insect pollination to wind pollination, which is the prevailing state in the crown-group. In *Ephedra*, the pollen morphology and the composition of the exine is closely related to the pollination biology. Its pollen is ellipsoid and characteristically polyplicate. Insect-pollinated species have smaller pollen grains with a significantly larger number of plica whereas wind-pollinated species have fewer plicae and a branched pseudosulci between each pair of plicae. The ultrastructure of the exine differs between the groups, which has consequences for the settling velocity of the grains and thus for the aerodynamic features of the pollen grains. The density of the granules in the infratectum is higher in *E. foeminea* compared to investigated wind-pollinated species. A higher settling velocity results in a lower flight capability for the insect-pollinated species. Investigated wind-pollinated species have, in contrast, a lower settling velocity and better flight capability. Also, the morphology of the female cones is to some degree related to the pollination biology. In wind-pollinated species the morphology of the female cones and the tilt towards the stem creates and aerodynamic environment that is so specific that is can sort out conspecific pollen grains. In the insect-pollinated *E. foeminea*, however, the morphology of the cone is not aerodynamically adapted for collection of pollen grains.

3. Inra
4. Ird

Pl@ntNet is a free web and mobile platform dedicated to automated, image-based plant identification and to collaborative gathering of plant observations (http://identify.plantnet-project.org/). It relies on crowdsourcing approaches and machine learning techniques for data production, validation and enrichment. First launched in 2013 on 800 French native species, it now covers a large part of European flora (6,200 spp.) and has been extended to other floristic domains, such as the Mascarene Islands, the Guiana Shield and Maghreb. Through its iPhone and Android apps (> 3 million downloads and 10,000-50,000 daily users), Pl@ntNet gathers increasingly large amounts of botanical observations voluntarily contributed by an array of people who are often novice in plant identification. These observations are continually checked and amended (for identifications and image quality) by hundreds of amateur botanists, through Pl@ntNet's collaborative web tools. We present the limits of this approach, as well as the perspectives of improvement, based on both the users feedback, and on analyses of the data already collected. This emphasize on one side, the potential of new technologies for botanical and ecological activities, and on the other side, the capacity of multi-disciplinary projects to address a few topical social needs at large scale.

Nucleolar dominance in grass allopolyploids – a closer look on interesting epigenetic phenomenon

Natalia Borowska-Zuchowska[1], *Ewa Robaszkiewicz*[1], *Miroslaw Kwasniewski*[2], *Alexander Betekhtin*[1], *Robert Hasterok*[1]
1. University of Silesia in Katowice, Faculty of Biology and Environmental Protection, Department of Plant Anatomy and Cytology
2. University of Silesia in Katowice, Faculty of Biology and Environmental Protection, Department of Genetics

Nucleolar dominance is an epigenetic phenomenon connected with the nuclear-encoded 35S rRNA genes. It is observed in several hybrids and allopoplyploids and consists in preferential suppression of rRNA gene loci inherited from one of the ancestral species. Considerable attention has been paid to discover the molecular mechanisms which stay behind this selective repression of rRNA gene loci. Most experiments using DNA hypomethylating agents, bisulphite-mediated 5-methylcytosine mapping and RNAi knock down of the genes encoding for chromatin modifying proteins proved that the nucleolar dominance has an epigenetic origin (Preuss *et al.,* 2008, *Molecular Cell* 32: 673–684). Despite the fact that more than 80 years have passed since the discovery of nucleolar dominance in *Crepis* hybrids, our understanding of exact mechanisms that determine this process is still fragmentary, especially in the case of the Poaceae family members. In 2008, the presence of this phenomenon has been described in the *Brachypodium* genus, which belongs to the grass family. *B. hybridum* is a natural allotetraploid (2n=30) with putative parental genomes originated from two diploid species, i.e. *B. distachyon* (2n=10) and *B. stacei* (2n=20). Preferential silencing of *B. stacei*-inherited ribosomal RNA genes in this allotetraploid was reported (Idziak and Hasterok 2008, *Genome* 51: 387-391). This presentation outlines the studies on the nucleolar dominance mechanisms in several *B. hybridum* genotypes originated from various geographic locations. The distribution of 35S rDNA loci inherited from ancestral species was determined in both mitotic and meiotic cells. Moreover, we aimed to investigate the epigenetic status of 35 rRNA gene loci in *B. hybridum* and its putative diploid ancestors by the determination of DNA methylation and selected histone modifications (e.g. H4K5ac, H4K16ac, H3K9ac and H3K9me2) immunopatterns. We also show the results of molecular characterisation of intergenic spacers (IGS) between 25S rDNA and 18S rDNA in *B. hybridum* and its progenitors as well as their physical localisation in metaphase chromosomes and interphase nuclei. In all IGS sequences we identified putative transcription initiation sites and spacer promoters followed by subrepeats. Their contribution in selective silencing of 35S rDNA loci is further discussed.

P0292

Pollen morphology of *Dionysia* Fenzl (Primulaceae) in comparison with other Primulaceae genera.

Dmitriy Britski
Komarov Botanical Institute of Russian Academy of Sciences; St.-Petersburg; Russia

Pollen morphology of 9 species, belonging to genus *Dionysia* (*Dionysia aretioides* (Lehm.) Boiss., *D. bryoides* Boiss., *D. hausskneсhtii* Bornm. & Strauss, *D. hedgei* Wendelbo, *D. hissarica* Lipsky, *D. involucrata* Zapriag., *D. leucotricha* Bornm., *D. michauxii* (Duby) Boiss., *D. microphylla* Wendelbo) was examined by light microscope (LM), scanning electron microscope (SEM) and transmission electron microscope (TEM). The pollen grains of species under study were of medium sizes, spheroidal, polycolpate. Exine patterns were microreticulate, reticulate. Study by TEM showed semitectate exine structure, with short, thick columellae and poorly pronounced foot layer. The results were compared with previous data on pollen morphology of *Primula* and other genera of Primulaceae. Pollen of Primula species can be regarded in frames of 3 morphological types: 1) 3-colporate (*P. farinifolia, P. longiscapa, P. darialica, P. japonica, P.zeylamica, P. forbesii, P.malacoides, P bulleyana*). Endoapertures are small and unclear. Exine pattern is reticulate. 2) Syncolporate (*P. malvacea, P.floribunda, P.verticillata, P. arctica, P. auriculata, P. involucrata, P. turkestanica, P. nivalis, P. pumilio, P. warschenewskiana P.capitellata, P.rosea, P.scotica, P. viali, P.sachalinensis, P.stricta, P. cortusoides, P. eugeniae, P. lactiflora, P. minkvitziae, P. olgae, P. pinnata, P. saxifragifolia, P. algida, P. baernii, P. moorcroftiana, P. tschuktschorum, P. beringiensis, P.laurentiana, P. farinosa, P. borealis, P. cuneifolia, P.elliptica*). Syncolporate type is the most common pollen type in the genus *Primula*. Pollen grains of only one species, *P. malvaceae,* has well pronounced endoapertures, easily visible with light microscope. Small poor pronounced endoapertures are typical for other studied species. In literature pollen grains of these species are usually described as syncolpate but as the more investigations are undertaken sometimes including CLSM method, the more evidence appears for the presence of endoapertures. 3) Polycolpate (*P. amoena, P. egaliksensis, P. elatior, P. finnmarchica, P. heterochroma, P. iljinskii, P. longiflora, P.*

macrocalyx, P. nutans, P. pamirica, P. polyantha, P. pseudoelatior, P. pseudosikkimensis, P. ruprechtii, P. sibirica, P. veris).The last morphological type of *Primula* pollen grain is exactly the same, that was exposed for *Dionysia*. Two others differ from Dionysia pollen significantly. The common feature is weak or absent foot layer. Pollen grains of the rest of Primulaceae are 3-colporate, or, in some cases (Cortusa, Dodecatheon), syncolporate. Pollen of *Lysimachia*, *Naumburgia*, *Anagallis*, *Trientalis*, *Ardisiandra*, *Stimpsonia* are medium-sized, 3-colporate, endoapertures equatorially elongated, usually with sharp tapered ends. Exine patterns are perforate, microreticulate and reticulate. Pollen grains of *Androsace*, *Douglasia*, *Gregoria* and *Pomatosace* are small to medium size, with small round or slightly elliptical endoapertures and perforate or microreticulate exine. Thus, pollen grains of *Dionysia*, being very similar to pollen grains of some sections of *Primula*, differ significantly from pollen of the majority of Primulaceae species. From the palynological point of view, *Dionysia* and part of *Primula* can be united in one group.

The early cretaceous coal-forming plants of southern part of East Siberia and Russian Far East

Eugenia Bugdaeva, *Valentina Markevich*
Federal Scientific Center of the East Asia Terrestrial Biodiversity, FEB RAS

Coal formation in the geological past was linked with the development of plant communities that produced a large biomass and at the same time possessed relatively simple structure. A considerable part of the swamp phytomass became mortmass. The coal seams are particularly the subject of paleobotanical research. Using bulk maceration of coals we obtained the spores and pollen, as well as dispersed cuticle of the plants that gave rise to the Early Cretaceous coals of the Transbaikalia (Khilok, Chita-Ingoda, Bukachacha, and Turga-Kharanor basins), the Amur River Region (Bureya Basin), and the Primorye region (Razdolnaya River and Partizansk basins). The plants of the Khilok Basin that produced coals mainly belong to the extinct ginkgoaleans (*Baierella averianovii*). The coal-forming plants of the Chita-Ingoda and Bukachacha basins are more diverse. They are in the former represented by the bryophytes, lycophytes, cyatheaceous ferns, Umaltolepidiaceae (*Pseudotorellia*), Sphenobaieraceae *(Sphenobaiera starukhiniae*), in the latter– by the cyatheaceous and gleicheniaceous ferns, *Pseudotorellia transbaikalica*, conifers of araucariaceous affinity *Farndalea* sp., *Pityophyllum* sp. having pinaceous affinity. The coals of the Turga-Kharanor Basin consist of remains of the bryophytes, lycophytes, cyatheaceous ferns, *Pseudotorellia kharanorica,* and cheirolepidiaceous plant *Pagiophyllum* sp. The Early Cretaceous coals of the Partizansk Basin, Primorye region, are mostly composed of remains of gleicheniaceous ferns, taxodialean *Elatides asiatica*, subordinate Miroviaceae, rare ginkgoalean *Pseudotorellia* sp., and bennettite *Nilssoniopteris rithidorachis.* The coal-forming plants of the Razdolnaya River Basin mainly belong to the cyatheaceous and gleicheniaceous ferns, to the Miroviaceae (*Mirovia orientalis*, ginkgoalean *Pseudotorellia krassilovii*, to a lesser degree the coals of this basin are composed of other groups of conifers (including scale-leaved *Athrotaxites orientalis*) and bennettites *Nilssoniopteris rithidorachis, N. prynadae,* and *Anomozamites* sp. Thus, the Early Cretaceous mire plant communities of southern part of East Siberia were dominated by bryophytes, lycophytes, cyatheaceous ferns, ginkgoaleans, plants having affinity with Pinaceae and Araucariaceae, whereas those of the Russian Far East – mainly by gleicheniaceous ferns, bennettites, Miroviaceae, and conifers having taxodiaceous affinity. These plants provided a basis for the Early Cretaceous coals.

Evolution of the process underlying floral zygomorphy development in pentapetalous angiosperm

Ghadeer Bukhari, *Jingbo Zhang, Wenheng Zhang*
Virginia Commonwealth University

Observations of floral ontogeny indicated that floral organ initiation in pentapetalous flowers most commonly results in a medially positioned abaxial (MAB) petal instead of a medially positioned adaxial (MAD) petal during early development. It was proposed that the conservation of patterns of floral organ initiation might impose developmental constraint that limited the displays of floral zygomorphy that evolved in Asteridae. Here, we has provided the first study of the evolution of developmental processes of floral zygomorphy in pentapetalous angiosperms to investigate whether the patterns of floral organ initiation leads to biases in the evolution of displays of floral zygomorphy. We analyzed patterns of floral organ initiation, displays of floral zygomorphy, and developmental processes that give rise to floral zygomorphy extracted from floral diagrams representing 405 taxa in 330 genera on a phylogeny using ancestral state reconstructions. The results indicated that the MAB petal initiation is the ancestral state of the pattern of floral organ initiation in pentapetalous angiosperms. The remaining taxa, displaying the MAD petal initiation, represent 30 independent origins from the ancestral MAB initiation. There are distinct developmental processes to give rise to floral zygomorphy along diverse lineages of pentapetalous angiosperms, which closely related lineages are likely to share a similar developmental process. We have demonstrated that the development indeed constrains the process that gives rise to floral zygomorphy, while the phylogenetic distance allows the constraint to diverge. Our work provides novel insights on the role that development plays in evolution of floral zygomorphy.

P0295

Phylogenomics of *Atractylodes* (Asteraceae) and domestication of *A. macrocephala* Koidz.

Minqi Cai, *Pan Li, Li Zheng, Luxian Liu, Chengxin Fu*
The Key Laboratory of Conservation Biology for Endangered Wildlife of the Ministry of Education, College of Life Sciences, Zhejiang University

Atractylodes DC. (Asteraceae) is a small genus endemic to East Asia, containing five to seven species. Species from the *Atractylodes* have been used as the famous Traditional Chinese Medicine “Baizhu” and “Cangzhu”. In this study, we used RAD-seq to reconstruct phylogenetic relationships of *Atractylodes*, and to analyze the relationships among different cultivars of *A. macrocephala*. The conclsions of this study are as follows: 1) Phylogenetic and interspecific relationship of *Atractylodes.* Total 115 samples form56 populations used in the study were collected from China, Rassia, Korean peninsula, and Japanese archipelago (including five taxa, one subspecies, one cultivar and one outgroup from Germany). The maximum likelihood method was applied to the dataset including 77,036 unlinked-SNPs loci. The phylogeney of *Atractylodes* was well resolved, showing that this genus contains 6 monophyletic taxa. These were *A. carlinolides, A. macrocephala, A. japonica, A. coreana, A. lancea and A. chinensis*. However, whether the*"luotianensis"*should be treated as the subspecies of *A. lancea* or not, it needs further study. *A. ovata* (Thunb.) DC., widely used in Japan, is proved to refer to the same species with *A. japonica* Koidz. ex Kitam. 2) Evolution history, biogeography and reconstruction of ancestral distribution area of *Atractylodes.* Using six fossil calibrations of Asterales from previous study, BEAST analysis based on four chloroplast fragments revealed that the divergence time among *Atractylodes* was around late Miocene 8.66Ma. Employing this result, we calibrated the lineage of *Atractylodes* using BEAST analysis based on SNPs dataset. The results were also combined with the geographical distribution to carry out the reconstruction of ancestral distribution area. The result revealed that *Atractylodes* most likely originated in sourthern China. Combined with paleogeographic and paleoclimatic events, the ancestor of *Atractylodes* spread along the East Asian mid-latitude arid zone to sourthern China during 13.5Ma ~ 9.7Ma. *A. corlinoides* and *A. macrocephala* were firstly formed in sourthern China, then the rest spread to the Korean peninsula, Japan and northern China. The genus finally formed adaptation to the humid climate, but the niche of *Atractylodes* reflects the preferences of drought. 3) Phylogenetic relationships among different *A. macrocephala* populations. The result showed that the cultivated 'Pingzhu' is the basal clade within *A. macrocephala*, diverged at 3.28Ma, indicating the existence of *A. macrophala* 'Pingzhu'. The wild population "Qizhu" was sister to all other populations of *A. macrocephala* except 'Pingzhu'. The cultivar 'Pingzhu' and wild "Qizhu" haven't been involved in the formation process of widespread cultivated *A. macrocephala*. However, they are important germplasm resources in urgent need of protection. Depend on our sampling result, The cultivated populations of *A. macrocephala* in this study showed the tendency of single-origin.

Machine learning algorithms improve the power of phytolith analysis: A case study of the tribe Oryzeae (Poaceae)

Zhe Cai, *Song Ge*
Institute of Botany, Chinese Academy of Sciences

Phytoliths, as one of the important sources of microfossils, have been widely used in paleobotany related studies, especially in the grass family (Poaceae) where abundant phytoliths were found. Despite this, several challenges remain when phytoliths are used in various studies, including the accurate description of phytolith morphology and the reliable utilization of phytolith traits in taxon identification or discrimination. In this study, we collected 1063 phytolith samples from 18 taxa representing seven main genera in the tribe Oryzeae (subfamily Ehrhartoideae) and five taxa in the subfamilies Bambusoideae and Pooideae. By focusing on the tribe Oryzeae that has been extensively investigated in terms of taxonomy and phylogeny, we were able to evaluate the discrimination power of phytoliths at lower taxonomic level in grasses. With the help of morphometric analysis and by introducing several machine learning algorithms, we found that 87.7% of the phytoliths could be classified correctly at genus level (support vector machine algorithm, false positive rate 0.02), significantly increasing the resolving power of phytolith evidence in these groups of plants compared with the results by traditional phytolith analysis method. On these bases, we proposed a pipeline of phytolith analyses, including data collection, morphometric analysis and classifier construction for phytolith discrimination. The pipeline should be applied to various studies across different groups of plants. This study provides new insights into the utilization of phytoliths in evolutionary and ecology studies involving grasses and plants in general.

P0297

Does a dynamic genome drive speciation in a mega-diverse genus?

Lucia Campos-Dominguez[1,2], *Catherine Kidner*[1,2]
1. University of Edinburgh
2. Royal Botanic Garden Edinburgh

Speciation events are always driven by genetic changes that cause phenotypic effects, which may be either adaptive, driven by selection, or can be fixed in genetically isolated populations through the action of genetic drift. Such changes can range from small point mutations to the activation of transposons, including large scale chromosome rearrangements such as duplications, deletions and/or inversions. Tropical areas contain the highest levels of biodiversity on Earth, being considered a very species-rich ecosystem. With more than 1900 species, the genus *Begonia* is one of the most species-rich in the tropics. Recent taxonomic studies on *Begonia* provide a robust phylogenetic background for the analysis of evolutionary patterns across the group, and confirm niche specificity cannot be the only factor driving speciation. Furthermore, previous studies have shown wide variation in genome size and repetitive element content across the genus. In this context, we aim to determine the role of genome dynamics and composition in driving the repeated bursts of speciation indicated by the phylogeny. To achieve this, species representing different *Begonia* clades have been selected for genomic structure analysis. Variation in DNA repeats and transposon composition across different radiations has been studied, as well as active transposable machinery using *Begonia* transcriptomes. Such approaches aim to reveal the genome dynamics behind the *Begonia* speciation events, providing new insights on the role of non-coding elements in plant genome evolution.

Guizhou Province—A holy land of musci flora

Wei Cao, *Yuanxin Xiong, Xianzhen Luo, Hongying Tan*
College of Life Science, Guizhou University, Guiyang, China

Guizhou Province is situated in the Southwest of China. It covers an area of 176 167km2, lying between 24°37′ and 29°13′N and between 130°36′ and 109°35′E. It is located in the eastern slope of the Yunnan-Guizhou Plateau. It belongs to subtropical climate, and in most part of Guizhou, the annual precipitation is ca 1000-1400 mm, and the annual temperature varies 11-19 ℃ . Because of its comfortable climate and complex geomorphic types, it becomes a high biological diversity region. For instance, the total number of bryophytes of Guizhou is just less than Yunnan Province which is one of regions with the highest biological diversity in China. A latest checklist of the Musci for Guizhou Province includes 1058 species, 32 varieties, 6 subspecies in 286 genera and 57 families. In this checklist, 57 species and 5 varieties are endemic to China, including 8 species are endemic in Southeast of China as well as 2 species and 3 varieties are just found in Guizhou. Furthermore, a total of 3 genera, 22 species, 2 varieties and 1 subspecies are newly reported for Guizhou. Moreover, there are some rare species such as Trachyloma indicum var. obtusifolium Y.-X.Xiong & X.-Z.Luo (Pterobryaceae) and Plagiomnium guizhouense Y.-J. Yi & S.He (Minaceae) are new species published past few years and just seen in a very narrow region, Erpodium (Erpodiaceae) is a newly recorded genus in China, and Cytodontopsis leveillei (Thér) P. C. Rao & Enroth (Cryphaeaceae) are recollected from Guizhou and so on. The information in this abstract is based on two monographs “Bryophyte Flora of Guizhou” Vols. I and II and more than 40000 specimens (collected from ca 80 counties of Guizhou, including 9 National Nature Reserves, 6 Provincial Nature Reserves, most of the forest parks and dozens of small nature reserves.) held in GACP, IFSBH and PE herbaria. In fact, the moss flora of Guizhou is still incompletely known by us, and the present list is relatively conservative. Besides, we still have a little knowledge of the liverworts and hornworts of Guizhou, more in-depth research about bryophytes in Guizhou is very necessary.

Past climate changes facilitated homoploid speciation in three mountain spiny fescues (*Festuca*, Poaceae)

Isabel Marques[1], *David Draper*[2], *Maria Luisa Lopez-Herranz*[1], *Teresa Garnatje*[3], *Jose Gabriel Segarra-Moragues*[4], *Pilar Catalan*[1]

1. Universidad de Zaragoza
2. Universidade de Lisboa
3. Institut Botanic de Barcelona
4. Universitat de Valencia

Apart from the overwhelming cases of allopolyploidization, the impact of speciation through homoploid hybridization is becoming more relevant than previously thought. Much less is known, however, about the impact of climate changes as a driven factor of speciation. To investigate these issues, we selected *Festuca picoeuropeana*, an hypothetical natural hybrid between the diploid species *F. eskia* and *F. gautieri* that occurs in two different mountain ranges (Cantabrian Mountains and Pyrenees) separated by more than 400 km. To unravel the outcomes of this mode of speciation and the impact of climate during speciation we used a multidisciplinary approach combining genome size and chromosome counts, data from an extensive nuclear genotypic analysis, plastid sequences and ecological niche models (ENM). Our results show that the same homoploid hybrid was originated independently in the two mountain ranges, being currently isolated from both parents and producing viable seeds. Parental species had the opportunity to contact as early as 21000 years ago although niche divergence occurs nowadays as result of a climate-driven shift. A high degree of niche divergence was observed between the hybrid and its parents and no recent introgression or backcrossed hybrids were detected, supporting the current presence of reproductive isolation barriers between these species.

Different colonization routes explain the genetic structure and diversity of the model grass *Brachypodium stacei* in the Western Mediterranean

Valeriia Shiposha[1], *Pilar Catalan*[1], *Marina Olonova*[2], *Isabel Marques*[1]

1. Universidad de Zaragoza
2. Tomsk State University

Mediterranean species of the genus *Brachypodium* are promising energy crops since their selfing nature and annual life cycles are an advantage in breeding programs. Some species, like the false brome *B. distachyon*, have already been sequenced and new genomic initiatives have triggered the *de-novo* genome sequencing of its close relatives such as *B. stacei*, a species that was until recently mistaken for *B. distachyon*. But the success of these initiatives hinges on detailed knowledge about the distribution of genetic variation within and among populations for the effective use of germplasm in a breeding program. Understanding population genetic structure is also an important prerequisite for designing effective experimental populations for genomic wide studies. However, population genetic data are still limited in *B. stacei*. We therefore selected and amplified 10 nuclear microsatellite markers to depict patterns of population structure and genetic variation among 181 individuals from 19 populations of *B. stacei* occurring in its predominant range, the Western Mediterranean area: mainland Iberian Peninsula, continental Balearic Islands and oceanic Canary Islands. Our genetic results support the occurrence of a predominant selfing system with extremely high levels of homozygosity across the analyzed populations. Despite the low level of genetic variation found, two different genetic clusters were retrieved, one clustering all SE Iberian mainland populations and the island of Minorca and another one grouping all S Iberian mainland populations, the Canary Islands and all Majorcan populations except one that clustered with the former group. These results, together with a high sharing of alleles (89%) suggest different colonization routes from the mainland Iberian Peninsula into the islands. A recent colonization scenario could explain the relatively low levels of genetic diversity and low number of alleles found in the Canary Islands populations while older colonization events are hypothesized to explain the high genetic diversity values found in the Majorcan populations. Our study provides widely applicable information about geographical patterns of genetic variation in *B. stacei*. Among others, the genetic pattern and the existence of local alleles will need to be adequately reflected in the germplasm collection of *B. stacei* for efficient genome wide association studies.

Comparative plastome genomics and phylogenomics of *Brachypodium*: Flowering time signatures, introgression and recombination in recently diverged ecotypes

Ruben Sancho[1], *Carlos Cantalapiedra*[2], *Diana López-Alvarez*[1], *Sean Gordon*[3], *John Vogel4*[3], *Pilar Catalan*[1], *Bruno Contreras-Moreira*[2]
1. Universidad de Zaragoza
2. Estación Experimental de Aula Dei-Consejo Superior de Investigaciones Científicas
3. DOE Joint Genome Institute

Few instraspecific genomic studies have been conducted in plants, and none of them have focused on the intra-specific diversity and evolution of their plastid genomes. We address this issue in *Brachypodium distachyon*, a model system for monocots, and its close relatives *B. stacei* and *B. hybridum*, for which a large genomic data set has been compiled. We analyze inter- and intra-specific plastid comparative genomics and phylogenomic relationships within a family-wide framework. While number of genes of the chloroplast genome of *B. distachyon* is greatly constrained as compared to its nuclear genome, full plastid sequences provided a wealth of genetic variants. Major indel differences were detected between *B. distachyon* and *B. stacei/B. hybridum* plastomes. Within *B. distachyon*, we detected two main lineages, an Extremely Delayed Flowering (EDF+) clade and a Spanish Turkish (S+T+) clade, plus nine chloroplast capture and two ptDNA introgression and micro-recombination events. Early Oligocene (30.9 Mya) and Late Miocene (10.1 Mya) divergence times were inferred for the respective stem and crown nodes of *Brachypodium* and a very recent Mid-Pleistocene (0.9 Mya) time for the *B. distachyon* split. Our comparative genomic study of whole plastome sequences of *B. distachyon* and its close relatives allowed us to detect intra-specific introgressions and other associated evolutionary events (e. g., biparental plastome inheritance, heteroplasmy) that could not be detected with single genes. The observed plastome admixture that goes along with the nuclear genome admixture in the *B. distachyon* Arn1 and Mon3 lines, and the essential swapping of plastomes among the three different *B. distachyon* plastome groups (EDF+, S+, T+), likely resulted from random backcrossing followed by stabilization through selection pressure. The pipeline for the assembly and annotation of plastid genomes is available at https://github.com/eead-csic-compbio/chloroplast_assembly_protocol.

Biogeographic events are not correlated with diaspore dispersal modes in Boraginaceae

Juliana Chacon[1], *Maximilian Weigend*[1], *Federico Luebert*[1,2]
1. Nees-Institut für Biodiversität der Pflanzen, Universität Bonn
2. Departamento de Silvicultura y Conservación de la Naturaleza, Universidad de Chile

Long-distance dispersal seems to be the main biogeographic event responsible for intriguing distribution patterns in plant groups in which sister taxa are separated by thousands of kilometers of distance across oceans and continents. The biotic and abiotic mechanisms behind such dispersal events are poorly understood and many attempts have been made to explain how plants can manage to disperse and survive these long journeys. The biogeographic history of Boraginaceae, a subcosmopolitan plant family with many disjunct clades, is here addressed and analyzed in the context of the different dispersal modes exhibited by the species. The lack of a clear pattern between the main dispersal events in Boraginaceae and the phylogenetic distribution of the dispersal modes indicates that no single dispersal mechanism can be associated with the events of dispersal in the family. Our study reveals that long-distance dispersal is a very complex process that needs to be analyzed in the context of climatic and environmental changes and the response of plants and their dispersal vectors to these variable conditions.

Species diversity and reticulate evolution in the *Asplenium normale* (Aspleniaceae) complex

Yanfen Chang
Xishuangbanna tropical boanical garden, Chinese Academy of Sciences

The *Asplenium normale* complex contains the widespread *A. normale* and several geographically restricted species: *A. boreale*, *A. hobdyi*, *A. kiangsuense*, *A. oligophlebium*, *A. pseudonormale, A. shimurae and A. pifongiae*. The taxonomy of this group is unclear with some entities treated infraspecifically or as synonyms. Furthermore, the existence of diploids and tetraploids in this species complex is suggestive of reticulate evolution. In order to achieve a natural classification and to investigate the relationships in this complex, phylogenetic analyses of plastid and nuclear sequence data, detailed morphometric analyses and inference of ploidy level were used to assess the distinctiveness of putative taxonomic units and their relationships. Both the evolutionary and morphometric results support the hypothesis that *A. normale* s.l. contains several species. The *Asplenium normale* complex was recovered as a monophyletic group comprising six principal chloroplast lineages. Two of the lineages corresponded to a single taxon: *A. kiangsuense* and *A. oligophlebium. A. normale* s.l. comprised the other four lineages in which except *A. jinpingense* formed a well separated diploid species, the other three lineages comprised both diploid and tetraploid taxa. Species classification recognizing six diploid and seven tetraploid entities in *A. normale* s.l. was outlined and species reticulate relationships in the *A. normale* complex were discussed.

2. University of Malaya
3. Singapore Botanic Gardens

A review of the division Anthocerotophyta in Malay Peninsula is presented based on herbarium specimens and field surveys.

Eleven species are recognized, belonging to 6 genera and 3 families. Of these 5 species are new records for Peninsular Malaysia: *Anthoceros punctatus* L., *Dendroceros javanicus* (Nees) Nees, *D. subplanus* Steph, *Folioceros amboinensis* (Schiffn.) Piippo, and *F. fuciformis* (Mont.) D.C.Bharadwaj. *Anthoceros angustus* Steph. is excluded from this area. The spore morphology through scanning electron micrographs of the species is provided. In addition, notes on the ecology and geographical distribution of the species are presented.

1. Chiang Mai University
2. Chiang Mai University
3. Singapore Botanic Gardens

Annonaceae are a large pantropical angiosperm family composed of c. 2400 species of trees, shrubs and lianas classified in c. 108 genera. The family is a characteristic and ecologically important element in lowland rain forests. Although subfamilial, tribal and generic delimitations within the family have become more and more settled with the aid of molecular phylogenetic data, revisionary work clarifying species boundaries is still required for the majority of larger genera. In general, species numbers for many genera seem to have been underestimated possibly because only morphology has been taken into account for species delimitation and incomplete material sometimes resulted in merging of two or more distinct and only distantly related species. This can be well exemplified in the sister genera *Marsypopetalum* and *Trivalvaria* belonging to tribe Miliuseae of subfamily Malmeoideae. Using up to seven chloroplast DNA regions (*rbcL*, *matK*, *ndhF*, *ycf1* exons; *trnL* intron; *trnL-trnF*, *psbA-trnH* intergenic spacers; up to c. 7500 bp), phylogenetic analyses indicated that there is considerable cryptic diversity in both *Marsypopetalum* and *Trivalvaria*. Several distantly-related species have been mistakenly identified as *Marsypopetalum pallidum*. Similarly, *Trivalvaria costata* and *T. macrophylla* are polyphyletic. Thorough morphological investigations on these species complexes and putative cryptic species identified a suite of characters distinguishing several species, i.e. inflorescence position, petal morphology, monocarp shape and size, and pericarp thickness for *Marsypopetalum*; petal morphology, sexual system, and monocarp and stipe length for *Trivalvaria*. This study will serve as a basis for modern revisions incorporating comprehensive phylogenetic data in combination with classical morphological examination.

Novelties in Asian Malmeoideae (Magnoliales, Annonaceae): A new tribe, a second genus of Monocarpieae, and a new genus of Miliuseae

Tanawat Chaowasku[1], *Tri Dung Ngo*[2], *Thai Hung Le*[3]
1. Chiang Mai University
2. Institute of Resources & Environment, Hue University
3. Hue University College of Agriculture and Forestry

Annonaceae are a pantropical flowering plant family prominent in lowland rain forests. The family is composed of c. 2400 species in c. 108 genera. Four subfamilies have been recognized, viz. Anaxagoreoideae, Ambavioideae, Annonoideae, and Malmeoideae. The last two subfamilies constitute the majority of diversity found in the family. Malmeoideae consist of seven tribes, viz. Piptostigmateae, Malmeeae, Maasieae, Fenerivieae, Monocarpieae, Dendrokingstonieae, and Miliuseae. The genus *Phoenicanthus* with two species endemic to Sri Lanka was inexplicably placed in the last tribe because it is a rare genus with only few complete specimens, profoundly hindering inferences on its affinity. Recent expeditions in Central Vietnam resulted in the discoveries of two unknown taxa: on the basis of gross morphology, the first one could belong to the canangoid clade of Ambavioideae or the Monocarpieae-Dendrokingstonieae-Miliuseae clade of Malmeoideae, whereas only a fallen single-seeded monocarp of the second one was available; later the seed germinated, revealing the leaves with a raised midrib on the upper surface. Molecular phylogenetic analyses of up to seven chloroplast markers (*rbcL*, *matK*, *ndhF*, *ycf1* exons; *trnL* intron; *trnL-trnF*, *psbA-trnH* intergenic spacers) revealed that *Phoenicanthus* (only one accession, *P. obliquus*, sequenceable) is recovered as the sister group of the Monocarpieae-Dendrokingstonieae-Miliuseae clade with strong support. Therefore, it undoubtedly deserves recognition as a new tribe in Malmeoideae, characterized principally by its miliusoid and highly reduced number of stamens. The first unknown Vietnamese taxon is recovered as the sister group of the genus *Monocarpia* with strong support. It primarily differs from *Monocarpia* in leaf intramarginal veins (absent or indistinct vs. conspicuous), inflorescence position (axillary vs. terminal), and monocarp appearance (cylindrical with longitudinal ridges vs. subglobose to ellipsoid without ridges). Based on these differences and the relative branch lengths of related lineages, this unknown Vietnamese taxon is better placed in a second genus of the monotypic Monocarpieae. The second unknown Vietnamese taxon belongs to the tribe Miliuseae, but its relationships to other genera are still largely obscure. These important novelties (especially in the case of *Phoenicanthus*) may shed light on the biogeographic scenarios of the large Asian-predominated clade (the new tribe plus Monocarpieae-Dendrokingstonieae-Miliuseae) of Malmeoideae when more sequence data are available.

P0307
Bryophytic diversity in the agricultural landscapes of Pantnagar located in the terai of Kumaun Himalayas, India

Sheetal Rana, ***Preeti Chaturvedi***
G.B.Pant University Of agriculture & Technology

Bryophytes are the second largest group of plant kingdom with about 34,556 species around the world (according to The Plant List, 2013). Although having such high diversity, bryophytes of plains particularly those of agriculture landscapes in the foot hills of Kumaun Himalayas are rarely included in biodiversity surveys. As the major emphasis in the Himalayan Terai is on cultivation of crops, cryptogamic diversity in the region is highly neglected. Moreover, human interference in plains of Terai especially the study area, Pantnagar (longitude, E 79˚ 28' 33" - 79˚ 31' 12" and latitudes N 28˚ 59' 36" - 29˚ 2' 34'', altitude-213-238m) also becomes a limiting factor. Pantnagar is an agriculture dominated area. Natural vegetation of the place has been mostly replaced by huge agricultural farms and cultivated plantations. Still, there are some bryophytes that are surviving, in some microhabitats. Therefore, conservation of bryophytes in these disturbed habitats and identification of those plant species is of utter importance to conserve the regional flora, to maintain the ecological balance and preserve the biodiversity. In the present study, total of 24 species belonging to19 genera of 12 families in 7 orders were recorded from the study area. 19 species in 15 genera of 8 families and 6 orders belonged to mosses whereas liverworts were represented by 5 species belonging to 4 families and 1 order only. Pottiaceae and Bryaceae were the dominant families in the study area with 5 species each followed by Funariaceae, Fissidentaceae and Ricciaceae with 3,2 and 2 species respectively. Dominant genera of the region included *Physcomitrium*, *Fissidens*, *Hydrogonium*, *Gemmabryum* and *Riccia* with 2 species each. Most of the bryophytes were terrestrial, only two were epiphytes.

A preliminary assessment of DNA barcodes for identifying *Setaria* (Poaceae) species in Taiwan

Chih-Hui Chen, *Hsien-Chun Liao*

Endemic Species Research Institute

There are eight wild species of *Setaria* in Taiwan, including *Setaria viridis* which has been developed as model systems of C4 photosynthesis for a few years. Basically, it is not difficult to distinguish them with examining their morphological characters except an interesting intermediate form between *S. viridis* and *S. verticillata* we found in Taiwan recently. In this study, we assessed the feasibility of chloroplast coding regions *rbc*L and *mat*K, chloroplast intergenic spacers *trn*H-*psb*A and *trn*L-F, and nuclear ITS regions as DNA barcodes for identifying the species. Totally 103 samples of the eight species were analyzed. The average lengths and number of parsimony-informative sites are 669 and 149 for ITS, 876 and 27 for *mat*K, 855 and 30 for *rbc*L, 488 and 10 for *trn*H-*psb*A, 846 and 26 for *trn*L-F. Among them, ITS has the highest percentage of parsimony-informative sites and provides the best resolution for identifying *Setaria* species of Taiwan. Nevertheless, in all phylogenetic trees based on the five DNA barcodes, *S. viridis*, *S. verticillata* and the intermediate form between them were grouped and mixed up in one clade. Regarding the other six species, we could identify them with the phylogenetic trees based on ITS, *mat*K, *rbc*L and *trn*L-F. Due to the poor percentage of parsimony-informative sites, we couldn't use *trn*H-*psb*A as DNA barcode to identify the *Setaria* species. Further studies for elucidating the relationship between *S. viridis* and *S. verticillata* are necessary.

The taxonomy of *Curcuma* from China

Juan Chen, *Nianhe Xia*

South China Botanical Garden, Chinese Academy of Sciences

Curcuma L. (Zingiberaceae), with at least 120 species, has been used frequently as spices, medicines, dyes and ornamentals. The genus is mainly distributed in south and south-east Asia. The genus has considerable economic importance; however, its phylogeny and taxonomy remain poorly understood. Diagnostic characters used for *Curcuma* species (rhizome color, position of inflorescences, color and shape of bracts and flower parts) are neither unique nor universal to all members of the genus. Meanwile, owing to scanty protologues and a lack of type specimens, many commonly used and cultivated species, are still unclear. Many synonyms, especially those established solely on the study of original discriptions and herbarium specimens, are unreliable. Therefore, the identity of *Curcuma* species form China is rechecked and discussed. Lectotypes are designated for previously untypifications names. Invalid names are discussed. Notes on critical taxa are provided.

Lineage diversification and evolution of pollinator trapping in *Artabotrys* (Annonaceae)

Junhao Chen[1]*, Daniel Caspar Thomas*[2]*, Richard Mark Kingsley Saunders*[1]

1. The University of Hong Kong

2. Singapore Botanic Gardens

Evolutionary diversification is influenced by disparate aspects of the biology, ecology and geographical distribution of species. Robust, well-sampled molecular phylogenies have the potential to test which environmental and species attributes likely contributed as evolutionary drivers. Our project investigates lineage diversification and the evolution of pollinator trapping in the species-rich, lianescent genus *Artabotrys* (c. 100 species; Annonaceae), a characteristic element in Old World tropical and subtropical lowland forests. We are reconstructing the phylogeny of the genus based on an extensive taxon sampling (c. 50 species) and a broad range of chloroplast (*matK*, *ndhF*, *psbA-trnH*, *trnL-F*) and nuclear (*AP3*, *LFY*, *ncpGS*, *PhyA*, *RPB2*) DNA markers. Preliminary results indicate that early diversification in the genus resulted in lineages that are markedly asymmetrical in species numbers: the main species-rich *Artabotrys* clade (MAC), characterised by flowers with basally concave petals that form a tightly enclosed pollination chamber relative to the species-poor early-divergent grade (comprising *A. brachypetalus* and *A. thomsonii*). We hypothesise that (i) the floral chamber in the MAC may function as a pollinator trap, with the pollinators attracted by floral scents but subsequently prevented from leaving the flowers by the closure of the chamber, and (ii) that pollinator trapping is synapomorphic for the MAC, and the putative 'xylopioid' traits in *A. brachypetalus* and *A. thomsonii* (separation of inner petals at anthesis and extended duration of the apical connivence of petals during floral development) may be plesiomorphic. To investigate these aspects, pollination ecology studies of exemplar species (*A. brachypetalus* in the early-divergent grade, and *A. hongkongensis* and *A. suaveolens* in the MAC) are being conducted, involving assessments of floral phenology, thermogenesis, scent chemistry, pollinator identification, and pollinator trapping; character mapping will be performed to further elucidate pollination chamber evolution and the morphological basis of pollinator trapping. Our preliminary field studies of *A. hongkongensis* in Hong Kong reveal that the flowers are protogynous, with anthesis over c. 27 hours, and are likely to exhibit pollinator trapping, although the effective pollinator is still to be unequivocally determined. The majority of *Artabotrys* species possess broad, flat, lanceolate petals (e.g., *A. hongkongensis*); narrow, terete, filiform petals have evolved independently in several MAC lineages (e.g., *A. suaveolens*), and may represent an adaptation to a different pollinator guild. Diversification rate analyses will be performed to investigate if pollinator trapping represents a key evolutionary innovation correlated with accelerated diversification in the MAC.

Genetic differentiation and adaptation of *Sonneratia alba* revealed by population genomics analyses

***Qipian Chen**, Jianfang Li, Suhua Shi*
State Key Laboratory of Biocontrol and Guangdong Provincial Key Laboratory of Plant Resources, Sun Yat-sen University

A series of historically demographic events have affected the extant population structure of organisms, which could provide important clues for investigating the population evolutionary history and speciation. Indo-West Pacific (IWP) region is a biodiversity center of mangroves, where the correlation between genetic divergence and complex geography pattern is of biological significance and great interests. In this study, we sequenced the whole genomes of 33 individuals from 7 populations across the IWP region to assess the population structure of *Sonneratia alba*. Our results revealed that, at genome level, *Sonneratia alba* hosts low levels of genetic diversities within each population, as well as strong genetic divergence among populations from different oceanic regions, indicating sea-level fluctuation during the ancient Pleistocene glacial periods. Moreover, population near the Malacca Strait showed an apparent genetic admixture of divergent lineages from the East Indian Ocean and the South China Sea, suggesting the secondary contact at the Indo-Pacific boundary region during interglacial periods. Notably, results of McDonald–Kreitman test revealed excess fixed difference in amino acid change between populations in South China Sea, especially within the highly divergent genes between two Hainan populations. Therefore, those highly divergent genes across the whole genome of *Sonneratia alba* might play a major role in local adaptation. Our study not only provided new insights into genetic variations but also enriched our current understanding of the adaptive evolution of mangroves.

P0312

The comparison and conservation of species diversity of *Begonia* (Begoniaceae) in Dian-Qian-Gui-Tonkin and Borneo regions, two biodiversity hotspots

***Wen-Hong Chen**, Radbouchoom Sirilak, Yu-Min Shui*
Key Laboratory for Plant Diversity and Biogeography of East Asia, Kunming Institute of Botany, the Chinese Academy of Sciences, Kunming 650204, P.R. China

Dian-Qian-Gui-Tonkin region which belongs to Holarctic and Palaeotropical Kingdoms is located in south China and north Vietnam, the region is one of the biodiversity centers in the word and dominated by the karst landforms. Borneo region which belongs to the Palaeotropical Kingdom is located in Indonesia, Malaysia and Brunei, and is one of the largest islands and of the biodiversity centers in Asia and worldwide. In this study, we focus on the biodiversity and conservation of the genus *Begonia* L. which occurs in the above two regions. *Begonia* is a mega-diverse genus of Begoniaceae containing more than 1800 species in the world, of which 169 species and 226 species are respectively distributed in Dian-Qian-Gui-Tonkin region and in Borneo region. There are 11 species described in Dian-Qian-Gui-Tonkin region (*vs.* 5 spp. in Borneo region) before 1900,36 species (*vs.* 23 spp.) from 1901 to 1950,9 species (*vs.* 12 spp.) from 1951 to 1980,3 species (*vs.* 8 spp.) from 1981 to 1990,40 species (*vs.* 20 spp.) from 1991 to 2000,47 species (*vs.* 46 spp.) from 2001 to 2010 and 23 species (*vs.* 114 spp.) from 2011 to 2016. With refer to the *Begonia* species in Dian-Qian-Gui-Tonkin region, there are ca. 47 new species described from 1991 to 2000, accordingly because of the fulfilment of "*Flora Reipublicae Popularis Sinicae*" and "Flora of China". In Borneo, from 2011, the discovery of new species of *Begonia* increased from 112 to 226 species, the largely increased species number is mainly due to the extensive exploration of the genus by the local botanists, a unique case of species extension in the tropics. Taxonomically, *Begonia* sect. *Petermannia* (Klotzsch) A. DC. and *B.* sect. *Coelocentrum* Irmscher, the two dominant groups respectively in the tropical forests of Borneo and at the karst habitat of Dian-Qian-Gui-Tonkin region, undergo possible rapid radiation under the different geographical background during the recent global climate optimum. However, the fragility and loss of the karst habitat and tropical forests will considerably threaten their biodiversity so that numerous endemic species will be limited in small distribution and under a small population.

Molecular systematics of Rosoideae (Rosaceae)

***Xun Chen**[1,2], Jinlu Li[1,2], Tao Cheng[2], Wen Zhang[2,3], Yanlei Liu[2,3], Shiliang Zhou[2], Ling Wang[1]*
1. Northeast Forestry University
2. Institute of Botany, the Chinese Academy of Sciences
3. University of Chinese Academy of Sciences

The four-subfamily subdivision of Rosaceae has been recently overthrown and a new classification of Rosoideae remains to be established on a basis of solid phylogeny. In this study, we sampled all 54 genera presumably belonging to Rosoideae and 12 genera belonging to other subfamilies or families and used twelve chloroplast regions (*mat*K, *rbc*L, *atp*B-*rbc*L, *trn*L, *trn*L-F, *ndh*F, *ycf*1, *trn*C-*ycf*6, *trn*S-G, *trn*S, *psb*A-*trn*H, *rpo*C1, and *trn*S-*ycf*9) to reconstruct their phylogeny. Our results demonstrated (1) exclusion of *Rhodotypos* and *Kerria* from Rosoideae and their inclusion in subfamily Spiraeoideae; and (2) exclusion of *Cowania*, *Chamaebatia*, *Cercocarpus* and *Dryas* from Rosoideae and inclusion in Dryadoideae, a sister subfamily of Rosoideae. There are six strongly supported lineages within Rosoideae which corresponding to six tribes, Potentilleae; Roseae; Sanguisorbeae; Rubeae; Courieae and Filipenduleae. Divergence of the subfamily was dated back to some 69.77 million years ago (Mya; 95% HPD = 61.28-78.33 Mya). And the divergence time within Rosoideae was dated from10.42 to 40.02 million years (Mya; 4.73-59.08 Mya), which formed the six lineages (Potentilleae crown 45.02 (Mya, 95% HPD =38.39-50.12 Mya); Courieae crown 44.94 (Mya, 95% HPD = 28.50-59.08 Mya);Sanguisorbeae crown 40.63 (Mya; HPD = 30.42-49.16 Mya); Rubeae crown 18.37 (Mya; HPD = 9.02-32.3 Mya); Filipenduleae crown 13.47 (Mya; HPD = 5.07-26.32 Mya); Roseae crown 10.42 (Mya; 95% HPD = 4.73-19.74 Mya)). The subfamily is probably of North American origin but thrives in north hemisphere, especially in Asia.

The complete chloroplast genome sequence of Five *Smilax* species (*Nemexia*): Comparative analysis, highly divergent regions and phylogenetic relationships

Yao Chen[1], Pan Li[1], Chengxin Fu[1], Kenneth Cameron[2]

1. College of Life Sciences, Zhejiang University, Hangzhou, Zhejiang 310012, China

2. Department of Botany, University of Wisconsin, Madison, Wisconsin 53706, USA

Smilax, the only genus in the greenbrier family (Smilacaceae), contains > 200 species of mostly woody climbers around the world. However, a clade of *Smilax* [sect. *Nemexia* (Raf.) A. DC.] are annual understory herbs with a unique eastern Asia (EA)-western North America (WNA)-eastern North America (ENA) disjunct pattern (two, one and eight species in these three areas, respectively). Previous studies revealed a sister relationship between Asian clade (*S. nipponica* + *S. riparia*) and North American clade (WNA *S. jamesii* + ENA clade), but failed to resolve the phylogenetic relationships within the eastern North American herbaceous *Smilax*. In order to reconstruct the relationships among them, here we report five complete chloroplast (cp) genomes of herbaceous *Smilax* (*S. nipponica, S. jamesii, S. herbacea, S. hugeri and S. biltmoreana*). The cp genomes of *Smilax* range from 157,049 bp to 157,656 bp in length, all including a pair of inverted repeats (IRa and IRb) separated by the large single-copy (LSC) and small single-copy (SSC) regions. The genomic comparison showed some differences located in the genomes, and IRs regions were more conservative than LSC/SSC regions. Phylogenomic analyses based on these complete cp genomes strongly support a topology of (*S. nipponica*, (*S. jamesii*, (*S. herbacea*, (*S. hugeri*, *S. biltmoreana*)))). Our findings proved the feasibility of employing cp genomes to infer phylogenetic relationships among closely related species. Besides, eight DNA markers (*psaC–ndhE*, *ndhC–trnV*, *ndhG–ndhI*, *ydf1* intron, *accD–psaI*, *ccsA–ndhD*, *petA–psbJ*, *atpI–rps2*) with number of variable sites greater than 1.0% were identified, and these may be useful for future population genetic and phylogeographic studies.

P0315

Taxonomy of *Plagiochila* in China

Xiafang Cheng

East China Normal University

Plagiochila (Dumort.) Dumort. is one of the largest genera of liverworts and its diversity centers are in Southeast Asia and the Neotropics. It currently contains ca. 700 species in the world, and 80 species occur in China. Molecular studies in recent years have led to new insights into the sectional classification and distribution of *Plagiochila*. Contrary to earlier recognition, many sections are proved to have intercontinental ranges, resulting in the synonyms of some sections. *Plagiochila* are now divided into 29 sections according to recent morphological and phylogenetic analyses, in which 12 sections occur in China. However, there are only 23 Chinese species being included in former molecular studies, which may cause unreasonable sectional classification. Here we conducted phylogenetic analyses of a dataset comprising nrITS and two chloroplast markers (*rps*4, *rbc*L) from 150 species with 57 Chinese species. Combination with the morphological evidence, the results proposed a natural classification of sectional belongings of *Plagiochilla* in China, and suggested several new sections and reinstatements of some synonymized sections in this study.

Ecological significance of phenology and functional traits of mistletoes in Taiwan, R. O. C.

Shau-Ting Chiu

Division of Biology, National Museum of Natural Science

Most of mistletoes in Taiwan, including 4 genera about 17 species, are dispersed by flowerpeckers and related birds. The phenology of the mistletoes are mutually affected due to the close relationship between the dispersal of mistletoes and the diet of flowerpeckers. For example, *Taxillus tsaii* S.-T. Chiu at low altitude flowers from March to July and bears fruits from June to November. Its major dispersal agent is *Dicaeum concolor* and, in a short season, *D. ignipectus* also participate in dispersal. Certain species at middle elevation, such as *T. rhododendricolus* (Hayata) Danscer., flowers from August to October and bears fruits from October to December. The foraging of their major dispersal agent, *D. ignipectus,* seemed to make for each other with concorde rhythm. In comparison, some seeds contained early emerging seedling when seed dispersal for aggressive invasion to guaranteed effective establishment on host plants. It suggests that the phenoloty, the dispersal and the seed germination in the life cycle of mistletoes are diverse because they have adapted to the different ecosystems with varying temperatures and lengths of the growing seasons. Not only are the phenology and the distribution of the mistletoes in Taiwan highly diversifies, but the hosts species the hosts are also highly varied, ranging from gymnosperms, angiosperms, trees, shrubs and lianas, to even other mistletoes as examples of hyperparasitism. The highest species diversity in Taiwan so far is 4 species per acre and 4 species per host individual. Further investigation may reveal an even higher diversity; especially, functional traits for ecological performance. Establishing morpho-physiophenological traits which impact fitness indirectly via their effects on growth, reproduction and survival, the three components of individual performance can become the foundation of ecological forensics. This study would initiate leaf functional traits about foliar mistletoes along altitudinal gradients for selected habitats. Carrying on the standard protocol of leaf functional traits can input, provide and accumulate long-term ecological forensics data. Mistletoes which grew in distinct micro-environment and included different host functional groups living different habitat, showed varied combination of leaf traits and phenology for the strategy of fitness. It would carry on the important mission of long-term monitoring and also provide renewal conservation information for Botanical Garden's and National Park's management and long-term ecological research in conservation.

P0317
Several molecular markers of chloroplast and nuclear genome reveal the origin and genetic structure of wild *P. yedoensis* (Rosaceae), endemic to Jeju Island, Korea

Myong-Suk Cho[1], *Chan Soo Kim*[2], *Gwanpil Song*[3], *Chul Hyun Jeon*[2], *Seung-Chul Kim*[1]
1. Department of Biological Sciences, Sungkyunkwan University, Suwon, Korea
2. National Institute of Forest Science, Warm-Temperate and Subtropical Forest Research Center, Seogwipo, Jeju-do, Korea
3. Jeju Biological Resources Co., Ltd., Jeju, Jeju-do, Korea

Wild flowering cherry of *Prunus yedoensis* (Rosaceae), naturally occurring on Jeju Island, Korea, has been suggested as of natural hybrid origin from two sympatric *Prunus* lineages on Jeju Island. However, its taxonomic distinctiveness from widely cultivated *P. ×yedoensis* 'Somei-yoshino' remains as highly controversial and enigmatic. This study aims to establish the taxonomic identity of wild *P. yedoensis* by clarifying the phylogenetic relationships among species of *Prunus* as well as to determine genetic structure of wild *P. yedoensis*. We took molecular phylogenetic and nuclear SSR genotyping approaches based on extensive sampling of both wild and cultivated *Prunus* species in Japan, Russia and Korea, including putative parental species. The phylogenetic relationships were elucidated based on nuclear (ITS, G3pdh, POLA1, and several RosCOS putative single copy genes) and chloroplast genome (7 noncoding regions and whole cp genome for two accessions). The cpDNA and nrDNA phylogeny strongly supported the previous study that wild *P. yedoensis* in Jeju Island is of hybrid origin with maternal parent of *P. spachiana* f. *ascencens* and precisely undetermined paternal parent from *P. serrulata* and/or *P. sargentii* complex. The cpDNA haplotype network suggested independent geographical contribution to the origin of wild and cultivated *P. yedoensis* in Jeju Island and Japan, respectively, which was reconfirmed by nrDNA phylogenetic analyses by ITS, POLA1, and RosCOS single copy genes. Several nuclear loci further indicated independent origin of wild and cultivated *P. yedoensis*. Nuclear SSR genotyping based on 83 individuals of wild *P. yedoensis* and 12 of *P. ×yedoensis* 'Somei-yoshino', revealed two genetic groups, corresponding to wild and cultivated *P. yedoensis*. Totally 171 alleles were found at 12 loci, ranging from 6 to 24 alleles per locus, and the population of wild *P. yedoensis* demonstrated much higher numbers of alleles (mean 13.222) comparing to the cultivated *P. ×yedoensis* 'Somei-yoshino' (mean 1.778). Of 83 presumably wild individuals, we found misidentified individuals (2), admixture (9) and unknown genetic contribution (3). We also found significantly higher genetic diversity in wild *P. yedoensis* in Jeju Island than in cultivated one. This study further corroborates our earlier finding that wild *P. yedoensis* in Jeju Island is a distinct taxonomic entity from cultivated *P. ×yedoesnsis* 'Somei-yoshino'. The evidence of gene flow between wild *P. yedoensis* and cultivated *P. ×yedoensis* 'Somei-yoshino' is also detected.

Phylogenetic relationships of *Pyrrosia* species (Polypodiaceae) inferred from nuclear and chloroplast DNA sequences

Tae Young Choi, *Chong-Wook Park*
Seoul National University, School of Biological Sciences

The genus *Pyrrosia* Mirb. (Polypodiaceae) comprises about 50 species. Most species within the genus are highly variable in morphology, resulting in taxonomic confusion in determining the boundaries and relationships of the species. We analyzed nrDNA *pgi*C region and cpDNA *rbc*L gene, *trn*L– *trn*F IGS, *atp*F –*atp*H IGS sequences from 31 taxa of the genus *Pyrrosia* to elucidate their phylogenetic relationships, and to investigate the parentage of putative hybrid taxa. Maximum parsimony and Bayesian inference analyses of the nrDNA and cpDNA sequence data showed three major clades: 1) a clade containing widespread *P. porosa* and the east Asian species, 2) a clade containing *P. lingua* and species found primarily in southeast Asia, 3) a clade consisting of *P. stigmosa* and *P. costata*. These groupings, however, appear to be incongruent with the traditional infrageneric classification scheme based on blade shape and spore morphology.

P0319
Understanding the diversification of *Eriocaulon* L. in South Asia using molecular phylogenetic approach

Ashwini Mukund Darshetkar[1], *Mandar Nilkanth Datar*[1], *Shubhada Ajit Tamhankar*[1], *Joongku Lee*[2], ***Ritesh Kumar Choudhary***[1]
1. Agharkar Research Institute
2. Chungnam National University

The genus *Eriocaulon* is distributed throughout tropical and subtropical regions of both hemispheres and has more than 525 taxa; about 485 species and more than 40 infra-specific taxa. South Asia harbors almost one fourth of the Eriocaulon diversity, having ca. 100 species. With its rich concentration in Asia, Africa and S America, the genus is known for its high intraspecific variability combined with the limited interspecific differences; producing big challenge to the classical taxonomists to properly identify/characterize/delimit them. Present study is a pioneer attempt to understand the diversification of *Eriocaulon* in South Asia using molecular phylogenetic approach. Further, attempts have been made to understand the pattern of morphological character evolution and phylo-geographic distribution which is an important adjunct to the molecular phylogeny of this genus. Using morphological as well as the nrDNA and cpDNA sequence data, this study has resulted in (i) unravelling the species relationships within this genus, (ii) tracing the geographic distribution pattern with special reference to the endemic and rare species, (iii) elucidating morphological character evolution in the genus (iv) testing the congruence of morphological and molecular data in systematic and phylogenetic assessment, and (v) development of possible DNA barcode of the endemic *Eriocaulon* species for their true identification and delimitation.

P0320
Phylogenetic study of genus *Homalomena* section *Chamaecladon* (Araceae: Homalomeneae)

Kek Shen Chua, *Sin Yeng Wong*
Universiti Malaysia Sarawak

Phylogenetic relationship among species of the genus *Homalomena* section *Chamaecladon* (Araceae) remains unclear as previous study on this genus emphasized on section *Cyrtocladon*. For examining monophyly of section *Chamaecladon,* DNA nuclear gene internal transcribed spacer (ITS), and chloroplast gene *maturase* K (*mat*K) sequences were analyzed. A total of 21 samples including several unknown species, from different localities (Borneo, Peninsular Malaysia, and Sumatera), were assessed in this study. Collection of taxa was conducted in nursery of Semenggoh Botanical Research, Kuching. Throughout the study, thirty nine sequences were newly generated as three unsound ITS sequences were not included. For outgroup species, one species from each sections under genus *Homalomena* (*Homalomena*, *Cyrtocladon* and *Geniculatae*), and one species from genera *Philodendron*, *Adelonema*, *Cercestis* as well as *Culcasia* were selected. Three phylogenetic analyses, namely maximum parsimony (MP), maximum likelihood (ML) and Bayesian analysis, were utilized to construct phylogenetic trees. The resulting phylogeny shown *Homalomena* Schott was monophyletic. However, section *Chamaecladon* was paraphyletic owing to the inclusion of *H. curvata* (sect. *Homalomena*) in the clade. In *mat*K analyses, there were two clades formed in MP analysis of section *Chamaecladon*, Clade I with all ingroup species and Clade II with *H. curvata, H punctulata* and other ingroup species. Species in Clade II remained unresolved in ML and Bayesian analysis of *mat*K. In ITS analyses, there were three clades formed in section *Chamaecladon*, namely *Griffithii* clade, *Paucinervia* clade, and *Humilis* clade.

Polyploidy and biogeography of subtribe Agrimoniinae (Rosaceae)

Kyong-Sook Chung
Jungwon University

Polyploidy is an abundant phenomenon in flowering plants that has provided an important pathway for diversity and evolution. A small taxonomic group, subtribe Agrimoniinae in Rosaceae, exhibits various levels of polyploidy associated with diverse life (habit) forms, morphological characters, and geographic distribution patterns. Inferred from nucleotide markers (*trn*L-F, *trn*G-S, and GBSSI), cytological, morphological, and biogeographic evolution of Agrimoniinae are evaluated. Subtribe Agrimoniinae comprises one widely distributed genus and four monotypic endemic genera: *Agrimonia* L. (about 20 species mainly in Northern Hemisphere), *Aremonia* Neck. ex Nestl. (Europe), *Leucosidea* Eckl. & Zeyh. (Africa), *Hagenia* J. F. Gnek. (Africa), and *Spenceria* Trimen (E. Asia). Two African genera are woody (shrubs or trees) whereas the other three genera are herbaceous. They exhibit polyploidy in various levels from a diploid to octoploids: *Hagenia* (tetraploid, 4x), *Aremonia* and *Leucosidea* (hexaploid, 6x), *Agrimonia* (4x and 8x), and *Spenceria* (diploid, 2x). All the sequence data support that Agrimoniinae is monophyletic, and *Spenceria* is basal to the rest of group. *Spenceria* (2x) is considered to be a relict species, occurring only in high mountains in China and Bhutan. In *Agrimonia*, North American tetraploids (*A. microcarpa* and *A. parviflora*) and an Asian tetraploid (*A. coreana*) form a strongly supported clade, and diverse levels of polyploids (4x, 6x, and 8x) of Asian, American, and European species are clustered. The tetraploid clade shares leaf and fruit morphology and restricted distribution. Unusually in Asia, endemism is found in tetraploids (*A. coreana* and *A. nipponica*) as well as in an octoploid (*A. gorovoii*) species. Fruiting hypanthia with hooked bristly epicalyxes in *Agrimonia* support allopatric speciation in the genus. The result suggests multiple dispersal events in diverse time periods following and/or followed polyploidization.

Chromosome number variation and species diversity of East Asian *Carex* (Cyperaceae)

Kyong-Sook Chung[1], *Takuji Hoshino*[2], *Tomomi Masaki*[2], *Hyoung-Tak Im Hyoung-Tak Im*[3], *Jong-Cheol Yang Jong-Cheol Yang*[4], *Seong-Jin Ji Seong-Jin Ji*[5], *Hyuk-Jin Kim Hyuk-Jin Kim*[4]
1. Jungwon University
2. Okayama University of Science
3. Chonnam National University
4. Korea National Arboretum
5. National Science Museum

Carex L. (Cyperaceae) is one of the most species-rich genera in flowering plants with more than 2,000 species worldwide, exhibiting a great chromosome number variation ranged from $2n = 12$ to $2n = 168$. The exceptional variation in chromosome numbers has been postulated due to a holocentric chromosomal structure. Previously reported chromosome numbers representing approximately 16% of the species in Cyperaceae manifest an apparent variation patterns for aneuploidy, agmatoploidy (chromosomal fission without gene duplication) and polyploidy; and a series of studies have proposed that chromosome divergence has played an important role in species diversity within the *Carex*. In East Asia vegetation, the genus is an important component occupying various geological and ecological habitats. In addition, recent phylogenetic studies revealed that early *Carex* linages diverged from East and Southeast Asia. To understand species diversity in East Asian *Carex*, chromosome number variations in the regions are evaluated in traditional as well as phylogenetic classifications. Sections with high species such as *Mitratae* (ca. 50 species in East Asia) and *Phacocystis* (ca. 40 species in East Asia) exhibit high chromosome numbers with broad variations ranged from $2n = 32$ to $2n = 90$. However, basal groups of each lineages usually have low chromosome numbers. The early lineage Siderostictae clade (*Siderostictae*, *Surculosae*, and *Hemiscaposae*) demonstrates polyploidy ($2n = 12$ or 24) rather than aneuploidy or agmatoploidy. The clade also shows large chromosomes from 1.5 to 4.0 μm long. The presentation explains diverse chromosome evolution mechanisms (aneuploidy, agmatoploidy, and polyploidy) in *Carex* species diversification, and demonstrate examples of East Asian taxonomic and/or phylogenetic groups.

Taxonomic revision of the genus *Verbascum* L. (Group D) in Turkey

Burcin Cingay[1], *Ahmet Faik Karaveliogullari*[2], *Birol Baser*[3], *Sezgin Celik*[4]
1. Nezahat Gokyigit Botanic Garden, Department of Science, Istanbul
2. Hakkari University, Yuksekova Vocational High School, Hakkari
3. Bitlis Eren University, Art and Science Faculty, Department of Biology
4. Yıldız Teknik University, Department of Biology Istanbul

In this study, the morphology, ecology, palinology and the seed surfaces of the “Group D” of the genus *Verbascum* L., in Turkey were investigated and new modifications with combinations were carried out for three taxa of the group. Moreover, new version of the descriptions of the genus in the Flora of Turkey has been done. During the field studies, there was no hybrid taxon observed. It is clear that, the number of stamens is not a sufficient character to classify the groups of the genus as given in the Flora of Turkey. The results of the study have showed that the pollen grains belonging to the species in Group D of *Verbascum* L. are tricolpate. The shapes of the pollens are prolate spheroidal and the structure of them is tectate. Furthermore, the ornemantion is reticulate. The narrow colpi of the pollens have recognizable margins. The group shapes of the seeds are varying as ovate and oblong and the seed surfaces are varying as reticulate and alveolate- reticulate, are brown in all the species. It has been seen that, there is a significant difference in terms of the physical characters, that was also calculated as statistically ($p<0.001$). However, there is no significant difference in terms of chemical values of the soils among the soil samples.

Leaf architecture of selected *Diplazium* species (Athyriaceae)

Jennifer Conda[1], *Inocencio Buot Jr.*[2]
1. Forest Products Research and Development Institute-Department of Science and Technology
2. University of the Philippines Los Banos

The diversity of characters and absence of sori during some season of the year made the identification of *Diplazium* species unresolved. Thus, leaf architecture study of the genus *Diplazium* was conducted to determine the usefulness and effectiveness of leaf characters, particularly, venation pattern in describing and differentiating fern species and to identify leaf architectural characters useful in taxonomic classification of pteridophytes. Herbarium specimen of twenty seven species of *Diplazium* at the Philippine National Herbarium were examined following the work of Hickey (1973), Leaf Architecture Working Group (1999) and book of Palmer (2003). Seven to fifteen pinna/pinnule per species were measure using ruler and protractor. The *Diplazium* species were then described and a dichotomous key was made. Through cluster and principal component analysis *Diplazium* species were divided into two major group namely: free venation group and anastomosing venation group and six clusters. The most unifying features of *Diplazium* included lanceolate pinna or pinnule, acuminate and acute apex, asymmetrical base and pinnate primary vein. Finer venation such as secondary vein angle of divergence and variation in 2° vein angle of divergence, tertiary vein category, 3° vein angle of divergence, variation in 3° vein angle of divergence, 3° vein spacing and lobation were stable and relevant features in differentiating closely related *Diplazium* species. This study proved the usefulness of leaf architecture in describing and differentiating fern taxa specifically *Diplazium* species just like many angiosperms. Leaf architecture, indeed, can be an alternative taxonomic tool of sterile fern species.

Correcting phylogenetic signal of homoplastic traits: The evolutionary history of perianth fusion in Myrtaceae

Thais Vasconcelos, Gerhard Prenner, Eve Lucas, ***Maria Conejero***
Royal Botanic Gardens, Kew

Shedding a fused perianth in the flowering bud as a calyptra during anthesis is a major evolutionary trend in Myrtaceae. The presence/absence of this character has been of historical systematic interest in at least 15 genera, including the megadiverse *Myrcia*, *Eucalyptus* and *Syzygium*. However, molecular phylogenies, very often do not support the calyptra as a strongly informative character. Evidence suggests that this trait shows low phylogenetic signal and has repeatedly appeared and disappeared during the evolutionary history of the family. In this study, we compare the development and anatomical structure of calyptrate flowers in distinct lineages of Myrtaceae to answer the following questions: 1) Is the calyptra homologous in the family? and 2) What is the variation in the trait’s phylogenetic signal before and after the homology test? Twelve species, including representatives from all lineages of calyptrate taxa and their non-calyptrate closest relatives, were sampled and distinct stages of flower development were analysed under SEM and LM. Images were compared between species and are discussed to define the level of homology in the Myrtaceae calyptra. Perianth behaviour during anthesis, a possible source of misperception of this character, was also recorded in the field. Results of the homology test are plotted against a previously published Myrtaceae phylogeny for phylogenetic signal estimation using the *geiger* package in R. Results show that the calyptra is not a homologous structure throughout Myrtaceae lineages. What has been called a calyptra corresponds to at least three anatomically and ontogenetically distinct structures, which are here coined “calycine calyptra”, when the calyx presents true gamosepally; “coralline calyptra”, when the corolla presents true gamopetally; and “pseudocalyptra”, when the free petals overlap during development and attach their surfaces, leading them to fall as a single unit that resembles a fused perianth. The homoplastic pattern of calyptrate structures persists in the phylogeny even after assessment of homology. However, estimates before and after homology tests show that phylogenetic signal increases when homologous structures are clarified, going from λ = 0.634, when presence/absence of calyptra is plotted without any distinction, up to λ = 0.651, λ = 0.782 and λ = 1 when the "pseudocalyptra", "calycine calyptra" and "coralline calyptra" are considered independently. Results presented here demonstrate that careful morphological analysis can improve the evolutionary understanding of a trait even when homoplasy is not completely resolved. Characters previously considered systematic and evolutionary irrelevant can present strong phylogenetic signal, once their structural details are clarified and re-incorporated into an existing phylogenetic framework. Unassessed homoplastic traits might hide phylogenetic signal relevant to understand large scale trait evolution and key-innovation in individual lineages. In Myrtaceae, convergences and parallelisms of a calyptrate structure are perhaps related to the brush blossom display, which reduces selective pressure of pollinator attraction on the perianth and frequently allows it to be disposable at anthesis.

Consequences of being flexible: The mean and variability of a floral trait have opposing effects on pollination and fitness traits

***Can Dai*[1], *Xijian Liang*[1], *Jie Ren*[2], *Laura Galloway*[2]
1. Hubei University
2. University of Virginia

Floral traits are essential for assuring successful pollination and reproduction in flowering plants. In particular, style and anther positions are key for pollination accuracy and efficiency. Variation in these traits among individuals has been well studied, but less is known about variation within flowers and plants and its effect on pollination and reproductive success. Style deflexion is responsible for herkogamy and important for pollen deposition in *Passiflora incarnata*. The degree of deflexion may vary among stigmas within flowers as well as among flowers. We measured the variability of style deflexion at both the flower and plant level. The fitness consequences of the mean and variation of style deflexion were then evaluated under natural pollination by determining their relationship to pollen deposition, seed production, and average seed weight using structural equation modeling. In addition, the relationship between style deflexion and self-pollen deposition was estimated in a greenhouse experiment. We found greater variation in style deflexion within flowers and plants than among plants. Variation of style deflexion at the flower and plant level was positively correlated, suggesting variability in style deflexion may be a distinct trait in *P. incarnata*. Lower deflexion and reduced variation in that deflexion increased pollen deposition, which in turn, increased seed number. However, lower styles also increased self-pollen deposition. In contrast, higher deflexion and greater variability of that deflexion increased variation in pollen deposition, which resulted in heavier seeds. Variability of style deflexion and therefore stigma placement, independent from the mean, appears to be a property of individual *P. incarnata*. The mean and variability of style deflexion in *P. incarnata* affected seed number and seed weight in contrasting manners, through the quantity and potentially quality of pollen deposition. This antagonistic selection via different fitness components may maintain diverse style phenotypes.

The herbarium perspective of biogeographical and ecological aspects of *Syzygium* genus (Myrtaceae) in Papua New Guinea

Kipiro Damas
Papua New Guinea Forest Research Institute

Syzygium is one of the speciose tree genus in the family Myrtaceae having over 500 plus species globally, Frodin, 2004 reported 1041 species in total and was 16th out of 57 most specious genera throughout the world. Craven & Damas, 2015 (unpublished in manuscript) recently reported 1100 - 1400 (-1500) species. Papua New Guinea has more than 4000 tree species and *Syzygium* is the first most speciose tree genus and is known to be widely distributed throughout from the lowlands to the highlands up to 3000 m.a.s.l. The global geographical distribution is sub-saharan Africa, Southern Asia and Indo – Pacific region (Neil Snow and Lynn A. Craven, 2010). The greatest morphological diversity and evolutionary diversity according to Snow and Craven, 2010 occurs in North Eastern Malaysian region. Papua New Guinea's National herbarium in Lae records up to 150 (- 200) known species and almost equal or higher number of species are taxonomically unknown. The enhancement of the taxonomic knowledge depends on more field collections in various forest types. The genus stands out as one of the important tree genus among the Myrtaceae family for its sweet tasting fruits edible to birds, insects, mammals and humans. Several species in the genus *Syzygium* in Papua New Guinea are harvested for timber however there has been confusion in the identifications of species because most species tend to share quiet similar morphological features. The basic or commonly shared characteristics include opposite leaf arrangements, leaf blades having distinct intra marginal venation. The genus is also claimed in an unpublished report (Oavika, 2007) as an indicator of an unproductive forest in terms of timber harvesting. This claim remains to be proven through further research. This is a Masters Research project which is being carried out two components (Laboratory and Field) to establish information on the diversity and composition of the genus in various forest, soil types and other related environmental parameters in PNG. This research intends to find out why this genus is so widely distributed in Papua New Guinea. These information on respective parameters will give us some understanding on why this genus is widely distributed throughout PNG. This paper only discusses all findings of its distribution, composition, diversity *etc.* using specimens stored in the Papua New Guinea National Herbarium in Lae.

Diversity and habitat analysis of the family Lejeuneaceae (Marchantiophyta) in the State Assam, India

Sudipa Das
Assam University, Silchar

The family Lejeuneaceae is one of the most advanced and complex groups of the order Jungermanniales, Marchantiophyta due to its great extent of morphological variations and scarcity of stable morphological characters. In India, the family is represented by 27 genera with main centers of diversity in Eastern Himalayas and Western Ghats. The state Assam, one of the forest dominated states of north-eastern India, is situated in the rain shadow of Himalayan ranges. Falling under the East Himalayan bryo-geographical territory, the state occupies a major area regarding bryophyte vegetation due to its vast range of topography and tropical-subtropical humid climate. As members of the family Lejeuneaceae prefer to grow in humid tropical-subtropical forests and constitute dominant composition of epiphytic liverworts (both corticolous and foliicolous), the state Assam has become a good abode for Lejeuneaceous members. The present ongoing study is based upon extensive collection of plant materials of the family Lejeuneaceae from different parts of the study area during 2014 – till date. The study reveals the occurrence of 23 species under 10 genera of Lejeuneaceae from Assam till date and it has been found that the family Lejeuneaceae dominates the Marchantiophyta flora of this region by occupying about 35% of the total taxa. Among the 10 genera found, genus *Cololejeunea* (Spruce) Schiffn. is found to be the dominant one with six species followed by genus *Lejeunea* Lib. with four species. Of the total taxa recorded till date, only 9% are found to grow as purely terrestrials, 78% as purely epiphytic (corticolous and/or foliicolous) and 13% do not show any habitat specificity hence grow both as terrestrials as well as epiphytes; among the epiphytic taxa reported, 61% are purely corticolous, 22% are purely foliicolous and 17% are found to grow both as corticolous as well as foliicolous. Both terrestrial and epiphytic taxa are found to grow in extremely moist and shady cool places inside the forests. Some common plants found to act as hosts for corticolous taxa are *Bambusa* sp., *Ficus* sp., *Morus* sp., *Shorea robusta*, etc; plants identified as phorophytes for foliicolous taxa are Ferns, *Gnetum* sp., various Bamboos, *Canna* sp., *Cinnamomum tamala*, *Licuala* sp., *Ophiorrhiza* sp, *Zingiber* sp., *etc.* Among the taxa reported till date, four species viz. *Archilejeunea apiculifolia* Steph., *A. minutilobula* Udar & U.S. Awasthi, *Cololejeunea furcilobulata* (Berrie & E. W. Jones) R. M. Schust. and *C. siangensis* G. Asthana & S.C. Srivast. are endemic to India. Among these, *Archilejeunea apiculifolia* is found only in the state Assam within the Eastern Himalayan bryogeographical region in addition to Kerala and Tamil Nadu of southern India; and *Cololejeunea siangensis* is confined within the Eastern Himalayan territory only in the states of Arunachal Pradesh and Assam. Eight taxa are found rare within the study area as represented by limited collections and two taxa viz. *Caudalejeunea reniloba* (Gottsche) Steph. and *Leptolejeunea epiphylla* (Mitt.) Steph. are found threatened due to habitat destruction.

Reticulate evolution and parental lineage reconstruction of polyploid moonwort species (*Botrychium*, Ophioglossaceae) using PacBio sequencing technology

Benjamin Dauphin[1], *Jason Grant*[1], *Donald Farrar*[2], *Carl Rothfels*[3]

1. University of Neuchatel

2. Iowa State University

3. University of California at Berkeley

Background — Polyploidy is a major speciation process in vascular plants, and the early divergent moonwort fern genus *Botrychium* well illustrates these recurrent hybridizations at the infrageneric level. However, the near absence of nuclear sequence data has prevented molecular phylogenetic investigations on its biparental patterns of inheritance. Yet, *Botrychium* has unique evolutionary history with an independent lineage from other ferns over 300 mya and the nuclear genomes among the largest known in plants. Henceforth, with the new sequencing possibilities and bioinformatics tools, it becomes accessible to investigate complex polyploid groups and retrace their past history. *Emphasizing main questions and goals* — Our study aims to identify the parental lineages of polyploids, retrace their origins, and characterize the dynamism of polyploidy in *Botrychium* through time and space. *Materials and methods* — We considered a complete taxonomic recognition of the genus *Botrychium* by including 37 taxa from Europe and North America. We designed over one hundred primer sets from three transcriptomes of the sister genera *Botrypus*, *Ophioglossum*, and *Sceptridium*, targeting 10 nuclear regions recently characterized in ferns. We used the PacBio platform to sequence long (up to 1.5 kb) nuclear loci from 48 specimens of 25 diploids, 20 polyploids, and three outgroups. Then, we analyzed raw sequences with the new bioinformatics pipeline PURC to remove PCR-mediated recombinant sequences and generated the final alignments according to the most appropriate parameter settings (of the 10 regimes tested). Finally, we implemented AlloPPNet to infer the multilabeled species tree and reconstruct phylogenetic relationships of the polyploid lineages. *Results* — We amplified and successfully sequenced three nuclear loci (3.5 kb) from a single PacBio run, producing 60151 circular consensus sequences (CCS) of which 33417 were kept after quality control. With the regime *d* retaining a mean coverage of 45.9 CCS per locus, we characterized homologous and homeologous copies for a total of 67,127, and 64 allele variants for *ApPEFP*, *CRY2*, and *Transducine* respectively. In addition, the pipeline PURC detected and removed 50 chimeras from the three final alignments, which were also inspected by eye for comparison and estimation of the accuracy of allele number inference. We found strong support for the monophyly of diploid lineages and we identified most of the parental donors of polyploids, highlighting the multiple origins of several of them. We discuss about the topology incongruence between nuclear and plastid phylogenies and present evidence for an asymmetry in maternal and paternal contributions of polyploids as well as gene silencing that seems to occur in several polyploid individuals. *Conclusions* — The PacBio sequencing technology combined with the use of the pipeline PURC provides new perspectives to study the phylogenetics of *Botrychium* and the major role of polyploidy in their speciation processes. Polyploidization in moonworts is presumably driven by biological mechanisms that foster maternal or/and paternal contributors and further investigations are critically needed to reveal how these parental preferences take place in natural populations.

P0330

New species of *Quambalaria* from *Eucalyptus* seed capsules and eucalypt-feeding insects in South Africa

*Sw Morgan, M Schroder, T Paap, S Marincowitz, Mj Wingfield, **Zw***

De Beer

Forestry and Agricultural Biotechnology Institute (FABI), University of Pretoria

The genus *Quambalaria* at present includes six known species. Some of these species were initially described in asexual Ascomycete genera like *Sporothrix* and *Ramularia*, but DNA sequences confirmed their placement in the *Microstromatales* (*Ustilaginomycetes*). Five of the species are causal agents of leaf, shoot and stem diseases of commercially grown *Eucalyptus* and *Corymbia* spp. in South Africa, Australia, Brazil, China and Southeast Asia. The sixth species, *Quambalaria cyanescens*, is not only an epiphyte of *Myrtaceae* trees, but has regularly been found in bark beetle galleries of hardwoods such as oak, and is also known widely as an opportunistic human pathogen. The aim of this study was to identify *Quambalaria*-like isolates obtained from *Eucalyptus* seed capsules and *Gonipterus* cadavers collected from two areas in Gauteng, using DNA sequences of three gene regions, the ribosomal LSU and ITS, as well as *EF-1α*. Phylogenetic analyses of sequence data revealed that the isolates from seed capsules represented two lineages distinct from all known species in *Quambalaria*. The isolates from *Gonipterus* beetles belonged to *Q. cyanescens*. This represents the first report of the latter species from South Africa. The two new species are in the process of being described. Further research is being conducted to test the pathogenicity of these isolates towards bark beetles and *Eucalyptus* trees and seed capsules, and their possible impact on seed production.

T2

P0331

A new genus and sister species described for the globally important, multi-host root pathogen, *Thielaviopsis basicola*

*Wj Nel, Ta Duong, Bd Wingfield, Mj Wingfield, **Zw De Beer***

Forestry and Agricultural Biotechnology Institute (FABI), University of Pretoria, Pretoria

The ascomycete plant pathogen *Thielaviopsis basicola* (= *Chalara elegans*) is the causal agent of black root rot on various agriculturally important crops, including chicory and groundnuts in South Africa. The fungus was first described in 1850 infecting peas (Fabaceae) and *Nemophila* (Boraginaceae) in the UK, and has since been reported from more than 50 plant families globally. Identifications to date have largely been based on morphology of the asexual chlamydospores and symptoms on the plants. A recent multigene study (de Beer *et al.,* 2014, Stud. Mycol. Vol: 79:187-219) showed that *T. basicola* forms a lineage distinct from well-defined genera such as *Ceratocystis* and *Thielaviopsis* in the *Microascales*. However, the absence of DNA sequences representing the holotype made it impossible to provide a definitive generic placement for the species. In this study, we reconsidered the genus and species level taxonomy of *T. basicola* using sequences for the ribosomal 60S, LSU, ITS, as well the MCM7, Actin, RPBI, and RPBII protein-coding gene regions. The study included 57 isolates from 14 geographical locations and various hosts worldwide. The resulting phylogenetic trees revealed that the *T. basicola* isolates formed a well-supported lineage, distinct from all known genera within the Ceratocystidaceae. Importantly, they also provided clear evidence that represents two cryptic species. An isolate from the Netherlands that closely resembles the holotype morphologically has been selected as epitype for *T. basicola,* and its sequence thus defined one of the two clades as representing that species. Isolates from the second lineage have been described as a novel species with slight morphological differences from *T. basicola*. A new genus in the *Ceratocystidaceae* (*Microascales*) was described to accommodate both species.

Floral development of *Hymenaea verrucosa*: An ontogenetic approach to unusual floral characteristics (Fabaceae - Detarieae clade)

*Fábio Junior Kochanowischi[1,2], Juliana Villela Paulino[3], Simone De Pádua Teixiera[4], Ana Maria Goulart De Azevedo Tozzi[1], **Vidal De Freitas Mansano**[2]*

1. Instituto de Pesquisas Jardim Botânico do Rio de Janeiro

2. Universidade Estadual de Campinas

3. Universidade Federal do Rio de Janeiro

4. Universidade Estadual de São Paulo, Ribeirão Preto

We evaluated the floral development of *Hymenaea verrucosa*, the only African species of the genus. This species has three normal and two vestigial petals. We took scanning electron microscopy images from the initial floral development stage to the final stage and others under light microscopy. The results indicated that sepals have helical initiation, the petals initiate simultaneously, but the two abaxial ones develop rapidly. In the intermediate stage, the abaxial petals stop growing, and the three adaxial ones continue to develop until anthesis. Ten stamens of different sizes are distributed in two whorls, where the antesepalous stamens are initiated before the carpel in a modified unidirectional order and the antepetalous stamens are initiated in a simultaneous order after the carpel. We speculate that the difference between the stamens may be related to changes in floral architecture due to the availability of space provided by the loss of abaxial sepals. The ovary has hairs that overlie a broad base and a stipe with central insertion. Secretory cavities were found in several flower regions, just like mucilaginous idioblasts. Secretory trichomes were found along with non-secretors at the base of the ovary. The calyx is tetramerous, and the three well-developed petals and the position of the stamens characterize a zygomorphic flower.

Nuclear ribosomal transcribed spacer polymorphism in some *Paeonia* species (Paeoniaceae): Recent divergence or hybridization?

*Sergey Efimov, **Galina Degtjareva**, Elena Terentieva, Tahir Samigullin, Carmen Vallejo-Roman*

M.V. Lomonosov Moscow State University

The genus *Paeonia* L. consists of approximately 35 species of perennial herbs and shrubs disjunctly distributed in the northern temperate region. The genus is taxonomically isolated, having been placed in its own monotypic family (Paeoniaceae), but species boundaries within the genus are difficult to determine due to a great morphological variability. Revealed by both morphological and molecular phylogenetic studies reticulate evolution and different ploidy level further obscure phylogenetic relationships within the genus. The hybrid species were identified by full or partial ITS sequence additivity of the putative parental species or by incongruent positions of the hybrid in multiple gene phylogenies. The focus of the present study is on the nuclear ribosomal transcribed spacer (ITS, ETS) and the plastid *ycf1* gene sequence diversity and species delineation in three groups of herbaceous species, namely, *Paeonia obovata* complex (*P. obovata*, *P. oreogeton*), *Paeonia anomala* complex (*P. anomala*, *P. hybrida*, *P. intermedia*) and *P. lactiflora*. All species were studied from several populations for investigation of infraspecific variation of sequences. The nucleotide sequences were obtained by direct Sanger sequencing of amplicons. The *Paeonia obovata* complex is widely distributed in East Asia and includes both diploid and tetraploid species. The *Paeonia anomala* complex comprises diploid species from Central Asia, Siberia, and adjacent northeastern European regions. *Paeonia lactiflora* is a systematically well isolated diploid species of central and eastern Asia. Our study shows that all species groups are characterized by a large number of nucleotide positions exhibiting additive polymorphic sites. Nucleotide additivity occurs in the ITS and ETS sequences of both diploid and teraploid species and characterizes the group of species as a whole (*Paeonia obovata* complex, *P. intermedia* + *P. hybrida*) or separate species (*P. intermedia*, *P. hybrida*, *P. anomala*, *P. lactiflora*). According to number of polymorphic sites, *Paeonia obovata* complex can be divided into three subgroups, which is not correlated with morphological characters and little correlated only with the geography. The smallest number of polymorphic positions was observed in accessions from the Sakhalin, as well as from the South Sikhote-Alin. Some additive nucleotides support hybrid origin of species postulated earlier, i.e. *P. anomala*. However a lot of additive nucleotides are not found in other species, which could be considered as parent forms. Interestingly, one polymorphic site observed in *P. anomala* did not have a presumably hybrid origin and could be treated as an apomorphy for the species. In many cases, the studied species are not characterized by nucleotide substitutions, but only by additive nucleotides. The groups characterized by additive polymorphic sites were supported by nucleotide substitutions in plastid *ycf1* gene, when variability of the region was sufficient. Different ITS types arise by means of nucleotide substitutions across the loci. The level of ITS variation is high if the rate of concerted evolution is lower than the mutation rate. It is possible, that additive polymorphism observed in nuclear ribosomal transcribed spacers reflects not only hybrid origin of species, but also recent divergence of the group. This work is supported by the Russian Science Foundation (grant #14-50-00029).

First occurrence of Icacinaceae fossil flower in amber of Le Quesnoy site (Ypresian, Oise, France)

Cédric Del Rio, *Dario De Franceschi*
Museum national d'Histoire naturelle

Since the beginning of the twenty first century, a substantial number of phylogenetic studies, focused on morphological and new molecular data, allowed to clarify the basal relationships within the Lamiid's clade and define the new order of Icacinales Tiegh. This new order includes Oncothecaceae Kobuski ex Airy Shaw and Icacinaceae Miers with 23 genus after its new monophyletic circonscription. This advances precise the evolution and diversification of this group, providing a supported framework for the studies of relevant fossils. Here, we discuss the morphology and affinities of a recently discovered flower, preserved in amber, from Le Quesnoy site (Ypresian, Oise, France). This flower is particularly small (about 2.5 mm diameter), actinomorphic, pentamerous, male or hermaphrodite and hypogynous. The calyx is cupulate, the petals are valvate, fused at base in a short cup and tomentose on inner surface with long, simple flattened and granular hairs. Stamens are alternipetal and erected but lacking anthera (not preserved). The globular ovary is presumed unilocular. Numerous small (20-25 µm) triaperturate and echinulate pollen grains around the flower and on hairs were extracted and have been considered as belonging to this flower. These criteria were used in a phylogenetic analysis with mixed DNA-morphological characters, which leads to place this flower as a member to Icacinaceae family, close to the genus *Hosiea* Hemsl. & E. H. Wilson. However this fossil reveals a combination of features unknown in Icacinaceae's current diversity. A new extinct genus of Icacinaceae was describing, within a clade bringing together 11 genus including *Hosiea*. We also found very similar hair of upper surface of petal on current genus *Nothapodyte*s Blume and *Mappia* Jacq. These taxa are basal in core Icacinaceae (excluded *Cassinopsis* Sond.) and this suggests a pleisiomorphic state of this character. Icacinaceae are well known in fossil records during the Paleocene and mostly Eocene. The fossils attributed to this group mainly consist of endocarps, but only a few leaves and wood were also described. However, no fossil flower has ever been described in this clade. Indeed, flower in amber remain rare and only one flower has been described for all the Lamiid's clade from Baltic amber (Gentianaceae Juss.). Exceptional preservation of fossil structures in amber allow a better understanding of evolution combining molecular/morphology phylogeny and description of fragile organs as flowers usually poorly preserved in other kind of fossilization.

Bipolaris in China

Hui Deng[1], *Yujie Guo*[1], *Yongchun Niu*[1], *Tianyu Zhang*[2]
1. Institute of Agricultural Resources and Regional Planning, Chinese Academy of Agricultural Sciences
2. Shandong Agricultural University

The genera *Bipolaris* Shoemaker is an important plant pathogenic fungal genus, which can cause diseases of plants in Gramineae. Molecular phylogenetic studies of the genus were reported during recent years. According to the reported multi-genes phylogenetic analysis, some species of *Bipolaris* were treated as the new combinations of the genus *Curvularia* and the species of *Bipolaris* were systematically studied. In this study, 255 strains of *Bipolaris* in our lab isolated from the specimens in China and preserved in Agricultural Culture Collection of China (ACCC) were used as materials. All of the strains were sequenced by ribosomal DNA ITS region and phylogenetic analyzed. More than 80 strains with rDNA ITS sequence difference were selected to sequencing the

GPDH and *EF-1α* genes, and the phylogenetic reconstructions of concatenated and individual gene trees were performed. The results show that 251 strains of *Bipolaris* belong to 16 published species, including *B. bicolor*, *B. coffeana*, *B. cookei*, *B. heveae*, *B. heliconiae*, *B. maydis*, *B. oryzae*, *B. peregianensis*, *B. pluriseptata*, *B. secalis*, *B. setariae*, *B. sorokiniana*, *B. victoriae*, *B. yamadae*, *B. zeae* and *B. zeicola*. Among them, the four species *B. coffeana*, *B. heliconiae*, *B. pluriseptata* and *B. secalis* are new records in China. Phylogenetic reconstructions of concatenated and individual gene trees indicate that the four strains do not belong to either *Bipolaris* species. Based on multilocus sequence analysis and morphology, the four strains are assigned to a possible new species of *Bipolaris*. The morphological characters of the representative strain from each species were described in detail, which were grown on the same condition. In this study, most species of *Bipolaris* were isolated from different hosts' species in Gramineae, while *B. sorokiniana* were found on Gramineae, Asteraceae, Cannabaceae, Linaceae, Leguminosae, Magnoliaceae, Malvaceae, Rosaceae, Solanaceae, Ulmaceae 10 families of plants in China. The results will add the knowledge of the species and diversity of the fungi resources *Bipolaris* genus in China, and applied the basis of the further research and utilization of these fungi.

Glacial refugia as genetic hotspots identified by mapping multi-species haplotype distribution

Tao Deng, *Sergei Volis, Hang Sun*
Kunming Institute of Botany, Chinese Academy of Sciences

Geological and climatic processes that led to creation of refuges could have a similar impact on many species, and refugial regions, compared with areas that have been colonized after the retreat of glaciers, are expected to have distinct patterns of intraspecific genetic variation. Comparative phylogeography, by comparing genetic imprints in multiple independently evolving species, can infer how the geographic ranges of co-distributed species have changed over time, and identify the areas of former refugia where many species survived during Quaternary climate oscillations. We calculated from chloroplast haplotype data for 117 species represented by 2458 populations two genetic diversity parameters, the haplotype genetic diversity and genetic uniqueness, for each species. Then we mapped the cell values on a 1° × 1° latitude/longitude grid map of China. Grid cells within the top 10% of highest values of either genetic diversity or genetic uniqueness were considered genetic hotspots. Although the haplotype diversity pattern matched some previously identified endemic richness hotspots and inferred Quaternary refugia, it suggested existence of many previously unidentified cryptic refugia. Our results suggest important roles of cryptic (or micro-) refugia in evolution of Chinese flora, and that an approach combining and summarizing species-specific haplotype diversity data can be useful for their identification. At the same time we found that, out of the two genetic parameters used, only genetic uniqueness (a proportion of unique haplotypes not found elsewhere) can reliably identify the refugia themselves, while the areas with highest genetic richness (a locally found proportion of haplotypes) are not necessarily the refugia themselves but the areas where genetic lineages arriving from different refugia likely admixed after recolonization.

Isolation and characterization of *MADS-box* gene from *Magnolia biondii* Pamp (Magnoliaceae)

Tian Deng, *Shouzhou Zhang*
Fairylake Botanical Garden, Shenzhen & CAS

The MADS-box transcription factors are one of the largest families of transcriptional regulators and play diverse regulatory roles in plant growth and development processes, especially in flower development. In this study, the MADS-box DNA-binding domain downloaded from Pfam protein families database was exploited to identify MADS-box genes from the *Magnolia biondii* tanscriptome using HMMER 3.0. The obtained amino acid sequences were analyzed with DNAMAN 6.0, MEGA6.0, DNAStar7.1 softwares. Totally 18 M. biondii MADS-box genes were found in the M.biondii tanscriptome. Phylogenetic analysis revealed that M. biondii MADS-box genes were classified into two Groups: MIKCC and MIKC*. The Group MIKCC was sub-divided into 8 distinct clades, group SEP, AGL6, AGL20, AG, AP1/FUL, SVP, I and AP3. Domain analysis indicated that the MIKCC type MADS-box genes are highly conserved which contained MADS-box region, I region, K-box region and C tail. Using RNA-seq data the expression of genes in four different transcripts (flower buds in pre-meiosis, flower buds in meiosis, completely open flowers and leafs) was analyzed. Most MADS-box genes only expressed in different flowers periods and the expression in AGL20 sub-family, SVP sub-family and MIKC* type MADS-box genes were high in leaf. Different expression always appears in the same family and these data might be used to analyze the conservatism, the diversity and the functional differentiation of MADS-box.

P0338

Abnormal flower phenotype caused by overexpression of the *Magnolia biondii MbAG-1* in *Arabidopsis*

Tian Deng, *Shouzhou Zhang*
Fairylake Botanical Garden, Shenzhen & CAS

Degenerate primers were designed using unigene sequences of *Magnolia biondii* transcriptome data and MbAG-1 gene was cloned by RT-PCR techniques, with flower buds of *Magnolia biondii* as the test material. The full-length sequence of MbAG-1 gene was 991bp with a complete open reading frame (ORF) of 672 bp and encoding a 223 amino acids protein. Molecular phylogeny analysis suggested that, MbAG-1 is an AG homology in Arabidopsis, at the transcriptional activation domain of C-terminal exist two conserved motifs: AG I and AG II. In addition, a sense expression vector of MbAG-1 has been introduced into Arabidopsis via agrobacterium-mediated method then screen positive transformation individuals. Compared with wild type, PBI121-MbAG-1 transgenic individuals appear premature flowering with small flower, short sepals, larger stamen and carpel, and some abnormal phenotype like petal converting into filament-like structure, Incurved leaf with long epidermal hair. Moreover, the abscissions of the outer three floral whorls (sepals, petals, and stamens) were inhibited during development of the siliques, which were bumpy. And the seed set rate are lower than that of normal seeds in the wild type. In summary, overexpression of the *Magnolia biondii* MbAG-1 gene in Arabidopsis could affect floral organ development, so lay the foundation for the floral organ development.

P0339

The status of an overlooked mistletoe genus *Dufrenoya* Chatin, Amphorogynaceae

Mohan Prasad Devkota
Amrit campus, Tribhuvan University

Dufrenoya Chatin (Amphorogynaceae) contains ca. 11 species of aerial parasites found in southeastern Asia. First named as *Viscum*, it has been known from Nepal since 1802 but rarely collected or studied. Two well-defined species, *D. granulata* and *D. platyphylla*, are known from the middle Mountain region in the eastern half of the country. To provide a modern treatment of the genus for Nepal, a study was conducted that examined their distributions (from herbarium records), a review of their complex nomenclatural history, morphological and anatomical descriptions, and a genus-level phylogenetic analysis of Amphorogynaceae using the nuclear ITS rDNA region. The molecular analysis showed that *Dufrenoya* is most closely related to *Phacellaria* (in agreement with Danser 1940) and this clade is distinct from another composed of *Dendromyza* and *Dendrotrophe*. Our results stand in contrast to the taxonomic treatment of Santalaceae for Flora of China where *Dufrenoya* was included within *Dendrotrophe.* These two genera can be distinguished by a number of morphological characters, e.g., *Dufrenoya* has umbellate male inflorescences whereas in *Dendrotrophe* it is racemose. The genera also differ in fruit characters. *Dendrotrophe* has a fleshy mesocarp and a tuberculate endocarp with chambers at the apex and the base as well as transverse chambers. The mesocarp in *Dufrenoya* consists of membraneous strands and its endocarp is smooth with chambers but no transverse chambers. Taken together, both morphology and molecules favor separate generic status for *Dufrenoya* and *Dendrotrophe*. Indeed, attention should be focused upon the generic status of *Dendrotrophe* and *Dendromyza*. We estimate that both species of *Dufrenoya* in Nepal should receive the IUCN classification of vulnerable because of human alteration of natural ecosystems where its host trees occur.

Geography shapes the phylogeny of frailejones (Espeletiinae Cuatrec., Compositae): A remarkable example of recent rapid radiation in Sky Islands

Mauricio Diazgranados[1], *Janet C. Barber*[2,3]
1. Natural Capital and Plant Health Department, Royal Botanic Gardens, Kew
2. Department of Biology, Saint Louis University
3. Missouri Botanical Garden

The páramo ecosystem, located above the timberline in the tropical Andes, has been the setting for some of the most dramatic recent rapid plant radiations, and it is one of the world's fastest evolving and most diverse high-altitude ecosystems. Today 144+ species of frailejones (subtribe Espeletiinae Cuatrec., Compositae) dominate the páramo. Frailejones have intrigued naturalists and botanists, not just for their appealing beauty and impressive morphological diversity, but also for their remarkable adaptations to the extremely harsh environmental conditions of the páramo. Previous attempts to reconstruct the evolutionary history of this group failed to resolve relationships among genera and species, and there is no agreement regarding the classification of the group. Thus, our goal was to reconstruct the phylogeny of the frailejones and to test the influence of the geography on it as a first step to understand the patterns of radiation of these plants. Field expeditions in 70 páramos of Colombia and Venezuela resulted in 555 collected samples from 110 species. Additional material was obtained from herbarium specimens. Sequence data included nrDNA (ITS and ETS) and cpDNA (*rpl16*), for an aligned total of 2954 bp. Fragment analysis was performed with AFLP data using 28 primer combinations and yielding 1665 fragments. Phylogenies based on sequence data were reconstructed under maximum parsimony, maximum likelihood and Bayesian inference. The AFLP dataset employed minimum evolution analyses. A Monte Carlo permutation test was used to infer the influence of the geography on the phylogeny. Phylogenies reconstructed suggest that most genera are paraphyletic, but the phylogenetic signal may be misled by hybridization and incomplete lineage sorting. A tree with all the available molecular data shows two large clades: one of primarily Venezuelan species that includes a few neighboring Colombian species; and a second clade of only Colombian species. Results from the Monte Carlo permutation test suggests a very strong influence of the geography on the phylogenetic relationships. Venezuelan páramos tend to hold taxa that are more distantly-related to each other than Colombian páramos, where taxa are more closely-related to each other. Our data suggest the presence of two independent radiations: one in Venezuela and the other in Colombia. In addition, the current generic classification will need to be deeply revised. Analyses show a strong geographic structure in the phylogeny, with large clades grouped in hotspots of diversity at a regional scale, and in páramo localities at a local scale. Differences in the degrees of relatedness between sympatric species of Venezuelan and Colombian páramos may be explained because of the younger age of the latter páramos, and the lesser time for speciation of Espeletiinae in them.

Oligocene fossil winged fruits of the endemic *Dipteronia* (Sapindaceae) from Southwest China and its palaeogeographical and palaeoecological implications

Wenna Ding[1,2], *Jian Huang*[1,2], *Tao Su*[1], *Yaowu Xing*[1], *Zhekun Zhou*[1,3]
1. Key Laboratory of Tropical Forest Ecology, Xishuangbanna Tropical Botanical Garden, Chinese Academy of Sciences
2. University of Chinese Academy of Sciences
3. Key Laboratory of Plant Diversity and Biogeography of East Asia, Kunming Institute of Botany, Chinese Academy of Sciences

The endemic genera, especially the palaeoendemics once beyond the present distribution ranges, play important role in tracking floristic relationships among continents throughout geological time. *Dipteronia* (Sapindaceae) is endemic to China nowadays, and is well known in the Paleogene deposits of western North America. Here, we reported the first fossil record of *Dipteronia* in East Asia, namely *D. brownie* McClain and Manchester, based on diagnostic winged fruit remains from the early Oligocene of Lühe Basin in southwestern China. The fossil species is characterized by samaroid mericarps, with a round wing completely surrounding the seed locule, except for a flat proximal edge representing the attachment scar; primary vein extending from the attachment scar, then deflecting sharply and extending straight to the centrally positioned seed. This new finding significantly expands the historical distribution of *Dipteronia* into southwestern China prior to the early Oligocene. It indicates the close floristic affinity between East Asia and western North America by the Oligocene. Moreover, the southward immigration and extinction of this genus from high latitude are consistent with the global cooling and seasonal intensification of precipitation in the Northern Hemisphere.

RAD-seq phylogenomics reconstructs a well-resolved phylogeny of a rapid radiation in the genus *Mosla*

Yanqian Ding, *Panan Li, Yingxiong Qiu*
Zhejiang University

The genus *Mosla* (Lamiceae) is a young but morphologically and ecologically diverse group distributed across Eastern Asia. Approximately 12 species occur in China, most of which are sympatrically distributed. They exhibit remarkable variation in floral morphologies and habitats. We hypothesized that habitat specialisation or pollinator specialisation might contribute to the radiation of *Mosla*. To establish the basic background to test this hypothesis, we need to recover a well-resolved phylogeny of the genus. However, despite several efforts, the evolutionary relationships among the species in the genus remain unclear. Here, we use extensive analyses of genome wide restriction-site-associated DNA sequencing (RAD-seq) data to determine the phylogenetic relationships among seven *Mosla* species. Three taxa (*Collinsonia canadensis*, *Keiskea japonica*, *Perilla frutescens*) were selected as outgroups based on previous molecular phylogenetic studies. Two methods of phylogenetic inference, maximum likelihood (ML) and Bayesian inference (BI), were applied to data sets that included as many as 80,648 RAD unlinked SNPs. Both methods yielded similar topologies that included two major clades: Clade I, composed of two species (*M. hangchowensis*, *M. chinensis*) occupying different microhabitats with divergent floral morphologies and overlapping distributions; and Clade II, composed of five species (*M. soochowensis, M. cavaleriei, M. dianthera, M. scabra, M. japonica*) characterized by relatively diversity in floral morphology. Our results show that, for closely related, recently diverged taxa, RAD-seq is likely the most comprehensive approach currently available for phylogenetic inference.

P0344
Floral development of Urticaceae with emphasis on the female diversification

Jia Dong[1], *Louis Ronse De Craene*[1], *Alexandre Monro*[2]
1. Royal Botanic Garden, Edinburgh
2. Royal Botanic Garden, Kew

Urticaceae, as one of the largest wind-pollinated family, has great diversification in the floral morphology, especially the female structures. Molecular phylogeny of Urticaceae has suggested it as a monophyletic lineage in the order of Rosales with four major clades (Urticeae, Elatostemeae, Boehmerieae and Cecropieae). However, the morphological character changes do not always corresponding with the molecular data. Morphological observation and floral development of 11 species from 4 different tribes were investigated to understand the diversity and evolution within a largely understudied and mainly tropical family. Dramatic variations occur among the groups in terms of sexuality, perianth merism and gynoecium morphology. Flowers are rarely bisexual, more often with a high dimorphism between male and female flowers arranged in monoecious or dioecious reproductive systems. We concentrated on the development of female flowers, which show the greatest diversity in the family. Despite the strong reduction of flowers and apparent homogeneity of structures, the details of development reveal an intricate diversity of forms. Particularly, the formation of inflorescence and the differentiation of organs are highly complex. The perianth is generally tetramerous, but has a high tendency for reduction to trimery or dimery. The nature of the tepals is clarified as sepal originated, but the boundaries between tepals and bracts are often unclear. The monomerous nature of the ovary is confirmed, with no evidence for a second carpel and the formation of the ovary, the stigma and the ovule indicates a special, more reduced but also more advanced developmental process within the urticalean families. Different hypotheses for the evolution of unisexuality are discussed based on the developmental evidence and the phylogeny of Urticaceae.

T2
P0345
Systematics and Biogeography of *Carex* section *Laxiflorae*

Jenna Dorey[1,2], *Robert Naczi*[1], *Takuji Hoshino*[3]
1. The New York Botanical Garden
2. CUNY Graduate Center
3. Okayama University of Science

Carex section *Laxiflorae* includes some of the most common sedges in forests of eastern North America, and several narrowly endemic species. These sedges are ecologically important in the forest understory, especially in the prevention of soil erosion. The section is currently comprised of 16 species in North America, but is in great need of taxonomic revision since several species appear to contain previously undocumented diversity, and the sectional boundaries are unclear. The phylogenetic study with most thorough sampling of *Carex* indicates that the *Laxiflorae* are part of a clade that also includes sections *Paniceae* and *Bicolores*, and contains approximately 50-60 taxa from Asia, Europe, and North America. This clade that includes section *Laxiflorae* appears to have two centers of diversity – one in eastern North America, and one in Eastern Asia. We, therefore, hypothesize this clade was once widespread throughout a continuous forest in the Northern Hemisphere and that the present-day patterns of diversity are due to species radiations on both continents. The goals of this research are to test the monophyly and ascertain the sectional limits of *Laxiflorae*, to delimit and circumscribe species within difficult complexes of *Laxiflorae* s.s., and to view the biogeographic patterns that led to the present distribution of sections *Laxiflorae, Paniceae, and Bicolores*. Here, we present results of ongoing field and herbarium work, morphometrics, and molecular systematics. A maximum likelihood reconstruction of 6 gene regions in over 100 individuals of about 65 taxa from North America, Europe, and Asia recovered section *Laxiflorae* as paraphyletic, with a predominantly North American clade separate from a predominantly Eurasian clade. Both molecular and morphological analyses also offer support for undescribed taxa in North America. These important results will lead to a revised classification of section *Laxiflorae,* and description of new taxa.

Evolution of tropical rainforest species: New insights into the diversification patterns and node dating of the Annonaceae

Eva Drukker[1], *Paul Hoekstra*[2], *Joeri Strijk*[3], *Lars Chatrou*[1]
1. Wageningen University and Research Centre
2. Naturalis Biodiversity Centre Leiden
3. College of Forestry, Guangxi University

Tropical rainforests form the terrestrial biome containing the highest diversity of plant species. Despite extensive ongoing work on floristics of tropical regions and phylogenetics of tropical clades, the evolutionary build-up of this huge diversity is not well understood. One of the approaches to improve our understanding of the origin and maintenance of rainforest hyperdiversity is to unravel the evolutionary history of large clades that are mainly confined to tropical rainforests. The Annonaceae almost exclusively occur in tropical rainforests and, assuming niche conservatism, the temporal and spatial evolution of the Annonaceae can be taken as a proxy for the evolution of the rainforest biome. By far the most species of the Annonaceae belong to two major (sister) clades; the Malmeoideae and the Annonoideae. Due to the different substitution rates of these clades, current models have been unable to produce consistent results with regards to inferring diversification rates and dating the crown nodes of the two clades. It is therefore still unknown whether the huge diversification of the Malmeoideae and Annonoideae clade was the result of a sudden or rather a steady diversification. Insights in these radiations and diversification patterns will help our understanding of the current biogeographical distributions of the Annonaceae and tropical rainforest distributions as a whole. The main goal of this study was to infer a phylogeny, assess diversification rates and date the important nodes of the Annonaceae, based on the most comprehensive dataset and improved modelling. With 7 outgroup species and over 1000 (out of 2400) Annonaceae species, a sampling size of almost 50% of the family was made. All the genera were included, only 5 genera had less than 20% of its species sampled. Of all the other genera more than 20% of the species was represented in the dataset. Newly discovered fossils of the Annonaceae were included for calibration. We applied improved substitution rate models in the programme RevBayes. Due to the flexibility of this programme, many of the issues encountered in previous studies could be accounted for in the RevBayes models.

P0347

Taxonomy and biogeography of the genus *Euonymus* (Celastraceae)

Cheng Du, Yunjuan Zuo, Yuan Wang, ***Jin-Shuang Ma***
Shanghai Chenshan Plant Science Research Center, Chinese Academy of Sciences/Shanghai Chenshan Botanical Garden

Euonymus L. consists of more than 129 species of five traditional sections, and is one of the largest genera of Celastraceae. The genus mainly occur in the temperate regions, with 88.5% species in Asia; however, most genera of the family are distributed in the tropical and subtropical regions of the world. Several taxonomic treatments have been proposed based on various morphological characters, but the taxonomy of *Euonymus* remains controversial due to the limited morphological descrpitions of reproductive organs for several species, the morphological plasticity in vegetative traits, and the lack of a robust phylogeny with extensively sampling to provide insights into the species delimitation. This study aims to infer evolutionary relationships among taxa of *Euonymus*, to test the diversification hypotheses in this rapidly diversified group in eastern Asia, and to provide a new classification system in the phylogeographic context integrated with taxonomic investigation. The phylogenetic relationships of *Euonymus* was reconstructed using the combined dataset of four chloroplast DNA fragments and the ITS regions, with 227 individuals of 87 species sampled. The phylogenetic analysis indicates that assessions of *Glyptopetalum* Thwaites and *Euonymus* clustered together, and seven divergent clades within this genus was identified with strong support. But this genetic grouping is incongruent with the division of five sections based on morphological characteristics of capsule. The fossil-calibrated phylogeny and ancestral area reconstruction analysis suggests that *Euonymus* originated in the temperate eastern Asian zone in Eocene, and diversified in this region during the late Oligocene to the early Miocene. The Antarctic land bridge may have been served as the corridor for the intercontinental dispersal across the continents from eastern Asia to western/eastern North America. The diversification process of *Euonymus* in temperate Asia was triggered by the past climate cooling and habit shifts in Oligocene. A taxonomic revision of the genus *Euonymus* is also presented on the basis of taxonomic literature, field investigation, herbarium specimens, morphological examination and phylogeny reconstruction. *Glyptopetalum* should be incorporated into *Euonymus* as a section to make a monophyletic *Euonymus* sensu lato. The well known five sections based on capsule morphology should be treated as seven sections according to our molecular data. The shape of capsule is no longer a key character for classification and subdivisions of the genus *Euonymus*. The infrageneric divisions of *Euonymus* sensu lato will be recognized, including nineteen new combinations, six new names, one new section and several synonyms.

P0348

A Plastid Phylogeny of the Fern Family Dennstaedtiaceae (Polypodiales)

Yifan Duan[1], *Liang Zhang*[2], *Yongfu Li*[1], *Dekui Chen*[3], *Ngan Thi Lu*[4], *Xianrong Wang*[1], *Libing Zhang*[5]

1. Nanjing Forestry University, Nanjing, Jiangsu 210037
2. Kunming Institute of Botany, Chinese Academy of Sciences, Kunming, Yunnan 650201
3. Chongqing Normal University, Chongqing 401331
4. Chengdu Institute of Biology, Chinese Academy of Sciences, Chengdu, Sichuan
5. Missouri Botanical Garden, P.O. Box 299, St. Louis, Missouri 63166-0299

Phylogenetic approaches with molecular data have resulted in substantial improvement in fern classification by identifying monophyletic groups and rejecting paraphyletic taxa. The family Dennstaedtiaceae is one of the least-known fern families in terms of its circumscription and phylogeny. Currently Dennstaedtiaceae are estimated to contain about 10 genera and 265 species. Previous studies typically had small taxon and character sampling. In the present study, DNA sequences of five plastid loci of 323 accessions representing about 130 species of Dennstaedtiaceae and 20 related genera were used to infer a phylogeny using maximum-likelihood, Bayesian-inference, and maximum-parsimony methods. Our major results included: (i) *Microlepia* is monophyletic and natural hybridization is possibly in this genera; (ii) *Oenotrichia* is resolved within Dennstaedtiaceae; (iii) *Dennstaedtia* is non-monophyletic, with a second clade being more closely related with *Microlepia*; and (iv) *Saccoloma* is polyphyletic, with some falling inside the Dennstaedtiaceae and others outside.

Further study on the phylogenetic relationships within the Paleotropical clade of the Bignoniaceae

Sutee Duangjai[1], *Rattapoom Ruam-Unyamanee*[1], *Wattanachai Tasen*[1], *Voladol Chamchamroon*[2]
1. Department of Forest Biology, Faculty of Forestry, Kasetsart University, Chatuchak, Bangkok
2. BKF herbarium, Department of National Parks, Wildlife and Plant Conservation, Chatuchak, Bangkok

The Paleotropical clade of the Bignoniaceae contains about 20 genera and approximately 150 species of tree. Out of 20 genera, four of them which are Asian, i.e. *Heterophragma, Pauldopia*, *Pajanelia*, and *Suntisukia*, have never been included in any previous phylogenetic studies. Moreover some genera such as *Dolichandrone*, *Markhamia* and *Stereospermum* have been under-sampled in previous phylogenies. Therefore in this study we aimed to investigate the placement of four Asian genera, *Heterophragma, Pauldopia*, *Pajanelia*, and *Suntisukia*, by using DNA sequence data from *ndhF* and *trnL-trnF* regions. We also tested the monophyly of some genera within the Paleotropical Clade. Four well-supported sub-clades within the Paleotropical clade of the Bignoniaceae were identified. Our results confirm the placement of four genera, *Heterophragma, Pauldopia*, *Pajanelia*, and *Suntisukia*, in the Paleotropical clade. They form a first well-supported sub-clade together with other genera, *Radermachera* and *Tecomella*. The genus *Heterophragma* is close to the genus *Santisukia* and together they are sister to the monotypic genus *Pajanelia*. On other hand the genus *Pauldopia* is close to *Radermachera* and *Tecomella*. The second well-supported sub-clade contains *Dolichandrone*, *Fernandoa*, *Kigelia*, *Markhamia*, *Newbouldia* and *Stereospermum*. Our results also indicate that these genera, *Dolichandrone*, *Markhamia* and *Stereospermum*, are not monophyletic. The third sub-clade contains *Catophractes*, *Rhigozum* and *Spathodea* and the last sub-clade is the member of tribe Coleeae from Madagascar.

T2
P0350
OMG *Boronia* (Rutaceae) is polyphyletic: Coping with large well supported clades that contain few morphologically useful characters.

Marco Duretto, *Margaret Heslewood*
Royal Botanic Gardens and Domain Trust

Boronia (Rutaceae) is a genus of 160 species found in Australia and New Caledonia. *Boronia* is particularly diverse in southern Australia with centres of diversity in both the south-west and south-east. It is found in a wide variety of ecological communities that are usually sclerophyllous in nature, such as heaths and eucalypt woodland or forest, though a few species are found in wetter communities such as swamps and rainforest edges. Species can be herbs, shrubs and sometimes small trees characterised by being sclerophyllous and by having leaves that are opposite decussate or rarely in whorls of three, 4-merous diplostemonous flowers, carpels being fused only along the style and dehiscent fruit. These features are common elsewhere in Rutaceae and a defining morphological apomorphy for the genus is apparently lacking. *Boronia* is classified into eight sections including section *Boronella*, once an endemic New Caledonian genus that was recently reduced to a section of *Boronia*. The subfamily and tribal classification of Rutaceae has not stabilised and the position of *Boronia* is important as it is the type genus of Tribe Boronieae (subfamily Amyridoideae) which has been shown to be polyphyletic. *Boronia* is taxonomically isolated and molecular evidence indicates it is sister to a large clade containing many rainforest genera, including *Melicope* and *Acronychia*, that are largely confined to Australasia, as well as two scleromorphic genera, *Zieria* and *Neobyrnesia*, which are traditionally placed in Tribe Boronieae. The remainder of Tribe Boronieae is sister to this larger clade and the entire clade sister to a clade containing *Flindersia* and relatives. The monophyly of *Boronia* has not been tested even though it has been subjected to a number of generic studies, where it had been assumed to be monophyletic, and been included in several larger studies investigating generic relationships within Rutaceae. These larger studies did not include a representative sample of the diversity found in *Boronia* with each study including species of only one or two sections. Sections *Algidae*, *Alatae, Cyanothamnus* and *Imbricatae* were never included in any of these larger studies. Here we present molecular phylogenetic analyses based on two nuclear regions (ETS, ITS) and two plastid regions (*psb*A-*trnH*; the *trn*L-F region, including the *trn*L intron and *trn*L–*trnF* intergenic spacer). Representatives of 42 genera (outgroup includes 8 genera) of the Australasian clade within subfamily Amyridoideae were included. 158 accessions of Boronia were included representing all eight sections plus two of the four species placed *incertae sedis*. Analyses indicate *Boronia* is polyphyletic with section *Cyanothamnus* sister to the *Melicope/Acronychia* clade and this clade sister to a *Zieria*/*Euodia* clade. *Boronia*, less *Cyanothamnus*, remains in the isolated position sister to the above clades. These clades are strongly supported with molecular data but lacking obvious morphological support; apomorphies are not obvious and/or homoplasious. *Cyanothamnus*, another Australian endemic, will be reinstated. The Australasian clade within subfamily Amyridoideae contains five distinct and strongly supported lineages adapted to sclerophyllous environments as well as three or four distinct rainforest lineages suggesting a complicated history of biome transition in the Australasian flora.

Some morphological and anatomical features of generative organs of the genus *Hydrocharis* L. (Hydrocharitaceae)

Andrey Efremov[1], *Cezary Toma*[2], *Andrey Filonenko*[3]

1. Omsk State Pedagogical University
2. Kazimierz Wielki University
3. Moscow Pedagogical State University

The species of the genus *Hydrocharis* spreads in tropical and temperate areas of the Old World: *H. chevalieri* (De Wild.) Dandy in Central Africa, *H. dubia* (Blume) Backer in Southeast Asia and the East coast of Australia and *H. morsus-ranae* L. in Europe, Central Asia and North America. This work is an attempt at a critical analysis of literaturary sources and original data on the morphology and anatomy of the generative organs of the genus *Hydrocharis*. The analysis was realized with the native and fixed material, in accordance with standard methods and techniques having used stereoscopic microscope. It is found, that on the whole the species of the genus *Hydrocharis* typically have large (3−5 cm in diam.), 3-membered entomophilic dioecious flowers, although *H. morsus-ranae* and *H. dubia* can occasionally be bisexual. The perianths of both types of flowers are alike. The calyx is segmented, consists of 3 ovate, white, greenish sepals, significantly shorter than the petals. The corolla is dialypetalous, consists of 3 petals, shaped from almost round to broadly ovate. The androecium of the male flower consists of 4−6 alternating circles, a number of fertile stamens varies, elements of androecium are occasionally fused in the base. 6−12 outer elements are fertile, 3−9 inner ones are sterile. There is a wide range of transitions from the typical fertile stamens to the secretory staminodes and the nectaries. The androecium of the female flower is formed by 2 circles, the inner circle consists of concavity nectaries, the outer circle − staminodes. The gynoecium typically consists of 6 carpels immersed in the ¾ or deeper in the receptacle. At the base of the gynoecium 6 isolated locules of the ovary can be clearly distinguished, septs consist of fused tissues of adjacent lateral walls of carpels. All gynoecium zones except the asimplicate one have 40−50 orthotropic ovules, the placentation is laminal diffuse. With that in mind the gynoecium of *Hydrocharis* should be considered as a lower hexamer hemiparacarpe. Male flowers may have a three-blade pistillodium. The fruit wall of *Hydrocharis* is formed by the tissues of overgrown receptacle (extracarpellary part) and the tissues of carpels (carpellary part). During the fruit ripening the covering tissue is destructed and water starts penetrating with the mesocarp aerenchyma, which causes swelling of the mucus and also triggers the break of the wall and dissemination. The fruit further develops in water. In accordance with the morphogenetic classification of fruits they should be best considered as lower hexamer hemiparacarp berries. Seeds are wide-ellipsoid, 1.0-1.3 mm long (not described in *H. chevalieri*), their surface is covered with soft, 1-3-celled, unequally thickened by outgrowths of exotesta. Consequently, the generative organs of *Hydrocharis* have a wide range of morphological adaptations conditioned by entomophily. The primary data on the morphology and anatomy of the gynoecium and fruit of *H. chevalieri* confirm some isolation of this species.

Flower morphology and development is associated with bee visitation pattern on *Chamaecrista desvauxii* (Leguminosae)

Anselmo Nogueira[1], *Lorena B. Valadão-Menezes*[2], *Poliana Cardoso-Gustavson*[1], *Marília M. Quinalha*[2], *Juliana Villela Paulino*[4], *Elza Guimarães*[2], *Juliana G. Rando*[5], ***Juliana Hanna Leite El Ottra***[3]

1. Universidade Federal do ABC
2. Universidade Estadual Paulista, Campus Botucatu
3. Universidade de São Paulo
4. Universidade Federal do Rio de Janeiro
5. Universidade Federal do Oeste da Bahia

Chamaecrista (Cassinae, Fabaceae) has floral traits associated with pollination by vibration. Their yellow corollas, poricidal heterantherous anthers, enantiostylous and asymmetric flowers without a nectary are a suite of features considered to have evolved several times within Cassiinae, due to convergent evolution towards buzz pollination mechanism. In such system, anthers are the most valuable tissues concealing pollen exploited by bees as sole floral resource. From the plants perspective, flowers needs to overcome the “pollen dilemma”, providing pollen for bee pollinators and also assuring the fertilization success, thought the development of heteranthery and other modifications in flowers, usually associated to the “division of labor” hypothesis among stamens. In this sense, floral morphology and timing of floral organ development have a crucial role in these plants because bees can feed on flowers in distinct floral stages, what could affect pollination. However, detailed studies focusing on differences in the pollen grains in heteromorphic stamens, as well as the relation of floral development to the floral biology has rarely been addressed in Cassinae. Here we investigated the association between floral morphology and growth patterns during flower development with the use of pollen by bees in *Chamaecrista desvauxii* var. *latistipula*. First we evaluated the detailed morphology and patterns of time of development from bud stage to flower opening, considering each inner floral whorl as well as the entire bud. We also evaluated bee visiting behavior, germination of pollen grains from different anther morphs (short and long), and stigma receptivity. We found that flower bud growth is initially fast until reach around 9 mm (elongation phase), gradually slowing down after. Petals and carpel have a delay in their development, showing an exponential growth pattern. Differently, both stamen whorls elongate linearly throughout flower development. Bee species like *Bombus* and *Oxea* had specific behaviors on anthers, and sonicated not only opened flowers but also advanced floral buds. In these flower stages, the stigma was receptive as well as the pollen grains were viable in both short and long anthers. Thus pollination can occur

before flower opening, considering that anthers were easily accessed by bees in advanced buds due to the delayed development of petals in this stage. We also found that pollen grains have the same structural and histochemical features regardless their original anther morph, refuting the 'division of labour' hypothesis in this aspect. However, qualitatively the three long anthers had more pollen grains than the short anthers, due to more space available in their thecae. Furthermore, the long anthers always were located facing the inner side of a large modified concave petal, and with similar length to the carpel, suggesting morphological adjustment for pollination. Thus the potential difference in the role of anthers with different sizes could not be associated with the pollen itself, but with relative position of anthers to other floral organs and in the amount of pollen available for transfer. This is one of the first studies in Fabaceae that related the absolute measured time in floral development to the floral biology of a species.

P0353
Floral structure of Neotropical Sapindales: Implications to the systematics and evolution of the order on a global scale

Juliana Hanna Leite El Ottra, *José Rubens Pirani*
Universidade de São Paulo - Instituto de Biociências

Sapindales is a monophyletic order within the malvids clade (core eudicots). The order comprises nine families with ca. 473 genera, mostly distributed in tropical and temperate areas of the world. In the Neotropical region six sapindalean families occur, *i.e*., Anacardiaceae, Burseraceae, Meliaceae, Rutaceae, Sapindaceae and Simaroubaceae. This region presents ca. 40% of the species of the order, making the neotropics one of its major diversity centres. Sapindalean taxa have well diverse floral morphologies and thus represent an interesting group to address questions on floral evolution. So far, the only previous study focusing on floral evolution in the order was based on a limited sample of taxa (only 13 genera), including few neotropical representatives. As a consequence, to date, there is still an incomplete knowledge on how the floral diversity among the Sapindales has evolved. More recently, a raising amount of detailed studies focusing on the floral structure and ontogeny of several sapindalean families has been carried out (i.e., Nitrariaceae, Kirkiaceae, Anacardiaceae, Burseraceae, Rutaceae and Simaroubaceae). Among the groups with neotropical representatives, only for the Meliaceae there are a few detailed comparative studies on floral structure. Nevertheless, there is a lack of studies describing the inner morphological surface of carpels of Meliaceae, preventing an accurate comparison to the gynoecium structure of other Sapindales where such studies are available, especially in relation to the most closely related families to Meliaceae, the Rutaceae and Simaroubaceae. As new molecular phylogenetic reconstructions of the Sapindales taxa are being made, current hypotheses on the relationships among its members have been changed and improved in several regions of the phylogeny. Still, some relationships among sapindalean families are not yet well supported, as for instance the sister relationship of Meliaceae to Simaroubaceae, and not to Rutaceae. Considering this context, we aim to conduct new structural and evolutionary studies on flowers of Sapindales members, aiming to provide novel characters to support systematic relationships from a structural point of view, and to achieve a better knowledge on the evolutionary patterns within the order. Among our preliminary results we highlight the following ones: structural and ontogenetical studies on the flowers of Meliaceae confirm previous assumptions that their gynoecium is truly syncarpous, with and extensive symplicate and synascidiate regions. This stands out very differently from the most common gynoecium structure reported for the Rutaceae and Simaroubaceae, whose carpels are mostly apocarpous, with an extensive plicate or symplicate zone. Other typical feature in these two latter families is a short remnant of the floral apex at the centre of carpels. We noticed that a similar remnant also occurs in Biebersteiniaceae, which is an early divergent lineage of Sapindales. Thus this feature likely represents a plesiomorphic state, with multiple evolutions within the order. Ancestral character reconstructions are being conducted in order to evaluate the probable evolutionary pattern of selected floral features, such as nectary shape and position, occurrence of tubular structures in the flower, and structural floral sex.

Sex, drugs and pupusas: Disentangling relationships in Echiteae (Apocynaceae)

J. Francisco Morales[1], *Mary E. Endress*[2], ***Sigrid Liede-Schumann***[1]
1. University of Bayreuth
2. University of Zurich

Apocynaceae are widely used in traditional medicine around the world due to their rich array of bioactive secondary metabolites, including complex indole alkaloids, steroidal alkaloids and cardenolides. In a few genera of apocynoids, a much more rare type of secondary compound is found – pyrrolizidine alkaloids (PAs). Although toxic secondary metabolites in plants have arisen as a means of phytochemical protection for the plant against herbivores, in diverse insect groups, certain lineages have become adapted to the toxic PAs and have evolved a close association with plants containing them. The poisons are ingested by the larvae as they feed on leaves of the host plants, or in a more derived behavior known as pharmacophagy, adult insects imbibe PAs from injured or withered plant parts. PA-adapted insects are able to sequester the toxic compounds and then put them to their own use against predators. Two groups of Lepidoptera – arctiid moths and danaid butterflies – have evolved an even more specialized use of PAs. Males use them as the chemical basis for male-mating pheromones. Experiments have shown that scent-producing glands of males with no PAs in their diet were merely two stunted stalks, whereas those of males that were fed PAs developed four long tubes densely covered with long pheromone-emitting hair-pencils, demonstrating that these species have evolved a dependence on the toxic PAs in their host plants to produce pheromones. At dusk males expand their hair-pencils, emitting pheromones that attract females as well as other males. The result is the formation of a lek, a mating arena in which group sex takes place. In Apocynaceae, the largest number of PA-producing genera is found in Echiteae. In order to determine the distribution of PAs within the tribe, we did a molecular phylogenetic analysis, including representatives of all subtribes and 17 of the 19 recognized genera, onto which we mapped PA-containing species. Echiteae and four of its subtribes

(Echitinae, Parsonsiinae, Peltastinae and Prestoniinae) as currently circumscribed were shown to be non-monophyletic. The fifth subtribe, Pentalinoninae, though monophyletic, was resolved as sister to a clade of Odontadenieae. Two genera, *Fernaldia* and *Peltastes*, were nested within *Echites* and *Macropharynx*, respectively, and were synonymized. Fourteen genera were maintained, divided among five subtribes. Species reported to have associations with PA-adapted insects were found in all subtribes except one, for which no data on secondary compounds was available. Since the characteristic secondary metabolites in the closest relatives of Echiteae, Odontadenieae and Mesechiteae, are cardenolides, we hypothesize that an evolutionary shift took place in the ancestors of Echiteae, in which these were replaced by parsonsine type PAs as the predominant defense compounds. In un-adapted vertebrates, PAs are slow-acting toxins that over time can lead to debilitating chronic medical conditions. In tropical countries, where Apocynaceae often figure prominently in treating a wide number of ailments, herbal teas, dietary supplements and traditional medicines made from plants containing PAs pose a potential health threat to the patients who consume them.

The 600-year vegetation dynamic record from western Thailand using palaeological approach

Apichaya Englong[1], *Paramita Punwong*[2], *Paweena Traiperm*[1]
1. Department of Plant Science, Faculty of Science, Mahidol University, King Rama VI Road, Bangkok
2. Faculty of Environment and Resource Studies, Mahidol University, Phutthamonthon Sai 4 Road, Nakhon Pathom

The last 600-year vegetation dynamics are reconstructed from pollen and sediment set within a chronological framework from radiocarbon dating of a core (NP3) collected from Nong Pling freshwater spring areas, in Thong Pha Phum, western Thailand. The results show that lowland forest and terrestrial herbaceous were established in this area at least 600 years ago suggesting drier conditions than present until around 340 years before present (BP). After that, wetter condition occurred indicated by a decline in lowland forest and an increase in freshwater spring taxa until around 140 years BP. Oscillations between freshwater spring taxa and lowland forest occurred probably due to climate variability particularly during the last century although these changes may also be due to human activities suggested by the presence of cereal pollen.

Crocus L. riddle, in the middle of its diversity center: A seek for a resolved phylogeny

Levent Can, *Osman Erol, Orhan Küçüker*
Istanbul University

The genus *Crocus* L. belongs to the family Iridaceae (Asparagales) and is distributed in the Northern Hemisphere, from western China to western Europe and north-western Africa, with a diversity center in Anatolia, Greece and the Balkan Peninsula. The plants belonging to this genus are geophytes with a subterranean corm, which helps the plant to survive the harsh conditions of a year, with a price of having a very short, a considerable cool and rainy time to flower and attract their pollinators. Most of the geophytes overcome this situation by producing flowers with remarkable colours and temptress scents for their pollinators, when not many other plant species are flowering. Consequently, like many geophytes, the crocuses obtained their places in rock gardens, private gardens or botanical gardens. The taxonomy and phylogeny of this genus is quite complex and yet unresolved. One of the reasons for that is the fact that the plant is much reduced and the exiguity of distinctive characters. Prophyll presence, corm tunics, style branching, flower and throat color are the most important characters, but additionally, distribution information and flowering periods are often used to distinguish the taxa. In most cases, the chromosome numbers are also not informative. Another difficulty is the “subspecies problem” in this genus, where many taxa with morphological similarities were ranked and grouped as subspecies. For instance, *Crocus biflorus* Mill. had more than 20 subspecies, which probably does not represent a natural systematics of the taxa. On top of that, the genus *Crocus* has been taxonomically and systematically very active in the last years. Recent studies have published a series of new taxa, and changed the taxonomy and phylogeny of the genus dramatically. Especially in Turkey, nearly as much as half of Turkish taxa were discovered and published in the past sixteen years. For these reasons above, here, we aimed to update the current number of crocuses, and to summarize the developments published recently, along with a brief review on the classification of the genus. We also aim to present the latest taxonomical and molecular systematics results of our target species complexes and to answer following questions: is *Crocus paschei* Kernd. a true species, does the *Crocus olivieri* J.Gay name involve two species as suggested 130 years ago, what is the relatedness of *Crocus flavus* Weston and *Crocus antalyensis* B.Mathew species groups, and what is the variation amongst *Crocus pallasii* Goldb. species group. By doing so, we hope to shed some light on the actual situation of the genus.

The Turkish endemic *Pseudodelphinium turcicum* (Ranunculaceae): An unusual population of *Delphinium* with peloric flowers that has persisted in the wild for 20 years

Felipe Espinosa Moreno[1,2], *Thierry Deroin*[1], *Kun-Li Xiang*[3,4], *Wei Wang*[3,4], *Myreya Pinedo Castro*[5], *James Byng*[6,7], *Zeki Aytaç*[8], *Sophie Nadot*[2], *Florian Jabbour*[1]
1. Muséum national d’Histoire naturelle
2. Université Paris-Sud
3. Chinese Academy of Sciences
4. University of Chinese Academy of Sciences
5. Pontificia Universidad Javeriana
6. Plant Gateway
7. Naturalis Biodiversity Center
8. Gazi University

The Turkish endemic *Pseudodelphinium turcicum* (Ranunculaceae) was described by Vural *et al.*, in 2012 based on a single population found in the salt lake basin of Tuz Gölü, Konya Province. Although the authors noticed morphological similarities between the specimens and the genera *Delphinium* and *Garidella*, they highlighted unusual features, which led them to describe a new genus name consisting of a single species, *P. turcicum*. We carried out morphological, anatomical, and palynological studies on individuals of this species. We also conducted a molecular phylogenetic analysis to identify the closest relatives of this species. Using this combination of approaches, we showed that the species belongs in *Delphinium* subg. *Delphinium*, distributed (exclusively or not) in Mediterranean and adjacent regions; it is more precisely sister to two species (*D. virgatum* and the Turkish endemic *D. venulosum*). We conclude that it is an unusual population of *Delphinium* presenting peloric flowers that has been maintained in the wild for at least two decades. We provide hypotheses concerning the identity of the floral organs, as well as an explanation for the origin of the floral teratological characters.

Revision of *Ixora* (Rubiaceae) in Vietnam

Thi Huyen Trang Thieu[1], *Sangho Choi*[1], *The Bach Tran*[2], ***Sangmi Eum***[1]

1. International Biological Material Research Center, Korea Research Institute of Bioscience and Biotechnology,

2. Institute of Ecology and Biological Resources, Vietnam Academy of Sciences and Technology

Ixora is a genus of Rubiaceae widespread in tropical Africa, America, Asia, Madagascar and Pacific islands. Thirty-four species have been reported in Indochina region by F. Ganepain and his colleagues since 1923. However the number of species of *Ixora* and its taxonomic status in Vietnam are still unclear and untouched up to now. In this study, all Vietnamese species of *Ixora* are taxonomically revised on the basis of morphological characters. The results after conducting field trip and examination of specimen in Vietnam enable us to confirm twenty four species and six varieties in Vietnam including a new recorded species, *I. auricularis* Chun & F.C. How ex W.C. Ko, previously has been known only from China and newly founded from northern and center of Vietnam. We also suggest that inflorescence, apex shape of corolla and base shape of leaf can be main key characters to identify for *Ixora* species in Vietnam. Details of distribution, illustrations for main species and an identification key of *Ixora* are provided.

P0359

Phylogeny of *Eremochloa* (Rottboelliinae: Panicoideae: Poaceae): Implications for an endangered species in Australia

Melodina Fabillo, *Tanya Scharaschkin*

Queensland University of Technology

Eremochloa is a genus of grasses, with approximately 12 species, found mainly in the open woodlands of Asia and Australia. *Eremochloa* is characterized by lower glumes bearing apical wings and spiny keels. The three species of *Eremochloa* that occur in Australia are also found in Asia. *Eremochloa bimaculata* and *E. ciliaris* are widely distributed in eastern Australia. *Eremochloa muricata* is known from only two records that are over 2000 km apart; one from Cape Flattery, Queensland (1976) and the other from Byron Bay, New South Wales (1912). *Eremochloa muricata* has been declared an endangered species in Queensland. Identification of the Australian species, using currently accepted keys, is problematic, especially as species descriptions do not consistently agree with the key. The monophyly of *Eremochloa* has not been tested and a genus-level phylogenetic study is lacking. The objective of this study was to conduct a comprehensive morphological and molecular study of the genus, so as to undertake a taxonomic revision of the Australian *Eremochloa* based on phylogenetic results, in conjunction with extensive fieldwork to gain a better understanding of the geographic range of the three Australian species. Preliminary results based on Bayesian inference, maximum likelihood and maximum parsimony analyses of chloroplast sequence data (*atp*B-*rbc*L spacer, partial *mat*K gene, partial *ndh*F gene, *trn*L-F intron and intergenic spacer) show that the genus *Eremochloa* is monophyletic. *Eremochloa bimaculata* is not monophyletic; the Asian accessions are more closely related to other Asian species of *Eremochloa* than to the Australian accessions of *E. bimaculata*. The endangered Australian species, *E. muricata,* is more closely related to Australian *E. bimaculata* than to the Asian *E. muricata.* These findings are consistent with our detailed observations of gross morphological features. The Australian accessions of *E. bimaculata* exhibit extensive morphological variation across the geographic distribution. The 1912 specimens of *E. muricata* has been incorrectly identified whilst the 1976 specimen cannot be differentiated from specimens of *E. bimaculata* collected in the vicinity of Cape Flattery as part of this study. Preliminary results indicate the need for the Australian *E. bimaculata* to be separated from the Asian species. *Eremochola muricata* from Australia should to be treated as a variation of the widespread and variable Australian species *E. bimaculata* and can be removed from the endangered species list. However, if further fieldwork in the Cape Flattery produces specimens that do indeed turn out to be *E. muricata*, these could just as well be first records of a non-native grass, with the potential of being naturalised and invasive, and should be eliminated rather than being listed as an endangered species.

P0360

Divergence times of the tribe Astereae inferred from cpDNA *trn*L/*trn*F and two nrDNAs, ITS and ETS sequences data in Iran

Tayyebeh Farhani

Tarbiat modares university

Astereae with approximately 222 genera and 3100 species is the second largest tribe of Asteraceae distributed worldwide especially in temperate regions with the major centers of diversity within southwestern North America, the Andes, South Africa, Australia, and New Zealand. This tribe comprises 15 genera and 38 species in Iran. The genus *Psychrogeton* with 11 species is the largest genus of tribe in Iran that distributed in higher elevation of Irano-Touranian region. The aim of the present study is to reconstruct the phylogenetic relationships and divergence times in the tribe using the concatenated nrDNA (ITS, ETS) and cpDNA (the *trn*L Intron and *trn*L/*trn*F Intergenic Spacer) data sets, based on Bayesian and BEAST analyses. In this study we used 95 species from 25 genera of Astereae. *Calendula officinalis*, *Chrysanthemum coronarium* and *Chrysanthemum indicum* as outgroups were also included in the analyses. The inferred phylogeny resulted from Bayesian presented a framework to reconstruct the origin of diversification in the tribe. The tree of BEAST analysis is largely congruent with those resulting from Bayesian analysis. Dating analysis of the combined data estimates the age of 58.4 Mya (Paleocene-Eocene boundary) for the stem node. Divergence time estimates indicate that Astereae began to diversify ca. 38.6 Mya (34.7–42.6 95% HPD) in the Middle-late Eocene and extension of the Range of lineage occured mostly during the late-Oligocene to Pleistocene. Our results represent the genus *Erigeron* has undergone rapid diversification and recent speciation in the Late Pliocene and the Early-to-Mid Pleistocene similar to *Erigeron* species in the European Alps, likely during the glaciations in Pliocene and Pleistocene.

T2

P0361

A preliminary infrageneric classification of the species-rich genus *Silene* (Caryophyllaceae): Molecular phylogeny and morphology revisited

Jafari Farzaneh[1], *Gholipour Abbas*[2], *Oxelman Bengt*[3], *Zarre Shahin*[1]
1. University of Tehran
2. Payame Noor University
3. University of Gothenburg

Silene L. with about 700 species is the largest genus of Caryophyllaceae. The delimitation of *Silene* has been controversial. Through merging the genera *Atocion* Adans., *Viscaria* Bernh., *Heliosperma* Rchb., *Pertrocoptis* A.Braun ex Endl., *Eudianthe* Rchb. and *Lychnis* L. in *Silene*, some authors proposed a lumping approach. However, the modern treatments of *Silene* suggest a narrower circumscription of the genus splitting it into distinct genera. The genus is widely spread throughout temperate regions of the North Hemisphere with centers of diversification In the Mediterranean area, SW Asia and Central Asia. The phylogenetic backbone of *Silene* and allied genera has been reconstructed in previous studies. None of the current infrageneric classifications are completely supported by those ones. In the present study, we conducted comprehensive phylogenetic analyses using nrDNA ITS and cpDNA *rps*16 sequences for 262 samples of *Silene* and its allied genera representing of 42 sections recognized by Chowdhuri. Maximum parsimony and Bayesian inference methods were used. STACEY v. 1.2.2 package was implemented in BEAST v. 2.4.4. to estimate species trees and minimal cluster trees. The results support dividing *Silene* to two subgenera, i.e. *S*. subgen. *Behenantha* (Otth) Endl. and *S*. subgen *Silene*, which is in agreement with the previous molecular phylogenetic findings and contradicts Rohrbach's classification. Our study corroborates recognizing following sections in *Silene*: *S*. sect. *Physolychnis* (Benth.) Bocquet, *S*. sect. *Melandrium* (Röhl.) R.K. Rabeler, *S*. sect. *Conoimorpha* Otth. Majority of *Silene* spp. are placed in *S*. subgen. *Silene*. According to the gained phylogenetic results of the present study: (1) *S*. sect. *Lasiostemones* is not monophyletic and majority of its representative are nested within *S*. sect. *Sclerocalycinae* in *S*. subgen. *Silene*. The circumscription of these two sections needs to be clarified; (2) The members of *S*. section *Auriculatae* (Boiss.) Schischkin characterized by perennial habit and auriculate petal claw form a clade with taxa from various sections that might be exauriculate, annual or perennial, gynodioecious or not; (3) Suffruticose plants of *S*. sect. *Spergulifoliae* (Boiss.) Schischkin are closely related to two annual members of *S*. sect. *Lasioclycinae* (Boiss.) Chowdhuri; (4) *S. gallica* L. as the type of the genus forms a core clade with some predominantly annual sections distributed in the Mediterranean area; (5) *S. nizvana* is isolated from other members of *S*. sect. *Auriculatae* sensu Melzheimer; (6) The members of *S*. sect. *Rigidulae* (Boiss.) Schischkin are splitted into several clades, and the circumscription of *S*. sect. *Rigidulae* need to be improved and reduced to exclude.

P0362

Genetic architecture of flower and leaf divergence in a pair of sympatric sister species of *Primulina*

Chen Feng[2], *Chao Feng*[1], *Lihua Yang*[1], *Ming Kang*[1]
1. South China Botanical Garden, CAS
2. University of Chinese Academy of Sciences

Cave-associated plants provide an attractive system for studying phenotypic evolution by the extreme habitats strongly selected a wide range of plant traits through abiotic and biotic properties. The plants in *Primulina* display remarkable interspecific variation in flower and leaf traits and occurs in diverse light regime (from exposed steep cliffs to twilight zones of caves), thus it is an excellent model for studying phenotypic adaptation to extreme cave environments. We conducted QTL analyses of 16 adaptive traits on a pair of *Primulina* sister species which were found sympatric in a cave entrance of Danxia Mountain. We found that interspecific divergence in all traits is due to many QTL with minor to medium effect including highly epistatic interactions among them. QTLST test results showed that flower size was under directional selection, while contrary for flowering time and leaf traits. Our findings are very important for understanding the genetic basis of adaption to cave and cave-like habitats in plants.

Allopatric divergence, local adaptation, and multiple quaternary refugia in a long-lived tree (*Quercus spinosa*) from subtropical China

Li Feng[1], *Yan-Ping Zhang*[1], *Jia Yang*[1], *Tao Zhou*[1], *Guo-Qing Bai*[1,2], *Jiao Yang*[1], *Zhong-Hu Li*[1], *Ching-I Peng*[3], *Gui-Fang Zhao*[1]
1. Northwest Universtiy
2. Xi'an Botanical Garden
3. Biodiversity Research Center, Academia Sinica

The complex geography and climatic changes occurring in subtropical China during the Tertiary and Quaternary might have provided substantial opportunities for allopatric speciation. To gain further insight into these processes, we reconstruct the evolutionary history of *Quercus spinosa*, a common evergreen tree species mainly distributed in this area. Forty-six populations were genotyped using four chloroplast DNA regions and 12 nuclear microsatellite loci to assess genetic structure and diversity, which was supplemented by divergence time and diversification rate analyses, environmental factor analysis, and ecological niche modeling of the species distributions in the past and at present. The genetic data consistently identified two lineages: the western Eastern Himalaya-Hengduan Mountains lineage and the eastern Central-Eastern China lineage, mostly maintained by populations' environmental adaptation. These lineages diverged through climate/orogeny-induced vicariance during the Neogene and remained separated thereafter. Genetic data strongly supported the multiple refugia (per se, interglacial refugia) or refugia within refugia hypotheses to explain *Q. spinosa* phylogeography in subtropical China. *Quercus spinosa* population structure highlighted the importance of complex geography and climatic changes occurring in subtropical China during the Neogene in providing substantial opportunities for allopatric divergence.

The high content of tannins in *Rhizophora apiculata* as a mechanism underlying high salinity tolerance

Xiao Feng, *Shaohua Xu, Jianfang Li, Ziwen He, Suhua Shi*
Sun Yat-sen University

As mangroves have colonized and well adapted to the extreme intertidal environment with high salinity, hypoxia and other abiotic stresses, they are attractive models for studying genetic mechanisms underlying environmental adaptations. *Rhizophora apiculata* is a typical mangrove with high contents of tannins which is likely related to salt resistance. Using high throughput RNA-seq data of *R. apiculata* treated with different salt concentrations, we detected tannin biosynthesis pathway significantly enriched of differentially expressed genes. Particularly, *RA_DFR (dihydroflavonol 4-reductase)*, a key enzyme coding gene in the pathway, not only had elevated expression level with salt treatment, but also retained another copy missed in inland relatives. To reveal the up-stream regulatory mechanism, we further identified candidate transcription factors that may regulate these differentially expressed genes in the pathway. The quantification of tannins in the root tissue samples confirmed that the content of tannins increased with salt treatment. Overall, this study identified genes that potentially associated with high tannin content, and shed light on the mechanism of tannin-based high salinity tolerance in *R. apiculata*.

Comparative analysis of complete chloroplast genomes improves phylogenetic resolution in Smilacaceae

Yu Feng, *Pan Li, Ying-Xiong Qiu, Cheng-Xin Fu*
Key Laboratory of Conservation Biology for Endangered Wildlife of the Ministry of Education, College of Life Sciences, Zhejiang University

Smilacaceae, composed of only one genus, *Smilax*, is a monocot family of lianas, shrubs and herbs widely distributed across the world. The family comprises more than 200 species characterized by climbing habit, reticulate leaf venation, paired petiolar tendrils, unisexual flowers, and superior ovaries. Previous molecular phylogenetic studies have recovered Smilacaceae as monophyletic. However, the deep-level relationships still remain poorly resolved, thus impeding our understanding of the evolution of the family. Plastome sequencing is now an efficient option for increasing phylogenetic resolution in plant phylogenetic and population genetic analyses. Here, the complete chloroplast (cp) genomes of 30 species covering its phylogenetic diversity and almost all geographic distribution of this family were sequenced, to better understand the evolutionary relationships among these plants and the mutation patterns in their cp genomes. The Smilacaceae chloroplast genomes exhibited a typical quadripartite structure and ranged from 157,646 bp to 158,691 bp in length. The cp genomes contained 113 unique genes, including 29 tRNA, 4 rRNA 78 protein coding genes and 3 pseudogenes (*ycf15*, *ycf68* and one copy of *ycf1*). Comparative analyses indicated that the overall cp genome structure among these taxa was quite similar. Sequence divergence in IR regions (Pi = 0.00174) was much lower than that in LSC (Pi = 0.0074) and SSC (Pi = 0.00918) regions. Seven highly divergent DNA regions (*accD*, *rbcL*, *ycf1* for protein coding regions and *trnK-atpA*, *trnT-trnM*, *accD-psaI*, *ndhF-trnL* for non-coding regions), suitable for species identification and phylogeographic analyses, were detected among the 30 cp genomes. Phylogenetic analyses based on whole cp genome data provided robust support for the deep relationships, verifying the ability of whole cp genome to solve deep-level phylogenetic relationships. The findings highlight the potential of the whole cp genomes for improving resolution in phylogeny as well as species identification in phylogenetically and taxonomically difficult plant groups.

5. Royal Botanic Garden Edinburgh
6. Botany Department, National Museum of Natural History, Smithsonian Institution, Washington, D.C.

Traditional molecular phylogenetic methods utilizing a few nuclear and chloroplast regions are increasingly being replaced by next-generation sequencing (NGS) approaches. Hybridization-based library enrichment (Hyb-Seq) has become a very efficient application allowing targeting several hundreds to thousands of loci with often a small amount of missing data across the whole family or even order. As the method is combined with genome skimming, nearly complete chloroplast sequences and the whole rDNA cistron are also obtained. Such phylogenomic datasets produce well resolved and highly supported evolutionary hypotheses. The Hyb-Seq methodology was applied in the ginger family (Zingiberaceae). 1,180 loci were captured and 694 loci were selected for the analysis of 225 species covering all tribes and almost all genera within the family. The species trees were constructed using concatenation, supertree (MRL) and coalescence-based methods (ASTRAL, ASTRID). Almost all nodes were highly supported except several deep nodes in the phylogeny. Within Zingiberoideae four main lineages were resolved: Globbeae (*Globba*, *Hemiorchis*, *Gagnepainia*), Curcumeae (*Curcuma*, *Camptandra*, *Pyrgophyllum*), *Monolophus*, and Zingibereae (all other genera). Within Alpinioideae there are many supported groups including six *Alpinia* lineages, five *Amomum* lineages, and three *Hornstedtia* lineages. Incongruence among the nuclear loci and the nuclear and plastome dataset pointed out the possible hybrid origin of some genera (i.e., *Newmania*, *Pyrgophyllum*, *Monolophus*, and some *Alpinia* and *Amomum* lineages). In summary, we demonstrated the utility of the Hyb-Seq method for constructing robust and well-resolved phylogenies of the whole family.

Systematics, diversity and historical biogeography of Neotropical synandrous Mimosoids – the Ingeae tribe

Julia Ferm[1], *Catarina Rydin*[2,3]
1. Uppsala University, Department of Organismal Biology, Systematic Biology
2. The Bergius Foundation, the Royal Academy of Sciences
3. Stockholm University, Department of Ecology, Environment and Plant Sciences

The delimitation of the legume tribe Ingeae, often referred to as synandrous (stamen filaments fused) mimosoids, have long been in a state of flux, with many segregate genera being proposed and/or merged with other genera. This study intends to investigate selected ingoid genera (*Cojoba*, *Punjuba*, *Zygia*/*Marmaroxylon* and *Zapoteca*) with questionable taxonomic status in relation to other genera in the tribe. The project is divided into several parts working at different taxonomical levels, exploring the phylogeny and taxonomy using both morphological and molecular data. With the phylogenetic hypothesis as a basis, the aim is to provide a classification as well as species and subspecies delimitations, that reflect the evolutionary history of the group. The project also aims at exploring the historical biogeography of these species, mainly distributed in the West Indies, Mexico together with Central America, and South America, as well as the evolution of morphological structures and cues.

Plant taxonomy via geometric morphometrics: Delimiting *Hydrocotyle* L. (Araliaceae) species from South America

Pedro Fiaschi, *Eduardo Nery*
Federal University of Santa Catarina

Geometric morphometrics (GM) is a set of methods that allow an independent quantification of shape and size of biological structures, as well as their statistic evaluation. Although disseminated in other fields of biological inquiry, GM is not applied in plant taxonomy. Nevertheless, GM can reveal morphological gaps along character variation, which could be useful to set boundaries between similar species. The similarity between species is a common issue in *Hydrocotyle,* in which species delimitation is complicated by a large interspecific morphological variation. Among the morphological variable species is *Hydrocotyle quinqueloba* Ruiz & Pav., which currently comprises nine infraspecific taxa, each more or less recognizable by their leaf morphology and indument. However, such treatment may include currently non-recognized species since *H. quinqueloba* displays a disjunct distribution between the Andes and the Brazilian Atlantic forest in South America. Hence, we investigated the morphological variation of *H. quinqueloba* to evaluate whether its current delimitation includes other species or not. We applied landmark-based GM on leaves of 210 specimens of *H. quinqueloba* to assess species' morphospace cohesion, and we compared specimen's morphology to find potential discontinuous and discriminant characters. A principal component analysis (PCA) revealed morphospace gaps among some infraspecific taxa, which could be separated into four groups. A nested analysis of variance (ANOVA) Procrustes indicated a significant effect ($p<.001$) of these groups on the major part (60%) of leaf shape variation. A Hotelling-Lawley T^2 test indicated significant differences ($p<.001$) of means among these four groups along different shape components (PCs). In a similar way, comparative morphology among these groups revealed discontinuous states of leaf margins, number of flowers per inflorescence, petal coloration and fruit size, and discriminant states were found along the indument and pedicel size. Considering the morphospace gaps and discontinuous character states, we proposed the recognition of three infraspecific taxa of *H. quinqueloba* as species. The first species correspond to *H. quinqueloba* var. *asterias*, with small sized leaves, triangular leaf lobes, non-mucronate leaf margins, 12-18 flowers per inflorescence, short pedicels and few large fruits. The second species correspond to *H. quinqueloba* var. *angulata,* with middle sized leaves, unequal and deltate leaf lobes, 20-25 flowers per inflorescence, and small fruits. The third species correspond to *H. quinqueloba* var. *macrophylla,* with large leaves, widely deltate leaf lobes, 45-70 flowers per inflorescence, and red veined petals. Thus, our study shows that GM can be used in taxonomical studies as a way of identifying morphological gaps and groups, which can later be corroborated by traditional comparative morphology.

Tovomita (Clusiaceae): Shedding light on the systematics of a neglected Neotropical tree genus

Lucas Marinho[1], *Benjamin Gahagen*[2], ***Pedro Fiaschi***[3], *Franciso De Assis Dos Santos*[1], *Cássio Van Den Berg*[1], *André Amorim*[4]
1. Feira de Santana State University
2. Ohio University
3. Federal University of Santa Catarina
4. Santa Cruz State University

Tovomita is the second largest genus of Clusiaceae in the Neotropics; yet, up to three years ago it was taxonomically poorly known when compared, for example, with *Clusia*, *Chrysochlamys*, and other smaller genera. Recent efforts to enhance taxonomical knowledge of Brazilian Atlantic Forest, Central American, and Caribbean species of *Tovomita* have been carried out through collaborative studies and herbarium determinations in Brazil, Europe and U.S.A. Field expeditions to search for poorly known species of *Tovomita* have been intensified in Brazilian Atlantic and Amazon rainforests, to collect samples for phylogenetic studies aiming to test current classification of Clusieae. In the last few years, the number of *Tovomita* species was increased from ca. 45 to 76 (increment of ca. 70%), due to description of 11 new species, re-establishment of eight names under synonymy, as well as proposal of new names for species previously included in *Dystovomita* and *Clusia*. Moreover, five synonyms and 12 lectotypifications were proposed, and the *Tovomita weddelliana* complex was assessed using a multivariate morphometric approach. Regarding morphological data, pollen morphology of 13 species have been studied, and leaf papillae were for the first time registered in the genus. Leaf macro- and micromorphology and a preliminary phylogenetic hypothesis based on nrITS provide support for the late nineteenth century Vesque's infrageneric classification of *Tovomita*. Current studies are underway to investigate the systematics, morphological characters of historical importance, and their value for the generic circumscription in Clusieae, with the purpose of proposing a phylogenetic classification for *Tovomita* and its allies.

3. Herbário HSTM, Universidade Federal do Oeste do Pará, Santarém, Brazil
4. Department of Botany, University of São Paulo, São Paulo
5. Department of Plant Biology, University of Vermont, Vermont

Phlegmariurus (Lycopodiaceae) is a genus of over 300 species of rainforest epiphytes and montane terrestrials that has a worldwide tropical and subtropical distribution. Extant chloroplast-based phylogenetic investigations of the family have reconstructed an ancient divergence between Neotropical and Palaeotropical clades of *Phlegmariurus* with subsequent long distance dispersal being considered relatively rare. This contrasts with the extant morphology-based systematic classification of *Phlegmariurus* that suggests long distance dispersal is relatively more common. We reconstruct an evolutionary and biogeographic history of *Phlegmariurus* using phylogenetic and phylogenomic data from richly sampled case studies in Oceania, Asia, Afro-Madagascar and the Neotropics. We investigate the roles of dispersal from the Neotropics and Palaeotropics in the diversification of *Phlegmariurus* in Afro-Madagascar and Oceania, how habitat change in the Andes and Brazilian highlands has influenced diversification in Neotropical terrestrials and how epiphytic specialisation has influenced diversification among Palaeotropical epiphytes. In a challenge to the popular concept that lycopod species are relicts from old diversifications, we find that patterns of species diversification and biogeography in *Phlegmariurus* are more likely to be congruent to those found in ferns and angiosperms.

Inflorescence, flower and fruit morphology of *Hopkinsia anoectocolea* (Anarthriaceae) and multiple origins of one-seeded fruits in the graminid clade of Poales

Constantin Fomichev[1], *Barbara Briggs*[2], *Terry Macfarlane*[3], *Dmitry Sokoloff*[1]
1. Department of Higher Plants, Faculty of Biology, Lomonosov Moscow State University, Moscow, Russia
2. National Herbarium of New South Wales, Sydney, Australia
3. Western Australian Herbarium, Perth, Australia

The majority of wind-pollinated species of flowering plants possess one-seeded fruits and often uniovulate gynoecia. There are several pathways of morphological evolution leading to gynoecia with a single ovule, but such changes have not been investigated in detail in some taxonomic groups. In addition, the same observations are sometimes used to support contrasting morphological interpretations. The graminid clade of Poales is of special interest, as within this group one-seeded fruits evolved in grasses as well as independently in several other lineages. We studied the south-western Australian family Anarthriaceae (included in Restionaceae in APG IV), in which one genus (*Hopkinsia*) has one-seeded indehiscent fruits and two other genera possess three-seeded capsules developing from a tricarpellate syncarpous gynoecium. The female flower of *Hopkinsia anoectocolea* has a trimerous two-whorled perianth (each tepal is vascularized by one bundle), three nonvascularized staminodia and one carpel. Tepal aestivation is unstable. Three vascular bundles depart towards the gynoecium. They are located on the radii of the outer whorl tepals. One of these bundles soon bifurcates tangentially, and each branch fuses with one of two other bundles. As a result, two vascular bundles can be seen at the base of the ovary. These can be interpreted as ventral and dorsal bundles of the carpel. Carpel orientation varies between median (abaxial) and transversal-adaxial; the former case is more common. Identification of carpel orientation relative to the flower-subtending bract required knowledge of inflorescence architecture that was controversially interpreted in earlier studies. Our data show that the basic units of the *Hopkinsia* inflorescence are spikelets, as in many other Poales. The exocarp is represented by cells with tannins. Their outer cell walls are covered by thick cuticle. There are about 13 cell-layers of mesocarp and one of endocarp. No mechanical elements were observed. The seed coat is thin and consists of two well-recognizable cell layers with tannin-like content. We interpreted these layers as exo- and endotegmen. The embryo is disk-like without any signs of differentiation. We interpret the evolutionary origin of the *Hopkinsia* gynoecium as total loss of two carpels of the ancestrally tricarpellate gynoecium (meristic variation). The *Hopkinsia* gynoecium, unlike the grass gynoecium, is therefore monomerous rather than pseudomonomerous. At the same time, we identified the special nature of the innervation of the *H. anoectocolea* carpel in comparison with related groups, which we associate with the new location of the single carpel in the center of the flower, in contrast to carpels of species having trimerous gynoecia. In the tricarpellate *Anarthria* gynoecium, there are three dorsal and three heterocarpellate ventral bundles. Carpel orientation is more labile in *Hopkinsia* than in many other lineages of Poales with one-seeded fruits. Morphological studies of CIF and DDS are supported by the Russian Science Foundation (project 14-14-00250).

Morphological and cytogenetic studies in genus *Senna* Series *Aphyllae* (Caesalpinoideae, Leguminosae): Taxonomic and evolutionary implications

Federico O. Robbiati[2,3], *Juan D. Urdampilleta*[2,3], ***Renée H. Fortunato***[1,2, 4]
1. Instituto Nacional de Tecnología Agropecuaria (INTA)
2. Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET)
3. Universidad Nacional de Córdoba
4. Facultad de Agronomía y Ciencias Agroalimentarias, UM

Series *Aphyllae* Benth. belongs to the genus *Senna* Mill. (Leguminosae) and is comprised of xeromorphic shrubs and subshrubs, with deeply woody roots; the leaves of the adult branch are represented by minute triangular or sublobate scales; the stem is junciform, green, and photosynthetic. In this group the specific and varietal delimitation is still problematic due to the high morphological variation within and among taxa. We assessed the intra and interspecific variability using morphological and cytogenetic analyses (*in situ* hybridization: FISH) to understand the patterns of morphological variation, phylogenetic relationships and to test hypothesis about speciation in the different specific group in series *Aphyllae*. Based on multivariate analyses two specific complexes were recognized: *S. aphylla*-*S. pachyrrhiza* and *S. crassiramea*-*S. rigidicaulis*. Our results, suggest that x = 12 is the basic number for series *Aphyllae.* Moreover, this series was revealed as a polyploidy group with 2n = 24,48. The FISH revealed that in the polyploidy species there is not a missing of ribosomal sites indicating a recent origin of these polyploidy. Moreover, our results suggest that some underlying evolutionary mechanisms such as incomplete lineage sorting and/or reticulate evolution (hybridization and introgression) are shaping the relationships in *Aphyllae*. A broader cytogenetic survey of a more representative number of populations, along the geographic distribution of the series *Aphyllae*, should be done to address questions such as if the polyploidyzation is supported by environmental differences.

A critique of the lineage concept of species and argument for a historical-phenotypic alternative

John Freudenstein[1], *Michael Broe*[1], *Ryan Folk*[2], *Brandon Sinn*[3]
1. Ohio State University
2. University of Florida
3. New York Botanical Garden

A conceptualization of species as lineages that are equivalent to single metapopulations has become common and has formed the basis for some analytical approaches to using molecular data for species delimitation. This approach is equivalent to delimiting species under a particular version of Mayr's "Biological" Species Concept. We argue that such a concept is suboptimal for a number of reasons. First, it only conceptualizes species in "width" (the size of a present group of organisms) and not in "length" (the extent through time of the species). Second, it equates species with another existing unit, the metapopulation, which is redundant. Third, it gives primacy to history with no regard to longstanding ideas about the meaning and relevance of species. We present an alternative to the strict lineage concept that focuses on the notion of biodiversity and its meaning. Species are commonly viewed as the key units of biodiversity; their importance in biodiversity is due to the unique role that each plays. Our approach, which combines elements from previous species definitions, views species as the smallest assemblages of related populations that have a distinct role. Distinct role is equivalent to having a distinct phenotype, since it is primarily phenotypic variability that specifies role. Lineages play a part in this concept, but are not the sole aspect of diversity that is viewed as important.

Population genetics and phylogeny of *Cryptomeria* Inferred from nSSR and cpDNA data

Qing Ma[1], *Goro Kokubugata*[2], *Chengxin Fu*[1]
1. The Key Laboratory of Conservation Biology for Endangered Wildlife of the Ministry of Education, College of Life Sciences, Zhejiang University, P. R. China
2. Tsukuba Botanical Garden, Department of Botany, National Museum of Nature and Science, Amakubo, Tsukuba, Ibaraki,305-0005, Japan

Cryptomeria D. Don is a genus from the Taxodiaceae family endemic to East Asia. The genus includes two species, *C. japonica* D. Don and *C. fortune* Hooibrenk according to historic records. However, recent studies have considered these two species as a single species, *C. japonica* (Thunberg ex Linnaeus f.) D. Don, with *C. japonica* var. *sinensis* Miquel been regarded as a variety. The phylogenetic relationship and evolutionary history of these two species has largely remained unknown. This study used molecular data from both plastid and nuclear genomes and comprehensive sampling of all known populations of *C. japonica* and *C. fortunei* to investigate the population structure and genetic diversity of *Cryptomeria* populations, infer species differentiation and demographic history of *Cryptomeria* lineages, and provide recommendations for sustainable conservation efforts on these two species. Preliminary results from nSSR data are as follows: 1) nuclear microsatellite genotyping based on eight SSR loci of 18 *C. japonica* populations collected in Japan, 18 *C. fortune* populations collected in China, and two cultivated *C. japonica* populations collected from Jiangxi and Hubei Province in China revealed high genetic diversity (0.717 vs 0.779), allele richness (3.471 vs 3.914), and number of effective alleles (4.154 vs 4.708). AMOVA analyses showed that 88.31% of the variation was within individuals. The global F_{st} value was estimated to be 0.117. 2) STRUCTURE analysis yielded the highest likelihood when all the 38 populations, 479 individuals were clustered into three groups. The analysis of the genetic components carried out at the population level showed that the18 *C. japonica* populations collected in Japan and the two cultivated *C. japonica* populations collected in China were mostly assigned to cluster A. *C. fortune* populations collected from Fujian, Henan, and part of Zhejiang Province in China were mostly assigned to cluster B, while *C. fortune* populations collected from Sichuan, Hubei, Guizhou, Hunan, and other part of Zhejiang Province were generally assigned to cluster C. Most populations of *C. japonica* and *C. fortune* displayed a mixture of both gene pools. 3) IBD analyes indicated evident effect of isolation by distance among all the 38 populations, while no evident effect of isolation by distance was detected in either the *C. fortune* populations from China and *C. japonica* populations from Japan. Mismatch distributions were unimodal for both *C. japonica* and *C. fortunei*. The non-significant SSDH_{Rag} values did not support the spatial and demographic expansions of populations within either China or Japan. 4) The current result supported a single species within the *Cryptomeria* genus, with populations from Tianmu and Wuyi Mountain being the probable early-distributed wild *Cryptomeria* populations in China. These populations display higher genetic divergence with the populations from Japan and may be the earliest diverged clades of *Cryptomeria*.

P0375

A taxonomic revision of Smilacaceae in Asia based on DNA barcoding and morphological traits

Xinjie Jin[1], *Pan Li*[1], *Zhechen Qi*[1,2], *Chengxin Fu*[1]
1. Zhejiang University
2. Zhejiang Sci-Tech University

On the basis of more than twenty years' research on morphology, molecular phylogeny and DNA barcoding, we present here a taxonomic revision of Smilacaceae in Asia, where is the diversification center of the family. Following the standard DNA Barcoding protocol, we sequenced 310 accessions comprising 1-3 individuals of 85 species from East Asia. The performance of five DNA barcodes (*rbc*L, *mat*K, ITS, ITS1 and ITS2) and their combinations were evaluated. The combination of *rbc*L + *mat*K + ITS provids the highest discrimination success (80.86%) in Smilacaceae. Therefore, DNA barcoding using *rbc*L + *mat*K + ITS can be employed as a supplementary means to make taxonomic revision in Asian Smilacaceae. Our revisons are as follows: (1) The genus *Heterosmilax* is reduced to be a section of *Smilax*, which makes *Smilax* the only genus in Smilacaceae; (2) A new taxonomic system for *Smilax* is proposed, which recognizes five subgenera and 22 sections, with about 129 species, 3 subspecies and 5 varieties occuring in Asia; (3) Five new species are discovered: *S. ligneoriparia* C.X.Fu et P.Li, *S. amamiana* Z.S.Sun et P. Li, *S. microdonta* ZS Sun et CX Fu, *S. hirtellicaulis* CY Wu & C Chen ex P.Li, *S. fui* ZC Qi et P Li; (4) A new name, *S. binchuanensis* P Li & CX Fu, is proposed for *H. yunnanensis* Gagnep.; (5) Six names are treated as synonyms: *S. hypoglauca* Benth. as the synonym of *S. corbularia* Kunth, *S. jiankunii* H Li as the synonym of *S. pottingeri* Prian, *S. tsinchengshanensis* FT Wang as the synonym of *S. minutiflora* A DC., *S. munita* SC Chen as the synonym of *S. myrtillus* A DC., *S. nigrescens* FT Wang & Tang ex.PY Li as the synonym of *S. castaneiflora* H Lev. & Vaniot; (6) Two status are changed: *S. luei* Koyama is reduced to be a subspecies of *S. nervo-marginata* Hayata, and *S. umbrosa* JM Xu is raised as an independent species; (7) Four species complexes are revealed: A. *S. chingii* FT Wang & Tang, *S. ferox* Wall., *S. lebrunii* H Lev., *S. ploycolea* Warb. and *S. outanscianensis* Pamp.; B. *S. lanceifolia* Roxb., *S. chapaensis* Gapnep, *S. hemsleyana* Craib. and *S. densibarbata* FT Wang & Tang; C. *S. aberrans* Gagnep. and *S. retroflexa* (FT Wang & Tang) SC Chen. D. *S. trachypoda* JB Norton and *S. vaginata* Decne. Although the phylogenetic relationships within the complexes have not been resolved, statistical analysis of morphological characters can distinguish the species from each other. Thus we tentatively consider them as independent species.

Allotetraploid cryptic species in *Asplenium normale* in the Japanese Archipelago, detected by chemotaxonomical and multilocus genotype approaches.

Tao Fujiwara[1], *Ayumi Uehara*[2], *Tsukasa Iwashina*[3], *Sadamu Matsumoto*[3], *Yi-Han Chang*[5], *Yi-Shan Chao*[4], *Yasuyuki Watano*[1]
1. Department of Biology, Graduate school of Science, Chiba University
2. Division of Life Science and Engineering, School of Science and Engineering, Tokyo Denki University
3. Department of Botany, National Museum of Nature and Science
4. Department of Biomedical Science and Environmental Biology, Kaohsiung Medical University
5. Hengchun Research Center, Taiwan Forestry Research Institute

Cryptic species are defined as 'morphologically indistinguishable, but reproductively isolated lineages'. Delimitation of cryptic species provides the appropriate understanding of biodiversity and opportunities to elucidate speciation processes. In tetraploid cytotype of a fern, *Asplenium normale*, extensive flavonoid variation has been reported, although the related species have no intraspecific variations in flavonoid composition. We hypothesized that Japanese *A. normale* still harbors multiple cryptic species with different flavonoid compositions, and tested the hypothesis by chemotaxonomical and multi-locus genotyping approaches. We determined the multi-locus genotypes (MLGs) of 230 samples from 37 populations for chloroplast DNA, *rps4-trnS* intergenic spacer, and three nuclear genes, *Leafy, Nia, PgiC*. To delimitating reproductively isolated lineages, population genetic approaches using MLGs were conducted. We also tested the correspondence between the genetically recognized groups and flavonoid compositions. To identify the origins of putative cryptic species, phylogenetic analysis of the DNA markers used in genotyping were conducted. Clustering results based on MLGs and flavonoid compositions showed clear correspondences. We recognized three putative cryptic species in tetraploid *A. normale* in Japan. Phylogenetic analysis revealed that cryptic species 1 and 3 had originated through allopolyploidization between diploid *A. normale* and ancestral diploid progenitor of *A. boreale,* and cryptic species 2 between diploid *A. normale* and *A. oligophlebium*. Our study demonstrated that intraspecific variation of secondary metabolites could be a good indicator of cryptic species in ferns. The two cryptic species with the same progenitor diploids suggests that speciation between allopolyploid lineages of independent origin would be more common than was previously considered.

P0377

Chromosome numbers of the genus *Micranthes* sect. *Rotun-*

difoliatae (Saxifragaceae)

Tomoko Fukuda[1], *Olga Chernyagina*[2], *Igor Bobyr*[3], *Aleksandr Taran*[4], *Hiroshi Ikeda*[5]

1. Dept. of Botany, National Museum of Nature and Science
2. Kamchatka branch of Pacific Institute of Geography
3. State Nature Reserve Kurilskiy
4. Sakhalin Botanical Garden
5. The University Museum, The University of Tokyo

The genus *Micranthes* sect. *Rotundifoliatae* is represented by *M. nelsoniana* (D. Don) Small and its subspecies and varieties, which has large distribution area from N. America to Siberia. The section includes some other species in Asia, as *M. fusca* (Maxim.) S. Akiyama et H. Ohba, from Japan to the Kuril Islands, *M. japonica* (H. Boiss.) S. Akiyama et H. Ohba, endemic to Japan, *M. Ohwii* (Tatew.) T. Fukuda et H. Ikeda (=*S. purpurascens* Kom.), mainly in Kamchatka, and some other species. Among these species, *M. nelsoniana* is reported to have high chromosome numbers up to 2n=84. Preliminary phylogenetic trees using cpDNA and nrDNA show large incongruence, and considered that it is partly due to the presence of hybridization and polyploidization. Therefore, we tried to reveal the chromosome numbers of these species, with special attention to the ploidy level. Though *M. nelsoniana* subsp. *nelsoniana* was reported as having high polyploidy level from Chukotka (W of Bering strait), 2n=ca. 60−84, the plant from south Kamchatka was 2n=28, and those from Esso, the central Kamchatka were 2n=56,60 and 64. There is a tendency that the chromosome number increases from south Kamchatka to the north up to Chukotka. *Micranthes nelsoniana* subsp. *reniformis* occurs in Sakhalin and Hokkaido. The chromosome number of *M. nelsoniana* subsp. *reniformis* in Sakhalin was 2n=26, while 2n=50 from Rishiri Island and 2n=ca. 80 from Mts. Taisetsu, Hokkaido. It seems that polyploidization with aneuploidal variation may take place in Hokkaido. We confirmed the chromosome numbers of *M. japonica* as 2n=28, and *M. ohwii* as 2n=24. The chromosome number of *M. fusca* was 2n=30 in a wide geographical range from Hokkaido to Kyushu, Japan, while 2n=45 and 2n=60 along with 2n=30 in Kunashiri Island, and 2n=40−50 in Etorofu (Iturup) Island. It is possible that polyploidization or hybridization between allied species may occur in the Kuril Islands.

Downward, bell-shaped flowers are not always bee pollinated: Floral adaptations to nocturnal moths in *Adenophora triphylla* var. *japonica* (Campanulaceae).

Daichi Funamoto[1], *Kazuharu Ohashi*[2]

1. Kobe University
2. University of Tsukuba

Pollination syndromes, i.e., suites of floral traits shared among distantly related angiosperm taxa, have long been hypothesized to reflect convergent adaptations for pollination by specific types of animals. During the last decades, however, many authors have provided evidence for the existence of apparent mismatches between pollinators inferred from floral traits and actual flower visitor spectrum. Here we demonstrate that investigations on relatively concealed floral traits, such as temporal patterns of anthesis and nectar productivity, together with investigations on relative contributions of diurnal and nocturnal pollinators, could greatly improve our understanding of how such apparent mismatches occur as consequences of floral evolution. *Adenophora triphylla* (Thunb.) A.DC. var. *japonica* (Regel) H.Hara (hereafter, *A. triphylla*) has pale blue, tubular-campanulate, pendent flowers without any noticeable sweet fragrance. Flowers with this combination of morphology and color are typically viewed as associated with bee pollination. In contrast to this expectation, recent studies have claimed that flowers of *A. triphylla* are frequented by nocturnal or crepuscular settling moths. To solve this discrepancy between prediction and observation, we conducted 3 years of field survey in two natural populations (Sugadaira and Tsukuba) of *A. triphylla* in central Japan. We investigated (1) temporal traits in flowers (timing of anthesis, timing of change in sexual phase, and diel pattern of nectar production), (2) flower-visitor fauna, and (3) contributions of diurnal and nocturnal visitors to seed set. First, we found that both diurnal insects (mainly hoverflies and skipper butterflies) and nocturnal settling moths (mainly noctuids and pyraloids) frequently visited flowers of *A. triphylla*. The observed visitation rates were similar between day and night in Tsukuba, while diurnal visits were more frequent than nocturnal ones in Sugadaira. Second, in contrast to the above observations, contribution of nocturnal visitors to seed set was much higher than that of diurnal visitors. Third, antheses and sexual phase changes from male to female mostly occurred around sunset, and nectar was produced almost entirely during night. This temporal correspondence between floral traits and moth activity strongly suggests that flowers of *A. triphylla* have specifically adapted to pollination by nocturnal moths rather than diurnal bees. Although it has been often presumed that flowers with downward, bell-shaped corollas are primarily pollinated by bees, this study and other recent studies show that at least some of these flowers are primarily pollinated by nocturnal moths. This growing evidence may suggest the existence of a new, previously overlooked pattern of moth pollination.

Phylogenetic relationships and biogeographic history of *Pseudognaphalium* Kirp. (Compositae, Gnaphalieae)

Adriel Acosta Maindo, Jessica Requena Ordoñez, ***Merce Galbany Casals***

Autonomous University of Barcelona

The genus *Pseudognaphalium* Kirp. is one of the most species-rich genera of the tribe Gnaphalieae, with c. 90 species. It is constituted by annual, biennial or perennial herbs. Although the vast majority of *Pseudognaphalium* species are distributed in the American continent, the genus has also a few representatives in Africa, Asia, Australasia and Hawaii, and *Pseudognaphalium luteoalbum* is subcosmopolitan. Previous phylogenetic analyses placed *Pseudognaphalium* within the *Helichrysum-Anaphalis-Pseudognaphalium* (HAP) clade, embedded within a paraphyletic *Helichrysum* Mill., but its monophyly was not statistically supported. In addition, incongruence between nrDNA and cpDNA involving *Pseudognaphalium* gave support to the hyphothesised allopolyploid origin of this genus. In the present study, with the use of two nuclear ribosomal (nrDNA) and one plastid DNA markers and an extensive sampling of the genus *Pseudognaphalium*, further evidence relevant to its origin and closest relatives is provided, and additional evidence for incongruence is discussed. A molecular dating of the nrDNA phylogeny and the superposition of distribution areas show that *Pseudognaphalium* originated in South Africa during the Late Miocene to Pliocene, and that subsequent several out-of-Africa migrations caused its striking current disjunct distribution by stepping-stone and long-distance dispersal events to other continents. In addition, the superposition of chromosome numbers on the nrDNA phylogeny suggests at least three independent allopolyploid origins of the genus and provides evidence of the important role of allopolyploidy in the colonization of new territories.

Macroevolution of the sunflower family (Asteraceae): A morphological explanation for the variation of diversification rates in a large family

Tiangang Gao[1], *Tania Hernandez*[2], *John Wiens*[2]

1. Institute of Botany, Chinese Academy of Sciences

2. Department of Ecology and Evolutionary Biology, University of Arizona

Asteraceae is one of the largest families of flowering plants, with over 1600 genera including 23,000 species. Members of this family are widely distributed in every continent but Antarctica. The subfamily & tribe–level differences in diversity within the family are great. Although some attempts have been made to explain how the family quickly colonized the entire planet and became so incredibly diverse, all of these hypotheses have not been strictly tested and we still don't know clearly how the family quickly became so incredibly diverse. Furthermore, diversification in the Asteraceae should best be explained by focusing on all the subclades (subfamilies or tribes) within the family, rather than treating the family as a unit. Here we studied specific morphological traits of the subclades in Asteraceae that might explain their different success.

Towards a better understanding to species: A case study on Eastern Asia alpine shrub *Rosa sericea* and *R. omeiensis* (Rosaceae) based on molecular genetics and environment niche modeling

Yun-Dong Gao, *Xin-Fen Gao*

CAS Key Laboratory of Mountain Ecological Restoration and Bioresource Utilization & Ecological Restoration and Biodiversity Conservation Key Laboratory of Sichuan Province, Chengdu Institute of Biolog

The delimitation on closely related taxa is a key to understand the speciation process and biodiversity. Plant species, which showed more ability to hybridize among different taxa within or without a genus, and therefore have much complicate population genetic structure and history. In present we chose a monophyletic alpine shrub of *Rosa sericea* and its sister species *R. omeiensis*, using nuclear single-copy maker and micro-satellites (EST-SSR) as well as plastid sequences based population genetics methods and environment niche modeling (ENM) to test the species boundary within this taxonomic difficult group. The results showed that although all three datasets from molecular only indicated a geographic affinity, these two taxa occupied different ecological niches; however, the niche diversity is not so significant. We speculate that this pattern is conducted by the glacial-interglacial cycles, which promote inter-specific gene communication while sympatric during the last glacial maximum (LGM). The ecological speciation is in process and the notion of species need to revisited since the study in present is just a tip of iceberg. At this stage as our knowledge we should include a time dimension since species is a dynamic identity rather than static.

Palynolomorphogical and molecular genetic analysis of species and hybrids of the genus *Ribes*

Olga Gavrilova, *Eduard Machs*

Komarov Botanical Institute RAS

In the family Grossulariaceae, which now consist of only one genus *Ribes* have been found pollen with each global and meridional aperture disposition. We have examined pollen morphology and fine structure of 47 species and 10 hybrids with light and scanning electron microscopies, partly with confocal laser scanning and transmissional electron microscopies. Meridional 4-6-colporate grains have been discovered in gooseberries (subgenus *Grossularia*) and one section of currants (subgenus *Ribes*) – *Heritiera*, other currants have 4-porate or 6-12-porate-orate grains with global aperture disposition. We found mainly psilate pollen ornamentation and tectate exine. Species from subgenus *Grossularioides* have 3-4-porate grains with global pore disposition and echinate, atectate exine. Some species have various apertural deviations, four species as well as some hybrids reveal different transitional forms of pollen grains with ectoapertures each colpa and pori. The ultrastructures features demonstrate differences between *Grossularia* and *Ribes* pollen types, between subgenera into the family, sometimes between sections. Genetic distances and specific nucleotide substitutions for parental forms and hybrids of known and unknown origin were evaluated by sequences of spacers and coding region of 5.8S rRNA gene. Comparison of genetic distances shows that all samples are divided into two subclades correlated with the types of pollen grains, but does not allow to solve the problem of the origin of the hybrids. On the other hand, the analysis of nucleotide substitutions indicates a relatively high overall and intragenomic polymorphism, especially in hybrids. Moreover, polymorphic positions of hybrids and presumed parental forms coincide for half of 198 variable positions. Comparison of matching positions and various types of nucleotide substitutions allows with a certain probability to determine parental forms of hybrids of unknown origin, especially in case of a few number of hybridizations. The investigations are supported by Russian Fund of Basic Research N 15-04- 06386a.

Introduction to the book Detailed Morphology of Chinese

Vascular Plants

Weiliang Ma[1], *Yong Chen*[2], *Hong Zhao*[3], *Hongqing Li*[1], *Kang Ye*[4], ***Binjie Ge***[5]
1. East China Normal University
2. Ningde Normal University
3. Shandong University
4. Shanghai Botanical Garden
5. Shanghai Chenshan Botanical Garden

All come from a creative attempt: the author used the micro photos of live plants' detailed morphology as teaching aids in taxonomic class and got the students' approval, which opened a period of 34 years (1982-2016) of the collection, dissection and shooting. The main content of this book is 7,000 carefully selected images out of 1,102 genera (one species was selected from each genera) taken during the last 34 years' field work which covered the major mountains of 26 provinces and autonomous regions of China, and 16 countries in Eurasia and North America. The most important feature of this book is based on detailed morphology to explore the survival strategies of plants and to understand their adaptability to the environment through micro-perspective. Therefore, it is of great theoretical value for the study of plant taxonomy and plant phylogenetic, and has important application value in botany teaching and plant science education. Through the completion of this book, we are "re-understanding" the plants around us: plants will achieve active pollination by "cleverly" moving the stamens and instantaneously twisting the style; "change" into much smaller shape to survive against the adversity; the evolution of a "pay firstly and then to get the racial life-and-death reward from the others" between the animal and plant symbiotic complex. Behind the discovery of each surprise, are activities hidden in the plant (mostly in the flower) year after year. We just acted as a faithful recorder, willing to share the stories "it is not the strongest of the species that survives, but the most adaptable" with the readers who have the curiosity and awe to the nature.

P0384

Molecular phylogenetics of *Solanum* sect. *Brevantherum* Seithe (Solanaceae), a group of pioneer and potentially invasive neotropical treelets

Leandro Lacerda Giacomin[1], *Gregory A. Wahlert*[3], *Lynn Bohs*[3], *João R. Stehmann*[2]
1. Instituto de Ciências e Tecnologia das Águas e Herbário HSTM, Universidade Federal do Oeste do Pará, Av. Mendonça Furtado 2946, Santarém, PA, 68040-050
2. Department of Biology, University of Utah, 257 South 1400 East, Salt Lake City, UT, 84112
3. Departamento de Botânica, Instituto de Ciências Biológicas, Universidade Federal de Minas Gerais, Av. Antônio Carlos 6627, Belo Horizonte, MG, 31270-901

The systematics of the giant and economically important genus *Solanum* (Solanaceae) has been the focus of several molecular phylogenetic studies in the past two decades, resulting in substantial advances in its understanding. Nowadays, most of the main defined lineages and groups within the genus have comprehensive molecular phylogenies, including the Neotropical *Solanum* section *Brevantherum*. The section, which is part of the larger Brevantherum clade, has long been defined by the plurifoliate, dichasial sympodia of its species, that present erect, terminal, many-branched inflorescences and an indumentum of stellate trichomes. In the last revision (1972), 27 species were assigned to it, a number that has grown since then, with the description of four species. Although easily recognizable and commonly found in disturbed sites and open habitats from Mexico and USA (Florida) to Argentina, the species relationships and character evolution within the section have not yet been investigated using a molecular phylogenetic approach. As three species of the section have become naturalized in the Old World and Australian tropics, it is desirable to understand species relationships in a group with such invasive potential. Considering this, a phylogeny inferred for the section was conducted using plastid *trnT-F* intergenic spacer, nuclear ribosomal ITS and low-copy nuclear *waxy* sequences for 42 accessions of 27 species. Our Bayesian and Maximum likelihood results support the monophyly of section *Brevantherum*. The results also showed that *Solanum bullatum* was not recovered in the Brevantherum clade, supporting earlier taxonomic conclusions that the species should be excluded based on its strongly accrescent calyx, a character not found in any other species of the section. Two well supported clades are recovered within the section and are informally named: i) the Abutiloides clade, containing Ecuadorian-Peruvian species that have lepidote scales (*S. oxapampense* and *S. verecundum*) together with the glandular pubescent *S. abutiloides* from xeric environments in Bolivia and Argentina and ii) the Erianthum clade, a larger clade containing the remaining species with typical porrect-stellate and echinoid trichomes. Within the Erianthum clade, the Brazilian Atlantic Forest species *S. granulosoleprosum*, *S. mauritianum* and *S. stipulaceum* form a strongly supported clade, as do some other Andean and Mexican species groups. Some characters used in the past to separate groups of species such as the few-rayed versus multi-rayed stellate trichomes of stems and peduncles are seemingly homoplasious. Considering that the gene regions used in our analysis contained few parsimony-informative characters (9.5% of 4,106 bp concatenated matrix), high throughput DNA sequencing techniques should be used to better clarify the relationships within sect. *Brevantherum.*

P0385

Hidden robbery: A new approach (δ^2H) discloses organic carbon-gain effectiveness of C_3-hemiparasites from C_3-host plants.

Philipp Giesemann, *Gerhard Gebauer*
University of Bayreuth

Introduction: Previous investigations with stable isotope analyses featuring carbon isotopes (^{13}C) showed for very few 'xylem feeding' C_3-hemiparasites utilizing C_4- or CAM-hosts the usage of two different carbon sources, autotrophy and heterotrophy [1]. This ^{13}C approach, however, failed for the much more frequently occurring C_3-C_3 parasite-host-pairs. To overcome this obstacle, we used hydrogen stable isotope (^{2}H) natural abundances as substitute for ^{13}C [2] within a C_3-Orobanchaceae-sequence (root parasites) graded by morphological features [3] and C_3-Santalaceae (root and stem parasite). Carbon-gain calculations for the parasites help quantifying the influence on host plants and on ecosystem carbon cycles.

Material & Methods: Parasitic Orobanchaceae and Santalaceae (9 species, 67 individuals) and fully autotrophic potential host plants (25 species, 199 individuals) were collected in 2016 in Germany and Austria. Seven parasitic species including their potential host plants were collected once in the vegetation period in five replicates each. Additionally, the Orobanchaceae *Rhinanthus minor* L. and the Santalaceae *Viscum album* L. were sampled several times during the vegetation period to estimate development-dependent differences. A multi-element stable isotope natural abundances approach was realized (EA-IRMS: $\delta^{13}C$, $\delta^{15}N$; TC-IRMS: δ^2H, $\delta^{18}O$). All sampled photosynthetic active plants perform C_3-photosynthesis, therefore major differences in $\delta^{13}C$ were not expected. Nutrient-gain efficiencies were calculated with an application of the two-source linear mixing model. Autotrophic reference plants were setting the lower endpoint (0% heterotrophy) and holoparasitic plants ('xylem-feeder': *Lathraea squamaria* L.) the upper endpoint (100% heterotrophy) of the model. The approaches of the intermediate C_3-hemiparasite signatures (δ^2H) to one or the other side were assumed to represent the parasitic effectiveness.

Results: Hydrogen isotope abundance in plant tissues is counterbalanced by two effects, transpiration (^2H depletion) and gain of host-derived organic matter (^2H enrichment). The transpiration effect can be subtracted out of the plant tissue δ^2H values through the plant tissue $\delta^{18}O$ values, which are exclusively driven by the transpiration difference between parasite and host. Based on these calculations a species-specific heterotrophic carbon gain ranging from 13 to 37% was estimated for the investigated hemiparasitic Orobanchaceae species. The sequence in heterotrophic carbon gain mostly met the sequence in root morphological features. Time series revealed development-dependent shifts (young: heterotrophic, adult: autotrophic) for the root parasite *R. minor* and stem parasite *V. album*.

Conclusions: Due to higher transpiration and lower water-use efficiency depletion in δ^2H, $\delta^{13}C$ and $\delta^{18}O$ compared to C_3 host plants should be expected for tissues of C_3 hemiparasites. However, stepwise enrichment in ^2H stable isotope is caused by the parasites' heterotrophic organic matter gain and can be used to estimate carbon gains from hosts. Time series approaches to evaluate development-dependent isotopic abundances are recommended for further parasitic species.

Origin of two anagenetically derived endemic species of *Scrophularia takesimensis* (Scrophulariaceae) and *Sorbus ulleungensis* (Rosaceae) on Ulleung Island, Korea

Hee-Young Gil[1], *Masayuki Maki*[2], *Elena Pimenova*[3], *Aleksandr Taran*[4], *Seung-Chul Kim*[1]
1. Department of Biological Sciences, Sungkyunkwan University
2. Division of Ecology and Evolutionary Biology, Graduate School of Life Sciences, Tohoku University
3. Botanical Garden-Institue FEB RAS
4. Sakhalin Branch of Botanical Garden-Institute FEB RAS

Ulleung Island, an oceanic volcanic island in Korea, is home for ca. 500 native species of vascular plants, 8% (40 species) of which are endemic to the island. The Ulleung Island has been recognized as an excellent model system to study the pattern and process of early stages of flowering plant evolutions on oceanic island. Unlike any other oceanic islands in the Pacific and Atlantic Oceans, the predominant mode of speciation on Ulleung Island is considered anagenetic speciation (88%) due to the factors of low vegetation heterogeneity and elevation. In this study, we investigated the origin and evolution of two anagenetically derived endemic species on Ulleung Island to provide an initial framework to further test the genetic consequences of anagenetic species in Ulleung Island. One example includes *Scrophularia takesimensis*, one of critically endangered endemic species in Ulleung Island. We conducted molecular phylogenetic analyses to determine the origin of *S. takesimensis* based on extensive sampling, including two putative progenitor species, from the East Asia. As a nuclear phylogeny, we generated a global scale ITS phylogeny including represented species of *Scrophularia* deposited at GenBank. The ITS phylogeny suggested that *S. takesimensis* is sister to the clade containing eastern North American/Caribbean species rather than to either *S. alata* or *S. grayanoides*. The global scale cpDNA phylogeny demonstrated that the eastern North America/Caribbean clade is sister to the clade containing three eastern Asian species. In addition, the monophyletic *S. takesimensis* is deeply embedded within paraphyletic *S. alata*, sharing its most recent common ancestor with populations from Japan (2n=94) and Sakhalin (2n=20). Geographically structured two divergent cp haplotype groups within *S. takesimensis* were found, suggesting at least two independent introductions from different source areas. The phylogenetic incongruence between nuclear and chloroplast genomes, polyploidization and aneuploidization of *S. takesimensis* (2n=80) and closely related species, and unusual intercontinental disjunct distribution require further detailed independent nuclear genealogical, cytological, and biogeographic analyses. Another example of anagenetically derived endemic species on Ulleung Island is *Sorbus ulleungensis* (Rosaceae). *S. ulleungensis* has been considered as *S. commixta* but recently described as endemic species in Ulleung Island based on morphological characteristics. As an attempt to investigate the genetic consequences of anagenetic speciation of this taxon, we generated preliminary chloroplast haplotype diversity data of insular derivative *S. ulleungensis* and continental progenitor *S. commixta*. The results suggested that *S. ulleungensis* is most closely related to the populations of *S. commixta* sampled from southern Japan, suggesting possibility of southern geographical origin rather than the Korean peninsula. We also found significant reduction in haplotype diversity of insular derivative *S. ulleungensis* compared to its continental progenitor. Details relationships among haplotypes found in two species and levels of genetic diversity and differentiation within each species will be presented.

Phylogenetic relationships among *Andrographis* s.l. (Acanthaceae: Andrographinae): Evidences from gross morphology, palynology, seed morphology and anatomy

Gnanasekaran G.[1,2], *Murthy G.V.S.*[2], *Carine M.A.*[3]
1. Madras Christian College (Autonomous)

2. Botanical Survey of India
3. The Natural History Museum

Andrographis Wall. ex Nees (Acanthaceae: Andrographinae) is a tropical Asian genus chiefly confined to southern India (Western and Eastern Ghats) and Sri Lanka. Phylogenetic relationships and generic delimitation in *Andrographis* are investigated using morphological cladistics analysis. The 29 species presently recognized, together with two outgroup species from *Haplanthodes* Kuntze, were coded for 39 morphological characters sourced from gross morphology, palynology, seed morphology and anatomy. Parsimony analysis resolves *A. laxiflora* (Blume) Lindau as sister to all other species of the genus. A clade comprising *A. alata* (Vahl) Nees, *A. chendurunii* E.S.S. Kumar, A.E.S. Khan & S.G. Gopal and *A. elongata* (Vahl) T. Anderson is the next branching lineage. These three species form a monophyletic group that is strongly supported and morphologically well-defined by seven synapomorphies. Within the remaining *Andrographis* clade, six species namely *A. beddomei* C.B. Clarke, *A. echioides* (L.) Nees, *A. glandulosa* (B. Heyne ex Roth) Nees, *A. longipedunculata* (Sreem.) L.H. Cramer, *A. rothii* C.B. Clarke and *A. serpyllifolia* (Vahl) Wight are identified as a distinct well-supported monophyletic subclade, characterized by seven synapomorphies. This clade broadly corresponds to the genus *Indoneesiella* Sreem. The results would support the following generic recircumscription: (i) *Haplanthus* Nees resurrected to accommodate *A. laxiflora*, (ii) *A. alata*, *A. chendurunii* and *A. elongata* to be recognized as a new genus and (iii) all other species to be retained as *Andrographis*. Whilst an '*Indoneesiella'* clade is resolved and is clearly defined, it is not recognized here as a distinct genus since doing so would render *Andrographis* paraphyletic. Molecular data would help to further clarify relationships and resolve poorly supported relationships.

P0388

Ambophily in *Gnetum* (Gnetales) and its implications for the primitive pollination mode of seed plants

Yan-Bing Gong*, Yang Min, Ya-Ru Zhu*
State Key Laboratory of Hybrid Rice, College of Life Sciences, Wuhan University

For the five lineages of extant seed plants, insect pollination is considered to be primitive in angiosperms, cycads and Gnetales; whereas *Ginkgo* and conifers originate from wind polination. Paleontological evidences show that ancient Gnetales, angiosperms and gymnosperms coexist in the early Cretaceous. Some genetic data suggest that Gnetales are sister to all other extant seed plant lineages. Thus, pollination mechanisms of the enigmatic group Gnetales provide an important key to understanding primitive pollination mode of seed plants. Here, we present a two years pollination study on two populations of *Gnetum montanum* (Gnetales), to explore the contributions of insect and wind pollination to this rare and endangered species. Pollinator observations in tropical rain forests of southern China revealed a spatiotemporal varying pollinator assemblage, including diverse insects from Blattodea, Coleoptera, Diptera, Hymenoptera and Lepidoptera. All groups of insects carried pollen grains and thus acted as effective pollinators. Aerodynamic experiment showed the terminal settling velocity to be 3.9 m/s, which was in the range of 1-10 m/s for anemophilous species in forest. Pollen grains of *G. montanum* were not sticky and could be intercepted by pollen traps near the male and female strobili. Pollination treatments applied to *G. montanum* revealed this species to be pollen limited and incapable of apomixis. Seed set in the netted treatment (anemophily) was significantly higher than in the bagged treatment (apomixis) but lower than open pollination (anemophily and entomophily), indicating that both wind and insect pollination contributed to reproduction of *G. montanum*. *Gnetum* (Gnetales) has long been regarded as insect pollinated due to its range-restricted distribution in tropical rain forests, where wind pollination is supposed to be detrimental. The occurrence of ambophily in *Gnetum* and the prevalence of anemophily in *Ehpedra* and *Welwitschia* suggest that wind may also play a role in the pollination of the ancient seed plants.

P0389

Understanding diurnal and nocturnal pollination systems using morphometry, ecological, and molecular tools in the genus *Hedychium* (Zingiberaceae) from the North-East of India.

Vinita Gowda*, Ajith Ashokan, Preeti S*
Indian Institute of Science Education and Research Bhopal

Competition is an important process that structures any community. According to competitive exclusion principle, species competing for the same resources cannot coexist and will evolve traits such as to minimize competition and maximize the use of the limiting resources. Plants can have multiple axes for competition such as flowering phenology, pollinator species, and dispersal species.The genus *Hedychium* is known for its vibrant and fragrant flowers. We studied, two nocturnal (*H. ellipticum*, *H. urophyllum*) and two diurnal species (*H. forrestii* and *H. stenopetalum*) in the North-East of India to understand their floral biology and pollination systems. All the four species are found in the same region (Meghalaya state) and share many similar floral traits (fragrant flowers, night blooming, multi-day, large inflorescence, clonal populations). We proposed that to avoid competition and attract different pollinators, sympatric species will resort to different visual signals (floral morphology) and/or differential rewards (nectar sugar content) to avoid competition. We therefore asked the following questions: (i) Which floral traits are important to distinguish plant species apart? (ii) Does the nectar sugar reward differ among the four species? (iii) How are these species related to each other in a molecular phylogenetic tree. From over 152 morphological characters we found that the color and size of the labellum and lateral staminodes were the most important morphological characters. Nectar sugar varied significantly on the different days for a species, as well as among the four species. Taxonomically, *H. forrestii* showed intermediate traits to *H. stenopetalum* and *H. ellipticum* and behaved as an intermediate or hybrid form of the two. Further, we identified two types of flower types within the *Hedychium* genus based on their ecological characteristics, strict and opportunist nocturnal and diurnal flowers respectively. We propose that these may represent the ecological adaptations that are present to reduce competition among sympatric species and therefore high variability may be expected in these characters on a population scale. Ongoing studies are testing these hypothesis in the wild populations of *Hedychium* in the North-East of India.

Worldwide systematics and phylogeography of the *Botrychium lunaria* complex (Ophioglossaceae)

Jason Grant, *Benjamin Dauphin, Vinciane Mossion, Alessio Maccagni*
Universite de Neuchatel

The *Botrychium lunaria* complex (Ophioglossaceae) is an assemblage of about a dozen diploid (and a single tetraploid) taxa that are distinguished by both morphology and DNA sequences. These taxa occur largely in mountainous and grassland areas in a continuous band across the Northern Hemisphere from Europe, Asia (Altai, Caucasus, Himalayas, Tien Shan, Turkey, etc), to North America (Alaska, Canada to Mexico), but they also occur on isolated islands and two other continents and including Africa (Atlas Mountains), Australia (Australian Alps, Tasmania), Azores, Falklands, Greenland, Iceland, Japan, New Zealand, South America (Patagonia), and Taiwan. In order to help identify and delineate the taxa in the complex that are often morphologically cryptic, both chloroplast and nuclear markers have been sequenced for hundreds of accessions, which is beginning to give us insight not only on the systematics and taxonomy but also on broader trends on worldwide phylogeography. Morphological characters on the trophophore and sporophore are being studied with the aim to present clear meaningful keys and illustrations so specialists and amateurs can identify taxa. Known published and accepted taxa include *Botrychium crenulatum*, *B. lunaria*, *B. lunaria* var. *melzeri*, *B. nordicum*, *B. tunux*, and *B. yaaxudakeit*. New taxa are known from Europe (the Alps especially) and continental Asia.

P0391
Phylogeny and delimitation of Galipeeae (Rutaceae, Sapindales), based on molecular data: Insights for evolution of zygomorphic flowers and staminodes.

Milton Groppo[1], *Carla P. Bruniera*[3], *Paola Lima Ferreira*[1], *Carolina Ferreira*[1], *José Rubens Pirani*[1], *Jacquelyn Ann Kallunki*[2]
1. Universidade de São Paulo
2. New York Botanical Garden
3. Universidade Federal de São Paulo

Tribe Galipeeae (Rutaceae, Subfamily Rutoideae) is the largest group of Rutaceae in the Neotropical Region, with 33 genera and c. 181 species. The tribe is composed of two subtribes, Galipeeae (28 genera and c.130 species) and Pilocarpinae (5 genera, 51 species), whose typical genus is *Pilocarpus*, a source of pilocarpine, an alkaloid used in the treatment of glaucoma. Subtribe Galipeinae is different from Pilocarpinae by the possession of zygomorphic flowers (v. actinomorphic flowers in Pilocarpinae) and by the constant presence of staminodes (v. all fertile stamens in Pilocarpinae.) A phylogenetic analysis was conducted to test the monophyly of Galipeeae and its two subtribes. A total of 99 terminals, representing 24 genera and 75 species of both subtribes were sampled. Species of *Balfourodendron, Choisya, Helietta, Hortia,* and *Plethadenia,* all from genera traditionally not included in Galipeeae were also used; *Zanthoxylum,* a phylogenetically more distant genus was used as outgroup in all analyzes. Molecular data included four regions, two from the cpDNA (trnL-trnF and rps-16) and two nuclear (ITS1 and ITS2) analyzes. Parsimony and Bayesian analysis were conducted. Results showed all Galipeeae grouped in a strongly supported clade (Bootstrap Percentages BP-100% BP, Posterior Probabilities PP = 1); Subtribes Galipeeae and Pilocarpinae appear as sisters, both clades with sthng support. However, *Balfourodendron* and *Helietta* appear as part of the Pilocarpinae and *Hortia* along with the Galipeinae, As a consequence, the Galipeeae groups and their two subtribes will only become monophyletic if they include *Balfourodendron*, *Helietta* and *Hortia*. Morphological characteristics such as the possession of zygomorphic flowers, presence of staminodes, embryo characteristics and foliar anatomy are also discussed.

P0392
Molecular phylogeny of the large South American genus *Eriosyce* (Notocacteae, Cactaceae): Generic delimitation and profound taxonomic changes

Pablo Guerrero[1,2], *Helmut Walter*[3], *Carol Peña*[1], *Ítalo Tamburrino*[2], *Isabel Larridon*[4]
1. Universidad de Concepcion
2. Institute of Ecology and Biodiversity
3. EX-SIS Conservation Program
4. Royal Botanic Gardens, Kew

Eriosyce is one of the most species-rich genera within Notocacteae (Cactaceae) harboring a variety of stem and flower morphologies, but joined by their fruits with basal abscission. The lack of a well sampled molecular phylogeny contributes to the current taxonomic labiality of the genus, where its circumscription and infrageneric classification has been questioned. Specimens of *Eriosyce* (63 taxa of *Eriosyce* plus 20 outgroups) were analyzed through sequencing three-plastid noncoding introns (*rpl32–trnL, trnL–trnF* and *trnH–psbA*), one plastid gene (*ycf1*), and one nuclear gene (*phyC*). A concatenated matrix was analyzed using maximum likelihood and Bayesian approaches. Phylogenetic analyses retrieved strong support for monophyly of *Eriosyce sensu lato*. Furthermore, seven sections within *Eriosyce sensu lato* were clearly defined based on well-supported branches. Also, several infraspecific taxa appear paraphyletic according to their scattered position in the phylogenetic tree. New combinations are proposed to update species nomenclature according to our inferred molecular phylogenies. Also, since some past taxonomic proposals received low phylogenetic support they should be discarded.

Determination of molecular phylogenetic properties of some *Ophrys* L. (Orchidaceae) species using the technique of DNA sequencing growing in Natural Flora of European Turkey

Necmettin Guler
Trakya University

The Orchidaceae family which is the most crowded group of the flowering plants (Angiospermae) with 880 genera and 22,000 accepted species as approximate, has a quite problematic systematic so that this family is drawing attention of researchers while applying the classification technics to this group. Thus, this study aims the sequencing of ITS and 18S regions of nrDNA of the genus *Ophrys* taxa belonging to Orchidaceae family, collected from European Turkey. Nowadays the molecular systematic is a method of systematics developing in a fast way and being popular because of the difficulties appeared while a new taxa, founded after the results of research is being included to the previous classifications, the fast and continual development of techniques which are used by molecular biology. Because of the deficiency of anatomic, morphologic, karyologic *etc.* classical methods in the classification of complex plant groups and the error of defining the mixed species. The results of the present study were compared with the molecular characteristics of some species of the genus *Ophrys*, whose DNA sequence analysis are available in literature, and a phylogenetic tree was constructed. The degree of relationships of the subspecies and upper species categories were determined and the distributions of the species within the genera in European Turkey were re-evaluated.

Morphological and karyological studies of *Lathyrus* taxa belonging to *Pratensis* section (Fabaceae) from Turkey

Fatma Güneş
Trakya University

Morphological and karyological analysis of 5 wild taxa from section *Pratensis* (*Lathyrus*, Fabaceae) growing in Turkey, have been described. These are *L. pratensis* L., *L. laxiflorus* (Desf.) O. Kuntze subsp. *laxiflorus, L. laxiflorus* subsp. *angustifolius* (Post ex Dinsm.) Davis*, L. czeczottianus* Bässler and *L. layardii* Ball ex Boiss. Examined taxa is shown the detailed descriptions, general drawning pictures, flower parts and the characterisrics of their fruits. Karyotype analysis was made in detail for the frist time for 2 of these taxa including 3 endemic species. For all species, the chromosome number has been determined as 2n=14. Long arm, short arm and total lengh of the chromosomes were measured, centromeric index and relative lenght were calculated. The photographs, drowing of flower parts and habits and showing metaphase chromosomes of the species, karyotypes and idiograms are included to the study.

ddRAD sequencing enables unprecedented phylogenetic resolution in Arundinarieae (Poaceae: Bambusoideae)

Cen Guo*, Zhen-Hua Guo, De-Zhu Li*
Kunming Institute of Botany

Background: Arundinarieae (Poaceae: Bambusoideae) is a large tribe which was resolved as a monophyletic group with 12 and 13 clades in plastid and nuclear phylogeny, respectively. But interrelationships within the tribe were still intricate because of limited taxon sampling and lack of informative markers. And the most scabrous relationships were focus in clades IV, V and VI, which had significant incongruence between the plastid and nuclear topology.

Methods: We have now generated a large reduced-representation genomic data set for 218 individuals in 205 species (200 temperate woody bamboos, plus five tropical woody bamboos as outgroups) using the double digest restriction-site associated DNA sequencing (ddRAD-seq) for our phylogenetic analysis. In order to identify more orthologous RAD tags and eliminate the massive missing data, we finally adopt the reference-guided strategy instead of the *de novo* assembling method for our data assembling.

Key Results: Using maximum likelihood inference, we obtain a most highly resolved and robust Arundinarieae tree with six monophyletic lineages. In this framework, *Ampelocalamus calcareus* is the first branch to diverge from the remainder of Arundinarieae, with the ADH lineage second, followed by *Gaoligongshania megalothyrsa* and the rest of Arundinarieae which can be further divided into the pachymorph lineage, *Indocalamus wilsonii* and the leptomorph lineage. Two new clades established by molecular evidence here, the pachymorph lineage and the leptomorph lineage, can also be well-characterized by their rhizome states using our analyses of character optimizations. Moreover, the deep-level relationships in most clades are well resolved and some systematically ambiguous genera are newly clarified as monophyly, such as *Phyllostachys*, *Chimonobambusa* and *Yushania*. Additionally, further network analyses largely confirmed the currently recognized six clades and conflicting phylogenetic signals are presented at several polyphyletic genera such as *Pleioblastus*, *Pesudosasa*, *Semiarundinaria* and *Indocalamus* in the lepotomorph lineage, which helps us to advance our understanding of some difficult and intricate relationships of Arundinarieae.

Conclusions: To date, using ddRAD data, this study represents the most comprehensive sampling and the largest informative SNPs matrix for Arundinarieae, providing genome-scale support for phylogenetic relationships of Arundinarieae and lays the phylogenetic groundwork for further analysis on the drivers of rapid radiation and reticulate evolutionary patterns across this diverse clade.

Evolutionary origin of flowers: A genome-wide study of floral development genes in seed plants

Chunce Guo[1,2]*, Claude Depamphilis*[2]*, Hong Ma*[1]
1. State Key Laboratory of Genetic Engineering and Collaborative Innovation Center of Genetics and Development, School of Life Sciences, Fudan University
2. The Huck Institute of the Life Sciences, Penn State University

Darwin famously characterized the origin and rapid diversification of the angiosperms as an abominable mystery. In recent years, new advances in the fields of molecular phylogenetics and evolutionary developmental biology have not only corrected the mistakes in previous theories and models, but also proposed new and testable hypotheses, revealed possible processes through which the flower first originated, and discussed the contributions of the duplication and diversification of floral developmental genes to the origin of flowers. However, previous studies are insufficient for a complete understanding the contributions of genomic changes to those biological innovations. Here, we examined the origin and duplication history of orthogroups containing 424 genes known to play roles in Arabidopsis floral timing and development, and found that upstream genes in the floral developmental regulatory network had higher frequencies of old orthogroups that originated with tracheophytes, and downstream genes were overrepresented by those in new orthogroups originated within derived angiosperms. Furthermore, the similar pattern was found when using 312 core-floral genes, which conserved expressed in flower tissues of water lily, rice, California poppy, and Arabidopsis. These results suggest that although much of the floral development genetic toolkit is ancient, gene recruitment has been an ongoing process in floral evolution, and that different components of the floral regulatory network have recruited genes at different rates through history, with a larger proportion of new orthogroups being represented by genes functioning in organ identity, development and maturation than by genes functioning in the environment sensing and floral timing.

3. Singapore Botanic Gardens, 1 Cluny Road, Singapore 259569, Singapore.
4. Institut de Recherche pour le Développement (IRD), UMR-DIADE, BP 64501, F-34394 Montpellier cedex 5, France.

The Annonaceae, the largest family in the early-divergent order Magnoliales, comprises 107 genera and c. 2,400 species. Previous molecular phylogenetic studies targeting different taxa have generated large quantities of partially overlapping DNA sequence data for many species, although a large-scale phylogeny based on the maximum number of representatives has never been reconstructed. We use a supermatrix of eight chloroplast markers (*rbcL*, *matK*, *ndhF*, *psbA-trnH*, *trnL-F*, *atpB-rbcL*, *trnS-G* and *ycf1*) to reconstruct the most comprehensive tree to date, including 705 species (29%) from 105 genera (98%). This provides novel insights into the relationships of five enigmatic genera (*Bocagea*, *Boutiquea*, *Cardiopetalum*, *Duckeanthus* and *Phoenicanthus*). Fifteen main clades are retrieved in subfamilies Annonoideae and Malmeoideae collectively, 14 of which correspond with currently recognised tribes. *Phoenicanthus* cannot be accommodated in any existing tribe, however: it is retrieved as sister to a clade comprising the tribes Dendrokingstonieae, Monocarpieae and Miliuseae, and we therefore validate a new tribe, Phoenicantheae. Our results provide strong support for many previously recognised groups, but also indicate non-monophyly of several genera (*Desmopsis*, *Friesodielsia*, *Klarobelia*, *Oxandra*, *Piptostigma* and *Stenanona*). The relationships of these non-monophyletic genera—and two other genera (*Froesiodendron* and *Melodorum*) not yet sampled—are discussed, with recommendations for future research.

P0398

Phylogeny of the temperate woody bamboos (Poaceae: Bambusoideas): With an emphasis on the leptomorphy group

Ying Guo
Kunming Institute of Botany, Chinese Academy of Sciences

The temperate woody bamboos are a monophyletic group with diverse morphology in Bambusoideae, recent phylogenetic researches indicate that it is a monophyletic lineage, Leptomorph-rhizome bamboos are a group of the temperate woody bamboos which have two types of rhizomes, Leptomorph rhizome and pachymorph rhizome, and phylogenetic relationships among them have not been clearly resolved till now. In this study, we reconstructed phylogeny of the temperate woody bamboos based on double-digest restriction-site associated DNA (ddRAD) sequencing data of a large sample set with an emphasis on the leptomorph rhizome bamboos. A total of 211 species in 22 genera were sampled, and five species of them were outgroups, i.e. *Fargesia spathacea*, *Yushania niitakayamensis*, *Yushania leigongshanensis*, *Thamnocalamus spathiflorus* and *Chimonocalamus delicates*. We utilized the STACKS software to discover SNP markers for phylogenetic analyses and found 334900 SNPs in the data set for subsequent maximum-likelihood analysis. The preliminary findings show that the leptomorph rhizome bamboos were a monophyletic group, four well supported clades were revealed in this group, i.e. the *Phyllostachys* + *Shibataea* clade, the *Arundinaria* clade, *Indocalamus wilsonii* and the *Chimonobambusa* + *Gelidocalamus* + *Indocalamus* clade. *Indocalamus wilsonii* was first diverged from the rest species .The *Phyllostachys* + *Shibataea* clade, which includes 62 species in 4 genera, and The *Arundinaria* clade, which includes 81 species in 10 genera, were sister groups, and they formed a clade, sister to the *Chimonobambusa* + *Gelidocalamus* + *Indocalamus* clade. At the genus level, many genera (e.g. *Pleioblastus*, *Indosasa*, *Acidocasa*, *Gelidocalamus, Indocalamus* and so on) defined according to the morphological features were not monophyletic, only *Arundinaria s.s.*, *Phyllostachys*, *Shibataea*, *Chimonobambusa* and *Ferrocalamus* were revealed as monophyletic. Our results also exhibited close relationships between *Gelidocalamus* and *Indocalamus,* and relationships among most species of the 2 genera were clearly resolved. However, phylogenetic relationships within the *Arundinaria* clade and *Phyllostachys* + *Shibataea* clade were not fully resolved, and further studies are needed to uncover evolutionary histories of them.

Exploring patterns of genomic divergence among reproductively isolated populations of the Arctic plant *Draba nivalis* (Brassicaceae)

A. Lovisa L. Gustafsson[1], *Michael Nowak*[1], *Siri Birkeland*[1], *Abel Gizaw Seid*[1], *Loren Rieseberg*[2], *Tanja Slotte*[3], *Christian Brochmann*[1]
1. University of Oslo, Natural History Museum
2. University of British Columbia, Department of Botany
3. Stockholm University, Department of Ecology, Environment and Plant Sciences

Understanding the process of speciation requires characterizing genes involved in reproductive isolation. To accomplish this goal, it is important to identify species with populations that are on the verge of reproductive isolation with one another. Previous studies have shown that allopatric populations of the Arctic plant *Draba nivalis* exhibit hybrid incompatibilities suggestive of an early stage in the process of species formation. Hybrid incompatibilities have been identified in multiple crosses between geographically divergent populations throughout the Arctic, and dysfunction in hybrid pollen and seed development has been mapped to 7 loci between Alaskan and Norwegian populations. To explore the patterns of genomic divergence between populations exhibiting partial reproductive isolation in this species, we have produced a *de novo* genome assembly and resequenced populations that exhibit hybrid incompatibilities in experimental crosses. We use these data to examine how sequence divergence between these populations is distributed throughout the genome, and to identify any large-scale chromosomal rearrangements that may be impacting the formation of hybrid gametes. Our production of a genome assembly and generation of comparative population genomic data makes *D. nivalis* an attractive model system for studying the earliest stages in the evolution of reproductive isolation in plants.

Floral and foliar morphological variation of *Magnolia rzedowskiana* in the Sierra Madre Oriental, México

Marisol Gutiérrez Lozano[1], *Arturo Sánchez González*[1], *J. Antonio Vázquez García*[2]

1. Universidad Autónoma del Estado de Hidalgo, Centro de Investigaciones Biológicas

2. Universidad de Guadalajara, Centro Universitario de Ciencias Biológicas y Agropecuarias

Magnolia rzedowskiana (Magnoliaceae), commonly known as Eloxóchitl ("corn flower") or May flower, is endemic of the mountain cloud forest (BMM) of the Sierra Madre Oriental (SMO), Mexico. Currently, their populations are distributed discontinuously (isolated) and fragmented in six localities in the state of Hidalgo, Queretaro, San Luis Potosi y Veracruz. Locally, the species is known by the beauty of its flowers, which are used in traditional medicine to treat heart problems, nerve or heal the fright, and especially with ornamental purposes. In order to determine the morphological variation of *M. rzedowskiana*, 10 individuals were randomly selected in each locality. Ten leaves, five flowers and two fruits were collected in each individual. Subsequently, 25 morphological characters of flower and leaf, and 7 of dasometric variables were analyzed. Data were analyzed by descriptive statistics, and multivariate methods: cluster analysis, principal components analysis and discriminant analysis. The results indicate that there is a wide morphological variation within and between populations, particularly in the number of stamens and carpels, which is attributed to a high phenotypic plasticity of the species. Because of the change in land use and habitat fragmentation by human activities, in some localities the degree vegetation disturbance is very high, resulting in lower population density (few hundreds of individuals), or in extinction of wild populations, as in Huayacocotla locality (Veracruz) case, where only cultivated individuals exist. It is noteworthy that the description of *M. rzedowskiana* is recent (2016), so little is known about basic ecological and genetic aspects, as to propose its inclusion in a risk category within Mexican Official Standard. To priori, according to the criteria of the International Union for Conservation of Nature (IUCN), this species could be include in the category of "critically endangered".

Resolving the backbone of *Ptilotus* (Amaranthaceae) using next-generation sequencing

Timothy Hammer[1], *Ian Small*[2], *Kevin Thiele*[1]

1. School of Biological Sciences, Faculty of Science, The University of Western Australia

2. Plant Energy Biology, ARC Centre of Excellence, The University of Western Australia

Family-level phylogenies of Amaranthaceae have identified the 'aervoid' clade, composed of *Ptilotus* (~110 spp.), *Aerva* (11 spp.) and *Nothosaerva brachiata.* A recent phylogeny of *Ptilotus* using ITS and *matK* sequences of 100 species resolved the genus to be monophyletic, but nested within a paraphyletic *Aerva*. The backbone of the *Ptilotus* phylogeny was unresolved, with a polytomy at the base of four large clades. In order to make use of the phylogeny to examine the evolution of novel characters, such as phosphorus hyperaccumulation, a resolved backbone is needed. To resolve the phylogeny, 30 whole-chloroplast genomes using Illumina next-generation sequencing were obtained for species in all major clades identified on the previous phylogeny. The resulting, fully-resolved chloroplast tree was used as a constraint in the reanalysis of the ITS and *matK* phylogeny to obtain a resolved tree of the 'aervoids'.

Lineage isolation in the face of active gene flow in a typical coastal plant wild radish is reinforced by differentiated vernalization responses

Qingxiang Han[1], *Hiroyuki Higashi*[2], *Yuki Mitsui*[3], *Hiroaki Setoguchi*[2]

1. Linyi University

2. Kyoto University

3. Tokyo University of Agriculture

The respective role and relative importance of natural selection and gene flow in the process of population divergence has been a central theme in the speciation literature. A previous study presented conclusive evidence that wild radish (*Raphanus sativus* L. var. *raphanistroides* Makino) on Japanese islands comprises two genetically isolated lineages: the southern (Ryukyu Islands) and northern (mainland Japan) groups. However, a general understanding of the lineage isolation in the face of frequent seed flow of the coastal plant species is still unclear. We surveyed nucleotide polymorphisms over 14 nuclear loci in 72 individuals across the Japan-Ryukyu Islands Arc to address the demographic history of wild radish using the isolation-with-migration (IM) model. In addition, we investigated the flowering times of the individuals with and without cold exposure to assess the vernalization responses of wild radish. Coalescent simulations suggested that divergence between the southern and northern lineages of wild radish began ca. 17,859 years ago, during the Last Glacial Maximum (LGM; ca. 18,000–22,000 years ago). We further addressed that cold exposure was not required for flowering in the southern group, but could advance the date of flowering, suggesting that vernalization would be facultative. In contrast, the northern group was unable to flower without prior cold exposure, and thus had an obligate requirement for cold treatment. We proposed that temperature profoundly affected the vernalization responses of wild radish, which may repress reproductive success and ultimately drive and maintain intra-specific differentiation between the two groups. Unexpectedly, after population divergence, bidirectional gene flow between southern and northern lineages was found at effective rates, attributing to the combination of high seed longevity and high dispersibility of seeds via sea current. Particularly, the gene flow from the southern to northern groups was significantly higher than that in the opposite direction, indicating effective dispersal of viable seeds via the northward Kuroshio Current. To conclude, divergent natural selection in the southern and northern regions generated trait variation in vernalization requirements as populations adapted to their local environments and in turn probably contributed to lineage isolation in the wild radish, despite the presence of ongoing gene flow. This work increases our understanding of how lineage isolation in flowering coastal plants is maintained by divergent natural selection generated by differing environments in the face of ongoing gene flow. This work also offers a new and fascinating story about wild radish, which is helpful to understand the mechanisms of adaptive evolution, particularly in the case of coastal plants, on a local scale.

P0403

Speciation mechanisms in one of the richest cactus genera: *Mammillaria*

Tania Hernandez-Hernandez[1], *Israel Loera-Carrizales*[2], *Betsabe Ruiz-Guerra*[2], *Andrea Lopez-Martinez*[3]
1. University of Arizona
2. Instituto de Ecologia, A.C.
3. Universidad Nacional Autonoma de Mexico

The genus *Mammillaria* has been considered the richest of the cactus family, including around 145 species. Although the distribution of the genus goes from the south of the United States in the North to a Southern limit in Colombia and Venezuela through the Caribbean Islands, Guatemala, Honduras and México; the latter country concentrates the vast majority of species. *Mammillaria* is practically a Mexican radiation, with species inhabiting all ecosystems present in this megadiverse region. The monophyly of *Mammillaria* has not been confirmed with molecular data, but evidence show it groups together with related genera into the Mammilloid clade. This clade has been reported as having one of the highest diversification rates within the family, a result that is intriguing given that these plants are slow-growing and long lived, with slow population growth rates. In this study, we use the cactus genus *Mammillaria* and related genera included in the Core Mammilloid clade (i.e. *Coryphantha*, *Escobaria*, *Ortegocactus* and *Neolloydia*) to study diversification mechanisms in the Mesoamerican biodiversity region. We focus our study in speciation mechanisms by comparing the ecological niches of sister species. We show evidence supporting the very recent origin of the group, with an allopatric mode as prevalent feature of its diversification. We discuss the possible mechanisms and ecological drivers of *Mammillaria* diversification.

P0404

Insights on the evolution of Mediterranean Island - mainland endemic species: The Iberian-Ibiza endemism *Carduncellus dianius* (Compositae) as example

Sonia Herrando-Moraira[1], *Sergi Massó*[1], *Deborah Zani*[2], *Jordi López-Pujol*[1], *Roser Vilatersana*[1]
1. Botanical Institute of Barcelona (IBB–CSIC–ICUB), Pg. del Migdia s.n., 08038 Barcelona, Spain
2. Millennium Seed Bank, Conservation Science, Royal Botanic Gardens Kew,, Wakehurst Place, RH17 6TN, United Kingdom

Long-term persistence of plant populations through multiple geological and paleoclimatic events has made the Mediterranean Basin a geographical center of species richness and endemism. *Carduncellus dianius* is a good example of a typical Mediterranean narrow endemic species, being restricted to less than 20 populations; about half of these populations are located in the mainland (in the Spanish Province of Alicante, eastern Iberian Peninsula) and half are located in western Ibiza Island (Balearic Islands). We combined molecular techniques with ecological niche modeling (ENM) methods to get insights into the species past evolutionary history, its current levels and distribution of genetic variation, and its potential future distribution. To obtain genetic information, 79 and 143 specimens were analyzed with three cpDNA regions and AFLP markers, respectively. Results from phylogenetic analyses using cpDNA data revealed that this species might have originated in the continental region. The colonization of Ibiza Island could have occurred by a single long-distance dispersal event, with a subsequent back-colonization from the island to the continent. During the Last Glacial Maximum (~20 kya) Ibiza presented higher habitat suitability for the species than the mainland, where harsher environmental conditions could have produced a genetic bottleneck. Reverse results were found in future projections of potential distribution in 2070, that show a considerable loss of suitable habitat in Ibiza, where the effects of climate change could, thus, affect seriously the conservation of island populations.

P0405

A evolutionary framework for *Castanopsis* (D. Don) Spach, a major component of Asian forests

Damien D. Hinsinger[2,1], *Joeri S. Strijk*[1,2]
1. Plant Ecophysiology & Evolution Group, State Key Laboratory for Conservation and Utilization of Subtropical Agro-bioresources, Guangxi University, Nanning
2. Plant Ecophysiology & Evolution Group, College of Forestry, Guangxi University, Nanning

Asia is one of the world's most diversified regions, in terms of environmental variation as well as in biodiversity values. This diversity is mainly due to climatic oscillations during the tertiary and quaternary, as well as to the geological changes that occurred from 30 mya to present. However, a great part of this biodiversity remains unknown, and a phylogenetic framework is still lacking for many taxa in the region. The genus *Castanopsis* (D. Don) Spach (Fagaceae) comprise 110-134 species, which are restricted to tropical and subtropical eastern Asia (from Japan to Indonesia), some of them being very common in subtropical forests. About half of the species are found in China, and 30 are endemic, in a wide range of habitat types, where they are often keystone species. Despite they are sometimes locally abundant, several species are currently threatened and Red Listed. With the recent development of next-generation sequencing methods, it is now possible to study complete genomes to precisely delineate the history and diversity of taxa. However, Whole Genome Sequencing remains unaffordable for many non-model taxa. For these groups, highly repeated regions sequencing, including chloroplasts and nuclear ribosomal cistrons, has been showed to be an efficient method to reconstruct evolutionary history. We obtained complete chloroplasts, nuclear ribosomal cistrons and repeated sequences data from Illumina genome skimming sequencing for a representative portion of the genus. We also generated Genotyping By Sequencing (G.B.S.) data, to get a genome-wide view of the evolution, diversity and taxonomy of the genus. Using both nuclear and chloroplast data, we performed phylogenetic analyses, molecular dating and biogeographical analyses to reconstruct the diversification and phylogeographic history of the genus. The close affinity between the genera *Castanopsis* and *Castanea* was confirmed, as well as the monophyly of the genus. Dating and biogeographic analyses indicated that the Eocene climatic optimum likely drove the divergence between the two genera. We found that climatic and geological changes occurring in Asia during the Cenozoic were a major driving actor in the diversification of the genus, especially the climate changes and eustatic sea level variations. We expect this study will serve as a cornerstone in improving our understanding of the origin and geographic distribution of genetic diversity in tropical trees, thereby aiding ongoing conservation efforts.

P0406
A ddRADseq approach to inform conservation priority decisions for closely related *Grevillea* species.

Gareth Holmes*, Trevor Edwards, Peter Weston, Julie Atkinson, Susan Hoebee*

Ecology, Environment & Evolution, La Trobe University

The Arenaria and Floribunda subgroups of *Grevillea* (Proteaceae) from eastern and south-eastern Australia comprise 16 species (19 taxa) including several that are listed as threatened under federal legislation. No phylogenetic studies have been undertaken to clarify the relationships of lineages within these subgroups. DNA sequence markers traditionally used in plant phylogenetic studies often provide little resolution among closely related Proteaceae. We therefore generated ddRAD data for all taxa and most variants within the subgroups and outgroups, processed the data with the pyRAD pipeline and inferred their phylogeny based on maximum likelihood analysis of organellar and nuclear DNA. Our results suggest that the Floribunda subgroup is not monophyletic with species from another subgroup (Rosmarinifolia) nesting within it. One species, *G. celata*, is nested within *G. chrysophaea* and may require reclassification as a subspecies. Alternatively, *G. chrysophaea* plants from one region could be recognised as a distinct species. There was little phylogenetic structure identified in the most widespread and morphologically variable species of the subgroups (*G. alpina*). Incongruence between phylogenies inferred from maternally inherited cpDNA and mtDNA markers and those of nuclear origin suggests the possibility of hybridisation between species. We conclude that the current informal subgeneric classification of the groups does not represent their evolutionary relationships in all cases and requires revision. The classification of *G. chrysophaea* and *G. celata* (the latter considered vulnerable) also requires revision. Our finding highlights the value of ddRAD in resolving phylogenetic and conservation questions in groups with complex evolutionary histories.

Taxonomic revision on the genus *Hedychium* J. König (Zingiberaceae) in China

Xiu Hu

Zhongkai university of agriculture and engineering

As a result of extensive studies of the literature, herbarium specimens, living plants, the genus *Hedychium* in China is revised here since eflora of China was published in 2000: (1). Two new species [*H. menghaiense* X. Hu & N. Liu (sp. nov.), *H. longipetalum* X. Hu & N. Liu (sp. nov.)], one new form (*H.* villosum f. *albifiamensum* X. Hu & N. Liu) and two newly recorded species (*H. gardnerianum* Rosc., *H. ellipticum* Ham. ex Sm.) are discovered; (2). For being the same entity and published late, *H. longipetalum* X. Hu & N. Liu (sp. nov.) and *H. efilament* Hand.-Mazz. are treated as the synonym of *H. champasakense* Picheans. & Wongsuwan and *H. wardii* C. E. C. Fisch. respectively; (3). Share the same morphology characters with *H. stenopelatum* Lodd., but differ in polyploidy levels, and published late, *H. puerense* Y. Y. Qian is treated as a variety of *H. stenopelatum* Lodd., i.e. *H. stenopelatum* Lodd. var. *puerense* (Y. Y. Qian) X. Hu; (4). Without obvious differences in morphology, *H. bipartitum* G. Z. Li, *H. tienlinense* D. Fang, H. *panzhuum* Z. Y. Zhu are treated as the synonyms of *H. flavum* Roxb., and *H. menglianense* Y. Y. Qian is treated as the synonym of *H. sinoaureum* Stapf.; (5). Lots of specimens identified as *H. forrestii* Diel. should be *H. puerense* Y. Y. Qian.; (6). *H. villosum* Wall. and *H. tenuiflorum* Wall. ex Bak. (or *H. villosum var. tenuiflorum* Wall. ex Bak.) are mis-identified on each other in most specimens and publications. At last?it is confirmed that there are thirty-two species, two varieties, one form in China, and a key to the species of *Hedychium* in China is given verified by the phylogenetic analysis of SRAP makers.

Phylogenetic relationships and phylogeography of *Juglans*

Yi-Heng Hu[1]*, Peng Zhao*[1]*, Ebrahimi Aziz*[2]*, Keith Woeste*[2]

1. Northwest University

2. Purdue University

Juglans L. as one of the typical phytogeographic disjunctions in the Northern Hemisphere, the biogeographic disjunction pattern between closely related plant in Eastern Asian and North American has been received considerable attention. This pattern is often explained by the some researches about bore tropical flora. Walnut (*Juglans* L.) is one of the eight living genera belong to the family Juglandaceae, which are including ~21 extant taxa which could be divided into four sections according to fruit morphology, wood anatomy, and foliage architecture. However, a limited number of DNA regions with insufficient phylogenetically informative sites were selected, and low mutation rates of selected regionswere account for the low resolution. Based on multiple markers cannot clearly elucidate the phylogenetic relationships and phylogeography patterns of *Juglans*. We collected the total of 56 individuals to represent all four recognized section of *Juglans* species, and 14 individuals from family Juglandaceae as outgroup. We collected representatives of many genera with ambiguous phylogenetic position. Complete chloroplast genomes and transcriptom used to analyze phylogenetic relationships. Our initial conclusion now is that: 1) Our study has clarified previously unresolved phylogenetic relationships among species of *Juglans* using chloroplast phylogenomic analyses. 2) Whole chloroplast genome data offer promise for generating adequate levels of variation for phylogenetic reconstruction among species, and suggestion *J. cinerea* belong to *Rhysocaryon*. 3) Genus-level analyses incorporating both extant and extinct genera of the Juglandaceae suggested that *Juglans* originated in North America, and migrated to Eurasia during the early Tertiary via the North Atlantic land bridge.

Sichuan university

The East Asian region is considered the cradle for many cosmopolitan plants and the uplifts of the Qinghai-Tibetan Plateau (QTP) in this region have played a key role in driving diversification and dispersal of numerous northern temperate plants. The hypothesis "out-of-QTP" suggests that the majority of northern temperate plants have originated and dispersed from the QTP and adjacent region. An interesting question is whether the biogeographic history of *Fritillaria*, widely distributed in the northern temperate region, coincides with the hypothesis "out-of-QTP"? In the present study, phylogenetic and biogeographical reconstruction of all eight genera of *Fritillaria* and including most of species endemic to the East Asian region were performed based on ITS, *matK*, *rbcL* and *rpl16* sequences. The results support *Fritillaria* as an"out-of-QTP" genus. The uplift of the QTP in the Miocene facilitated the origin and diversification of *Fritillaria*, orogenies of QTP and Hengduan Moutains and the advent of drying and cooling climates during the Miocene and Pliocene may have fragmented the distribution disjunctly of the genus in the east Asian and Mediterranean-Turanian (MT).The migration from East Asia to North America via the Bering Land Bridge in the late Miocene has been supported. The present study highlights the influence of QTP uplifts on the origin and diversification of northern temperate plants.

Incipient speciation in a dune sunflower species

Kaichi Huang[1], *Katherine Ostevik*[2], *Rose Andrew*[3], *Loren Rieseberg*[1,4]

1. Botany Department, University of British Columbia
2. Biology Department, Duke University
3. School of Environmental and Rural Science, University of New England
4. Department of Biology, University of Indiana

An ecotype of prairie sunflowers (*Helianthus petiolaris*) has adapted to sand dunes in the Great Sand Dune National Park over the past 5,000 years. The dune ecotype is isolated from its non-dune progenitor due to extrinsic ecological isolation, as well as conspecific pollen precedence. Conspecific pollen precedence is stronger in the contact zone of two ecotypes, which is a hint for reinforcement. Genomic analyses also found some potential "reinforcement" regions on different chromosomes of the species. We are currently using genetic mapping and GWAS approaches to identify the genetic mechanisms underlying the speciation process of this system.

Multiple origins of *Aquilegia ecalcarata* revealed by the combination of chloroplast and nuclear DNA sequence data

Lei Huang, *Fangdong Geng, Cheng Xue, Juqing Kang, Jianqiang Zhang, Yi Ren*

College of Life Science, Shaanxi Normal University

Floral evolution and its relationship with speciation attract a lot of attention in the past decades. The genus *Aquilegia* has been considered as new model system for plant evolution, ecology and development researches. Several studies have demonstrated that pollinator shift and ecological habitats drove the radiation of some *Aquilegia* species in North America. In these cases, the spur length varied a lot across different closely related species and is under strong selection by pollinators. Of all the approximately 70 species in this genus, *A. ecalcarata* is the only one which is spurless (or very short spur no more than 2mm) with the loss of nectar. *A. ecalcarata*, together with other three Chinese endemic species: *A. yabeana*, *A. oxysepala* var. *kansuensis* and *A. rockii* comprised a monophyly according to the previous phylogeny results based on just one individual for each species. This cannot fully solve the origin of *A. ecalcarata*, given that the uniqueness of *A. ecalcarata* in whole genus, more efforts are required to deeply uncover this question. Here we reported an extensive population study in 42 representative populations of four closely related species using three chloroplast loci and ten single-copy nuclear gene sequence data. The Phylogenetic tree, STRUCTURE and PCoA analysis all indicated the mutiple origins of *A. ecalcarata*, and *A. ecalcarata* I was possibly originated from *A. oxysepala* var. *kansuensis* (with long and curly spur) while *A. ecalcarata* II more likely from *A. rockii* (with long and erect spur). By molecular clock model, the estimated divergence time of each *A. ecalcarata* I and *A. ecalcarata* II originated from ancestors was less than 1 Myr. Genetic differentiation results showed that divergence between *A. ecal-*

carata I and *A. ecalcarata* II was significantly higher (F_{ST} 0.273) than that between *A. ecalcarata* I and *A. oxysepala* var. *kansuensis* (F_{ST} 0.090), or between *A. ecalcarata* II and *A. rockii* (F_{ST} 0.092). The differentiation within *A. ecalcarata* I and *A. ecalcarata* II was at intermediate level (F_{ST} 0.439,0.477) and both supported the Isolation by Distance model. The similar habitat and phenotypes implicated the parallel evolution in *A. ecalcarata* I and *A. ecalcarata* II.Pollinator shift and ecological habitat were both the possible driving force for it. Our findings enrich the knowledge about floral especially spur evolution and species divergence.

Fossil woods of *Castanopsis* (Fagaceae) from the upper Oligocene of Guangxi (South China): The most ancient evidence of this genus in Southeastern Asia

Luliang Huang[1,2], *Jianhua Jin*[1], *Cheng Quan*[2], *Alexei A. Oskolski*[3,4]
1. Sun Yat-sen University, Guangzhou
2. Jilin University, Changchun
3. University of Johannesburg, Johannesburg,
4. Komarov Botanical Institute of the Russian Academy of Sciences, St. Petersburg

Two new species attributed to the genus *Castanopsis* (*C. nanningensis* and *C. guangxiensis*) were described on the basis of well-preserved mummified wood from the upper Oligocene Yongning Formation of Nanning Basin in Guangxi Province, South China. They represent the most ancient reliable fossil record of this genus not only in China, but also in southeastern Asia, the region of greatest diversity of its extant species. This fossil evidence strongly suggest that the species of *Castanopsis* migrated to South China from northeastern Asia in the late Oligocene via the humid margin formed along the ocean coast due to the development of monsoon climate system during this time. The presence of numerous *Castanopsis* woods with faint or absent growth ring boundaries occasionally co-occurred (in *C. nanningensis*) with prominent ring-porous pattern in the Yongning Formation of Nanning Basin confirms that Guangxi (South China) had seasonal (probably monsoonal) tropical climate during the late Oligocene.

A temporal perspective on Brassicaceae family-wide radiation and diversification

Xiao-Chen Huang, *Dmitry German, Markus Kiefer, Nora Hohmann, Eva Wolf, Marcus A. Koch*
Heidelberg University

Brassicaceae is an important model family for evolutionary and molecular research, comprising 52 tribes, 325 genera, and about 3990 species. It comprises not only the most important model for molecular plant biology (*Arabidopsis thaliana*), but also important crop plants such as rapeseed and cabbage. Evolutionary processes can only be understood if the correlations between environmental dynamics and evolutionary changes are known within a well-resolved temporal context. However, in the past divergence time estimates for Brassicaceae varied among markers as well as calibration points that were used. Consequently, reliable time estimates of all major lineage splits in Brassicaceae are still insufficient and herein tested rigorously using chloroplast phylogenomics. Based on these temporal anchor points from the chloroplast genome backbone, we estimated chronograms on tribal level using ITS datasets comprising more than 2000 species in total. We estimated crown-group ages for these tribes and provided also some evidence for respective stem group ages. Molecular clock estimates revealed that the majority of tribes started diversification between c. 8 to 15 Mya, coinciding with the mid-Miocene climate transition and optimum. This is further correlated with subsequent increasing speciation rates in most species rich tribes indicating radiation throughout the Miocene and Pliocene. Furthermore, it is shown that the Pleistocene also played an enormous role to further increase speciation rates. These results suggest that Brassicaceae evolution and diversification is generally highly correlated with major geological and climatic changes often favored by a transitions towards lower temperatures and drier conditions.

Asian *Begonia* biogeography tracks mountain building and microplate tectonic movement in Southeast Asia

Mark Hughes[1], *Lakmini Darshika Kumarage*[2], *Adi Mahardika*[1], *Rosario Rubite*[3]
1. Royal Botanic Garden Edinburgh
2. University of Peradeniya
3. University of the Philippines Manila

Begonia is a superb group of plants for tracking the biography of tropical floras. The genus has a high proportion of micro-endemics, is species rich, is found throughout Southeast Asia, and is poorly dispersed. Genetic evidence shows some Begonia populations are very long lived and potentially can remain in-situ for timescales measured in millions of years. Since the first insights into Asian *Begonia* biogeography by Thomas (2011) showed a continental origin for the Malesian species, followed by Miocene east to west dispersal across Wallace’s line, three further more focussed regional studies have added detail this picture. Through expanded chloroplast marker phylogenies, increased sampling has shed light on the origin of Sri Lankan, Sunda Shelf and Philippine *Begonia*. We show Sri Lankan endemic *Begonia* to be the result of late Miocene/early Pliocene immigration, followed by in situ Pleistocene speciation. We found no evidence of relict endemics in the Sri Lankan *Begonia* flora. On the Sunda Shelf, Borneo is likely to be an area of origin for the clade containing the bulk of the ca. 500 species in Malesia. Sumatra is also a key area for development of the Malesian flora, with dispersal to Peninsular Malaysia and Borneo in the early Pliocene, following diversification during the Barisan Range mountain uplift in this period. Philippine *Begonia* sect. *Baryandra* (ca. 60 species) are the result of a monophyletic radiation which entered the north of the archipelago during the late Miocene, when the northern islands Luzon, Panay and Palawan were near-contiguous. The *Begonia* floras of these 3 islands show a rapid 3-way phylogenetic split following their separation during the ensuing micro-plate movements in the Philippine region. Mindanao *Begonia* are highly nested in the phylogeny and relatively young compared to species in more northern parts of the archipelago. This corresponds with the very rapid movement of the Mindanao microplate north across the equator to its current position.

Towards a new alaskan flora: Integrating paper floras, specimens, observations and taxonomic changes

Campbell Webb, Jordan Metzgar, ***Stefanie Ickert-Bond***

Herbarium (ALA), University of Alaska Museum of the North, Fairbanks, Alaska, U.S.A.

Alaska is vast, sparsely populated, and sufficiently under-explored botanically that new species and occurrences are still frequently found. Taxonomic problems abound, partially due to parallel but non-interacting botanical efforts in other Arctic nations. Many of these are highlighted in the Panarctic Flora Checklist. The last comprehensive flora (by Eric Hultén) is almost fifty years old, and there is a pressing need for a new Alaskan Flora to support research. We are beginning to develop a New Alaskan Flora which will integrate i) Hultén's and other paper floras, ii) the 262,000 digitized specimens in the herbarium of the University of Alaska (ALA; http://arctos.database.museum/), iii) taxonomic accounts from online floras (e.g., the Panarctic Flora, the Flora of North America), iv) new, up-to-date taxonomic reviews of some plants groups by collaborating experts, and v) photographs and observations from public biodiversity platforms (such as iNaturalist). Where available, morphological descriptions will be parsed and reconciled to a master phenotype ontology (based on Peter Steven's work at the Angiosperm Phylogeny website), and will be used to generate new descriptions and keys. The core output will be an API (Application Program Interface) that serves the integrated data as XML, JSON and RDF, using Darwin Core biodiversity information standards. This API will be used to dynamically generate attractive taxon pages on a project website which present the viewer with congruent and contrasting information, all carefully linked to data sources. Regular snapshots of the data will also be available in ePUB format, enabling printing of a paper flora, and downloading to portable devices for use in the field. Android and iOS apps may also be developed in the future. At the core of this data integration is a 'taxonomic intelligence engine' that keeps track of evolving and conflicting taxon concepts and taxon names, and manages synonyms in the determinations of specimens. The starting point for name integration is The Plant List from the Royal Botanic Gardens, Kew, but other relevant monographs and revisions will be digitized and integrated into this engine, as will taxonomic data from other online resources. This taxonomic flexibility will permit the user direct access to the full taxon concept history of each species, and crucially, allow the user to see at a glance which species are 'difficult' (and for which any determinations must be viewed with some doubt), and which are 'easy' (monotypic taxa with distinct morphotypes, and little geographic variation). We believe that creating this integrated botanical resource, which will make available the full history of a taxonomic name, present associated images from ALA, and include vetted (research-grade) citizen-science observations, will spur additional botanical research and discovery of new taxa in the Far North.

P0417

Geographic distribution of ploidy level and intraspecific phylogeny of East Asian shrub *Clerodendrum trichotomum* sensu lato

Leiko Mizusawa[1]*, Fujii Shinji*[2]*, Isagi Yuji*[3]

1. Fukushima University

2. University of Human Environments

3. Kyoto University

Clerodendrum trichotomum is widespread and common shrub of East Asia. This species complex distribute East China, Korean peninsula, Japan archipelago, Taiwan island and Philippine islands. Two varieties of *C. trichotomum* have been known from Southern Japan: *C. trhichotomum* var. *yakusimense* and *C. trichotomum* var. *esculentum*. Moreover, one close relative of *C. trichotomum* have been known from Izu Islands, Japan: *C. izuinsulare*. Here, we call these four taxa "*C. trichotomum* sensu lato". Previous study (Zeng *et. al*., 2011) reported that Chinese var. *trichitomum* are diploid on the basis of karyotypes of materials collected from wide area of China. However, ploidy level of Japanese var. *trichotomum*, var. *yakusimense*, var. *esculetnum* and *C. izuinsulare* are unknown. During the process of development of microsatellite markers on *C. trichotomum* sensu lato, we got results that suggest both diploid and tetraploid lineages exist in *C. trichotomum* sensu lato. Here we report that the results of estimation of ploidy level and phylogenetic relationships in *C. trichotomum* sensu lato based on five microsatellite markers and 1267 pb of chloroplast DNA sequence. Totally, 89 materials were collected from Japan archipelago, China and Korean peninsula. The microsatellite genotypes strongly suggested that var. *esculentum*, Chinese var. *trichotomum* and *C. izuinsulare* are diploid whereas var. *yakusimense* and Japanese and Korean var. *trichotomum* are tetraploid. Neighbor-joining tree based on the microsatellite genotypes showed following three clades: Clade-I [var. *yakusimense* and Chinese, Japanese and Korean var. *trichotomum*], Clade-II [*C. izuinsulare*] and Clade-III [var. *esculentum*]. Chinese var. *trichotomum* (diploid) was completely nested in cluster of tetraploid var. *trichotomum*. On the other hand, Bayesian phylogenetic tree based on chloroplast DNA showed following three clusters: clade-I [Chinese var. *trichotomum*], clade-II [Japanese and Korean var. *trichotomum* and *C. izuinsulare*] and clade-III [var. *esculentum* and var. *yakusimense*]. These results suggest two following possibility for diversification of *C. trichotomum* sensu lato. Firstly, tetraploid lineages have evolved repeatedly in this taxon. Secondly, chloroplast haplotypes have been shared between diploid and tetraploid lineages by past hybridization.

Systematics of the genus *Kaempferia* L. (Zingiberaceae) in Laos

Oudomphone Insisiengmay[1,3]*, Thomas Haevermans*[1]*, Mark Newman*[2]

1. Muséum Nationale d'Histoire Naturelle

2. Royal Botanic Garden

3. Ministry of Science and Technology

During the 19th century, the genus was studied by botanists such as P. Horaninow (1862), G.Bentham and J.D. Hooker (1883), and K. Schuman (1900). The oldest specimens of Zingiberaceae form former Indochina (Cambodia, Laos and Vietnam) date from 1742, probably with Loureiro's collections, a Portuguese Jesuit missionary and botanist. He published the first flora of Southeast Asia the "*Flora Cochinchinensis*" in 1790 in which 13 species in tree genera of Zingeberaceae were described including K. galanga. (Skornickova and Newman, 2015). The most recent revision of the Zingiberaceae in Cambodia, Laos and Vietnam has been made by F. Gagnepain for Lecomte's *Flore Générale de l'Indochine*. His account, which was published in 1908, is long now out of date.
With the advent of molecular phylogenetics, it became possible to test previous classifications based on macromorphology only. In 2002, Kress and collaborators published a new classification for Zingiberaceae based on molecular evidence. Their results confirmed many of the groupings established by earlier morphologists. Kress et al. did however, make some adjustments for some group ranks and created a few new ones. this classification divides the family into four subfamilies and tribes. My research project is centered on a modern integrative systematic study of genus *Kaempferia*, encompassing new molecular data from complete chloroplasts and selected nuclear genomic regions along with new morphoanatomic characters. This work will also offer the possibility to monograph the genus and evaluate the IUCN statuses for each species, which was never done before.

Phenetic analysis of floral morphology in the banana family (Musaceae)

Wandee Inta, *Sasivimon C. Swangpol*
Department of Plant Science, Faculty of Science, Mahidol University

It is well-known that the banana family (Musaceae) is the basal clade in the ginger order (Zingiberales). However, its classification into three genera—*Musa*, *Ensete* and *Musella*—and the infrageneric ranking are still ambiguous. Within the *Musa* genus, four formerly separated sections based on seed morphology, molecular data and chromosome number were recently merged and only the *Musa* and *Callimusa* sections have been recognized. Aim of this research is to classify banana taxa in Thailand based on male floral morphology and anatomy using phenetic approach. Fifty-five native and exotic accessions of 24 taxa were investigated. Sixteen quantitative characters were analyzed using Principal Component Analysis (PCA) and Discriminant Analysis (DA), meanwhile, cluster analysis with the Unweighted Pair Group Method with an Arithmetic Mean (UPGMA) was performed on 41 qualitative characters. While the quantitative analysis did not separate *Musa* from *Musella*, the PCA showed that *Ensete* is distinct from the two genera according to width and length of fused tepal lobes, adaxial inner tepal shape and length of style and of ovary. The split was confirmed by the DA based on adaxial inner tepal shape and length of ovary. In contrary, the UPGMA showed that *Musella* was grouped with *Ensete* instead of with *Musa*. Unique characters like having papillate cells on all parts of perianth and capitate stigma placed *Musella* as a distinctive genus. At the sectional level, *Musa* shows variations, e.g. different shapes of papillate cell, adaxial inner tepal and stigma. Nevertheless, only *Musa nanensis* was clearly separated from two other sections by PCA and DA on several characters such as width, length and shape of fused tepals. In conclusion, the quantitative and qualitative characters of flowers supported the arrangement of the three genera within Musaceae and a proposal to add a new section to the *Musa* genus.

Unique parallel radiations of high-mountainous species of the genus *Sedum* (Crassulaceae) on the continental island of Taiwan

Takuro Ito[1,2], *Chih-Chieh Yu*[3], *Kuo-Fang Chung*[4], *Goro Kokubugata*[2,1]
1. United Graduate School of Agricultural Science, Tokyo University of Agriculture and Technology
2. Department of Botany, National Museum of Nature and Science
3. School of Forestry and Resource Conservation, National Taiwan University
4. Biodiversity Research Cente

Evolutionary radiations, namely, rapid increases in diversity within lineages, provide insight into the dynamics of diversification. Recently, radiations in certain plant groups can be recognized in mountain ranges around the world. Notably, high levels of diversification have been observed in mountains located in tropical-subtropical areas, particularly the Andes and Himalayas. Taiwan, a small continental island (ca. 36,000 km^2) in East Asia located in the tropical-subtropical zone that has exceptionally well-developed mountain systems, including a central range that traverses the island from north to south and features approximately 200 peaks greater than 3,000 m in height. The island shares many characteristics with mountain environments in areas such as the Andes and Himalayas. Previously, several plant radiations have been documented in Taiwan, including *Berberis* L. (Berberidaceae) and *Scutellaria* L. (Lamiaceae). Especially, in case of *Berberis*, the radiation was occurred in high mountain. Considering the geography of Taiwan, it is likely that further radiations have occurred in other plants, particularly in the mountain areas. In the present study, we focused on the plant genus *Sedum* L. (Crassulaceae), which is highly diversified within Taiwan and exhibits extreme ecological and morphological variation among species. Our phylogenetic and ancestral area reconstructions analysis of eastern Asian *Sedum* members based on nrITS and cpDNA sequences showed that Taiwanese *Sedum* comprised two lineages that independently migrated from Japan and Eastern China. Furthermore, the genetic distances among species in these two clades were smaller than those of other East Asian *Sedum* clades; and the Taiwanese members of each clade occupy extremely varied habitats with similar niches shifts in high-mountain regions. These data indicate that species diversification occurred in parallel in the two Taiwanese *Sedum* lineages, and that these parallel radiations could have occurred within a small continental island of Taiwan. Moreover, the estimated time of divergence for Taiwanese *Sedum* indicates that the two radiations might have been correlated to the formation of mountains in Taiwan during the early Pleistocene. In conclusion, we propose that the parallel radiations observed in

Taiwanese *Sedum* could have resulted from, the formation process of the Taiwanese mountains, and high-biological ability of *Sedum* to adapt to newly released ecological niches following multiple migration events to Taiwan.

16. Edinburgh Botanic Garden

Eriocaulon is a genus of about 400 species of monocotyledonous flowering plants in the family Eriocaulaceae. The genus is widely distributed in the world, with the centers of diversity in tropical regions, such as tropical Asia and tropical Africa. A previous molecular phylogeny implied an African origin for *Eriocaulon* as a sister relationship between the genus and an African endemic one was recovered. The species of *Eriocaulon* primarily grow in wetlands while some inhabit shallow rivers and streams with an apparent adaptive morphology of elongated submerged stems. Polyploidy is known from the genus. In this talk, we provide preliminary results of our molecular phylogenetic analysis of the genus aiming to i) assess the biogeographic origin, ii) explore phylogenetic origins of submerged species, and iii) address the evolutionary role of polyploids.

Updated phylogeny and divergence time estimations of *Centaurea* sects. *Centaurea, Jacea, Lepteranthus* and *Phalolepis* (Asteraceae)

Arnelas Seco Itziar[1], *Perez Collazos Ernesto*[2], *Devesa Alcaraz Juan Antonio*[2], *Lopez Eusebio*[3], *Catalán Pilar*[2]

1. Universidad Tecnica Particular de Loja
2. Universidad de Zaragoza
3. Universidad de Cordoba

Centaurea is one of the most diversified genera of tribe Cardueae (250 taxa) in the daisy family. Sections *Centaurea, Jacea, Lepteranthus* and *Phalolepis* belong to the circum-Mediterranean/Eurosiberian (cME) Cardueae clade. In order to reconstruct an updated phylogeny of this group, we sampled individuals from 30 species (48 taxa), representing nearly 60% of the recognized taxonomic variation of these sections. Haplotypic networks and phylogenetic trees were reconstructed using *trnTL-LF* and ITS sequences. Bayesian dating analysis was performed with the ITS data set. We found two main lineages within cME: (1) a W Mediterranean *C.* sects. *Centaurea* and *Phalolepis* plus *C. diffusa* (CP) clade; and (2) an E Mediterranean Eurosiberian sects. Jacea and *Lepteranthus* (JL) clade. Our analyses provide alternative reconstructions for species of *Jacea* and *Lepteranthus* that differ from those found in recent phylogenetic studies but agree with our new taxonomic findings. The inferred divergence times indicated an early split of the CP/JL clades during the Serravalian (13.6 ± 6.6 Ma), followed by the consecutive splits of *Jacea/Lepteranthus* in the Tortonian (10.85-8.96 Ma), the Late Messinian (7.04-5.07 Ma) divergences of *C. hyssopifolia*, *C. gr. Janeri*, *C. exarata–C. corcubionensis–C. stuessyi* and a Pliocene split (3.55 Ma) for *C. linifolia*/*C. antennata*. Interspecific hybridizations and polyploidizations likely ocurred during Pleistocene (1.48-0.75 Ma) interglacials, when several hybrid lineages apparently originated (e. g. *C.* x *decipiens*). Allopatric speciation might have played an important role in the diversification of the *Centaurea* taxa, since the origins of several endemic species were estimated to have ocurred during the late Pleistocene (2.2-1.31 Ma) in several geographically disjunct Iberian ranges.

P0423

History of dispersal of Monimiaceae: Molecular and morphology data.

Anton Iurmanov

M. V. Lomonosov Moscow State University, Geographical Faculty, Department of Biogeography

The aim of our investigation is reconstruction of the dispersal history of Monimiaceae family based on an integrated morphological and molecular analysis. For the reconstruction of the history of dispersal history of Monimiaceae were analyzed 20 species of 18 genera (from 25 total) from all parts of the family range. We was selected *Gyrocarpus americanus* (Hernandiaceae *s. l.*) as an outgroup. For the molecular analysis the gene 5.8S ribosomal RNA and ribulose-1,5-bisphosphate carboxylase/oxygenase large subunit (*rbcL*) gene. Using data on the nucleic acid sequences from GenBank, in WinClada program were constructed molecular cladogram for genera of Monimiaceae and *Gyrocarpus americanus* using bootstrap analyze. Morphological phylogenetic model, which is based on morphological characters of the original data matrix (27 were studied for morphological and anatomical characters), was built to reflect the most parsimony cladogram. The complex cladograms were obtained as a result of the synthesis of molecular and morphological data. Our conclusions are following. *Xymalos* is basal genus of Monimiaceae, and therefore *Xymalos monospora* – the basalmost genus of the family. The next clade is occupied by Sri Lanka endemic genus *Hortonia*. Intrusion of Monimiaceae in South America through Antarctica occurred not later than the end of the Cretaceous period. At present time the southernmost genus in South America is *Peumus*, it was could be the most resistant to climate change, which allowed him to gain a foothold on the west coast (app. nearly 40 degrees south latitude). Later range of Monimiaceae in South America moved to the north, along with climate change (such genera as *Mollinedia*, *Grazielanthus*, *Hennecartia*, *Macropeplus*). Based on the Tertiary fossils of Monimiaceae in Oman and Germany, we are conclude that for intrusion to Australia Monimiaceae required to make a long way through the coast of East Africa, South Asia (where, in Sri Lanka, remained ancient oligotypic genus *Hortonia*) and after to Malesia (*Kibara*) and Australia (*Hedycarya*, *Palmeria*, *Austromatthaea*, *Steganthera*, *Wilkiea*). New Zealand was intrusion by Monimiaceae from Australia (*Hedycarya*). Madagascar (*Decarydendron*, *Ephippiandra*, *Tambourissa*) and the Mascarene Is (*Tambourissa*) were intrusion by Monimiaceae from New Caledonia (*Kibaropsis*, *Hedycarya*) or Eastern Australia, but it is likely Madagascar could be inhabited by Monimiaceae, which later became extinct.

P0424

Extensive phylogenetical study of the lichen genus *Pyrenodesmia* (Ascomycota, Teloschistaceae) in Eurasia

Ivan Frolov[1,2], *Jan Vondrák*[1,3], *Jiří Košnar*[1]
1. University of South Bohemia
2. Ural Federal University
3. Institute of Botany ASCR

The genus *Pyrenodesmia* was established in XIX century for crustose lichens from the family Teloschistaceae sharing the lack of anthraquinones and the presence of dark brown to black acetone insoluble pigments (Sedifolia-grey). However, in our days it was shown that the genus is closely related to a group of species with anthraquinones in apothecial disk – so called *Caloplaca xerica* group – and probably it is not monophyletic. Pending further study, here we treat *Pyrenodesmia* as a probably polyphyletic group of closely related exclusively epilithic taxa (the group is monophyletic if exclude *Caloplaca xerica* group) always without anthraquinones, but with Sedifolia-grey. The genus is widespread across different geographic regions in the Northern Hemisphere. In Eurasia, it is especially diverse in the Mediterranean and Irano-Turanian regions, inhabiting mainly xerothermic calcareous localities. Currently 24 species and two variations of *Pyrenodesmia* are recognized. During the last several years we collected about 1500 specimens of the genus *Pyrenodesmia* on extensive areas of Europe, Near East and Central Asia. Finally, we made a set of 220 samples which encompasses the whole morphological and geographical variability of the genus in our collection. For this set we sequenced four loci of the nuclear DNA – ITS, β-tubulin, MCM7 and RPB2 – and made a concatenated alignment. Four-locus coverage was complete for 169 individuals, while three loci were obtained for 45 individuals and two loci were obtained for six individuals. We inferred phylogenetic reconstructions by means of both Bayesian and maximum likelihood analyses which were almost identical. We distinguished 28 well-supported clades which have specific recognisable morphology. We call them “species”. On our phylogeny, there are also more than 30 single lineages which are combined on the base of morphology neither with each other nor with any clades. We studied type specimens for almost all known *Pyrenodesmia*’ s names; compiled list of taxa consists of about 60 names. Currently 26 of these names are accepted. Other names were considered as synonyms to these 26 taxa. We could superpose with currently accepted taxa 15 of our 28 clades. Specimens of *P. oblongula* and *P. ochromela* genetically are not distinguished from *P. pratensis* and *P. diphyodes* respectively. Also, it is not possible to put all clades and lineages of *P. erodens* and *P. variabilis* together to two monophyletic clades, although these samples fit to morphological species concepts of these two taxa. Also, three of more than 30 single lineages could be attributed to known accepted taxa. Thus, we obtained molecular data from 22 of 26 currently accepted taxa and four taxa are lacking. Besides clades that we could superpose with currently accepted taxa we got 13 well-supported clades with specific recognisable morphology, however we could not find any names for them among both currently accepted taxa and synonyms to them. Probably, these clades (as well as about 30 single lineages) represent still undescribed taxa. Eight unknown clades occur in Asia, four – in Europe and one – both in Asia and Europe. The study was supported by RFBR grant 16-04-01488.

Hybridogeneous species of *Diphasiastrum* in Russia.

Yury Ivanenko
1. Saint Petersburg State University
2. Komarov Botanical Institute

Diphasiastrum Holub (Lycopodiaceae) includes about 20-25 species. The species of *Diphasiastrum* hybridize, and the resulted intermediate forms are considered by taxonomists either as hybrids (Wilce, 1965; Kukkonen, 1967) or as species (subspecies) of a hybrid origin (Pacyna, 1972; Holub, 1975; Stoor *et al.,* 1996; Ivanenko, Tzvelev, 2004). We consider these morphological intermediates to be species of hybrid origin because they are comparatively stable and fertile, at least partially. There are 4 primary or parental species of *Diphasiastrum* in Russia, namely *D. alpinum*, *D. complanatum*, *D. sitchense*, *D. tristachyum*. There is also *D. nikoense* in the Kuril Islands, but the latter taxon is closely related to *D. sitchense* and hardly deserves more than subspecific rank. *D. alpinum* and *D. complanatum* have extensive ranges in Russia, their distribution areas overlap considerably in the northern part of the country, particularly in the Urals and in the mountains of Siberia and the Russian Far East. *D. tristachyum* has much more limited range than the last two species. It is distributed in the southern part of taiga from the northwestern European Russia to the southwestern Siberia. *D. tristachyum* has a disjunctive range in Russia and becomes increasingly rare toward the east. *D. sitchense* is distributed in the Far East of Russia, generally in the Kuril Islands and Kamchatka. There are 3 hybridogeneous species of *Diphasiastrum* in Russia. *D. issleri* (*D. alpinum* × *D. complanatum*) is the most rare species among them. In Russia, *D. issleri* is still known only from one site in the Khibiny Mountains (Jessen, 1991). All the other reports of *D. issleri* findings in the Kola Peninsula (Ivanenko, 1991), in the Altai Mountains (Shmakov, Tikhonov, 2005), or in the Republic of Tyva (Krasnoborov, 2007) are incorrect. These indications really apply either to *D. alpinum*, or to *D. complanatum*. *D. takedae* (*D. alpinum* × *D. sitchense*) is known from the Kuril Islands, Kamchatka and Magadan Oblast. There are more than 20 localities of *D. takedae* in the Russian Far East (Ivanenko, 2006). The most common and widely distributed among the 3 hybridogeneous species is *D. zeilleri* (*D. complanatum* × *D. tristachyum*). The range of *D. zeilleri* generally coincides with the range of *D. tristachyum*, but the eastern limit of *D. zeilleri* distribution in Siberia is located further to the east (in Novosibirsk Oblast and Tomsk Oblast). Furthermore, *D. zeilleri* is much more common than *D. tristachyum*. Comparison of ranges of the parental species and the hybridogeneous species of *Diphasiastrum* demonstrates that the species of hybrid origin are distributed mainly in the territory where the parental species ranges overlap. Hybridogeneous species of *Diphasiastrum* deserve more attention of botanists. There are some unresolved problems concerning the distribution of these taxa in Russia. For example, we do not know why *D. issleri* is very rare there in comparison with a relatively common *D. zeilleri*.

The effect of mechanical force on the floral development of *Arabidopsis thaliana*

Akitoshi Iwamoto*, Suzuka Kikuchi, Yuna Yoshioka*
Department of Biology, Tokyo Gakugei University

The floral development of *Ceratophyllum demersum* suggested that mechanical force on floral apex may have a key role to determine a phyllotactic pattern in flower (merosity). In particular, the mechanical force on the adaxial side of the flower meristem of *Ceratophyllum demersum* could be an important factor explaining the meristic variation in this species; trimerous, tetramerous and spiral flowers. To demonstrate this theory, we have developed the experimental system to give artificial mechanical force on the abaxial side of young floral apex of *Arabidopsis thaliana* and induce flowers other than tetramerous one. A micromanipulator with silicon device is used to cause the contact pressure on the floral apex. We have obtained some distorted flowers probably due to the mechanical force imposed by the micromanipulator, but we cannot still change the meristic pattern in *Arabidopsis* (i.e. tetramerous). In our poster, the details of our experimental system will be shown and the linkage between the developmental change in the flower of *Arabidopsis* and the mechanical force, will be discussed including the additional results of experiments using our system.

Carpoanatomical study and its significance in taxonomy of Apiaceae of Northern-Western Ghats

Neeta Jadhav
Department of Botany, B. K. College, Belgaum, Karnataka, India

The family Apiaceae with about 300 genera and 3000 species are distributed throughout world. The members of the family have attracted number of workers for their medicinal, commercial and condimental importance. The Apiaceae are represented by about 68 genera and about 240 species in India. The family is well known for its diversity of fruits. Fruit morphology is of considerable significance in its taxonomy at genus and species level. Therefore attempts have been made to study the morphological and anatomical characters of various species of the family found in Northern-Western Ghats. External and internal anatomy of 17 species belonging to 11 genera has been studied. Observations have been made on size, shape, trichomes and internal anatomical characters of all the species found in Northern-Western Ghats. Significance of fruit characters and their correlation with distribution and habitat preferences of the species have been evaluated. Based on external fruit morphology and anatomical characters a botanical key for identification of various species found in Northern-Western Ghats is provided.

The Global Flora: A series of global taxonomic treatments

James Byng[1,2]*, Maarten Christenhusz*[1,3]
1. Plant Gateway
2. Naturalis Biodiversity Center
3. Royal Botanic Gardens, Kew

Two-hundred and sixty four years since Linnaeus published his *Species Plantarum* our species-level knowledge of many families of vascular plants is still incomplete and is in many cases poorly documented. There are still huge numbers of new species to describe in many groups, whilst others are in need of either minor or major revision as new evidence is generated. Most taxonomic groups are treated in regional floras, sometimes by different authors often decades apart, but few global revisions of taxa are being undertaken which is resulting in laborious paper chases and potentially an error strewn taxonomy. Global treatments of taxonomic groups are urgently needed. Plant Gateway is publishing a series of updatable global taxonomic treatments to document accepted family-level species classifications based on the molecular data available and re-examining the literature and herbarium specimens. Each family will have a description, distribution data and other relevant information, as well as, detailed wood anatomy and pollen descriptions. Each species will have detailed type information listed, a description, ecology and distributional data and all specimens seen in major herbaria. Each treatments will be richly illustrated throughout making them useful to a broad range of users from herbarium taxonomists to horticultralists and conservationists. Notable global treatments to be published first will be the recently named Kewaceae, recently re-circumscribed Metteniusaceae and the species rich genus *Syzygium* (Myrtaceae).

An educational poster of the Angiosperm Tree of Life

James Byng[1,2]*, Greg Kenicer*[3]*, Erik Smets*[2]*, Maarten Christenhusz*[2,4]
1. Plant Gateway
2. Naturalis Biodiversity Center
3. Royal Botanic Gardens, Edinburgh
4. Royal Botanic Gardens, Kew

Bentinckia, a palm genus is restricted to Indian subcontinent with *B. nicobarica* restricted in distribution to Nicobar Islands. Usually, Island species are quite frequently within their limited area of distribution not having any chance of migration, so that destruction of even a small forest area may render the endemic species high threat over their existence. The Andaman and Nicobar Islands represent 86% of forest coverage including tropical rain forests, tropical moist deciduous forests, lowland forests *etc.* with a total geographical area of 8249 sq.km, while the Nicobar group of Islands cover an area of 1841 sq.km. *B. nicobarica* belonging to the family *Arecaceae* is one of the hardest, tall palms growing up to ±50 m height with small globose, blackish fruits (when ripen) in big bunches. It specifically grows in moist hills, valleys, plains and slopes of lowland forests of Nicobar Group of Islands mainly in Great Nicobar, Kachal, Nancowry group, Teressa, Chowra and Car Nicobar Islands. In the year 1988, "The IUCN Red List of Threatened Species" assigned this species endangered category. *B. nicobarica* is used in the Islands for housing, furniture, boat making, *etc.* by the tribal of Nicobarese and Shompen. The emerging shoots are eaten by the local people as vegetable and the fallen fruits are eaten by pigs. Due to all these activities over the time the species population has declined very much in these islands. Considering the importance of the species the present study has been taken to investigate its population, multiplication and reintroduction. The method of Ecological Niche Modelling (ENM) map is applied by using the modeling algorithms of DIVA-GIS and MAXENT. Nineteen bioclimatic variables are used as environmental variables for modeling, which includes Annual Mean Temperature, Mean Diurnal Range, Isothermality, Temperature Seasonality, Maximum Temperature of Warmest Month, Minimum Temperature of Coldest Month, Temperature Annual Range, Mean Temperature of Wettest Quarter, Mean Temperature of Driest Quarter, Mean Temperature of Warmest Quarter, Mean Temperature of Coldest Quarter, Annual Precipitation, Precipitation of Wettest Month, Precipitation of Driest Month, Precipitation of Seasonality, Precipitation of Wettest Quarter, Precipitation of Driest Quarter, Precipitation of Warmest Quarter, Precipitation of Coldest Quarter *etc.* Through this modeling, we could predict the potential area of occurrences the species and their reintroduction for the population study and the limiting factors. More than four thousand seedlings of *B. nicobarica* are raised so far in controlled condition in polyhouse of Dhanikhari Experimental Garden Cum-Arboretum, Botanical Survey of India, Andaman and Nicobar Regional Centre and being reintroduced in the identified habitat for improving their conservation status.

Character evolution, circumscription and taxonomic novelties in the sections *Casparya* and *Semibegoniella* (Begonia, Begoniaceae)

Orlando Adolfo Jara-Muñoz[1], *James E. Richardson*[1,4], *Santiago Madriñán*[2,3]
1. Universidad de los Andes
2. Universidad del Rosario
3. Jardín Botánico de Cartagena Guillermo Pi?eres
4. Royal Botanical Garden Edinburgh

Sections *Casparya* and *Semibegoniella* are some of the richest groups of *Begonia* in the North Andean region. Taken together, both sections are clearly recognizable respect to other sections of *Begonia* because the particular fruit type, but to separate the two is less easy. The gamophyllous perianth and unilamellar placenta has been proposed as diagnostic characters for *Semibegoniella*, however it has been problematic the presence of intermediate species, and the lack of documentation about these characters in several species. Using three chloroplast markers and ITS, we present a phylogeny of the sections *Casparya* and *Semibegoniella* (*Begonia*, Begoniaceae) and representative species of related sections. We demonstrate the paraphyly of section *Semibegoniella* that we now synonymize with *Casparya*. Fruit type is a synapomorphy for *Casparya*, but character evolution analysis reveals evidence of multiple examples of convergence and parallelism in characters frequently used to separate infrageneric groups in *Begonia*. We also include the description of five new species of the section, founded during the course of the study.

Cytological and reproductive studies of the fern genus *Platycerium* and their hybrids

Tassanai Jaruwattanaphan, *Phannipa Sukmueng*
Department of Horticulture, Faculty of Agriculture, Kasetsart University

Platycerium Desv. is a pantropical fern comprising 18 species. Chromosome numbers of 16 species namely *P. alcicorne, P. andinum, P. bifurcatum, P. coronarium, P. elephantotis, P. ellisii, P. grande, P. hillii, P. holttumii, P. ridleyi, P. stemaria, P. superbum, P. veitchii, P. wallichii, P. wandae and P. willinckii* and 2 hybrid cultivars were counted. The chromosome numbers observed were diploid (2n=2x=74) in all 16 species, this includes 7 species are reported for the first time and for the remaining 9 species matched those previously reported. Chromosome numbers were established for two hybrid cultivars, *P. ×kitshakoodiense* and *P. 'Charles Alford'*, were tetraploid (2n=4x=148) and triploid (2n=3x=111) respectively. The reproductive modes of *P. coronarium* and *P. ridleyi*, which produced only 8 spored sporangia, and their hybrid, *P. ×kitshakoodiense*, were determined in this study. Gametophytes of these three plants produced normal antheridia and archegonia. Young sporophytes were not produced directly on the gametophytic tissue. This result concluded that all these three species are not agamosporous species.

Phylogeny and biogeography of *Acaena* (Rosaceae): Evidence of long-distance dispersal from the Southern Hemisphere

Javier Jauregui Lazo[1], *Daniel Potter*[2]
1. University of California, Berkeley
2. University of California, Davis

Spatial distribution and history of plants in the Southern Hemisphere have been hot topics in biogeography in recent decades. Ancient Gondwanan connection or subsequent trans-oceanic dispersal events are the primarily drivers of the distribution of extant taxa in Southern Hemisphere. Currently, dispersal events have been proposed as dominant explanations for disjunct distributions because of more accurate phylogenetic reconstructions (San Martin and Ronquist, 2004). *Acaena* Mutis ex L. is an important element in the vegetation of temperate climate regions in Chile, Argentina, New Zealand and Subantarctic Islands (Grondona, 1964; Marticorena, 2006). A few *Acaena* species are also found in South Africa, Central America, California and Hawai'i (Macmillan, 1998). The genus comprises around 45 species that are recognizing by having an unusual reduction of the floral parts (numbers of petals, stamens and carpels) and inflorescence type (raceme or spike) compared to other members of Rosaceae (Potter *et al.,* 2007). However, the most distinctive feature of *Acaena* is the presence of a conspicuous hypanthium, which is commonly armed with hooked prickles (Marticorena, 2006). Due to its exceptional disjunct distribution and extraordinary floral characters, the current study was conducted to show the phylogeny, biogeographic pattern and ancestral character reconstruction of *Acaena*. Phylogenetic analyses of non-coding nuclear (ITS) and chloroplast (trnL-F) gen loci suggest that *Acaena* as currently circumscribed is not monophyletic group. *Margycarpus*, *Tetraglochin*, and *Polylepis* are nested within it. Long-distance dispersal is the main explanation for the Amphitropical and Gondwanan distributions of the genus. Along these lines, it is likely the genus originated in South Africa around 8-5 mya, migrated into South America and subsequently diversified in the temperate regions of Chile and Argentina. From there, the genus migrated to New Zealand and Australia to begin a recent rapid diversification. The species found in California and Hawai'i are more closely related to the species found in Chile and New Zealand, respectively. This highlights an uncommon direction of dispersal from the Southern to the Northern Hemisphere among the temperate taxa. Due to the observed tree topology it is likely that the ancestral state for the inflorescence type was a raceme that evolved into a spike and a head multiple times in the core group of *Acaena*. The apetalous flower seems to be an apomorphic character for *Sanguisorba, Cliffortia, Polylepis*, and *Acaena* (Sanguisorbinae). An independent evolution of the reduction in number of stamens from five to two stamens is also seen in the genus. Some individuals of *A. magellanica* present genetic variation that may justify their treatment as a separate species. Likewise, *A. pinnatifida var. californica* is not closely related to *A. pinnatifida* as expected and can be treated as different lineage. The evolutionary relationships in *Acaena* combine a history of recent diversification, long-distance dispersal and genetic variation in some particular taxa. Future research should attempt to clarity the infraspecific classification of *A. magellanica.*

P0433

Utility of RosCOS (Rosaceae Conserved Orthologous Set) markers for resolving phylogenetic relationships in recently diverged and closely related species of *Rosa* section *Synstylae* (Rosaceae)

Ji-Hyeon Jeon[1], *Seung-Chul Kim*[1], *Masayuki Maki*[2]
1. Sungkyunkwan University
2. Tohoku University

The genus *Rosa* (Rosaceae) is comprised of approximately 150-200 species and distributed widely in the temperate and subtropical regions of the northern hemisphere. Of four subgenera recognized by Rehder (1940), the subgenus *Rosa* includes most species within the genus and it is further divided into ten sections. Of ten sections, *Synstylae* and *Chinenses* occur mainly in East Asia and include most of the wild ancestors of modern cultivated roses. In particular, section *Synstylae* is one of the most recently diverged section in genus *Rosa*. In previous studies, not only have low support values *Rosa* sect. *Synstylae* species in branches of their phylogenetic tree, but some of those could not be delimited in their phylogeny with conventional molecular phylogenetic markers, such as nuclear ITS or single/low copy nuclear genes like GAPDH. Even in much recently diverged and closely related species in this section, dozens of chloroplast markers showed identical sequences, unable to distinguish those species in their phylogenies. Albeit nuclear markers showed more diverse sequence than chloroplast ones, sequence divergences were not sufficient enough to resolve phylogenetic relationships among the species with good nodal supports. Though recently developed several NGS-based genomic data are extremely valuable to reconstruct phylogenetic relationships of such recently diverged and closely related species, the highly conserved single copy genes could also be quite useful for resolving close species relationships. As Cabrera *et al.,* (2009) developed Rosaceae Conserved Orthologous Set (RosCOS) markers from single copy *Arabidopsis* genes, we tested those RosCOS markers on *Rosa multiflora* and its close relatives in sect. *Synstylae*. Of 33 markers that were selected based on the RosCOS database (Cabrera *et al.,* 2009), we selected a total of eight markers to test their phylogenetic utility in *Rosa* sect. *Synstylae*. The sequence identity values among accessions were ca. 96% and 8% were polymorphic sites, whereas those of ITS region were ca. 99% and 2%, respectively. The concatenated data matrix resolved not only phylogenetic relationships of *R. multiflora* and its relatives but also species delimitation with high support values. In addition, some putative hybrid accessions based on morphological traits were supported based on the RosCOS markers. Our results suggest that RosCOS markers are highly variable and phylogentically informative compared to conventional molecular markers and can provide sufficient resolutions with high support values for complex relationships of recently diverged and highly reticulated lineages of the genus *Rosa*. Detailed phylogenetic relationships among species of sect. *Synstylae* and some cases of reticulate evolution with in the section will be presented.

T2

P0434

Phytogeographic implications of a fossil endocarp of *Diploclisia* (Menispermaceae) from the Miocene of eastern China

Hui Jia[1], *Bainian Sun*[2], *David Ferguson*[3]
1. Xi'an Shiyou University
2. Lanzhou University
3. University of Vienna

Menispermaceae endocarps became common in the Paleogene as the global temperature rose, while *Diploclisia* was present in NE China in the Early Eocene. As the genus is currently known from S China, it could be assumed that the genus continued to be present in China during the Neogene. However, so far there was no evidence to support this supposition. An excavation at Jiahu Village, Zhejiang has revealed the presence of an endocarp affiliated to the Menispermaceae in the late Miocene Shengxian Formation. This endocarp has been investigated using both light microscopy and X-ray microtomography. Comparisons with fruits of living and fossil Menispermaceae, indicate that it is a new species belonging to the genus *Diploclisia*, which is named as *D. praeaffinis*. The present fossil endocarp helps to fill the more than 40 Ma gap in the fossil record by demonstrating that it was indeed present in the region in the late Miocene. As *Diploclisia* was already widely distributed in the Northern Hemisphere by the beginning of the Middle Eocene, it probably originated in the Paleocene (66-56 Ma) at the latest. The past and present distribution of *Diploclisia* shows that the genus has undergone various phases of expansion and contraction afterwards. In the Late Eocene and Oligocene (37-23 Ma), as temperatures fell globally, its distribution became restricted. It was no longer present, or too rare to leave a fossil record, between latitudes 43-58°N. By the Neogene, it seems to have become restricted to East Asia, even on the verge of extinction. *Diploclisia* is currently considered to consist of two species, *D. glaucescens*, which is widespread in S and SE Asia, and *D. affinis*, endemic to S China. Molecular phylogenetics suggest that these species diverged some 17 million years ago. The close resemblance of our fossil to the endocarps of *D. affinis*, would indicate that this species or a similar taxon already existed some 10 million years ago. Based on the greater similarity of the endocarps of *D. affinis* to their Cenozoic counterparts, the location of these fossils and the fan-shaped distribution of extant *Diploclisia*, it would suggest that *D. affinis* is the more plesiomorphic of the two living taxa, which was firstly throughout southern China. Then the more apomorphic species, *D. glaucescens*, probably expanded into S and SE Asia. As it did so, the fruits became increasingly large. This would explain why the largest fruits in the genus are recorded from the Moluccas and New Guinea. This southerly expansion would have been driven by the increasing cold of the Pleistocene glaciations, and facilitated by the low sea-levels (-125±35m) occurring during these pleniglacials.

P0435

Genomic diversity in *Litsea* (Lauraceae) assessed by organelle and nuclear data

Guo-Feng Jiang[1,2], *Damien D. Hinsinger*[1,2], *Joeri S. Strijk*[2,1]

1. Plant Ecophysiology & Evolution Group, Guangxi Key Laboratory for Forest Ecology and Conservation, College of Forestry, Guangxi University, Nanning, Guangxi, PR China;

2. Plant Ecophysiology & Evolution Group, State Key Laboratory for Conservation and Utilization of Subtropical Agro-bioresources, Guangxi University, Nanning, Guangxi, PR China

Lauraceae comprise about 55 genera and more than 3000 economically and ecologically important species, widespread in tropical and subtropical regions. Due to the absence of clear vegetative characters that can aid in successful identification in the family, few data are available to study its evolution or biogeography. *Litsea* species can be distinguished from other Laureae by its umbellate inflorescences, unisexual and trimerous flowers, its fruit with small to rather large cupules, and its leaves usually alternate. *Litsea* species are widely used for industrial oil and charcoal production as weel as for agroforestry (e.g. as Vanilla culture support). *Litsea* represents a middle-size genus in Lauraceae, contains about 200 species, mainly distributed in tropical and subtropical Asia with a few species in Australia and from Central America to subtropical South America; 74 species are found in China (47 are endemics). Despite they are sometimes locally abundant, several species are currently endangered according to the IUCN Red List. The relationships between *Litsea* and related genera remains unclear. Indeed, previous studies resulted in low-resolution phylogenetic hypotheses (mainly due to low-variability loci), hampering our understanding about evolution and biogeography of *Litsea* species. The current emergence of chloroplast-based phylogenomic allows to obtain a highly informative and discriminate marker. In combination with complete nuclear ribosomal cistrons, it provides useful data to assess the genomic diversity, test and reassess the morphological characters used in former classification systems. Here, we used a subsample of *Litsea* species, for which we reconstructed the complete chloroplast genomes, nuclear ribosomal cistrons and repeated sequences data from Illumina genome skimming sequencing. We assessed the diversity found in the different categories of genes and showed that the genomic diversity is unevenly distributed in the plastid genome and among the species, with clusters clearly separating groups of species. We analyzed the plastid repeats and SSRs content and performed a phylogenetic analysis based on the sequences data. The phylogeny retrieved most of the groups corresponding to the diversity clusters. We expect this study will pave the way to other studies – studying both the generic and specific taxonomic level. A better knowledge of the genomic diversity in tropical and subtropical tree species will help us to face the current biodiversity crisis.

P0436

Tracing the dynamics of Neogene Eurasia Tethyan flora: An insight from the biogeography of *Quercus* group Ilex (Fagaceae)

Xiao-Long Jiang, *Min Deng, Ying Li*

Shanghai Chenshan Botanical Garden

Eurasia Tethyan disjunction is commonly occurred in subtropical plants. However, the spatial and temporal diversification pattern of this flora are still not well understood, as the species phylogeny of the keystone families are not resolved and it further complicated by the intense paleogeoclimatic changes in Neogene Eurasia. *Quercus* group Ilex, a monophyletic group with ca. 32 species widespread in Eurasia, is keystone trees in Eurasia subtropical forests with rich fossil records since Oligocene. Therefore, this group offered an ideal opportunities to investigate the dynamics of Tethyan flora. In this study, we employed RAD-seq to reconstruct the phylogeny of *Quercus* group Ilex. The divergent time and ancestor distribution ranges were also analyzed using BEAST and RASP. A total of 38 species (incl. 27 species from Group Ilex and 11 species as outgroup) were analyzed. ML and BI tree yielded identical topology and the species phylogeny in *Quercus* Group Ilex were well resolved. Six lineages with quite different distribution were detected: Himalaya gorgy (I) and Sino-Japan (II); Indo-China (III) were derived accordingly. Heterobalanus (IV) and Engleriana (V) forming a clade is the sister group to the

Europe-West Himalaya (VI) lineage. Divergence time of *Quercus* group Ilex was dated to Oligocene. The ancestor distribution area reconstruction inferred southwest China was the original place of *Quercus* Group Ilex. It is dispersal to East Asia and Indo-China during early Miocene. The dispersal from East Asia-Himalaya, through West Himalaya, then to the Mediterranean occurred in Middle Miocene. The split between Himalaya subalpine lineage to its low-middle elevation relatives occurred at later Miocene. The diversification ratio of *Quercus* Group Ilex was constant as inferred by LTT. Our results demonstrate the Himalaya during Middle Miocene was a corridor rather than an obstacle barrier to the biota between the Eurasia and Central and southern Asia was much humid than the present. The drastic uplifting of Himalaya occurred at later Miocene. Our study provide a critical context to understand the impacts of Neogene paleogeoclimatic changes to shape the subtropical flora in Eurasia.

P0437

Effect of forest fragmentation on epiphyllous liverworts presence in China

Yanbin Jiang
College of Resources and Environment, Huazhong Agricultural University

Forest fragmentation is a continuous process and one of the most important threats to biodiversity and the ecological functions of forest. Epiphyllous liverworts is a special group of bryophytes exclusively inhabiting leaves surface of understorey vascular plants in humid tropical and sub-tropical forest, and very sensitive forest fragmentation. The aim of this study was to investigate of forest types and their fragmentation on epiphyllous liverworts presence in China. MAXENT was employed to model the distribution of epiphyllous liverworts based on species presence data and environmental variables; then applied FRAGSTATS to characterize forest fragmentation based on MODIS Land Cover map. Four forest types related to epiphyllous liverworts presence were extracted in China: mixed forest (MF), evergreen broadleaf forest (EBF), Woody savannas (WS), Cropland/Natural vegetation mosaic (NVM), and Deciduous broadleaf forest (DBF). Epiphyllous liverworts were mostly present in MF, then in EBF. MF covered most land area compared with other forest types, and EBF was the least fragmented forest. Presence of epiphyllous liverworts was positively related to EBF area and all forests area, with EBF explained more than all forest together. At nature reserve level, EBF also has the most explanation ability to epiphyllous liverworts presence, no matter by its total area, or by the largest patch area. The results suggested that forest fragmentation including patch size reduction and isolation are influential on the epiphyllous liverworts. Construction of nature reserves for habitat protection is essential and must take into account the connectivity between forest patches and remaining amount of habitat.

Complete chloroplast genome of *Lespedeza maritima* (Fabaceae), a Korean endemic shrub

***Dong-Pil Jin**, In-Su Choi, Jong-Soo Park, Jong-Won Park, Byoung-Hee Choi*
Inha University

Lespedeza maritima Nakai (Fabaceae; Papilionoideae; Desmodieae) is a Korean endemic shrub, which grows in warm-temperate forests of mountain along southern-eastern coastal line. Although some phylogenetic studies of genus *Lespedeza* were conducted based on sequences of partial chloroplast region, each species was not monophyletic due to frequent hybridization and/or rapid diversification. Analysis using chloroplast genome could be helpful in this case, but there is no information. In the present study, we report complete chloroplast genome (cp genome) sequence of *L. maritima*, and it is first report of *Lespedeza*. The cp genome is 149,022bp in length, including a large single copy (LSC) region of 82,429 bp and a small single copy (SSC) region of 18,939 bp, and a pair of inverted repeats (IRs) of 23,827 bp that separated LSC and SSC. The degree of CG content is 35.0%, and this genome contains 134 unique genes, consisting of 72 protein-coding genes, 18 transcription/translation, 36 tRNAs and 8 rRNAs. Moreover, cp genome characteristics and its phylogenetic significance were also assessed within subtribe Lespedezinae by PCR screening and a genome phylogenetic tree.

T2

P0439

Phylogeny and plastome evolution of the legumes family (Leguminosae)

***Jian-Jun Jin**[1,2], Rong Zhang[1,2], Yin-Huan Wang[1,2], Stephen A. Smith[3], Ting-Shuang Yi[2], De-Zhu Li[2]*
1. Kunming College of Life Sciences, University of Chinese Academy of Sciences
2. Kunming Institute of Botany, Chinese Academy of Sciences
3. University of Michigan, Ann Arbor

Many parts of the phylogeny of legume family (Leguminosae), the third largest family in angiosperms with great ecologically diversity and economically importance, are still enigmas. The main issues include the relationships among the six subfamilies and the relationships among tribes. Furthermore, the legume plastid genomes (plastomes) show unusual structure variations, mainly the expansion, contraction and loss of IR regions and the large-scale inversions. But the panoramic history and the mechanisms of plastome structure evolution remains unclear. To explore these issues, we assembled 296 complete/near-complete plastomes together with published ones, representing 315 genera of legumes. We reconstructed the phylogeny using multiple dataset combination including coding and noncoding and various methods, including concatenation and coalescence. We conducted divergence time estimation using a penalized likelihood approach and a Bayesian approach. We reconstructed the ancestral plastomes, evaluated the inversions across the evolutionary history of legumes using an adjacency-based maximum likelihood approach. We discussed the correlations between the structure variations and the potential driven roles. The deep relationships of Leguminosae were fully resolved and strongly supported at most nodes, and divergence ages of major clades were estimated. Our results provided a general time-scaled image of the evolutionary history of the legume plastomes, with the mechanisms of the evolution of structure variations addressed. Our results supplied basis for revising the tribal classification of the legume family, and also provided a good sample for investigating the underlying mechanisms of plastomes evolution.

Utilizing morphological and molecular data to determine if species of *Trema* (Cannabaceae) are forming interspecific hybrids on Hispaniola

Kristina Jordan*, Nancy Garwood, Kurt Neubig, Nicholas Flowers*
Southern Illinois University Carbondale

The Neotropical pioneer tree *Trema* can be found growing in many areas throughout the Neotropics, including Hispaniola. Unfortunately, the taxonomy and phylogeny of species in *Trema* is highly unresolved; the species *Trema micrantha* (L.) Blume encompasses multiple unrelated lineages. Hybridization is likely a contributing factor to this confusion. Multiple distinct clades of *Trema* on Hispaniola grow in close proximity to one another, providing ideal conditions for interspecific hybridization. The purpose of this research is to determine, using a combination of DNA data and leaf morphological characters, if *Trema* is hybridizing on Hispaniola. DNA sequence data was used to evaluate the phylogenetic relationships between species and raw sequence data were used to identify patterns associated with hybridization. Leaf trichomes were imaged using scanning electron microscopy, and overall leaf morphological characters were analyzed in a Principal Components Analysis. We determined that *T. micrantha* and *T. cubensis* (Urb.), as well as *T. micrantha* and *T. lamarckiana* (Roem. & Schult.) Blume are naturally hybridizing on Hispaniola. Analysis of DNA shows that each parent species is a clearly distinguished lineage, and the putative hybrids show phenomena consistent with hybridization. Morphological characters distinguish species and are intermediate in the hybrid offspring. These results are significant as hybridization is a major force in evolution and potentially speciation.

Phylogenomic investigations of the *Haploclathra* (*Caraipa* + *Kielmeyera*) clade: Taxonomic and biogeographical implications

Rafaela J. Trad[1]*, Fernanda N. Cabral*[1]*, Benicio Cardoso-Silva*[1]*, Zhenxiang Xi*[2]*, Volker Bittrich*[4]*, Peter Stevens*[3]*, Maria C E Amaral*[1]*, Charles Davis*[2]
1. University of Campinas
2. Harvard University
3. Missouri Botanical Garden
4. Rua Dr. Mario de Nucci 500,13083–290 Campinas, SP, Brazil

The majority of species in the genera *Kielmeyera* Mart. & Zucc., *Caraipa* Aubl. and *Haploclathra* Benth. (Calophyllaceae) are unique in having alternate leaves and a distinctive geographical distribution. *Kielmeyera* comprises 48 species that grow in Atlantic coastal rainforest and ‘cerrado’ in Eastern Brazil, while *Haploclathra*, with five species, and *Caraipa*, with 41 species, occur throughout Amazonia and have a few representatives in savannas. Although these genera together form a well-supported clade, relationships within the group have been largely unexplored. An ongoing revision has greatly clarified species delimitations within these genera, including the recognition of 15 new species, thus establishing a solid framework for focused phylogenetic investigation. To resolve their phylogeny we first sequenced four loci (plastid *ndh*F and *rps*3; and nuclear emb and ITS) from ~70% of the species in this clade (~68 species and 200 individuals). Our phylogeny inferred using maximum likelihood and Bayesian Inference confirmed the monophyly of the clade, established the monophyly of each genus, and clarified relationships among the genera. In contrast to previous research, our results identified *Haploclathra* as sister to *Caraipa* + *Kielmeyera*. Relationships within each genus, however, were largely unresolved. To break this impasse, we developed a sequence capture probe set targeting 425 low copy nuclear loci and 36 ultraconserved-like regions. Here we will describe the additional phylogenetic insights gleaned from these new phylogenomic data, and discuss their systematic and biogeographical implications, especially in light of recent monographic efforts. In addition to demonstrating the utility of phylogenomics to resolve rapidly radiating groups, the broad distribution of members of this clade makes it an important proxy for understanding the origin of hotspots of South American biodiversity, including ‘cerrado’, Atlantic coastal rainforest, and Amazonian forest.

Global Genome Initiative: Targeting taxonomic DNA barcode gaps in GenBank

Jose Zuniga
Smithsonian Institution

The Global Genome Initiative (GGI) is a Smithsonian Institution program to collect, share, and study genomic samples of non-human species along the major branches of the Tree of Life. Specific goals include preserving genetic material of at least one species of half of the 160-200k estimated genera and sequencing 8k DNA barcodes for taxa for which there is no genetic data available (“dark” taxa). GGI’s barcoding strategy is guided by a data-mining approach in which GenBank is periodically queried to detect taxonomic groups that do not have sequences flagged as barcodes, thus allowing GGI to focus all sequencing efforts on lineages that are not represented in this repository. To date, GGI has generated 2k barcode sequences from four loci for more than 500 plant genera that are not currently represented in GenBank. Ongoing work preserving and sampling legacy collections of large plant diversity projects at the Smithsonian will yield at least 3k additional barcodes for more than 900 dark plant genera during 2017.

Diversity, development and ecological importance of the corolline corona in Apocynaceae

Lize Joubert[1,2]*, Linde De Jager*[1]*, Beverley Glover*[2]
1. University of the Free State
2. University of Cambridge

The Apocynaceae is characterized by a complex floral morphology with two key innovations, the staminal or gynostegial corona and pollinaria, which are both restricted to and potentially important in the diversification of the milkweed group (Secamonoideae and Asclepiadoideae). However, among the more basal sub-families of the Apocynaceae (Rauvolfioideae, Apocynoideae and Periplocoideae), a corolline corona is wide spread and may occasionally co-occur with the staminal corona in some of the basal milkweed lineages. The five corolline corona lobes (occasionally elaborated to form an annulus) arise from meristematic zones formed after postgenital fusion between five petals in each flower, an evolutionary novelty within the Gentianales. Coronas in the Apocynaceae may have various functions, including attracting, positioning and, in some cases, rewarding potential pollinators with nectar. Recent studies focusing on the pollination biology of the Asclepiadineae (Asclepiadoideae) have shown that, in some members of this tribe, the staminal corona functions as a morphological filter, allowing pollination specialization by limiting access to the reproductive part of the flower based on the overall body size of pollinating insects. In some members of the Periplocoideae the corolline corona may play a similar role in pollination specialization. The Periplocoideae corolline corona is highly labile and is morphologically more diverse than in any of the other four sub-families. We evaluate the evolutionary importance of the corolline corona by comparing various corona morphologies and developmental patterns in a phylogenetic context and testing their correlation with pollen transfer efficiency in representative members of the Periplocoideae.

Systematics and diversification of southern African genus *Tephrosia* and allies (Millettieae, Fabaceae)

Ronny Kabongo[1], *Anthony Magee*[2], *Michelle Van Der Bank*[1], *James Boatwright*[3]

1. African Centre for DNA Barcoding, University of Johannesburg

2. Compton Herbarium, South African National Biodiversity Institute

3. Department of Biodiversity and Conservation Biology, University of the Western Cape

Comprising of some 350 species, *Tephrosia* Pers. is a large genus of legumes that are mostly African, but also extend to North and Central America, Australia and Asia. Two subgenera are recognized within the genus, i.e. *Tephrosia subg. Barbistyla* Brummit and *Tephrosia subg. Tephrosia.* Relationships within the genus and among its close relatives in the Millettieae (*Apurimacia* Harms, *Chadsia* Bojer, *Mundulea* Benth, *Pyranthus* Du Puy & Labat, *Ptycholobium* Harms and *Requienia* DC., i.e. the *Tephrosia* clade) are not well understood. This study presents results of nuclear internal transcribed spacer (ITS) and plastid DNA sequence data (*matK, rbcLa, ycf1*) generated and analysed for the *Tephrosia*-clade, based on a representative sampling (236 taxa) of these genera across the world, and especially within *Tephrosia.* Preliminary results indicate that *Tephrosia* is polyphyletic, with *Chadsia, Mundulea, Ptycholobium* and *Requienia* embedded within. *Apurimacia* and *Pyranthus* are placed outside of the main *Tephrosia* clade, although the support for this is weak in some analyses. In addition, *Tephrosia subg. Barbistyla* is none monophyletic in most analyses, while *Tephrosia subg. Tephrosia* polyphyletic. These results and their implications for generic and infrageneric classification within the *Tephrosia*-clade will be discussed.

Polymorphic complex *Trifolium lupinaster*: How many species?

Valentina Kalinkina[1], *Yuliya Mikhaylova*[2], *Dmitriy Kislov*[1]

1. Botanical Garden Institute FEB RAS,

2. Komarov Botanical Institute RAS

The Leguminosa is the largest family of flowering plans, and genus *Trifolium* L. is one of the largest genera in the family. The species of *Trifolium* were found in the old and new world, as well in Africa and South America. The systematic of the genus is a very complicated due to the high degree of polymorphism in some species. Currently the taxonomy of the section *Lupinaster* (Fabr.) Ser. from the *Trifoliastrum* Moench subgenus is still controversial. Main disputes of botanists are focused on systematic position of *T. lupinaster*, because this species is characterized a disjunctive range, wide environmental amplitude and high morphological variability. Different contribution of plant traits (morphometric features of lamina, morphological variability of underground part, biochemical variability), polyploidy and wide distribution area lead to division of polymorphic species *T. lupinaster* to a number of single species. Today, different scientists treated the *T. lupinaster* as an aggregation species (*T. lupinaster* L.) or different variations names (*T. baicalense*, *T. litwinowii*, *T. tundricum*, *T. romanicum*, *T. criswogense*, *T. spryginii*, *T. pacificum, Lupinaster popovii*, *Lupinaster albus*). Statistical analysis showed that the variation of morphometric parameters of *T. lupinaster* L. leaflets linked to habitat conditions of individuals, particularly, influenced by temperature and amount of rainfall during the growing season. Leaf kseromorphism is observed in east-to-west direction, but in Western and Eastern Siberia one can see clear deviations from this trend. Namely, on this territory we can see abundance of isolated *T. lupinaster* forms, variations and species, which is determined mostly by measurable characteristics of a leaflet. However, the results of the statistical analysis we carried out do not support this division of *T. lupinaster*. Despite the fact that some species were previously treated as distinct species and races with different set of chromosomes, there is no morphological or genetic studies exists to consider them as separate species. Molecular phylogenetic analysis showed that the variability of ITS and trnL-trnF sequences in *Lupinaster* section is very low. Sequences of the ITS region of the *T. lupinaster* complex, including highlighted as a separate genus *Lupinaster*, are identical and represented by a single haplotype. Chloroplast haplotype pattern of *T. pacificum* collected from Japan is slightly differed. Statistical analysis of the leaf sheet features of *T. pacificum*, showed there are no significant differences in sizes of a leaflets, but they are significantly different in leaf shape, and they have a quite narrow habitat, specific development of specimens. This may be caused by isolated island state for this population, which, in turn, leads to the accumulation of variability. Against the background of significant morphological plasticity species of *Lupinaster* section, and particularly complex *T. lupinaster*, are surprisingly uniform genetically. After complex morphology and molecular study we consider *T. lupinaster, T.*

pacificum, T. gordejevii, *T. eximium* as separate species of section *Lupinaster*. Dedicated earlier species *T. baicalense*, *T. litwinowii*, *T. criswogense*, *T. spryginii*, *L. albus* are not an independent, but represent variants of a life form of *T. lupinaster.*

Diversity of the genus *Arisaema* Mart. (Araceae) in India

Manudev Kambiyelummal Madhavan[1], *Santhosh Nampy*[2]
1. St. Joseph's College (Autonomous)
2. University of Calicut

The genus *Arisaema*, with about 215 taxa, is the third largest genus of Araceae. It is distributed from Central and East Africa towards South East Asia via Yemen, Oman, Pakistan, Afghanistan, the Himalayan ranges including India, China, Korea, Japan and Siberia eventually to North America with centre of diversity in tropical Asia (Gusman & Gusman, 2006; Govaerts, 2017). A recent taxonomic revision of the genus resulted in enumeration of 50 species and 6 varieties in India under 9 sections, mostly centered in Western Ghats, Eastern Himalayas and Western Himalayas. During the study five new species are described and two taxa *viz*. *Arisaema ciliatum* H.Li var. *liubaense* Gouda & Gusman and *A. pangii* H.Li, are reported new to India. The protologues of two species are emended based on data acquired during field studies and lectotypes are selected for 19 names conferring to the latest code of nomenclature. A morphometric analysis of species occurring in India is also conducted and a cladogram is drawn using the software NTSYSpc 2.02e based on 69 morphological characters. The cladogram supported the infrageneric classification of the genus proposed by previous workers (Murata *et al.,* 2013) with minor deviations. The present paper discusses the taxonomy and diversity of Indian species of *Arisaema* with updated nomenclature, colour photographs and distribution in India.

Detection of genetic variation of anthocyanin biosynthesis pathway genes between and within population in *Hepatica nobilis* var. *japonica* involving flower color polymorphism within population

Shinichiro Kameoka[1], *Tomomi Wakabayashi*[1], *Yuki Mitsui*[2], *Keisuke Tanaka*[2], *Tsukasa Iwashina*[3], *Yoshinori Murai*[3], *Hitoshi Sakio*[4], *Harue Abe*[4], *Hiroaki Setoguchi*[1]
1. Kyoto University
2. Tokyo University of Agriculture
3. National museum of nature and science
4. Niigata University

What the factor maintains the polymorphisms both in phenotypic and genetic levels is the fundamental question in evolutionally biology. Some possible mechanisms to maintain the polymorphisms have been suggested: negative frequency dependent selection and so called high polymorphism, the phenomenon in which a specific position significantly deviates from the neutral equilibrium have been recognized as major reason. *Hepatica nobilis* var. *japonica* (Ranunculaceae) involves significant floral color polymorphism within population and can be divided into three types, white, red and blue by the anthocyanin pigment types. SSR analysis showed these flower colors cross randomly and no strong restriction of gene flow exist in natural habitat. Moreover, in the field observation, blue, the minority flower color within the population, might enjoy ecological advantage from the view point of the number of seeds and damage of tepals. In this study, we aimed to identify the candidate gene relating to the flower color polymorphism using transcriptome analysis, and to reveal that of polymorphic sites and nucleotide diversity. We compared the amount of expressed gene among different flower color type and picked up the anthocyanin biosynthesis pathway genes (e.g., *F3'H*, *F3'5'H* and *DFR*). Specifically, *F3'5'H* which required to produce the blue pigment showed higher nucleotide diversity than the other candidate genes. We detect the nucleotide diversity of those genes and test whether the patterns of polymorphisms are compatible with neutral equilibrium, then, conclude about the mechanism of maintenance in genetic polymorphism.

P0448

Pollen morphology of some taxa of *Vicia* L. subgenus *Vicia* (Fabaceae) from European Turkey (Turkish Thrace)

Ciler Kartal, *Necmettin Guler, Ihsan Yalcin*
Trakya University, Faculty of Science, Department of Biology, Balkan Campus, Edirne/TURKEY

In this study, the pollen morphologies of 15 taxa belonging to the subgenus *Vicia* of genus *Vicia* L. (Fabeae, Fabaceae) naturally growing in European Turkey (Turkish Thrace) were studied using Light Microscopy (LM) and Scanning Electron Microscopy (SEM). The taxa studied are *V. galilaea, V. grandiflora* var. *dissecta, V. grandiflora* var. *grandiflora, V. hybrida, V. lathyroides, V. lutea* var. *hirta, V. narbonensis* var. *narbonensis, V. pannonica* var. *pannonica, V. pannonica* var. *purpurascens, V. peregrina, V. sativa* subsp. *incisa* var. *cordata, V. sativa* subsp. *incisa* var. *incisa, V. sativa* subsp. *nigra* var. *nigra, V. sativa* subsp. *nigra* var. *segetalis* and *V. sativa* subsp. *sativa. V. hybrida was found to be the taxa with the longest pollen grains respect to the polar axis (*P = 42.7 µm; E = 22.8 µm) while *V. narbonensis var. narbonensis* has the largest pollen grains in terms of the equatorial axis (P = 41.5 µm; E = 26.9 µm). *V. lathyroides* has the shortest pollen grains (P = 25.4 µm; E = 23.3 µm) with regard to the *polar axis*, although *V. sativa* subsp. *incisa* var. *incisa* has the narrowest pollen grains (P = 33.0 µm; E = 21.1 µm) in terms of the equatorial axis. The pollen grains are prolate-spheroidal in *V. lathyroides* (P/E = 1.09), subprolate in *V. sativa* subsp. *nigra* var. *nigra* (P/E = 1.29) and prolate shape in the other taxa studied. The pollen grains of all taxa examined are trizonocolporate. Colpus length (Clg) ranges from 12.50 µm (in *V. lathyroides*) to 32.20 µm (in *V. peregrina*). Porus length (Plg) ranges from 5.20 µm (in *V. lathyroides)* to 8.60 µm (in *V. narbonensis* var. *narbonensis*). Ornamentation of the mesocolpium is psilate-perforate in *V. lathyroides*, reticulate-perforate in *V. sativa* subsp. *nigra* var. *nigra,* rugulate in *V. narbonensis* var. *narbonensis*, perforate in *V. hybrid* and *V. lutea* var. *hirta* and reticulate in the remaining taxa. The results indicated that the morphological features of the pollens could be useful in distinguishing the examined taxa.

P0449

Taxonomic studies of the family Trichocoleaceae (Marchantiophyta) in Central and South America; *Trichocolea sprucei*, *Trichocolea floccosa*, and *Leiomitra flaccida*

Tomoyuki Katagiri
Hattori Botanical Laboratory

The genus *Leiomitra* Lindb. (Trichocoleaceae, Marchantiophyta) is a small genus including about 10 species and distributed mainly from tropical and subtropical areas of Central and South America and Southeast Asia. *Leiomitra* is distinguished from the other genera of the family (*Trichocolea* Dumort. and *Eotrichocolea* R.M.Schust.) by such characters as succubous leaf insertion, well-differentiated (anisophyllous) leaves and underleaves, and presence of well-developed calyptra and perianth. *Trichocolea sprucei* was described by Stephani in 1909 from Dominica. Schultze-Motel & Menzel (1987) suggested *Trichocolea sprucei* to be a variety of *Leiomitra flaccida*, and Schuster (2000) recognized it in the genus *Trichocolea*. However, the taxonomic position of the species remained tentative, since no reproductive characters were known. In the course of worldwide taxonomic studies on the Trichocoleaceae, it has been possible to study original material of *T. sprucei*, and to find reproductive structures. The presence of perianth lead to the conclusion that the type belongs to the genus *Leiomitra. Trichocolea floccosa* Herzog & Hatcher was described in 1957 from Costa Rica. According to Hatcher (1957), *T. floccosa* was distinguished from *T. sprucei* by the leaf disc of 1 cell high with the cells 55 × 18 µm (1–2 cells high with the cells 91 × 29 µm in *T. sprucei*). Schultze-Motel & Menzel (1987) treated *T. floccosa* as a variety of *Leiomitra flaccida*. However, our examination of the holotype shows *T. floccosa* have 1–2 cells high leaf disc and it should be treated as a synonym of *T. sprucei*, although the type specimen lack reproductive characters. *Leiomitra flaccida* have 4–5 cells high leaf disc and can be easily distinguished from *T. sprucei* (1–2 cells high leaf disc). *Leiomitra flaccida* was described by Spruce in 1885 from Ecuador. Spruce did not specify the holotype and the species concept has not been well circumscribed. In the Spruce collection of the herbarium of University of Manchester (MANCH), the specimen MANCH-13001 annotated with "*Trichocolea tomentosa* var. In sylva Canelos. Julis 1857" was selected as the lectotype of *Leiomitra flaccida* because the information on the label and plants completely fit the original description including the information on gynoecia, although this specimen also contains *Trichocolea tomentosa*. Other specimens annotated with "*Trichocolea flaccida*" in his collection have different locality data from the original description: MANCH-10865 with "Tunguragua, ad Pasa"; MANCH-10866 with "Chimborazo"; MANCH-10867 with "Rio Janeiro"; MANCH-10868 with "Campana". The two specimens from Ecuador MANCH-10865 and MANCH-10866 correspond to *T. flaccida*, but the specimen from Brazil, MANCH-10867 turned out to be corresponding to *Trichocolea brevifissa* Steph., in having higher leaf disc being 8–10 cells high. The plants from Campana (Peru), MANCH-10868, was originally described as a forma with the gynoecia restricted to short lateral branches, but was turned out to be a etiolated form of *Leiomitra mastigophoroides* R.M.Schust. (Katagiri 2016).

Morphological and anatomical characteristics of *Clinopodium graveolens* subsp. *rotundifolium* (Lamiaceae) in Turkey

Ayla Kaya
Anadolu University, Faculty of Pharmacy, Pharmaceutical Botany, 26470 Eskişehir-Turkey

Clinopodium graveolens (M. Bieb.) Kuntze subsp. *rotundifolium* (Pers.) Govaerts, is an erect or ascending annual (in Turkey) herb which grows in 0-2200 m and it is the most widespread in Turkey. In the current study, morphology and anatomical characteristics *C. graveolens* subsp. *rotundifolium*, previously treated as *A. rotundifolius* Pers. in Flora of Turkey, is studied for the first time and detailed descriptions and illustrations of general appearance of plants and their, leaf, bract, flower, calyx, corolla and fruit shapes and anatomical descriptions and illustrations of root and stem are described and illustrated. The plant is 2-34 cm. Leaves are lanceolare-ovate or obovat to orbicular shaped. Corolla is purple-lilac coloured. The root is orbicular in outline in cross-section. The seconder tissues is only observed in root anatomy of species. The stem is almost square in shape and contain non-glandular and glandular hairs in transverse sections. The vascular bundles are well-developed at the corners of the stem.

P0451

A phylogenetic study of the genus *Tanacetum* (Asteraceae–Anthemideae) in Iran

Marzie Kazeminoureini[1], *Ali Sonboli*[2]
1. Tarbiat Modares University
2. Medicinal Plants and Drugs Research Institute, Shahid Beheshti University

With around 160 species, *Tanacetum* L. is the third largest genus of the Compositae–Anthemideae, after the species-rich genera *Artemisia* L. and *Anthemis* L. Its members are found in the circum-Mediterranean region, central and eastern Asia, and parts of northern America. Likely ancestral distribution range of this genus is Eastern Europe, Caucasus and Asia Minor; and dispersal (vs. vicariance) plays a significant role in this genus' distribution to all above mentioned area during mid-Miocene, when likely many of the floras of Iran entered there, from Africa and Anatolia. Despite high morphological diversity of this genus, sequence divergence among *Tanacetum* representatives included in previous studies was found to be very low, leading to unresolved phylogenetic relationships within the genus. In this study, datasets of three molecular markers, (cpDNA *rpL32-trnL*$_{\text{UAG}}$, *ndhF-rpL32* spacers and nrDNA ITS) were generated for 67 *Tanacetum* accessions and closely related genera, covering most of the previously recognized sections of this genus in Flora Iranica as well as some accessions from Turkey and Europe. The main aims of our study have been: 1) evaluation the monophyly of *Tanacetum*, 2) phylogenetic reconstruction of this genus to assess its phylogenetic delimitation and to explore the possibility of phylogenetic based infrageneric classification, 3) testing previous taxonomic hypothesis on infrageneric relationships. Furthermore we represent here the first dated ITS sequences-based phylogeny of *Tanacetum* s.l. with special reference to its species and speciation time in Iran, which is housed by at least 36 *Tanacetum* species including numerous enigmatic species complexes. This dating was performed using Bayesian uncorrelated relaxed molecular clock available in BEAST. This analysis revealed that the ancestor of the genus *Tanacetum* was diverged from its sister *Cota-Tripleurospermum* clade and has undergone rapid radiation through the first 1-2 million years after divergence. It seems that diversification and speciation of this genus occurred in Iran mostly through vicariance and followed by subsequent dispersal events to different localities in various directions.

T2

P0452

Molecular phylogeny of some spiny-cushion forming of *Astragalus* species (Fabaceae) based on nrDNA ITS sequences

Zohreh Khalili[1], *Shahrokh Kazempour Osaloo*[1], *Ali Asghar Maassoumi*[2], *Shahin Zarre-Mobarakeh*[3]
1. Department of Plant Biology, Faculty of Biological Sciences, Tarbiat Modares University
2. Research Institute of Forests and Rangelands
3. Department of Plant Biology, Faculty of Biological Sciences, Tehran University

Rhacophorus is one of the major sections of *Astragalus*. The center of speciation and diversity is Iran and Turkey. Delimitation of its boundaries with other spiny sections is too difficult due to extreme variation and high levels of homoplasy in morphological characters. The morphological studies have changed the boundaries in spiny *Astragalous* In addition, displacement occurred among with spiny *Astragalus* sections and intermediate species considered especially among *Adiaspastus and Rhacophorus* which made the boundaries uncertain. It is a very variable section with several Toorly defined species. It is also close to sect. *Prerophorus* and sect. *Macrophyllium*. According to previous studies, sections of *Rhacophorus*, *Macrophyllium*, *Adiaspastus*, *Prerophorus*, *Brachycalyx*, *Hystrix*, *Polystegis*, *Stenonychium*, and *Platonychium* located in Tragacantha subgenera because of producing the valuable tragacanth gum. Members of *Rhacophorus* are characterized by spiny shrubs with paripinnate leaves and spiny rachis; leaflets with white-simple-hairy. Flowers are sessile and forming a dense inflorescence. Bracteoles absent or unlike the calyx lobes. Legume included within the persistent corolla, unilocular, 1 (-2)-seeded. The present study aims to reconstruct phylogenetic relationships in some spiny-cushion forming of *Astragalus* species, using nuclear sequences (ITS). The nrDNA ITS region was amplified using appropriate primers by PCR. Each DNA region was aligned using MUSCLE software. Phylogenetic analyses were performed using maximum parsimony approach as implemented in PAUP* software. Bayesian and Maximum Likelihood phylogenetics analyses applied for 60 species as representatives of sects. *Adiaspastus*, *Rhacophorus*, *Brachycalyx*, *Platonychium*, and *Pterophorus* in Iran and Turkey. *A. stocksii*, *A. boeticus*, and *A. cryptocarpus* were selected as outgroups. The present study represents that studied sections are not monophyletic. Incomplete resolution in sect. *Rhacophorous* indicate that analysis based on chloroplast sequences should be combined to resolve the branches. Relationship among with sects. *Brachycalyx*, *Adiaspastus* and *Platonychium* mostly form the basal branches and are close to members of sect. *Pterophorus*. Our phylogenetic analysis suggest that the current classification of studied sections dose not properly reflect the phylogeny of sect. *Rhacophorus* and allied sections.

P0453

Genetic structuring, dispersal and taxonomy of the high-alpine populations of the *Geranium arabicum/kilimandscharicum* complex in tropical eastern Africa

Tigist Wondimu Kifilemichael
Addis Ababa University

The scattered eastern African high mountains harbor a renowned and highly endemic flora, but the taxonomy and phylogeographic history of many plant groups are still insufficiently known. The high-alpine populations of the *Geranium arabicum/kilimandscharicum* complex present intricate morphological variation and have recently been suggested to comprise two new endemic taxa. Here we aim to contribute to a clarification of the taxonomy of these populations by analyzing genetic (AFLP) variation in range-wide high-alpine samples, and we address whether hybridization has contributed to taxonomic problems. We identified only two genetic groups. One corresponded to *G. kilimandscharicum*, which has been reported as exclusively high-alpine and confined to the eastern Rift mountains in East Africa. The other corresponded to *G. arabicum*, reported from lower altitudes on the same mountains as well as from a wide altitudinal span in Ethiopia and on the western Rift mountains in East Africa. The four populations analyzed of a recently described species from the Bale Mts in Ethiopia were admixed, indicating that they result from recent long-dispersal of *G. kilimandscharicum* from East Africa followed by hybridization with local *G. arabicum* in naturally disturbed habitats. Some admixture between the two genetic groups was also inferred on other mountains, supporting earlier suggestions of introgression based on morphology. We did neither find support for recognition of the recently suggested new subspecies of *G. arabicum* in Ethiopia. Interestingly, the high-alpine *G. kilimandscharicum* lacked clear geographic structuring, suggesting a recent history of colonization of the different mountains or extensive intermountain gene flow.

P0454

Phylogenomic inference and molecular dating of tribe Forsythieae (Oleaceae)

Young-Ho Ha[1], *Changkyun Kim*[1], *Kyung Choi*[2], *Joo-Hwan Kim*[1]
1. Gachon University
2. Korea National Arboretum

The tribe Forsythieae (Oleaceae) is composed of two genera: *Forsythia* and *Abeliophyllum*. The former consists of 13 species distributed in the Far East Asia except *F. europaea* which is located in northern Albania, *Abeliophyllum* is monotypic endemic genus of the Korean peninsula. Most of the species of tribe Forsythieae are endangered in East Asia and their natural habitats have been disappearing. Despite their important roles as medicinal and ornamental resources, there are no consistent systematic studies on this tribe without argument. Here, we report the complete chloroplast (cp) genome sequences of 10 species of *Forsythia* and *Abeliophyl-*

lum using Illumina platform. The chloroplast genome of *Abeliophyllum* showed a highly similar gene content and arrangement in comparison with *Forsythia*, except for 400 bp of the indels. Both phylogenetic analyses (Maximum Likelihood and Bayesian inference methods) based on concatenated 78 protein-coding gene derived identical topology with strong support. *Abeliophyllum* was sister to rest of *Forsythia* species. *F. likiangensis* and *F. giraldiana* were basal lineages followed by *F. europaea* which shared minutely serrate or entire margin. The remaining seven species which distributed in East Asia formed two major clades: one clade of *F. ovata, F. velutina*, and *F. japonica*, which is morphologically supported by broadly ovate leaves, and another clade of *F. suspensa, F. saxatilis, F. viridissima*, and *F. koreana* that have lanceolate leaves. The Bayesian molecular clock dating and biogeographical analyses using four cpDNA sequences (*atpB, matK, ndhF*, and *rbcL*) suggested that Forsythieae and its sister group (*Fontanesia*) estimates at 44.99Mya in the middle Eocene. Forsythieae originated in East Asia with its crown group dated at 12.91Mya in middle Miocene and dispersed to West China and East Europe (northern Albania).

Phylogeny and historical biogeography of Melanthiaceae (Liliales) : A case of intercontinental dispersal from North America to East Asia

*Sang-Chul Kim, Changkyun Kim, **Joo-Hwan Kim***
Gachon University

Intercontinental floristic disjunction between East Asia and North America in the North Hemisphere has been received much attention during the past three decades, but few studies have focused at the family level. Melanthiaceae, containing 196 species and 17 genera circumscribed in five tribes (Chionographideae, Heloniadeae, Melanthieae, Parideae, and Xerophylleae), is disjunctly distributed in East Asia and North America and it represents on excellent for studying the evolution of biogeographic patterns in this region. Here, we employ phylogenetic, molecular dating, and biogeographic methods to reconstruct the evolutionary history of Melanthiaceae based on comprehensive sampling scheme using four chloroplast DNA regions (*atpB*, *rbcL*, *matK*, and *ndhF*). The BEAST analysis produced a well resolved phylogeny of Melanthiaceae indicating the monophyly of the family and the relationships among the five tribes. Melanthieae is found to be sister to the rest tribes of the family and the remaining taxa are divided into two major clades consisting of the Chionographideae + Heloniadeae clade and the Parideae + Xerophylleae clade. The molecular clock dating and the ancestral area analyses suggest that Melanthiaceae most likely originated in North America with its crown group dated at 90.3 Ma (95% HPD 76.0–103.2 Ma) in the late Cretaceous. In the family, five independent migrations into East Asia from North America are inferred to have occurred in the Oligocene and the Miocene-Pliocene via historical paleo-land bridge connections. Cooling trends during the Oligocene resulted in the present East Asia-North America disjunction distribution, while the warm period during the middle Miocene and habitat heterogeneity stimulate the diversification from East Asia.

P0456

Chloroplast DNA assessment for the anagenetic speciation of *Sedum takesimense* (=*Phedimus takesimensis*) (Crassulaceae) in Ulleung Island, Korea

*Hee-Seung Seo, **Seung-Chul Kim***
Sungkyunkwan University

Sedum L., with approximately 470 species, is the largest genus of the family Crassulaceae. The recent molecular phylogenetic study suggests that the genus *Sedum* is highly polyphyletic. Of three endemics among 11 species recognized in Korea, *Sedum takesimense* occurs exclusively in Ulleung-do and Dok-do Island, which is known for unusually high level of anagenetic speciation among oceanic islands. *Sedum kamtschaticum* (=*Phedimus kamtschaticus*), which commonly occurs in northeastern Asia, is considered as continental progenitor species of *S. takesimense* in Ulleung-do and Dok-do Island. The earlier survey of intraspecific cpDNA variation has little value in fully capturing genetic diversity for the progenitor-derivative pairs due to limited sampling in individuals and DNA sequences. In this study, we investigated genetic diversity and structure of *S. takesimense* (derivative) and *S. kamtschaticum* (progenitor) pairs to assess the genetic consequences of anagenetic speciation. We extensively sampled populations of progenitor (*S. kamtschaticum*; 11 pops. from Korean peninsula, 88 individuals) and derivative (*S. takesimense*; 14 pops. 140 individuals from Ulleung-do and 1 pop. 10 individuals from Dok-do) and sequenced five noncoding regions of cpDNA (*atp*I/H, *trn*C/*ycf*6, *trn*L/F, *rps*16/*trn*K, and *ndh*J/*trn*F; ca. 3500 base pairs). We found nearly three times higher haplotype diversity in insular derivative species (21 haplotypes in 93 individuals), which derived from the most common haplotype found in southern and eastern part of Ulleung Island, compared to its continental progenitor species (8 haplotypes in 67 individuals). Only one haplotype found in Dok-do Island was derived from the southwestern population of Ulleung Island. We found no geographical structuring within the island population and very strong genetic differentiation between the island species *S. takesimense* and its continental progenitor *S. kamtschaticum*. These results suggest that the genetic consequences of anagenetically derived species of *S. takesimense* are consistent with other examples of endemic species on Ulleung Island (i.e., *Acer takesimensis* and *Dystaenia takesimana*). The genetic consequences of anagenetic speciation in *Sedum takesimense* based on extensive sampling from northeastern Asia will be further explored using nuclear microsatellite markers. The example of *S. takesimense*, as one representative endemic lineage of Crassulaceae on island, will be of important value in generalizing and synthesizing the genetic consequences of anagenetic speciation in oceanic islands.

P0457

Genetic variation and evolution of *Filibryum* in Yakushima Island

Wonhee Kim[1], *Tomio Yamaguchi*[2], *Hiromi Tsubota*[3]
1. Division of Plant Resources, National Institute of Biological Resources
2. Department of Biological Science, Graduate School of Science,

Hiroshima University
3. Miyajima Natural Botanical Garden, Graduate School of Science, Hiroshima University

Filibryum is a member of Hypnaceae and pleurocarpous moss. This genus consists of three species, which are *F. ogatae* (Broth. & Yasuda) W.Kim & T.Yamag., *F. yakoushimae* (Cardot) W.Kim & T.Yamag. and *F. deguchianum* W.Kim & T.Yamag. *F. yakoushimae* and *F. deguchianum* are Japanese endemic species. On the other hands, *F. ogatae* is widely distributed in Japan and Korea. In the case of *F. deguchianum*, its morphological traits are distinguished from others. However, the circumscription of the interspecific morphological difference between *F. ogatae* and *F. yakoushimae* is unclear. So, this study analyzed the genetic variation between both species in order to solving the problem. Furthermore, this study examined the genetic variation of *F. ogatae* related to the geographical distribution. For analysis of the genetic variation, 30 samples were collected from 10 regions, which are 7 regions from Japan and 3 regions from Korea, and analyzed nrDNA ITS, cpDNA *psaA*-*rps*4 region and mtDNA *nad*5 sequences. There was *ycf*3 gene between *psa*A and *trn*S, and this gene consists of 3 exons and 2 introns (total 1,930 bp). Especially, interspecific genetic variations between *F. ogatae* and *F. yakoushimae* were verified on *ycf*3 Intron 1 region. Then, samples were categorized as three groups according to distribution regions, which were Japan, Korea and Yakushima population. As the result of analyzing the genetic variations, Yakushima population has distinct genetic differences presented on 4 regions, which are ITS 1 region, *psaA/ycf*3 spacer, *yacf*3 Intron 1 and *rps*4. However, their morphological characteristics were not distinct. Therefore, morphological variations related to geographical distribution were not verified in *F. ogatae*. Therefore, it is possible that Yakuahima population of *F. ogatae* may be a cryptic species derived through anagenetic divergence processes. Such as a cryptic species in Yakushima Island, it was also reported in vascular plants (Kimuara *et al.,* 2014). Recently, it was emphasized that the importance of an anagenetic speciation/evolution in the island (Stuessy *et al.,* 2006). Additionally, *F. yakoushimae* is an endemic species in Yakushima Island, and its genetic variation pattern is similar to the Yakushima population of *F. ogatae*. As the result, it is considered that *F. yakoushimae* was derived from Yakushima population of *F. ogatae* built up genetic variations. Consequently, the present study assumes that both species of *Filibryum* in Yakushima Island are undergoing a cladogenetic divergence process after an anagenetic divergence.

P0458
Taxonomic review of the genus *Catalpa* (Bignoniaceae)

Joseph H. Kirkbride Jr.[1], *Richard T. Olsen*[2]
1. Smithsonian Institution/Department of Botany
2. USDA Agricultural Research Service

Bignoniaceae tribe Catalpeae DC. ex Meisn. is monophyletic and consists of two genera, *Catalpa* Scop. and *Chilopsis* D. Don, and their hybrid ×*Chitalpa* T. S. Elias & Wisura. *Chilopsis* is monotypic and sister to the monophyletic clade *Catalpa*. *Chilopsis linearis* (Cav.) Sweet has been hybridized with *C. bignonioides* Walter, and the hybrids have been named ×*Chitalpa tashkentensis* T. S. Elias & Wisura. The genus *Catalpa* consists of eight species. Four species form the monophyletic clade *Catalpa* section *Macrocatalpa* Griseb., whose members are tropical evergreen and endemic to the Greater Antilles, *C. brevipes* Urb., *C. purpurea* Griseb., *C. longissima* (Jacq.) Dum. Cours., and *C. macrocarpa* (A. Rich.) Ekman, occurring from Jamaica across Cuba and Hispaniola to the Bahama Islands. The other four species form the monophyletic clade *Catalpa* section *Catalpa*, sister to the clade *Catalpa* section *Macrocatalpa*. Those species are temperate deciduous. Two are endemic to the eastern USA, *C. bignonioides* and *C. speciosa* E. Y. Teas, and the other two are endemic to China, *C. bungei* C. A. Mey. and *C. ovata* G. Don. The ancestor of section *Catalpa* dispersed to China, and from there an ancestor of the North American species dispersed to the USA. The Chinese *C. ovata* has been hybridized with the North American *C. bignonioides* and *C. speciosa*, and these hybrids have been named *C.* ×*erubescens* Carrière and *C.* ×*galleana* Dode, respectively.

Aloe taxonomy and phylogeny: Current status and future prospects

Ronell R Klopper[1], *Olwen M Grace*[2]
1. South African National Biodiversity Institute
2. Royal Botanic Gardens, Kew

Aloes are widespread in Africa, the Arabian Peninsula, Madagascar and some of the smaller Western Indian Ocean islands. These rosulate succulents are very popular worldwide amongst succulent plant collectors and a number of species are revered for their medicinal or other cultural values. Several aloes are considered to be taxa of conservation concern and all aloes (except *Aloe vera*) are thus listed on CITES appendices. Aloes (±630 taxa) and their relatives has been the subject of numerous recent studies to elucidate the phylogenetic relationships among these plants. In this light the family Asphodelaceae has been incorporated into a substantially larger family concept that also includes the Xanthorrhoeaceae s.str. (Australian grass trees) and Hemerocallidaceae (day lilies). Furthermore, molecular and phylogenetic studies have necessitated a reassessment of the classification of the genus *Aloe* s.l. and related genera. This resulted in the establishment of segregate genera for the scrambling aloes (*Aloiampelos*), tree aloes (*Aloidendron*), the fan aloe (*Kumara*), and variegated aloes (*Gonialoe*), as well as the inclusion in *Aloe* of species previously treated in the genus *Chortolirion*. Similar generic adjustments were also made in the genus *Haworthia* where three segregate genera are now recognised, namely *Haworthia*, *Haworthiopsis* and *Tulista*. Phylogenetic analyses of plant utilisation can provide a means to better understand observed patterns in the value of global plant diversity. A phylogenetic framework was used with success to investigate possible links between leaf succulence and medicinal use in aloes. These analyses have also shed light on the origin and diversification of aloes in general. The recent revision of two groups of aloes utilising DNA-based analysis has shed light on the ability of molecular tools to recognise aloe taxa at species level and below. These studies have shown that DNA barcodes might not be able to distinguish between certain species. This can have consequences for conservation-related activities, e.g. identification of traded material. This presentation will provide an overview of the genus

Aloe s.l. with specific emphasis on its current distribution and diversity, as well as its evolutionary history. Recent changes in the family and genus classification of aloes and their relatives will be discussed. The value of molecular tools, especially barcodes, and how informative these techniques are at species level in aloes will be considered. Future research prospects for aloes will also be emphasized.

A newly discovered oligocene flora from the Maoming Basin, South China: Taxonomy and paleoclimatic implications

Tatiana Kodrul[1,2], *Galina Aleksandrova*[2], *Natalia Maslova*[3], *Robert Spicer*[4], *Jian Yang*[5], *Alexei Herman*[2], *Teresa Spicer*[5], *Yan Wu*[1], *Jianhua Jin*[1]

1. State Key Laboratory of Biocontrol and Guangdong Provincial Key Laboratory of Plant Resources, School of Life Sciences, Sun Yat-sen University, Guangzhou

2. Geological Institute, Russian Academy of Sciences, Moscow

3. Borissiak Paleontological Institute, Russian Academy of Sciences, Moscow

4. School of Environment, Earth and Ecosystem Sciences, The Open University, Milton Keynes

5. State Key Laboratory of Systematic and Evolutionary Botany, Institute of Botany, Chinese Academy of Sciences, Beijing

The fossil Shangcun flora comes from the Maoming sedimentary basin, located in southwestern Guangdong Province, South China. Plant megafossils including leaves, stems, fruits, cones and seeds were recovered from the Shangcun Formation exposed within the Shangcun (21.79778°N; 110.8094°E) and Lishan (21.84417°N; 110.7786°E) quarries. The Shangcun Formation, 300–500 m thick, consists of mudstones and siltstones with minor intercalations of oil shales and coal seams in the lower part (Zhou and Chen, 1988). Plant fossils are distributed in a scattered pattern in greyish brown mudstones and siltstones representing a lacustrine environment. Preliminary taxonomic analysis revealed that the Shangcun flora contains at least 95 taxa belonging to leafy bryophytes (Bryopsida), horsetails (Equisetaceae), ferns (Osmundaceae, Polypodiaceae), conifers (Pinaceae, Cupressaceae, probably Taxaceae) and angiosperms (Platanaceae, Lauraceae, Fagaceae, Malvaceae, Calophyllaceae, Juglandaceae, Fabaceae, Rhamnaceae, Cornaceae, Myricaceae, Menispermaceae, Simaroubaceae and Palmae). Ferns are scarce in the Shangcun flora, but relatively diverse, while mosses and horsetails are very rare. Compared to the older Eocene fossil floras of the Maoming Basin conifers are relatively abundant and diverse in the Shangcun flora, and are composed mainly of pinaceous (*Pinus*, probably *Tsuga)* and cupressaceous (*Calocedrus*, *Sequoia*) taxa. The majority of Shangcun species are angiosperms, dominated by Fagaceae (*Quercus, Castanopsis),* Lauraceae, Myricaceae (*Myrica*), and probably Moraceae. The genera *Palaeocarya* (Juglandaceae), *Paliurus* (Rhamnaceae), and *Ailanthus* (Simaroubaceae) are recognized on the basis of fruit remains. The genus *Burretiodendron* (Malvaceae s. l.) is represented by fruits and associated leaves. Extant species of *Burretiodendron* are mainly distributed in the monsoonal tropical regions of East Asia. *Calophyllum* (Calophyllaceae), recognized on the basis of leaves, is also confined to moist tropical regions of the world. Palynological assemblages from the Shangcun Formation in the Lishan quarry indicate the Eocene-Oligocene transition near the base of the studied section marked by a sudden increase of conifer taxa, loss of megathermal angiosperms and the presence of *Persicarioipollis* sp. pollen and grass pollen. *Persicarioipollis* sp. is characteristic of the early Oligocene in Eastern Asia (Yu, 1983; Shaw, 1998; Yi *et al.,* 2003) and unknown in the Eocene. Higher in the section megathermal angiosperms recover in terms of abundance and diversity, but lack key taxa typical of the Eocene. Palynological assemblages from the upper part of section correspond with the "warm" palynoflora that occurs in the second half of the early Oligocene (Wu *et al.,* 2003). Although many Shangcun plant megafossils were not collected *in situ*, the palynomorph spectra obtained from the same matrix as the leaf fossils are similar to that above the conifer-rich horizon and so the Shangcun megaflora is dated to the second half of the early Oligocene. Based on plant megafossils the Shangcun flora is similar to the Oligocene floras of adjacent regions (e.g. the Oligocene flora from the Ningming Formation, Ningming Basin, Guangxi). As determined by Climate Leaf Analysis Multivariate Program (CLAMP) the early Oligocene Shangcun flora indicates rainfall seasonality approaching that seen in South China today.

P0461

A multilocus phylogenetic reconstruction of *Aconitum* subgenus *Lycoctonum* (Ranunculaceae) in China: Indicating allo- and autopolyploidization in combination with morphological and karyotypic evidence

Hanghui Kong[1], *Yu Hong*[1], *Yu Zhang*[1], *S. Michael Barker*[2]

1. Key Laboratory of Plant Resources Conservation and Sustainable Utilization, South China Botanical Garden, Chinese Academy of Sciences

2. Department of Ecology and Evolutionary Biology, University of Arizona

Polyploidization has long been recognized as one of the most important driving forces of plant evolution. *Aconitum* subgenus *Lycoctonum* (Ranunculaceae) has a wide distribution range and well-known background of polyploidy, thereby providing a potentially valuable model to explore polyploid origin and evolutionary history. In the current study, 29 species including diploid, tetraploid and hexaploid species were sampled in subg. *Lycoctonum*. Using four cpDNA regions (*ndh*F-*trn*L, *psb*A-*trn*H, *psb*D-*trn*T and *trn*T-L) and two nrDNA regions (internal transcribed spacer, ITS and external transcribed spacer, ETS), phylogenetic relationship was reconstructed and showed consistence with previous taxonomical and cytological results. No evidence showed that polyploidization directly led to an increase of diversification rate. Furthermore, in combination with cpDNA haplotype network, S-DIVA analyses as well as morphological and karyotype evidence, polyploidization was interpreted in subg. *Lycoctonum*. Allopolyploidization was inferred for *A. angustius* with intermediate morphologies and heteromorphic chromosomes. *Aconitum finetianum* was suggested to be the maternal progenitor of *A. angustius* due to their highly similar morphologies and overlapping distribution range. Autopolyploidization was inferred for tetraploids in the Hengduan Mountains (HDM) with eight groups of chromosomes of four homologous. Local origin was inferred for tetraploids in the HDM, which diverged approximately 3.00 Ma in the same period with the orogeny of the HDM. The hexaploid *A. apetalum* was inferred to suffer from geographical isolation due to the formation of the Qinghai–Tibetan Plateau (QTP) and the HDM. Hybridization and heterogeneous habitats in the HDM were suggested to play an important role in the polyploidization in subg. *Lycoctonum*.

P0462

Leaf micromorphology of the *Persicaria* sect. *Cephalophilon* (Polygonaceae) and its systematic re-evaluation

Min-Jung Kong, *Suk-Pyo Hong*
Kyung Hee University

A comparative study of leaf epidermal microstructures in *Persicaria* section *Cephalophilon* was investigated by light microscopy (LM) and scanning electron microscopy (SEM) on 22 taxa in order to evaluate their systematic significance. The leaves are either amphistomatic or hypostomatic in the studied taxa, and the both found with similar number of taxa, and the size range of the guard cells varied among 16.96–41.96 x 13.30–37.30 μm; the small ones was found in abaxial side of *P. strindbergii* (17.34–24.02 x 13.41–17.90 μm) and abaxial side of *P. glacialis* var. *glacialis* (17.98–21.87 x 13.39–18.21 μm), while the largest one occurred to adaxial side of *P. chinensis* var. *chinensis* (32.97–35.84 x 26.14–30.63 μm). Anomocytic and anisocytic stomata complex were usually occurred on the adaxial and abaxial epidermises of same leaf. Paracytic type is a characteristic feature of both *P. palmata* and *P. criopolitana*. The anticlinal wall patterns of subsidiary cells on both sides varied from straight to sinuate. The striation of cuticles was observed in 17 taxa, and it was distributed only in adaxial side (except *P. microcephala* var. *microcephala* – on both sides). Seven different types of trichomes were found: five types of non-glandular trichomes (NGT; stellate trichome with smooth surface, multiseriate trichome with smooth or striate surface, and uniseriate trichome with smooth or papillose surface), and two types of glandular trichomes (GT; peltate gland and long stalked pilate gland). The peltate GT consisted of 4-, 6-, 8- or multi-celled head. The stellate NGT was only found in *P. palmata*. The systematic significance of various stomatal characters and trichome types in *Persicaria* section *Cephalophilon* is discussed.

P0463

Functional differentiation between the inner and outer leaves in a mechanical support by a pseudostem of *Veratrum album* subsp. *Oxysepalum*

Lingshuang Gu[1], *Yasuo Konno*[2]
1. Henan Polytechnic University
2. Obihiro University of Agriculture and Veterinary Medicine

The pseudostem of *Veratrum album* consists of radical leaves, which have tubular and concentrically aggregated petioles. We examined a hypothesis that the major role of the inner leaves is to raise the leaf blades higher for increased photosynthesis, while that of the outer leaves is to mechanically support the inner leaves at the expense of displaying their leaf blades. The removal of outer leaves resulted in the collapse of the remaining inner leaves, showing outer leaves provide important support for inner leaves. The estimation of mechanical properties for the constituting leaves revealed that inner leaves possess greater mass of leaf blades for their capacity of mechanical support them compared to outer leaves. These results uphold the hypothesis that the primary role of inner leaves is to display leaf blades for photosynthesis, while that for outer leaves is to mechanically support the less stable inner leaves.

P0464

Nuclear and plastid phylogeny of *Lotus* (Leguminosae) and phylogeography of *Lotus corniculatus* complex

Tatiana Kramina, *Galina Degtjareva, Tahir Samigullin, Carmen Valiejo-Roman, Dmitry Sokoloff*
Lomonosov Moscow State University

Lotus comprises ca. 130 species of Old World herbs, semishrubs and shrubs, including important pasture crops and a model legume, *L. japonicus*. Earlier nrITS-based phylogenies were incongruent with all taxonomic classifications of the genus. In particular, members of the former genus *Dorycnium* were unexpectedly placed near species of *L.* sect. *Lotus*. We present a global phylogenetic study of *Lotus* that uses both plastid (*psb*A-*trn*H IGS and *rps*16 intron) and nuclear (ITS and ETS) markers. The rooting of the *Lotus* phylogeny, its major clades and basic biogeographic patterns are discussed. The placement of the segregate genera *Dorycnium* and *Tetragonolobus* in the synonymy of *Lotus* was confirmed. Analyses of plastid data strongly supported a basal split of *Lotus* into two clades, one comprising species of sect. *Lotus* plus those traditionally placed in *Dorycnium* and the other including the rest of the species. The former clade has a centre of species diversity in Europe and N Asia, and the latter in Macaronesia, Africa and S Asia. Only the "Southern" clade is resolved in analyses of nrITS and nrETS data. Trees inferred from plastid, nrITS and nrETS data shared the occurrence of several smaller clades corresponding to traditionally recognized infrageneric taxa or species groups as well as the occurrence of some well-supported clades that differ from traditional taxonomic concepts. Several instances of incongruence were documented between nuclear and plastid markers and between the two nuclear markers, possibly resulting from reticulate evolution. The extant geographic patterns of *Lotus* are likely biased by at least one round of area fragmentation followed by expansion coupled with extensive speciation associated with the complex history of the Mediterranean biome. *Lotus corniculatus* complex that belongs to the section *Lotus* is the most agriculturally important, but taxonomically problematic group of the genus. The presence of at least two ploidy levels and interspecific hybridization confuses the system of the group. Phylogenetic relationships among *L. corniculatus* complex and other groups of the section *Lotus* vary in reconstructions inferred from different DNA markers. However, all studies clearly demonstrate a highly supported monophyly of the *L. corniculatus* complex. Phylogenetic analysis of the section *Lotus* using *trn*F-L IGS and *trn*L intron of cpDNA revealed taxonomic significance of indels in these DNA regions. A haplotype network of the *L. corniculatus* complex constructed using statistical parsimony method in TCS program allowed to make the following suggestions concerning phylogeography of the group: we revealed a specimen of uncertain morphology with a haplotype related to *Lotus conimbricensis* (the closest relative of the *L. corniculatus* complex), which may shed light on the origin of the complex; a haplotype from one of West European glacial refugia (Systema Central, Spain) found in *L. alpinus* is the closest to a hypothetical ancestral haplotype of the *L. corniculatus* complex; derived haplotypes were spreading eastward from W. Europe and gave two peaks of diversity: high in C. and E. Europe and a smaller one in Asian part of Northern Eurasia. The origin of East African and Japanese lineages of the complex is also discussed.

T2

P0465

Morphobiological features of the nomenclatural type of *Allium nigrum* L., nom. cons.

*Lyudmila Krasovskaja, **Igor Levichev***
Komarov Botanical Institute of the Russian Academy of Sciences

Goal of research. To describe the ontogenetic features of *A. magicum* as an independent taxon not identical to *A. nigrum*.
Methods. Living plants in the nature and under cultivation were used for long-term studies. The main stages of *A. magicum*'s ontogenesis from seedlings to the pre-senile stage are shown (habitually and on sections). The development of seedlings is showcased using transparent containers made of organic glass.
Results. The absence of black ovaries both in annual cycles, and in ontogenesis is demonstrated. Formation of a vegetative bulbil on the tip of a top leaf, a unique feature of *A. magicum* mentioned by Theophrastus and represented by a number of authors before Linnaeus, is steadily combined with many other signs which are absent in related species including *A. nigrum* sensu Linnaei. Demonstrated are features of the replacement shoot and vegetative reproduction, including the addorsed and gorgonoid position of bulbs. The gemmiferous leaf is interpreted to belong to the nature of phylloclade. Explained traits: the ability to embed the base of cotyledon into the soil to 20 cm deep, starting and final localization of a digeotropic growth area, and the seedling structure. Sometimes the cotyledon continues growing, but it unable to push the bulb deeper. Therefore, the bulb rotates by 180 degrees, while the root and cotyledon form a characteristic “S-shaped” curve.
Discussion. Conservation of the name *A. nigrum* as a standard sample of *A. magicum* violates against the basic principle of typification – to serve as a standard of species binomen, and excluded the use of the last name in taxonomy. It is necessary to cancel conservation and select the epitype from among the *A. nigrum* forms which are still cultivated in botanical gardens of European countries.

P0466

Pollen tracking in the food-deceptive, flower colour dimorphic orchid *Dactylorhiza sambucina* showed no predominant switching behaviour of pollinators

Agnes M. Groiß[1], *Andreas Braun*[1], *Josef Greimler*[2], ***Matthias Kropf***[1]
1. University of Natural Resources and Life Sciences, Institute for Integrative Nature Conservation Research
2. University of Vienna, Department of Botany and Biodiversity Research

The non-rewarding (i.e. nectar-free) orchid *Dactylorhiza sambucina* is assumed to cheat its pollinators effectively by showing two flower colour morphs. This hypothesis implies common pollinator switches between yellow- and purple-flowering plants. However, pollen flow within and between morphs has never been tested under field conditions by using a pollen tracking technique. We studied a dimorphic population located in the southern “Wienerwald” (Vienna Woods) in Austria to obtain frequencies of inter- and intra-morph pollinator switches. Pollinia were marked using fluorescent dye powder to observe pollen flow, i.e. the spatial distribution of pollen, pollen export and deposition (i.e. male and female reproductive success) as well as the transport distances from donator to receptor plants. For specifically analysing the switching behaviour of (bumblebee) pollinators, we labelled yellow- and purple-flowering plants morph-specifically using two different dye colours. In our study system, yellow-flowering plants were dominant (70% in 2006; 67% in 2014). In the study year 2014, we labelled 582 pollinia from yellow- and 239 from purple-flowering individuals reflecting the yellow-dominance (71%). In total, 473 marked pollinia were exported by potential pollinators, of which 72.3% originated from yellow flowers. We found that movements of pollinators from yellow to yellow (YY) flowers dominated the four possible pollination events by far (i.e. 93 of all 155 deposits of labelled pollen). Even considering the dominance of yellow-flowering plants in our study population, only 70 respective events (i.e. YY; out of 155) would have been expected, if switching behaviour was by chance. The purple intra-morph movements (i.e. PP) were also higher than expected (i.e. 24 instead of 17 expected), leading to disproportionately high YY- and PP-observation rates (X^2=25.154, df=3, p<0.0001). Therefore, the assumption that pollinators alternate randomly between colour morphs was not supported by our results. The longest pollen transport distance observed was 237m. Moreover, 135 manually conducted cross-pollinations on 47 individuals were evaluated: Seed viability analyses indicated no differences between the four possible crosses. Consequently, the dominance of the yellow morph at our study site could be the primary result of the most frequently observed cross-combination (i.e. YY.).

T2

P0467

Reproductive biology of *Anacamptis* (*Orchis*) *coriophora* (Orchidaceae): A broad pollinator spectrum mediates frequent outcrossing

*Susan El-Heliebi, Monika Kriechbaum, **Matthias Kropf***
University of Natural Resources and Life Sciences, Institute for Integrative Nature Conservation Research

In Central Europe, *Anacamptis* (*Orchis*) *coriophora* is a critically endangered species. Over the past decades, populations of this species have almost become extinct in vast areas. One of the few large, still existing populations was studied in the “Donau-Auen” (Danube floodplain) National Park in the Viennese Lobau (Austria). The aim of our study was to draw conclusions from the reproductive system of this nectariferous orchid with respect to its dependence on (different) pollinators. Another aspect discussed in our analysis is the role of cross- and self-pollination in *A. coriophora*, including geitonogamy. Direct pollinator observations showed that *A. coriophora* is attractive for a wide range of pollinating and visiting insects. In addition to (solitary) bees and bumblebees being common (and expected) pollinators of this species, pollinating Coleoptera and Diptera were also frequently identified. Observed plants mainly attracted the following species: *Apis mellifera*, *Lasioglossum xanthopus*, *Bombus terrestris*, and *B. humilis* (Hymenoptera: 52.8% of all observations), but also *Oedemera femorata, Oxythyrea funesta* (Coleoptera: 44.4%*)* and *Eristalis tenax* (Diptera: 2.8%). Based on pollination experiments (hand pollination and bagging of flowers with fine netting for pollinator exclusion to test possible reproduction mode of agamospermy, spontaneous and manual self- and cross-pollination) and subsequent seed viability tests, self-compatibility and dependence on pollinator action were documented. Furthermore, the species is not capable of asexual reproduction by agamospermy. Due to duration of stay and pollinator behaviour of some of the observed insects (e.g. Coleoptera) and given the short bending times of the species (bending starts already after 18.7 ± 5.8 sec), increased geitonogamy rates must be expected. In summary, allogamy and geitonogamy were identified as the dominant reproductive modes of *A. coriophora* and the optimal reproductive success is a result of cross-pollination by various insects leading to high overall fruit set. Pollinator frequencies, reproductive success, and recent population trend lead to the assumption that the population of *A. coriophora* studied here is currently very vital.

A pheromone-related switch on mating behaviors in ferns: A case in *Deparia lancea*

Li-Yaung Kuo[1], *Cheng-Wei Chen*[2], *Yu-Ling Hung*[3], *Chia-Wen Ko*[2], *Fay-Wei Li*[1], *Wen-Liang Chiou*[4], *Chun-Neng Wang*[3]

3. Instituite of Plant Biology, National Taiwan University
4. Dr. Cecilia Koo Botanic Conservation and Environmental Protection Foundation/ Conservation Center

Ferns are the second largest group among extant vascular plants, and have evolved a complex mating system. Diploid ferns often develop dioecious gametophytes through the regulation of a sex-determination pheromone – antheridiogen. Mature gametophytes secret antheridiogens that induce nearby young gametophytes to differentiate into males (i.e. with only sperm-producing antheridia), and thus promote outcrossing. In contrast, in poylploid ferns, gametophytes tend to be bisexual, having both antheridium and archegonium simultaneously, and under the most extreme situation, a single gametophyte can self infragametophytically, resulting in a complete homozygous sporophyte. However, to date the mechanism for such different modes of gender expression between diploid and polyploid ferns has remained unclear. To shed light on this, we compared the gametangium development in autohexaploidy *Deparia lancea*, and its conspecific diploids. We found that in mix-aged gametophyte populations, the hexaploids are biased being bisexual, while the conspecific diploids displayed a higher degree of dioecy. In the further transplant experiments, we found that for the hexaploids, gametophytes in the later developmental stages, which were matured enough to produce archegonia, were most sensitive to antheridiogen, and, on average, produced more antheridia per individual. By contrast, gametophytes of the diploids were most sensitive to antheridiogen during the earlier stage when the notch meristem has not yet developed. Our results imply that the inbreeding syndrome in polyploidy ferns can be achieved via delaying sensitivity to antheridiogen, and, consequently, their gametophytes can produce both male and female gametangia at the same developmental stage. Our finding is the first to provide direct evidence supporting that a mating system switch in ferns involves a heterochronical regulation on antheridiogen sensitivity.

Pollen and NPP evidences of the ecosystem’s response to environmental changes during the Middle-Late Holocene in the Bale Mountains (East Africa)

Evgeniya Kuzmicheva
A.N. Severtsov Institute of Ecology and Evolution, Russian Academy of Sciences

The study of vegetation and climate dynamics is one of the most topical issues in view of current global changes. Research in this field provide a way to determine trends in natural and anthropogenic environmental changes and use it to predict the ecosystem`s response to global changes in the future. Here we present the results of pollen and non-pollen palynomorphs (NPP) analyses of the zoogenic deposit found in the Bale Mountains (Ethiopia) (06°43′N, 39°44′E; 2700 m a.s.l.). This deposit type is a unique source of palaeodata in default of the common deposit types such as peat and lacustrine sediment. We made an attempt for the NPP analysis, the first known for Ethiopian deposits. The deposit is very interesting in palaeoenvironmental aspect since it is located on the southern slope of the Bale Mountains, characterized by unique forest area (called “Harenna forest”), which is almost gone in East Africa. The age-depth model was built on the basis of the radiocarbon dates; it shows that sedimentation began about 6500 calibrated years (cal yr) BP. Pollen spectra in 6500-4600 cal yr BP are characterized by the predominance of non-arboreal palynotypes (mainly grasses (Poaceae) and sedges (Cyperaceae)), which most probably indicate the absolute dominance of the bamboo. Such vegetation points on wet climate of the African humid period (AHP). At about 4600 cal yr BP vegetation changes indicate the decrease of humidity: Cyperaceae falls off, and Poaceae concentration also drops dramatically in response to the end of the AHP. The accumulation rate of Katcha deposit significantly decreases at about 4600 cal yr BP, which also points on the climate aridization trend. At the same time *Celtis*-type appears in significant concentrations in the spectra. Presumably around 4600 cal yr BP bamboo thickets become sparser in response to the gradual decline in humidity, while *Celtis*, which is considered as a forest species, is rapidly colonizing the areas cleared from forest, capturing all suitable habitats. The climate aridization continues in further period: around 2500 cal yr BP there is extensive development of dry forests type of olive (*Olea*), *Hagenia* and *Podocarpus*. There are no distinct signals of climate change during the last two thousand years. Perhaps the climate signals are masked by other factors. For instance, similar pollen spectra (with numerous and asynchronous changes in pollen concentrations) are recorded for recurrent wild fires. Increase in the concentration of *Gelasinospora* cf. *cratophora* ascospores (HdV-1093) also indicates frequent wild fires. Frequent fires are most likely caused by human activities in the Harenna forest over the past 2000 years. Direct anthropogenic impact was recorded during the last 1000 years with an increase in the concentration of non-pollen palynomorphs such as *Delitschia* spp. (UG-1066), *Podospora*-type (HdV-368), *Cercophora*-type (HdV-1013), and *Sordaria*-type (HdV-55). This indicates an intense development of the cattle breeding. This research was funded by the Joint Ethiopian-Russian Biological Expedition, the Russian Fund for Basic Research (Grant No. 16-34-00292,15-04-04721) and the Russian Programs 'Origin and Evolution of the Biosphere', 'Wildlife' and 'Fundamental Basics of Biological Resources Management'.

The allopolyploid origin of *Dryopteris dilatata* (Hoffm.) A. Gray and how gene loss can give misleading results

Dennis Larsson[1], *Catarina Rydin*[1,2], *Niklas Wikström*[1,2]
1. Stockholm University, Department of Ecology, Environment and Plant Sciences, SE-106 91 Stockholm, Sweden
2. Bergius Foundation, the Royal Academy of Sciences, Box 50005, SE-104 05 Stockholm, Sweden

The origin of putative allotetraploid *Dryopteris dilatata* (Hoffm.) A. Gray has recently been disputed. The hypothesis that *D. dilatata* is an allotetraploid hybrid between the diploid *D. expansa* (C. Presl) Fraser-Jenk. & Jermy and *D. intermedia* (Muhl. ex Willd.) A. Gray has been challenged by an European team who claims *D. dilatata* is autotetraploid since they only found one expansa-type copy in the nuclear region pgiC. An American team however found two copies in the nuclear regions pgiC and GapCp and claims *D. dilatata* is indeed allotetraploid. In order to settle the dispute a phylogenetic analysis was done on 30 *D. dilatata* specimen (26 herbarium specimen and 4 fresh specimen) using the nuclear regions pgiC and GapCp. By using copy-specific primers designed to mismatch on one of the two copies, both copies in both gene regions were successfully sequenced. The copies found showed either a common origin with *D. expansa* or with *D. intermedia*. The results are consistent with the hypothesis that *D. dilatata* is an allotetraploid hybrid between *D. expansa* and *D. intermedia*. Furthermore, the study show that alleles and entire copy types have been lost in some specimen, most likely through recombination between homeologous chromosomes of the parent genomes. Of the 21 specimen which was successfully sequenced for both loci, 16 had multiple copies in one or both loci and of those, 6 had only one copy-type in one locus while having two copy-types in the other locus. These findings explain the results of the European team. The specimens they collected had either lost theirintermedia-type copies through the before mentioned recombination, or was actually specimens of *D. expansa*, a possibility that can only be conclusively excluded if the ploidy level is known. These findings show that recombination can alter the presence of copies in allopolyploids and that it happens often enough that it can give misleading results and should therefore be taken into account when making phylogenies involving allopolyploids.

A panmictic Amazonian world?

Alice Ledent[1], *Patrick Mardulyn*[2], *Sylvia Mota*[3], *Rick Overson*[4], *Jairo Patiño*[5], *Marta Pereira*[6], *Norman Wickett*[4,7], *Charles Zartman*[6], *Alain Vanderpoorten*[1]
1. Université de Liège (ULg)
2. Université Libre de Bruxelles (ULB)
3. Naturalis Biodiversity Center (NBC)
4. Chicago Botanic Garden (CBG)
5. Instituto de Productos Naturales y Agrobiología (IPNA-CSIC)
6. Instituto Nacional de Pesquisas da Amazônia (INPA)
7. Northwestern University (NU)

Understanding connectivity over different spatial and temporal scales is fundamental for biodiversity conservation and management. The Amazonian rainforest, one of the most diverse biodiversity hotspots, has experienced dramatic range contractions and expansions due to Pleistocene climate oscillations, and its human-induced fragmentation has accelerated at an unparalleled pace in the course of the Anthropocene. In this context, epiphytes, with their relatively short life-cycles, offer an ideal model to investigate the impact of past and present fragmentation on patterns of genetic structure and diversity. Due to the necessity to switch from one host tree to another, or from one leaf to another, epiphytic bryophytes typically exhibit high dispersal syndromes. In line with such high dispersal capacities, recent metacommunity analyses have arisen the intriguing question that Amazonian epiphytic bryophyte communities are homogeneous across very large spatial scales, ultimately raising the notion that they might behave as a basin-wide panmictic population. Here, we implement fine-scale population genetic analyses to address the following questions: (i) Do Amazonian epiphytes exhibit population structure at regional (< 500 km) scale; (ii) If the hypothesis of a panmictic population is rejected, (iia) at which spatial scale does genetic structuring occur, and (iib) do neutral (isolation-by-distance) or ecological (isolation-by-ecology) processes shape patterns of genetic variation? We sampled exemplars of 15 epiphytic bryophyte species from two ecologically contrasted forest types (lowland rainforest and white-sand forest) in a 50,000 km^2 area in the middle Rio Negro. Genome-wide genetic data were produced using Genotyping By Sequencing. To circumvent severe taxonomic issues in challenging groups, which, like the Calymperaceae, are dominant in the epiphytic flora, we first implemented species delimitation analyses to sort-out specimens taxonomically. We then described the fine-scale genetic structure of each species and performed isolation-by-distance analyses to detect significant spatial genetic structuring. We finally determined whether isolation-by-distance or ecological filtering contribute to the observed patterns of genetic variation. The study will provide key information on the populations dynamics of highly mobile species integral to the iconic Amazonian forest, which may further be employed to refine future conservation policies in the face of accelerating climate change and anthropogenic-mediated deforestation.

Dynamic evolution of the chloroplast IR borders in Cyperaceae

Bora Lee, *Sangtae Kim*
Sungshin Women's University

Cyperaceae is the third largest family in monocots, comprising ca. 5,000 species in the world. Our previous study, which is the first report of the chloroplast genome sequence in Cyperaceae (*Carex siderosticta*), showed the potential of the IR border regions in the phylogenetic study including DNA barcoding in the family. We explored the chloroplast IR border sequences in 84 Korean Cyperaceae species to test the phylogenetic utility of these regions. We sequenced four IR border regions (B1 for LSC/IRa, B2 for IRa/LSC, B3 for LSC/IRb, and B4 for IRb/SSC) and determined the IR borders by comparison of two complementary IR sequences. Surprisingly, in some cases, there are "transitional zones" in two IRs of which sequences are slightly different. We hypothesized two different scenarios to explain the expansion/reduction process for the IR regions: 1) gradual and random substitutions in both IRs and 2) deletion/insertion of a region of sequence in one IR. We found cases showing both scenarios in our study, indicating that the evolution of the IR borders in Cyperaceae is dynamic and is not explained by only one scenario. Phylogenetic analyses of four IR border regions showed similar clades as previous phylogenetic studies and provided 56.7% species resolution for DNA barcoding. Plotting of the expansion/reduction status of the IR borders on the phylogenetic tree addressed the evolutionary pattern of IR border changes in the process of diversification. Clade-specific expansions and reductions were detected in the tree. For example, expansion of 504 bp in B2 border was found in a clade of *Trichophorum, Eriophorum, Rhynchospora,* and a part of *Scirpus.*

Reticulate evolution in *Asplenium anogrammoides* complex from Korea

Chang Shook Lee[1], *Kyong-Sook Chung*[2], *Sung Hee Yeau*[3], *Atsushi Ebihara*[4]
1. Department of Science Education, Ewha Womans University, Seoul 03760, Korea
2. Department of Medicinal Plant Science, Jungwon University, Goesan 28023, Korea
3. Department of Science Education, Ewha Womans University, Seoul 03760, Korea
4. Department of Botany, National Museum of Nature and Science, Tsukuba 305-0005, Japan

Asplenium anogrammoides has been hypothesized as the hybrid between *A. sarelii* and *A. tenuicaule* (allotetraploid; Lin & Viane, 2013). A recent cytological study revealed the ploidy level of *A. sarelii* and *A. tenuicaule* as a diploid (2x, n=36). *A. sarelii* (Doldamgosari in Korean) has been recognized in Korea, but it was proposed that some populations of the species should be verified as *A. agnogrammoides* (4x, n=72; counted only from Japanese populations) according to the taxonomic scheme by Lin & Viane (2013). The natural hybrid taxa (autoploidy and/or allopolyploidy) of *Asplenium* occur often in sympatric regions with putative parental species. *A. pekinense* is an autotetraploid of *A. sarelii.* In Korea, great morphological variations in *A. anogrammoides* have been found within populations. Based on their sympatric species and morphological characters, we hypothesize that the hybrid *A. anogrammoides* has undergone additional hybridization events with *A. pekinense*, *A. sarelii*, or *A. tenuicaule*, resulting the hybrid taxa with a series of polyploidy levels from diploids to hexaploids. To evaluation the taxonomic delimitations and phylogenetic relationships of *A. anogrammoides* and relative taxa; and estimate the hybridization origins of them, we present the results of phylogenetic analyses of morphological, chloroplast DNA sequence, and DNA content (flow cytometry) data; and discuss reticulated hybridization processes in the *Asplenium anogrammoides* complex (4x and 6x).

P0474

Reevaluation of two new taxa of *Hypodematium* (Hypodematiaceae) from Korea

Chang Shook Lee[1], *Kanghyup Lee*[2], *Kyong-Sook Chung*[3], *Sung Hee Yeau*[4]
1. Department of Science Education, Ewha Womans University, Seoul 03760, Korea
2. Korea National Arboretum, Pocheon 11186, Korea
3. Department of Medicinal Plant Science, Jungwon University, Goesan 28023, Korea
4. Department of Science Education, Ewha Womans University, Seoul 03760, Korea

About 16 species of the genus *Hypodematium* Kunze are distributed in limestones or rock crevices of subtropical and temperate regions of Asia and Africa with high species diversity of 12 species in China (8 endemic species). In Korea, it has been known only one species, *H. glanduloso-pilosum.* However, we have recently found one new taxon and one unrecorded taxon of the genus *Hypodematium* on rocks at a limestone mountain in Okcheon and Yŏngwŏl, Korea, respectively. For the new taxon, *Hypodematium angustifolium* C.S. Lee & K. Lee is newly given based on its morphology. Its morphology is most similar to *Hypodematium sinense* known from Shantung, north China. In addition, *Hypodematium squamuloso-pilosum* Ching is newly found in Korea, which is widely distributed in only China as an endemic plant. Traditionally, these taxa were often distinguished by several vegetative characters such as pinnatifid lamina, glandular hairs, dense or rare long white hairs or scales on stipes and rachis, and longer and narrower or linear lanceolate scales on stipe bases. As an ongoing attempt to determine the phylogenetic status between two new taxa in Korea and related taxa of *Hypodematium*, we have extensively analyzed two new and relative taxa of *Hypodematium* populations from China, Japan and Korea. The cpDNA phylogenetic analyses and flow cytometry data suggest that *H. angustifolium* and *H. squamuloso-pilosum* are genetically distinct species in a diploid (2x) clade.

Evidence for narrow species concepts in the subcosmopoli-

tan leafy liverwort genus *Lejeunea*

Gaik Ee Lee[1], *Julia Bechteler*[2], *Matt Renner*[3], *Jochen Heinrichs*[2]

1. University of Malaysia Terengganu, Malaysia

2. Ludwig Maximilian University, German

3. Royal Botanic Gardens and Domain Trust, Sydney

The recognition of all extant plant species is an ongoing challenge despite remarkable progress since Linnaeus. Liverworts are a prime example illustrating difficulties in establishing reliable species circumscriptions, reflected in strongly deviating estimates of the global species diversity. Estimating liverwort species richness may be complicated by their rather conservative morphology and limited range of taxonomically relevant characters. Nevertheless, these characters are required in taxonomic research relying on the identification of diagnostic morphological differences. Molecular investigations have often identified complex genetic structuring within morphologically rather uniform liverworts, suggesting the frequency of morphologically cryptic species is higher than currently appreciated. Molecular phylogenies have also enabled reconsideration of morphological evidence, and have enabled researchers to identify out subtle morphological differences between species that were earlier united under a single binomen. The subcosmopolitan genus *Lejeunea* includes between “more than 100” and 300 species, and is well known for its extensive morphological homoplasy. Molecular data are therefore essential for reconstructing relationships between taxa and deriving robust species hypotheses that reflect actual diversity. In the framework of an ongoing taxonomic revision of *Lejeunea* in Asia, morphology has been critically analyzed and revised within the context of an integrative (molecular-morphological) approach. The investigation has led to a deeper understanding of some of morphologically vague and controversial species complexes and also identified several new species. The newly produced data point to narrow species concepts and suggest that species diversity within *Lejeunea* is likely closer to higher estimates, than to conservative estimates that consider species to be morphologically (and ecologically) variable.

Systematic study of *Chrysosplenium* L. series *Pilosa* Maxim. (Saxifragaceae)

Yong-In Kim[1], *Seong-Hyun Cho*[1], *Jung-Hoon Lee*[2], *Bo-Yun Kim*[2], *Roman V. Doudkin*[3], *Young-Dong Kim*[2]

1. International Biological Material Research Center, Korea Research Institute of Bioscience and Biotechnology

2. Multidisciplinary Genome Institute and Department of Life Science, Hallym University

3. Botanical Garden-Institute FEB RAS

Chrysosplenium series *Pilosa* Maxim. consists of 11 to 15 taxa, mainly distributed in NE Asia. Many species of the series are known to exhibit severe morphological variations, which led to proposals of many intraspecific taxa and synonyms. To address taxonomic issues pertaining to series *Pilosa*, molecular phylogenetic trees were reconstructed for 11 taxa using nuclear (ITS) and plastid (*psb*A-*trn*H, and *psb*K-I) sequence data. A total of 116 accessions representing the ingroup taxa was collected from China, Japan, Korea, Russia and Taiwan, covering whole distributional range of the series. For some problematic taxa, habit of sterile branches and micro feature of seeds were critically reexamined as well. In general, results from the ITS data was turned out to be useful in the species delimitation of the examined taxa, while the trees based on plastid sequences did not agree with species tree. Lacking the evidence for hybridization among the species, it was postulated that the incongruence between the plastid sequence trees and species delimitation was due to incomplete lineage sorting of the plastome. Several taxa, which have been treated conspecific to other taxon, were found to form distinct clades, respectively. For example, *C. villosum* has long been treated as a synonym of *C. valdepilosum* (=*C. pilosum* var. *valdepilosum*). However, multiple accessions of *C. villosum* collected from its type locality formed a distinct clade, well segregated from a *C. valdepilosum* clade. Likewise, Korean populations of *C. sphaerospermum* (formerly recognized as *C. barbatum*) formed a distinct clade, segregated from Japanese populations of *C. sphaerospermum*. In addition, *C. album* var. *stamineum* was turned out to merit regaining of its species status as it exhibited a sister group relationship with *C. pseudopilosum* rather than with *C. album* var. *album*. In this study, we detected at least four additional novel lineages from Russia and Korea, and some of the lineages were found to have diagnostic morphological characters, especially formerly overlooked feature such as habit of sterile branch. Our data indicated that the morphology of sterile branch at after fruiting as well as seed coat is important for the species delimitation within the series.

P0477

Taxonomic identity of *Astilbe koreana* (Saxifragaceae) based on EST-SSR data

Jung-Hoon Lee[1], *Yong-In Kim*[2], *Seong-Hyun Cho*[2], *Bo-Yun Kim*[1], *Qiang Fan*[3], *Young-Dong Kim*[1]

1. Multidisciplinary Genome Institute and Department of Life Science, Hallym University, Chuncheon

2. International Biological Material Research Center, Korea Research Institute of Bioscience and Biotechnology, Daejeon

3. State Key Laboratory of Biocontrol and Guangdong Provincial Key Laboratory of Plant Resources, Sun Yat-sen University

Astilbe (Saxifragaceae) is a well-known herbaceous genus including various ornamental taxa such as *A. chinensis* and *A. japonica*. *A. koreana* is a Korean endemic species, which can be exploited as an additional source of garden cultivars. The species is commonly distributed in central and southern part of Korean peninsula. Its taxonomic identity, however, has been questioned by various authors due to the paucity of unambiguous morphological and molecular characters distinguishing the species from its closely allied taxa. Currently, *A. koreana* is treated as a synonym of *A. grandis*, *A. chinensis*, and *A. rubra* var. *divaricata* (*A. rubra* sensu Hara), depending on taxonomists. Although recent molecular phylogenetic studies based on ITS data indicate that *A. grandis* is the most distinct species among the four taxa, the relationships and taxonomic identity of the rest species are yet to be clarified. We have developed EST-SSR markers to examine more detailed phylogenetic relationships between *A. koreana* and its three relative taxa. Using the transcriptome data of *A. koreana*, a total of 20 EST-SSR loci, each consists of 2 to 7 alleles, were successfully selected. A total of 199 accessions from 10 populations, representing *A. koreana* (100 accessions - central and southern Korea), *A. chinensis* (20 accessions - China, Jilin; 20 accessions - Russia, Primorsky Krai), *A. rubra* var. *divaricata* (19 accessions - central Korea), and *A. grandis* (20 accessions - China, Hunan; 20 accessions China, Guangdong) were employed to examine the population differentiation and phylogenetic relationships. As a result of genotyping for the 20 loci, *A. koreana* and *A. grandis* turned out to be tetraploid species while *A. chinensis* and *A. rubra* var. *divaricata* were confirmed as diploid taxa. The UPGMA dendrogram based on Nei's genetic distance clustered the 10 populations into two main groups consisted of *A. grandis* populations and populations of the rest three taxa, which is well congruent with previous ITS trees. All accessions of *A. rubra* var. *divaricata* and *A. chinensis* populations shared most of the alleles, being clustered as a single group in Discriminant Analysis of Principal Component (DAPC). The total number of alleles amplified from 20 loci of *A. koreana* was 105 (3 to 9 alleles per locus), among which 52 alleles (1 to 6 alleles per locus) observed from 18 loci were the ones exclusively found within the species. This suggests that *A. koreana* might be a distinct evolutionary unit, and not be originated by direct autopolyploidization of its relative taxa. On the other hand, two populations of *A. grandis* formed two distinct geographical clusters in DAPC, with high degree of genetic differentiation. The clustering result is also in accord with our expanded ITS tree, in which the representative accessions of the geographic clusters positioned in two different clades. These results suggest that utility the of newly developed EST-SSR markers can be extended to address taxonomic issues of neighboring taxa as well as *A. koreana*.

P0478
A phylogenetic study of the genus *Scutellaria* based on multiplex amplicon sequencing with the NGS platform

Yoonkyung Lee, *Sangtae Kim*
Sungshin Women's University

Scutellaria L. is the second largest genus of the Lamiaceae, with approximately 468 recognized species. The current classification system based on the morphological study contains seven sections placed in two subgenera, subgenus *Scutellaria* and subgenus *Apelthanthus*. Twelve morphological species-groups have been suggested in the section *Scutellaria*, the largest section in the genus (ca. 240 species), without any taxonomic rank. Molecular phylogenetic studies to test the monophyly of each subgroup in the classification system have not yet been performed. Advances in Next Generation Sequencing (NGS) and in high-throughput sequencing of multiple amplicons using dual-index sequences have enabled us to perform quick and cost-effective phylogenetic studies. In this study, we selected 224 taxa (198 species) representing each subgroup of *Scutellaria,* which account for approximately 42.3% of the recognized species in *Scutellaria*. Ten fast-evolving DNA regions in the chloroplast genome (*ccsA*, *matK*, *ycf4~cemA*, *ndhG*, and *ndhA*) and in the nuclear genome (ITS, ETS, *LEAFY*, *XDH*, and *APETALA3*) were selected based on the analysis of the three previously reported chloroplast genomes (*Tectona, Ajuga, Premna*) and phylogenetic studies in Lamiaceae. Amplicons from each taxon were labeled with seven bp dual-index sequences. Approximately 2,500 amplicons were combined and sequenced at once using the MiSeq platform. The result showed the first molecular phylogenetic relationship among species of *Scutellaria* and it will be the basis for a new classification system in the genus.

Ferns are the second most diverse major plant radiation with over 400 million years of evolutionary history. The fern fossil record is rich and phylogenetic relationships of living ferns are well understood. It has been suggested that the rise of angiosperms during the Cretaceous dramatically affected the fern evolution, either by causing major extinctions as inferred from the fossil record, or resulting in massive adaptive radiation of epiphytic fern lineages. This background makes ferns an ideal group to study macroevolutionary questions, such as the roles of biotic and abiotic factors in diversification through time. In this study, we modelled the changes in fern biodiversity and estimated their origination and extinction rates from the fossil record. We tested whether variation in these rates could be the result of interactions with other plant groups, responses to climate change or other environmental variables, and geological events. We developed and implemented a Bayesian model that jointly estimates 1) the factors that significantly correlate with the diversification dynamics of ferns, 2) whether these factors affect positively or negatively on the origination and extinction rates, and 3) the strengths of each correlation coefficient. Our model indicates diversity-dependent origination rate and environmentally driven extinctions. Angiosperm diversification is insignificant factor in our model, thus contrasting the previous hypotheses of fern diversification drivers. Different taxonomic lineages have succeeded each other as dominant fern groups. We investigated whether lineages that have passed their 'golden age' are less adaptive than currently expanding lineages by modelling the rate of niche evolution over the phylogeny of living species. Despite the dramatic diversification rate shifts observed in the phylogeny, we found no evidence that diversification rate changes correlate with rate of adaptation. We conclude that origination appears to be a largely neutral process unlinked with adaptation, and that environmentally driven extinctions are the main drivers of diversity dynamics.

Phylogenetic placement of the enigmatic groups within cyperid tree of life

Viktorie Brozova[2], ***Lenka Zaveska Drabkova***[1]
1. Institute of Experimental Botany and Intitute of Botany, the Czech Academy of Sciences
2. University of South Bohemia in Ceske Budejovice

Cyperids encompass around six thousand species from three main families: Cyperaceae, Juncaceae and Thurniaceae (incl. Prionicaceae). It has a primarily pantropical distribution originated in West Gondwana, South America and Africa. Previously, infrageneric classifications have been proposed but none has been based on molecular phylogenetic evidence in this complete view. Moreover, most studies have treated genera from only one geographical region. In this study, chloroplast and nuclear regions were employed from more than thousand species of cyperids covered all infrageneric groups from whole distributional range. *Rbc*L sequence data resolved a part of the supraspecific phylogeny, but many clades remain polytomic (e.g. tribe Cypereae, genus *Luzula*). For this reason, the noncoding regions were included (*trn*L intron, *trn*L-F intergenic spacer and ITS1-5.8S-ITS2). We intended to create hypotheses of relationships among families and within them and to test the classification of the subgenera and sections, but a primary goal was finding stable phylogenetic positions of some taxa or groups with enigmatic relationships (*Juncus capitatus*, genus *Cladium*). Furthermore, we tested the influence of different rooting and ingroup composition on the tree topology. All analyses (MP, ML and Bayesian) revealed several well-supported lineages (genera *Luzula*, *Cladium*, *Rhynchospora, Eleocharis* and few more). Additionally, the phylogenetic tree was dated with the Bayesian uncorrelated relaxed molecular clock incorporating cyperid fossil-based calibration. We will discuss the traditionally distinguished taxonomic groups of cyperids in the light of molecular data.

Evolution of reproductive isolation in outcrossing *Arabidopsis* species

Johanna Leppälä[1], *Martin C. Fischer*[2], *Alex Widmer*[2]
1. Division of Plant Biology, Department of Biosciences, University of Helsinki
2. Institute of Integrative Biology, Department of Environmental Systems Science, ETH Zurich

A major interest in speciation research is to identify reproductive barriers that arise early during divergence, rather than barriers that have evolved after reproductive isolation is complete. Therefore, we have focused on examining post-pollination and intrinsic postzygotic reproductive barriers between outcrossing, perennial *Arabidopsis* species, *A. arenosa*, *A. halleri* and *A. lyrata*, as well as between populations of *A. lyrata*. These three *Arabidopsis* species form genetically distinct entities, but natural hybrid zones and polyploid hybrid species exist. As reproductive isolation is usually formed jointly by several incomplete pre- and postzygotic barriers, we have estimated the strength of these individual barriers, starting from pollination barriers between species all the way to F_1 hybrid fertility. We found that within species, the first barrier that evolves is hybrid male fertility, whereas between species a strong seed developmental barrier exists, in addition to hybrid male fertility reduction. The correlation between genetic distance and the strength of the different postzygotic reproductive barriers is variable. We emphasize that reproductive barriers both within and between outcrossing *Arabidopsis* species are not fixed but instead are highly polymorphic and are thus ideally suited to study the evolution of reproductive isolation in plants.

Evolutionary modes and trends during origination of angiosperms

Igor Levichev
Komarov Botanical Institute of the Russian Academy of Sciences

Goal of research. To complement aspects of the telome theory of Walter Zimmermann with new results of comparative studying of the shoot structure in diverse groups of *Tracheophyta* and illustrate key aromorphoses of evolution using contemporary models, schemes and paleobotanic reconstructions.
Methods. The author used a set of techniques providing side-by-side comparison of modular units in the structure of sions of diverse taxonomic groups of contemporary and fossil plants with structural organization of sporophyte and gametophyte, pioneers of land of the Silurian period. Rather than ascertaining difference of forms and functions, novelty was provided by searching for similarity and continuity. Comparison was made not from the perspective of telome (an obvious structural ancestor), but its immediate derivative – mesome. More specifically, from the perspective of bipolar mesome and its historically later superposition and juxtaposition unit associations in metameric and colonial soma with individually different structural and modular organization within taxonomical groups. Another methodologic pool of original and new concepts was the system approach to institute of recapitulations within the Haeckel's basic biogenetic law and neotenic divergence. The stopping of organ morphogenesis at an early stage of intrabud development (which corresponds to embryonic condition of any ancestor) and extrabud grandization of such embryonic organ up to the actual sizes of the descendant's soma is the essence of neoteny in plants. The thesis of "Evolution is penetrated by neoteny" belongs to A. Takhtajan and it was not adequately understood by contemporaries. Material for study was mainly provided by live models in the nature and culture.
Results and discussion. On the land, in the support-free air environment, it was not telome but mesome that underwent evolution, and quantitative and qualitative interfaces of mesome based on their ageotropic and geotropic structures. Transformation of a 5-axis mesome with an equal dichotomy up to extreme manifestation of dichopodiality ("monopodium"), at obligatory right or left rotation of axes of each metameric module, reliably ensured vertical stability and 7-dimensional capture of individual scope

of habitat (on the land, in air and in the course of time). The ancestral bipolarity of telom went over to mesome and successively ensured the evolutional freedom of its simpodiya, *etc.* transformations during formation of the root, stele, phyllomes of various nature, geotropic branch of the sympodium, *etc.* At the same time, mesome bipolarity brought about the unprecedentedly ample opportunities for protection of bud and reproductive structures. It was preceded by emergence of the true leaf from a single lateral sporangium. Emergence of dimerism in angiosperms (coupling of ageotropic monopodium and geotropic sympodium in a single metamer) was an outstanding evolutional aromorphosis. In monocotyledonous plants, the superposition organization of innovation shoot from dimeric modules is outwardly not different from mesome structure of pioneers of land, but has different evolution history and specialization. Juxtapositional coupling of two dimer has signaled the emergence of dicotyledonous plants with their most perfect protection all growth localizations, which ensures their present domination on the planet. That said, ovules in both monocotyledonous and dicotyledonous plants always have 2 integuments. This, as well as many other structures (stipules, bicarinate prophyll of sympodium, 2 circles of tepals, intrasheath scales, *etc.*) demonstrate recapitulation of dimer to the embryonic and preceding ancestral fusion of “monopodium” and sympodium. Many of contemporary *Araceae* tend to form, on a single internode, 2 laminas, at a single lateral bud. Perhaps, this paves the way for transition to a new evolutionary level which ?an be notionally named “Gorgonoid angiosperms” in which two dimeric phytomers are consistently formed on a single shoot segment (on a common “podium”). Empirical, inflorescences of the gorgonian type consist of three and from many flowers.

Molecular evidence for natural hybridization between *Cotoneaster dielsianus* and *C. glaucophyllus*

Mingwan Li[1], *Sufang Chen*[1], *Renchao Zhou*[1], *Qiang Fan*[1], *Feifei Li*[2,3], *Wenbo Liao*[1]

1. Guangdong Key Laboratory of Plant Resources and Key Laboratory of Biodiversity Dynamics and Conservation of Guangdong Higher Education Institutes, Sun Yat-sen University, Guangzhou 510275, China

2. State Key Laboratory of Environmental Criteria and Risk Assessment, Chinese Research Academy of Environmental Sciences, Beijing 100012, PR China

3. College of Life and Environmental Sciences, Minzu University of China, Beijing 100081, PR China

Hybridization between distinct lineages accompanied by polyploidization has variously been viewed as a driving force of evolution and speciation in many plants, particularly in the family of Rosaceae. Interspecific hybrids can form isolated evolutionary units, especially when mechanisms increasing viability and fertility, like polyploidy and apomixis, are involved. The genus *Cotoneaster* is a good example to study the evolutionary process of hybridization associated with both polyploidy and apomixes, which has tetraploid taxa as high as about 70% including most of the apomictic taxa. Despite *Cotoneaster* hybrids are common in cultivation, nonetheless, no sufficient genetic evidence is provided for natural hybridization occurred in this genus, inevitably, relevant mechanism seems far from proven. In this study, we collected all the four *Cotoneaster* species (putative hybrid, *Cotoneaster dielsianus*, *C. glaucophyllus*, and *C. franchetii*,) distributed in Malipo county (Yunnan, China) and five low-copy nuclear genes and six chloroplast DNA fragments were sequenced. Additionally, the ploidy level of each taxon was estimated indirectly by flow cytometry technique, and the results showed that only *C. glaucophyllus* is diploid whereas other three taxa are tetraploidy. *C. dielsianus* and *C. glaucophyllus* were well separated with a total of 36 fixed nucleotide substitutions and one fixed 5-bp indel in the five nuclear gene data sets. All individuals of the putative hybrid showed chromatogram additivity at these 36 fixed sites. In the haplotype analysis, each taxon exhibited a low level of haplotype diversity, and no more than three haplotypes were observed at each of the five genes, and the two haplotypes in putative hybrid at each of five nuclear genes were shared with those of *C. dielsianus* and *C. glaucophyllus*, and no one was unique to putative hybrid. The haplotypes of *C. franchetii* were well separated from those of the three other taxa. Among the six chloroplast regions, *C. dielsianus* and *C. glaucophyllus* were well separated and individuals of hybrid were always identical with *C. glaucophyllus*. Our study provided convincing evidence for natural hybridization between *C. dielsianus* and *C. glaucophyllus*, and all the hybrid individuals were likely F1s. The hybridization was unidirectional and *C. glaucophyllus* was the maternal parent of the hybrid. Combining with the overlapping geographic range and the same flowering periods between biparental individuals and hybrids, we inferred the hybridization followed by polyploidization and produced one F1 individual with reproduction through apomixis. Therefore the genetic isolation might give rise to maintain species integrity between hybrids and the both parents despite hybridization. Disturbance of local habitats was deduced to be the major factor promoting hybridization. Given the small size of hybrid population, conservation strategy has been designed and we will continue to observe the influence of habitat destruction in only hybrid zone we found.

The life span of leaves in fern species of Taiwan

Pei Hsuan Lee[1,2], *Yao Moan Huang*[2], *Wen Liang Chiou*[2], *Ho Yih Liu*[1]

1. National Sun Yet-sen University

2. Taiwan Forestry Research Institute

Leaves of ferns could be vegetative organs and reproductive ones. Ferns can control the leaf lifespan by getting the return on investment and ensuring plant survival and population renewal. However, leaf lifespan is controlled by internal and external factors, including genes, sex, season and environment. The fern research team in Taiwan calculated leaf lifespan from measuring time intervals between emergence and senescence in the long term monitoring. The leaf lifespan about 30 species of Taiwan native ferns has been accumulated. It show different spans in different species, not exception in close-related species. The ratios of fertile/sterile leaves’ lifespan (F/S) in dimorphic species (n=3) were 0.16 – 0.20 and those in monomorphic ones (n=27) were 0.76 – 1.82. The fertile leaves in the dimorphic species were 4 – 5 times shorter in life than the sterile ones, but it’s almost the same between the fertile and sterile leaves of the monomorphic species. These situations mean that the fertile leaves of the dimorphy are senescent after spore release in very short time, and the ones of the monomophy are still alive for photosynthesis after spore release. The emerged seasons could affect the leaf lifespans, for example that the spans of sterile leaves of *Osmunda cinnamomea* were longer in the early emergence than in the late one. But the applicable species in this factor appears to be limited. Few studies said that the external environmental factors could be correlated with leaf senescence, so leaf lifespan could be affected by these factors, including in different climate regions. However, it's little evidences for these. In the future, the study of fern leaf lifespan needs to cooperate with phenology and ecophysiology, to understand the reasons of the expression of leaf lifespan.

P0485

Phytologic exchange between India and Pacific Asia prior to the late Oligocene

Qijia Li[1], *Qiongyao Fu*[2], *Jianhua Jin*[2], *Cheng Quan*[1]
1. Jilin University
2. Sun Yat-sen University

The final continental accretion of India to Asia, namely the "hard collision", and the consequent bidirectional biotic exchanges between Gondwanan and low-latitude Oriental regions in the Cenozoic remain an open topic that attracts comprehensive investigations. However, due to the complex nature of tectonic evolution and the fact of lacking suitable indicators at large as conclusive evidence, the accurate time of final terrestrial connections, and the resulted biotic dispersals between India and Asia originally on the opposite sides of the Neotethys Ocean is still highly debated. Here we describe seeds of Annonaceae from the late Oligocene Yongning Formation of Guangxi province, southern China on the basis of ovate to elliptic seed shape, thicker seed testa, lamelliform rumination and the obvious cone-like plug, providing new evidences for botanic exchange between India and Pacific Asia based on fossil records. Furthermore, more than 7 family 8 genus botanic exchange betweenIndiaand Pacific Asia during that period have also been reviewed, nearly negating the possibility of these botanic exchange by random and infrequent dispersals across an ocean barrier. All these biogeographical evidences indicate that the final terrestrial connection which simultaneously triggerred massive terrestrial botanic migrations and invasions from the Gondwana to low-latitude Asia, and vice-versa occurred prior to the late Oligocence.

P0486

Evolution and historical biogeography of Zingiberaceae -- From the perspective of chromonsome evolution

Jian-Li Zhao, ***Qing-Jun Li***
Laboratory of Ecology and Evolutionary Biology, State Key Laboratory for Conservation and Utilization of Bio-Resources in Yunnan, Yunnan University

Zingiberaceae is a pantropical monocot family across Asia, Africa and America, including Alpinioideae (~20 genera), Zingiberoideae (~29 genera), Siphonochiloideae (2 genera) and Tamijioideae (1 genus). Around 95% genera of Zingiberaceae grow in Southeast Asia. Reconstruction of evolution and historical biogeography of Zingiberaceae would be a key to understand the evolution of biodiversity in tropics, especially in paleotropics. Here we reconstructed the phylogeny, historical biogeography and Chromosome number evolution of Zingiberaceae. Alpinioideae has seven types of chromosome counts (90% is 2n=48) and Zingiberoideae has 29 types of chromosome counts (proportion of the most one is less than 16%). Our results indicated Zingiberaceae originated at Africa during the Late Cretaceous. Ancestor of Asian gingers drifted to Asia with India plate from the Upper Cretaceous to early Paleocene. Divergence between Alpinioideae and Zingiberoideae occurred during the Late Paleocene and diversification of Alpinioideae and Zingiberoideae both started during the Middle Eocene respectively. These two events coincided with two similar climate optimums before/after temperature peak during the Early Eocene. Ancestral basic chromosome numbers of Zingiberaceae, Alpinioideae and Zingiberoideae were likely n=12, n=24 and n=11 respectively, indicated ancestor of Alpinioideae underwent a palaeopolyploidization event and ancestor of Zingiberoideae underwent a chromosome loss event when these two subfamilies separated from each other. Ancestor of *Aframomum* (Africa), *Renealmia* (Africa+America) and *Alpinia*-FAX clade (South India+Sri Lanka) came from Eurasian continent from late Eocene to early Oligocene. Divergence between *Renealmia* and *Alpinia*-FAX clade was likely caused by long-distance dispersal event. This research suggested divergence between Alpinioideae and Zingiberoideae may be driven by chromosome shift under past environmental change rather than geological events, diversifications of Alpinioideae and Zingiberoideae were two different evolutionary strategies that one type with polyploidization and diverse chromosome types respectively, *Alpinia*-FAX clade should be listed as a new genus based on its phylogenetic position and evolutionary history.

The contributions of Chinese botanists to International Botanical Congress

Shuai Liao[1], *Cheng Du*[1], ***Jin-Shuang Ma***[1]
1. Shanghai Chenshan Plant Science Research Center, Chinese Academy of Sciences
2. Shanghai Chenshan Botanical Garden

The International Botanical Congress (IBC) is a global convention that brings together botanists from around the world to discuss scientific research about plants, particular on the *Code*. Since 1900 when first modern IBC held in Paris, France, it has been held nineteen times until now. The first time, Jing-Yue Zhang, a Chinese botanist, attend IBC, is in Ithaca, USA, 1926. Four years later, five Chinese botanists, Chong-Zhen Lin, Huan-Yong Chen [Woon-Young Chun], Jing-Yue Zhang, Ren-Chang Qin [Ren-Chang Ching], and Xing-Jian Si attended the V IBC in Cambridge, UK, 1930. Followed by another five years later, Huan-Yong Chen [Woon-Young Chun] and Ji-Tong Li attended the VI IBC in Amsterdam, Netherlands, 1935. In the next 46 years, Chinese botanists are absent from the VII IBC to the XII IBC for various reason. Since 1970s when China opened their door to the world, the Botanical Society of China sent more than 40 delegates from China to the XIII IBC in Sydney, Australia, 1981. In the past three decades, Chinese botanists paid great enthusiasm to every IBC, from Berlin, Tokyo, Saint Louis, Vienna to Melbourne, with hundreds of delegates. Today, Chinese botanists, with great honor, host the XIX IBC at their home "China: Mother of Gardens". As an important part of the IBC, Nomenclature Section, is organized to discuss and revise (if necessary) the *International Rules/Code of Botanical Nomenclature*, which was renamed as *International Code of Nomenclature for algae, fungi, and plants* (ICN) for better governance of the scientific naming of algae, fungi, and green plants. The formal set of rules for botanical nomenclature is Alphonse de Candolle's *Lois de la Nomenclature Botanique* (Laws of Botanical Nomenclature), which was published in 1867 for the fourth annual IBC in Paris, France, 1867. Since then, 15 official editions of the *Rules/Code* were published for the IBC. As the importance of the *Rules/Code*, several official editions were translated by Chinese botanists for better acquirement and utilization. In order to show the concentration and contribution of Chinese botanists on the *Rules*/*Code*, here we present the Chinese translation made by Chinese botanists from beginning as below. Details of the Chinese delegates in IBC and full Chinese translation record of the *Rules/Code* can be found in the poster.

Relicts and refugia: Evidences from some important mountains in the east China mainland, monsoon climate zone

Qiang Fan[1], *Wei Guo*[2], *Wanyi Zhao*[1], *Yunsheng Song*[1], *Jianhua Jin*[1], ***Wenbo Liao***[1], *Hungta Chang*[1]
1. State Key Laboratory of Biocontrol and Guangdong Key Laboratory of Plant Resources, School of Life Sciences, Sun Yat-sen University, Guangzhou, China
2. Department of Horticulture, Zhongkai Agricultural Engineering College, Guangzhou, China

The relict plants can be divided into taxonomic relict species and geographic relict species depending on systematic and geographic characteristics. The relict plants are of great significance in revealing the antiquity of a flora. According to the phyto-geographic theory, the differentiation of relict plants combined with fossil evidence and paleo-geographic features can be used to determine migration routes following the Pleistocene ice ages and to infer the location of refuge. The Chinese seed plant flora contains a great number of ancient gymnosperms and angiosperms, including many basal groups, and many typical relict genera and/or species. First, according to an analysis of 3,200 genera of Chinese seed plant flora, it shows that 162 families and 345 genera and about 943 species was considered as relict genera and/or species, which accounted for 10.78% of the total genera and 3.60% of the total species, including 9 families, 31 genera and 132 species of gymnosperms and 153 families, 314 genera and 811 species of angiosperms. Second, among above 345 relict genera in China, 228 genera belonged to 87 families were discovered owning fossil records, and analyzing by combined with the different geological age and the geologic climate events, those relict genera could be considered that there was 4 important evolution stages, i.e. Cretaceous period, Paleocene-Eocene period, Oligocene-Pliocene period and Pleistocene-Holocene period. Third, based on the analysis of floras, the relict genera and species of several important mountains in China was revealed as following: Luoxiao mountain (LXm) has 142 relict genera and 239 relict species, Wuyishan mountain (WYm) has 117 genera and 169 species, Nanling mountain (NLm) 113 genera and 166 species, Wuling mountain (WLm) 126 genera and 206 species, Mount Shennongjia (SNJ) 100 genera and 149 species, Mount Emeishan (EMS) 99 genera and 141 species, Qinling mountain (QLm) 104 genera and 139 species, Taiwan mountains (TWm) 90 genera and 122 species, Hainan mountains (HIm) 89 genera and 130 species, *etc.* Fourth, as might be expected from the above numbers, the East China mainland, a monsoon climate region also preserves a great of relict genera, and relict plant communities composed by some important relict species or populations such as *Cathaya argyrophylla*, *Abies beshanzuensis* var. *ziyuanensis*, *Amentotaxus argotaenia*, *Cunninghamia lanceolata*, *Fokienia hodginsii*, *Pseudotaxus chienii*, *Taxus wallichiana* var. *mairei*, *Tsuga chinensis*, *Disanthus cercidifolius* subsp. *longipes*, *Exbucklandia tonkinensis* and *Cyclocarya paliurus etc.* So, judging from the present abundant biodiversity and great number of relict plants, some typical mountains of east China mainland, such as Wuling mountain, Nanling mountain, Wuyi mountain, Luoxiao mountain, *etc.* could be considered as the important refuges during the Tertiary and Quaternary ice age.

DNA barcoding: Genus-level reference library for Korean vascular plants

Ji-Eun Choi, Se-A Ryu, Byoung-Yoon Lee, Min Hwan Suh, ***Chae Eun Lim***
National Institute of Biological Resources

Since 2008, National Institute of Biological Institute (NIBR) have conducted a DNA barcode research of Korean indigenous species for the taxonomical studies of living species and the following purposes: (1) to secure evidence for the intellectual property right or ownership claim of living species; (2) to obtain evidence to determine new or unrecorded species; (3) to confirm food safety, the quality of ingredients, and the authenticity of purity certification; and (4) after judging that it has high applicability as objective and scientific evidence for the ecological, environmental diagnosis and evaluation. Up to date, we produced the DNA barcode information of 7,623 species, which consist 16.2% of the Korean indigenous species. In Particular, we obtained approximately 50% DNA barcode data of Korean vascular plants. Recently, there has been a rapid increase on the cases of misuse, mixed use, forge, and falsification of main biological industrial resources whose species are difficult to be identified. In the present study, we examined the *rbcL* sequences of 1,122 genera for construct the Genus-Level Reference Library for Korean vascular plants. In Korean peninsula, It has been reported that there are 222 Families, 1,155 Genera, and 4,338 taxa of vascular plants (Ministry of Environment, 2011). However, 33 genera, which are distributed only in North Korea, have been excluded in this study. According to the neighbor-joining analysis on 1,122 Korean vascular plants, they are clearly divided into 3 groups; pteridophyta, gymnosperm, and angiosperm by the sequence of *rbcL* region. The analyzed 1,122 taxa had a high resolution of >95% in the genus-level. Based on the results, *rbcL* is very useful to identify Korean vascular plants on the genus-level.

DNA barcoding of Korean Gentianaceae

Su Min Han[1,2], *Hyosig Won*[2], ***Chae Eun Lim***[1]
1. National Institute of Biological Resources
2. Department of Biological Sciences, Daegu University, Gyungsan, Gyungbuk 38453

Family Gentianaceae is a species-rich plant group, and many species have been used in traditional medicine in Asia and Europe. Gentianaceae is consisted of ~1,700 species in 878 genera, eight subtribes and six tribes, and has worldwide distribution, mostly in the temperate regions and alpine habitats. In Korean peninsula, there are 25 taxa beloning to seven genera, two subtribes (Gentianeae and Swertiinae) of tribe Gentianeae. As a part of building DNA barcode identification system of Korean flowering plants, we have analyzed several DNA barcode regions of Korean Gentianaceae. In this study, we investigated four DNA barcode regions, chloroplast *rbc*L, *mat*K genes, and *trn*L-F IGS, and nuclear ribosomal ITS. The taxon sampling has been expended from herbarium of National Institute of Biological Resources (NIBR). Totally 66 accessions of 21 taxa in seven genera, two subtribes were sampled and sequence variation and characteristics were examined to discrimiate the species. Based on four DNA barcodes, all accessions were clearly distinguished at the subtribe and genus level; (1) subtribe Gentianinae; genus *Gentiana,* and *Tripterospermum* (2) subtribe Swertiinae; genus *Swertia*, *Anagallidium*, and *Halenia*. The chloroplast DNA barcode markers showed high PCR amplification efficiency and sequencing success (86.4~95.4%), while the nrITS the lowest sequencing success (72.2%). The degree of species resolution for each DNA barcode marker ranged from 53.3% (*trn*L-F) to 85.7% (ITS). Among four barcodes, nrITS provided the highest resolution power for species discrimination, although the fragment has the lowest sequencing efficiency. In conclusion, the result from nrITS indicated that each species has unique DNA sequence and the nrITS region can be used as a barcoding marker to distinguish Gentianaceae species in Korea.

P0491
Comparative DNA sequence analyses of five *Hosta* (Asparagaceae) complete chloroplast genomes

Se-A Ryu, Byoung-Yoon Lee, ***Chae Eun Lim***
National Institute of Biological Resources

Hosta (ca. 23-45 species) is restricted to China (two species), Japan (recognized 18 species and seven varieties), Korea (recognized 11 species and two varieties), delimitation has been problematic due to a long history of cultivation, hybridization and selection, from the 18th century onwards. *Hosta* plants are herbaceous perennial, commonly used ornamentally or for medicine, and are thus widely cultivated in parks and botanical gardens throughout the region, know as common name ‘Plantain Lily’. Over 100 species, varieties and cultivars of the genus *Hosta* have been discribed globally to date. Genus *Hosta* is taxonomically and phylogenetically regarede as one of the difficult taxa in plant. *Hosta* is related genera, including *Hemerocallis*, *Agave*, and *Yocca*, has been located in the Liliaceae, Agvaceae, or monogenertic Hostaceae (often erroneously called Funkiaceae, it is invalid) but according to molecular phylogenetic studies it has been suggested as Asparagaceae *s.l.*, in the oder Asparagales (APG III). The chloroplast genome sequences are useful genetic markers for DNA barcoding, transplastomic studies and evolutionary studies from the population level, as well as for phylogenetic relationships. Chloroplast genomes are usually 120-170kb in length approximately 100-130 genes are located along the circular genome structure of chloroplasts with a circular quadripartite structure involving two inverted repeat (IR) that divide the rest of the genome into large and small single copy regions. The structure and gene content of chloroplast genomes were relatively conserved in whole land plants with the exception of non-photosynthetic parasitic plants. At present, complete chloroplast genome of *Hosta ventricosa* have been available in NCBI GenBank. Here We report the sequence and characteristics of complete chloroplast genome of five *Hosta* species [*Hosta capitata*, *H. clausa*, *H. minor*, *H. venusta*, *H. yingeri.,* three of them (*H. minor*, *H. venusta*, *H. yingeri*) are as endemic distributed only in Korea] and to reconstruct phylogenetic relationships among the five *Hosta* species using their cp genome sequences. We here sequenced the complete chloroplast genomes of five *Hosta* species using Next-generation sequencing (NGS) data via a combination of *de nove* and reference-guided assembly. The five *Hosta* species chloroplast genomes is a typical double-stranded circular DNA with 156,417-156,756bp in length, exhibit the quadripartite structure common to most land plant chloroplast genomes with large single copy regions and small single copy regions separated by two copies of the inverted repeat. The five *Hosta* species have an identical set of 131 functional genes (85 protein coding genes, 38 tRNA and 8 rRNA genes). Based on comparative analyses of chloroplast genome in five *Hosta* species, *H. venusta* and *H. minor* has a similar to 99.99%, *H. capitata* and *H. yingeri* were confirmed that showed a similarity of 99.6%. Phylogenetic analyses using maximum likehood (ML) methods of a dataset composed of 18 monocotyledon chloroplast genomes.

P0492
Effects of floral color dimorphism on reproduction of *Roscoea cautleoides* (Zingiberaceae)

Tial Cung Ling
Kunming Institute of Botany, Chinese Academy of Sciences

Floral color polymorphism within plant species is considered to be maintained by selective agents such as environmental factors, pollinators, as well as by random genetic drift. Although *Roscoea cautleoides* (Zingiberaceae) shows a sympatric appearance of yellow- and purple-flowered individuals, it is still unknown what are the factors leading to the maintenance of flower color dimorphism in this species. We studied the soil trace-elements, flowering phenology, and morphological characters. We tested the hypotheses that pollinators may discriminate and prefer one of the morphs by monitoring the pollinator’s visitation rate and behavior, coupled with foraging time and pollen deposition. We also checked the breeding system and seed production in relation to the morph proportions in five natural sites in purpose to examine whether these proportions affect reproductive success. There were no significant differences in trace-elements, flowering phenology and pollinator visitation rate between the yellow and purple morphs, showing that they are completely sympatric and have a similar flowering season. However, flower density and sugar concentration of the nectar, were higher in the yellow flowers, while the purple flowers had larger ovule numbers and longer corolla tubes and floral lifespan than the yellow ones. The reflectance spectral analysis showed that pollinators could discriminate between the two morphs. The bumblebees, which had shorter tongued-lengths than that of moths, visited the yellow flowers, whereas moths preferred the purple flowers, and therefore their inter-morph visitation rate was significantly low. This result reveals that the selection of pollinator in *Roscoea cautleoides* is based more on flower color and size than on the nectar's concentration. Foraging time and pollen deposition of the bumblebees were significantly higher than that of the moths, showing that bumblebees may be more effective in pollen transfer than moths in this species. Bagged flowers in both color morphs show a low level of spontaneous self-pollination and produced few seeds, in which seed production of the yellow flowers in selfing was significantly less than that of the purple ones. However, reciprocal (inter-morph) hand-pollinated flowers set as many seeds as flowers hand-pollinated with outcross pollen (intra-morph but different flowers) or self-pollen (intra-morph from same flowers = geitonogamy), showing that a high capacity of seed production when the two color morphs are reciprocally pollinated. However, not only bagged and natural control flowers produced significantly fewer seed numbers than that of hand pollinations but also natural seed production in 2016 was significantly fewer than seed production in 2015 as a consequence of lower flower density and visitation rate in 2016. These results suggest that this species mostly depends upon pollinators for pollination. Nevertheless, the overall natural seed numbers of yellow flowers in all morph proportions were significantly higher than that of the purple flowers and showed neither negative nor positive frequency-dependent selection through pollinator preference. In summary, pollinator inter-morphs visitation between the two color morphs may maintain flower color dimorphism in this species.

Plastids, ploidy and phylogeography of Chinese strawberries (*Fragaria*, Rosaceae)

Aaron Liston[1], *Shannon Straub*[2], *Luxi Chen*[3], *Gao Song*[3], *Yao-Bin Song*[4], *Junmin Li*[3], *Ming Dong*[4], *Tia-Lynn Ashman*[5]
1. Oregon State University
2. Hobart & William Smith Colleges
3. Taizhou University
4. Hangzhou Normal University
5. University of Pittsburgh

China is the center of diversity for the genus *Fragaria* (Rosaceae), with 13 species of wild strawberry. However, species delimitation has not previously been examined with population level sampling and molecular markers. Using published *Fragaria* chloroplast genomes, we determined that the *ndh*A intron is the most variable plastid sequence. This 1200 bp intron was sequenced in 2112 individuals from 148 populations of Chinese *Fragaria*. We identified 96 unique haplotypes. These sequences were aligned, insertions and deletions were scored as binary characters, and a haplotype network was reconstructed. In addition, flow cytometry was used to estimate ploidy in 439 of these individuals. Six putative species, five diploid and one tetraploid, could be diagnosed by one or more haplotypes. We intensively sampled the diploid/tetraploid species pair *F. pentaphylla*/*F. moupinensis* obtaining 1366 chloroplast *ndhA* sequences and 48 haplotypes. We also made 354 ploidy estimates, and found that 51% of the individuals were predicted to be tetraploids. Only four of the haplotypes had mixed diploids and tetraploid estimates, and thus most of the haplotypes were potentially diagnostic for ploidy. Our results indicate that *F. vesca* and *F. orientalis* are absent from southwestern China, in contrast to published taxonomic treatments. We confirmed that *F. viridis* is present in Xinjiang province, and we confirmed the phylogenetic distinctiveness of *F. nilgerrensis* and *F. daltoniana*. *Fragaria nubicola* is monophyletic in the haplotype network, separated from *F. pentaphylla*/*F. moupinensis* by a single mutation. We identified a clade of diploid individuals from Shaanxi province that possess a unique set of haplotypes; we provisionally consider this *F. chinensis*. We apply *F. corymbosa* to a clade of tetraploids that share a unique 23 bp tandem duplication. These haplotypes are primarily distributed in northeastern China with scattered individuals in the southwest.

A taxonomic revision of four complexes in the genus *Pourthiaea* (Rosaceae)

Binbin Liu, *Deyuan Hong*
Institute of Botany, Chinese Academy of Sciences

The taxonomy of these four complexes (*Pourthiaea pilosicalyx* complex, *P. salicifolia* complex, *P. zhijiangensis* complex, and *P. arguta* complex), distributed in E, S, and SE Asia, is extremely controversial. The lack of proper analysis and evaluation of the characters at population level used previously may have caused these controversies among taxonomists. The present study is the first comprehensive taxonomic revision of these four complexes. We conducted extensive field observations, population sampling, examination of a large number of specimens, and subsequent statistical analysis of the characters. All morphological characters used in previous taxonomic treatments were evaluated one by one, they are length, breadth, margin, base, apex, and shape of leaf blade, length of petiole, number of lateral veins, type of inflorescences, length of pedicel, and density of indumentum on leaf blade and inflorescences. All these characters were found to be extremely variable within a population and continuously varied between populations, and thus they are of no value for delimiting species. However, seven characters, i.e. breadth of leaf blade, lateral veins parallel or not, lower surface of leaf blade glabrescent or not, type of fruits, sepals caducous or not, number of carpels, and ratio of number of fertile seeds to total seeds, were found distinctly different (for qualitative characters) or statistically discontinuous (for quantitative characters); therefore, they are valuable for species delimitation in these four complexes. As a result, we recognized four species and two subspecies, *P. pilosicalyx*, *P. salicifolia*, *P. zhijiangensis*, and *P. arguta*: subsp. *arguta* and subsp. *pustulata*. Forty taxa were reduced as new synonyms, and 22 lectotypes were designated here.

Phylogeography and intraspecific divergence of *Triosteum himalayanum* (Caprifoliaceae) on the Qinghai-Tibet Plateau and adjacent regions

Hai Rui Liu[1,2], *Qing Bo Gao*[1], *Fa Qi Zhang*[1], *Shi Long Chen*[1]
1. Northweset Institute of Plateau Biology, Chinese Academy of Sciences
2. University of Chinese Academy of Sciences

The extensive uplift of the Qinghai-Tibetan Plateau (QTP) during the Quarternary had great impact on the topography and climate of east Asia following by the evolution of biota. To understand the phylogeographic pattern of *Triosteum himalayanum* (Caprifoliaceae), we sequenced three chloroplast DNA fragments (*rbc*L-*acc*D, *rps15*-*ycf1*, *trn*H-*psb*A) from 238 individuals representing 20 populations. 19 haplotypes (H1–H19) are identified based on 57 polymorphisms. Most haplotypes were restricted to single population or to neighbouring populations. Analysis of molecular variance for overall populations revealed that most of the genetic variance was found among populations (89.43%), and only 10.57% within populations, indicating the high genetic differentiation across the sampled regions. The difference between G_{ST} (0.781) and N_{ST} (0.929) of overall populations was also significant, showing clear phylogeographic structure. Similar results were also found in two regional groups. We found ecoregions with relatively high genetic diversity or high frequence of private haplotypes, these suggest that this alpine herbaceous plant underwent enhanced allopatric divergence during survived in multiple refugia during the Last Glacial Maximum (LGM) or former glaciations. Our study support the indication that phylogeographic pattern difference between variable species on the QTP could be significant, and searching the evolutionary process details of alpine plants on the QTP could be interesting.

P0496

The ddRAD-based phylogeny of the BDG complex of paleotropical woody bamboo (Poaceae: Bambusoideae)

Jing-Xia Liu[1,2], *De-Zhu Li*[1,2]
1. Kunming Institute of Botany
2. University of Chinese Academy of Sciences

The *Bambusa-Dendrocalamus-Gigantochloa* (BDG) complex mostly consists of *Bambusa, Dendrocalamus, Gigantochloa* and *Melocalamus*. Species of this group occur exclusively in tropical and subtropical areas of Asia, and most of them are of great economic, cultural and ecologic value. The classification of the BDG complex based on morphology and anatomy is long in dispute and still unresolved. In addition, a plethora of molecular studies provide ambiguous and controversial results because of insufficient information sites for such a rapid diversified clade. In order to investigate phylogenetic relationships within the BDG complex, we obtained a large set of SNPs data using the “double-digest” restriction site-associated DNA sequencing (ddRAD-seq) strategy, and performed phylogenetic analyses based on SNPs. Complete chloroplast genomes of some taxa are also sequenced and examined. We collected a total of 93 individuals for ddRAD-seq data collectionincluding 36, 16, 5 and 35 species of *Dendrocalamus*, *Gigantochloa*, *Melocalamus,* and *Bambusa*, respectively. Our sampling covers the major and core groups of the BDG complex. Three species (*Kinobaluchloa* sp., *Neomicrocalamus prainii, Bonia amplexicaulis*) were used as the outgroup based on previous studies. Main conclusions were as follows: 1. Maximum Likelihood (ML) analysis performed on the large data set resulted in a well resolved topology in the BDG complex: 1) Five major clades were well supported, clade I include all the individuals of *Dendrocalamus* and *Gigantochloa*. clade II, clade III and clade IV all consist of species of *Bambusa*. Within clade V, *Melocalamus* was resolved as a monophyletic group with strong bootstrap support, and proved to be sister to all of the rest genera. 2) Within clade I, *Gigantochloa* was a well resolved genera. However, *Dendrocalamus* was not supported to be monophyletic, but clustered with *Gigantochloa* to formed a clade with high statistical support. 3) *Bambusa* was not been well resolved, species of the genera were controversial, and more samples are needed for further researches. 2. The results of Network and Structure showed that there are high genetic identities among the BDG complex, but contain a variety of components especially in *Bambusa*. It demonstrated that the group has undergone a complex evolutionary history. In this context, incomplete lineage sorting and horizontal gene transfer are possible reasons for closely related species and populations to have incomplete reproductive isolation. 3. Additionally, the complete chloroplast genome were used to reconstruct the phylogenetic relationship of BDG complex with 43 representatives, but no robust topology gained. It indicates that the chloroplast genome may be not suitable for the phylogenetic relationships of this complex.

Drought memory of moss

Li Liu
Kunming Institute of Botaty, Chinese Academy of Sciences

The drought stress memory response, which is induced by pre-exposure to various stresses, could play an important role in stress resistance and recovery in plants. However, whether moss exhibits drought stress memory and what molecular mechanism underlies this process are currently unknown.We discovered 271 novel lncRNAs that appear to function during drought treatment. Interestingly, three lncRNAs, TCONS_00028557, TCONS_00021167and TCONS_00013513, might function in the formation of drought memory. Osa-MIR1428e produced by TCONS_00028567 could activate the ABA-dependent SAPK10 signaling pathway to initiate drought resistance, which indicates that miRNA is likely also an important regulatory factor. Memory genes were compared between moss and other land plants. These results open a new window to understanding the epigenetic regulatory network underlying stress memory mechanisms.

Revisit the phylogeny of wheat powdery mildew uncovered more relaxed host specialization

*Parivash Shoukouhi, Nicole Beck, Sarah Hambleton, Quinn Eggertson, **Miao Liu***

Agriculture and Agri-Food Canada, Ottawa Research and Development Centre, 960 Carling Ave. Ottawa, ON K1A 0C6, Canada

The species originally described as *Erysiphe graminis*, is an important pathogen that can cause severe damage to various cereal crops. This species was re-classified in a monotypic genus *Blumeria* based on unique morphological characteristics of conidia and chasmothecia, as well as molecular evidence. Host specialization of *B. graminis* was studied by inoculation experiments (Mains 1933, Cherewick 1944, Eshed & Walh 1970), and more recently by analyzing DNA sequences (Inuma *et al.,* 2007). Multigene phylogenetic analyses of the samples from Japan, Iran and Switzerland have revealed nine distinct lineages. In general, samples from individual host genus belonged to a single lineage except for the samples from *Lolium* and *Bromus*. Using historical herbarium specimens housed in the National Mycology Herbarium (DAOM) in Canada, we were able to obtain ITS sequences for isolates on various hosts of mainly North American origin including a few from arctic regions. The phylogeny based on combined sequences generated in this study and those by Inuma et al (2007) largely agreed with previous recognition of nine clades. However, isolates from *Hordeum* spp. were grouped into three different clades, and the host ranges of Dactylis-clade, Poa-clade, and Triticum-clade have expanded by additional 1-4 host genera. In addition, a new lineage was uncovered that include samples on *Deschampsia*, *Elymus* and *Hordeum.*

Unravelling the evolutionary dynamics of ancient and recent polypoidization events in *Avena* (Poaceae)

Qing Liu[1]*, Lei Lin*[1]*, Xiangying Zhou*[1,2]*, Paul M. Peterson*[3]*, Jun Wen*[3]

1. Key Laboratory of Plant Resources Conservation and Sustainable Utilization, South China Botanical Garden, Chinese Academy of Sciences

2. University of Chinese Academy of Sciences

3. Department of Botany, National Museum of Natural History, Smithsonian Institution, Washington, DC 20013-7012

Understanding the diversification of polyploid crops in the Mediterranean biodiversity hotspot is a challenging issue for evolutionary biology. Sequence data of three nuclear genes and three plastid DNA fragments from 109 accessions of *Avena* L. (Poaceae) and those from outgroups was used for maximum likelihood and Bayesian analyses. The evolution of cultivated oat (*Avena sativa* L.) and its close relatives was inferred to have involved ancient allotetraploidy and subsequent recent allohexaploidy events. The crown ages of two infrageneric lineages (*Avena* sect. *Ventricosa* Baum ex Romero-Zarco and *Avena* sect. *Avena*) and the *A. sativa* lineages were estimated to be in the early to middle Miocene and the late Miocene to Pliocene. These periods coincided with the mild seasonal climatic contrasts and the Mediterranean climate establishment in the Mediterranean Basin. Our results suggest that polyploidy, lineage divergence, and complex reticulate evolution has occurred in *Avena*, and this exemplifies the long-term persistence of tetraploids and the multiple origins of hexaploids related to paleoclimatic oscillations during the Miocene-Pliocene interval in the circum-Mediterranean region. This newly-resolved infrageneric phylogenetic framework represents a major step forward in understanding the scenarios for the origin of cultivated oat. Acknowledgements. Immediate evolutionary impact of whole genome duplication on RNA alternative splicing, using the recently formed polyploid *Tragopogon* (Asteraceae) as a model

Xiaoxian Liu[1,2]*, W. Brad Barbazuk*[1,3]*, Pamela S. Soltis*[2,3]*, Douglas E. Soltis*[1,2, 3]

1. Department of Biology, University of Florida, Gainesville, FL 32611-8525, USA.

2. Florida Museum of Natural History, University of Florida, Gainesville, FL 32611-7800, USA.

3. Genetics Institute, University of Florida, Gainesville, FL 32610, USA.

Plant species that have experienced whole-genome duplication (WGD; polyploidy) during their evolutionary history usually undergo changes in gene number, expression, and regulation. However, it is unclear whether or not such genomic modifications are sufficient to generate the phenotypic novelty that characterizes most polyploids and has allowed many polyploids to occupy new habitats. RNA alternative splicing (AS) is a major regulatory mechanism of gene expression and a major factor promoting functional innovation and proteomic diversity. Yet, no studies have assessed the immediate impact of WGD on AS. The goal of our research is to address the role and extent of AS in recently formed naturally occurring allopolyploids and help elucidate the connections among AS, polyploidy, and diversity. Here, we use allopolyploid species in the flowering plant genus *Tragopogon* (Asteraceae), a model for the study of very recent and recurring allopolyploidy, to study the impact of WGD on AS patterns. Using transcriptomes generated by PacBio Iso-Seq^{TM}, we compare both natural populations of independent origin and synthetic lines of the allopolyploid *T. miscellus* (~80 years old) to its diploid parents (*T. dubius* and *T. pratensis*) to assess the role of AS after polyploidization. The results will provide a better understanding of how AS influences genetic and potentially proteomic diversity in polyploid plants.

Nitrogen resorption and release by understory mosses in an old-growth fir forest

Xin Liu*, Zhe Wang, Xiaoming Li, Weikai Bao*
Chengdu Institute of Biology, Chinese Academy of Sciences

Mosses are dominant in understory layer of boreal and subalpine forest, where they strongly affect nitrogen (N) cycling. However, mosses differed substantially from vascular plants in terms of plant structure, which may lead to distinct characteristics in nutrient resorption and release. Here, we measured the N resorption efficiency (NRE), N release rate by leaching and the percentage of N left in litter using stable isotope (^{15}N) techniques. We find that NRE of the studied species, *A. hookeri* and *H. splendens*, was 61.67% and 52.16%, respectively. The mosses release 8.65% and 13.62% of tissue N annually and 23.19% and 33.62% of N from new-growth to senesced by leaching. 15.14% and 14.22% of tissue N was left in the senesced tissue and released by litter decomposition in the following years for respective species. Our results indicate that the forest floor mosses resorb N in senescing tissue at a relatively high efficiency. Given the less N left in senesced tissue and low decomposition rate, N leaching is a more important process that understory moss layer releases N than litter decomposition. Thus, N resorption and leaching release of the forest floor mosses control N flux through the ecosystem.

DNA barcoding evaluation and implications for phylogenetic relationships in Lauraceae from China

Zhi-Fang Liu[1,4]*, Xiu-Qin Ci*[1,4]*, Lang Li*[1]*, Hsi-Wen Li*[2]*, John G. Conran*[3]*, Jie Li*[1]
1. Xishuangbanna Tropical Botanical Garden, Chinese Academy of Sciences
2. Kunming Institute of Botany, Chinese Academy of Sciences
3. School of Biological Sciences, University of Adelaide
4. University of Chinese Academy of Sciences

Lauraceae are an important component of tropical and subtropical forests and have major ecological and economic significance. Owing to lack of clear-cut morphological differences between genera and species, this family is an ideal case for testing the efficacy of DNA barcoding in the identification and discrimination of species and genera. In this study, we evaluated five widely recommended plant DNA barcode loci *mat*K, *rbc*L, *trn*H–*psb*A, ITS and ITS2 for 409 individuals representing 133 species, 12 genera from China. We tested the ability of DNA barcoding to distinguish species and as an alternative tool for correcting species misidentification. We also used the *rbc*L+*mat*K+*trn*H–*psb*A+ITS loci to investigate the phylogenetic relationships of the species examined. Among the gene regions and their combinations, ITS was the most efficient for identifying species (57.5%) and genera (70%). DNA barcoding also had positive role for correcting species misidentification (10.8%). Furthermore, based on the results of the phylogenetic analyses, Chinese Lauraceae species formed three supported monophyletic clades, with the *Cryptocarya* group strongly supported (PP = 1.00, BS = 100%) and the clade including the *Persea* group, Laureae and *Cinnamomum* also receiving strong support (PP = 1.00, BS = 98%), whereas the *Caryodaphnopsis–Neocinnamomum* received only moderate support (PP = 1.00 and BS = 85%). This study indicates that molecular barcoding can assist in screening difficult to identify families like Lauraceae, detecting errors of species identification, as well as helping to reconstruct phylogenetic relationships. DNA barcoding can thus help with large-scale biodiversity inventories and rare species conservation by improving accuracy, as well as reducing time and costs associated with species identification.

Floral evolution in Rubiaceae – a morphological overview

Stefan Löfstrand[1]*, Sylvain G. Razafimandimbison*[2]*, Catarina Rydin*[1,3]
1. Stockholm University; Department of Ecology, Environment and Plant Sciences
2. Swedish Museum of Natural History; Department of Botany
3. Bergius Botanic Garden

The coffee family (Rubiaceae, Gentianales) is estimated to have originated in the mid-Cretaceous and is one of the largest flowering plant families with more than 13,000 species. Rubiaceous flowers can be unisexual or bisexual, homostylous or heterostylous, large or small, and all main types of pollination systems are represented. However, there are surprisingly few detailed studies on floral biology within Rubiaceae and few floral synapomorphies have been suggested at or above tribal level. We have reached a point in time where we (mostly) understand the phylogenetic relationships, but not the evolutionary patterns and pathways that lead to the extant structural diversity. More than any other structures in plants (e.g. leaves), flowers provide a direct testimony of evolutionary history, albeit not always phylogenetic relationships, making them highly interesting for the study of distribution patterns of floral characters in extant angiosperm clades. We therefore need to delve deeper into the complex structures of flowers. Are floral traits synapomorphic or ancestral in Rubiaceae? Are they homologies induced by similar biotic and abiotic forces acting on the taxa throughout evolution? In essence, we need to gain more knowledge about what distinguishes rubiaceous flowers beyond general observations. This study aims to, with a broad sampling from all major lineages of Rubiaceae (subfamilies, tribes, genera), investigate general aspects of floral form (e.g. color, calyx lobe number, corolla tube length, and style length), particularly in relation to heterostyly, a trait that appears to have evolved in several lineages in the family. This much-needed review of floral form in Rubiaceae will hopefully result in hypothetical renderings of flowers of the last common ancestor of key clades, such as tribal complexes, subfamilies, and the family as a whole.

P0504
The family Oleaceae in South America

Julio Antonio Lombardi
UNESP - State University of São Paulo

The Oleaceae are trees, shrubs or lianas, monoecious or rarely polygamo-monoecious, trichomes when present generally peltate, leaves are simple or compound, trifoliolate or imparipinnate, unstipulated, petiolate, opposite or rarely alternate (*Jasminum* species), rarely scale like, margins entire, crenate or serrate, pilose domatia often present in the axils of secondary veins on the abaxial face, stomata occasionally in crypts; inflorescences are paniculate, racemiform or fasciculate, or flowers solitary; flowers are actinomorphic, often aromatic, with perianth 2-6-merous, calyx and corolla present and distinct, absent (*Forestiera*), or one whorl missing, either the calyx (*Forestiera*, *Priogymnanthus*) or the corolla (*Forestiera*, *Nestegis*), the calyx is gamosepalous, truncate or lobed, valvar or imbricate, sepals 4 (-15), the corolla is gamopetalous or dialipetalous, imbricate, valvar or contorted, petals 4 (-12), stamens 2 (4), united to corolla or free, all fertile, filaments present or null, anthers dehiscence longitudinal, introrse or latrorse, intrastaminal disc present or absent, gynoecium bicarpellate and bilocular, ovary superior, (1)2 (-4) axillary ovules per locule, rarely numerous (*Forsythia*), style 1, apical, stigma bilobed or capitate, dry; fruits are schizocarpous with circumscissile or indehiscent mericarps (*Menodora*) or loculicidal, or a drupe with a hard or brittle endocarp; seeds are winged or not. The family includes 25 genera and about 600 species, with nearly cosmopolitan distribution. In Neotropics Oleaceae comprises nine genera and over 45 described species, in South America are recognized 27 native species included in five genera: *Chionanthus* L. (18 species, *C. abriaquiensis* Fern. Alonso & Cogollo, *C. colonchensis* Cornejo & Bonifaz, *C. compactus* Sw., *C. crassifolius* (Mart.) P.S.Green, *C. ferrugineus* (Gilg) P.S.Green, *C. filiformis* (Vell.) P.S.Green, *C. fluminensis* (Miers) P.S.Green, *C. greenii* Lombardi, *C. guianensis* (Aubl.) Pers., *C. implicatus* (Rusby) P.S.Green, *C. megistocarpus* Fern.Alonso & Cogollo, *C. micranthus* (Mart.) M.Lozano & Fuertes, *C. parviflorus* Cornejo, Lombardi & W.W.Thomas, *C. pubescens* Kunth, *C. subsessilis* (Eichler) P.S.Green, *C. tenuis* P.S.Green, *C. trichotomus* (Vell.) P.S.Green, and *C. wurdackii* B.Ståhl,), *Forestiera* Poir. (one species, *F. ecuadorensis* Cornejo & Bonifaz), *Menodora* Bonpl. (four species, *M. decemfida* (Gillies ex Hook.) A.Gray, *M. integrifolia* (Cham. & Schltdl.) Steud., *M. pulchella* Markgr., and *M. robusta* (Benth.) A.Gray), *Priogymnanthus* P.S.Green (three species, *P. apertus* (B.Ståhl) P.S.Green, *P. hasslerianus* (Chodat) P.S.Green, and *P. saxicolus* Lombardi), and *Schrebera* Roxb. (one species, *S. americana* (Zahlbr.) Gilg), besides four naturalized species in the genera *Jasminum* L. (one species, *J. fluminense* Vell.), and *Ligustrum* L. (three species, *L. japonicum* Thunb., *L. lucidum* W.T.Aiton, and *L. vulgare* L.). (CNPq - Conselho Nacional de Desenvolvimento Científico e Tecnológico # 307997/2013-8; FAPESP - Fundação de Amparo à Pesquisa do Estado de São Paulo # 2013/06296-9).

The genus *Zinowiewia* (Celastraceae) and its first record in the Brazilian Flora

Leonardo Biral[1], ***Julio Antonio Lombardi***[2]

1. UTFPR- Universidade Tecnológica Federal do Paraná

2. UNESP - State University of São Paulo

Zinowiewia Turcz. (Celastraceae) is an endemic taxon of the Neotropical region distributed in both South and Central America and Mexico from 250 to 3,150 m elevation. The genus has nine species currently recognized, after some new synonyms were proposed in the recent taxonomic revision for Flora Mesoamericana. The taxon includes trees or shrubs, and can be characterized by glabrous opposite and decussate leaves, with entire margins, inflorescences axillary cymes forked one to several times, flowers bisexual, 5-merous, ovary 2-locular, fruits samaras with one apical wing, and one (rare two) linear-oblong seed. *Zinowiewia* is easily distinguishable from *Plenckia* and *Wimmeria*, the other Neotropical genera with samaras, by its opposite leaves (vs. alternate). It can also be differentiated from *Wimmeria* by flowers 5-merous and samaras with a single terminal wing (vs. flowers 4-merous and samaras with 3-4 longitudinal wings). The genus was created by Turczaninow in 1859 as a new combination for *Wimmeria integerrima*, published by him a year before, but with questions about its generic position. After Turczaninow's delimitation, it took almost 80 years for an additional species to be described in the genus. Of the 17 names published in *Zinowiewia*, 13 were created by Cyrus Lundell between 1938 and 1987, several of them being reduced to *Z. integerrima* and *Z. rubra*, after the treatment on Mesoamerica. The genus was classified in the subfamily Tripterygioideae by Loesener because the winged fruits with one or two seeds without aril, but a phylogeny provided for Tripterygioideae based on morphological and molecular characters showed that *Zinowiewia* is the sister clade of *Microtropis* + *Quetzalia*, sharing with those opposite leaves, ovary two carpelate, and molecular synapomorphies in the ITS region. Currently, Tripterygioideae has been recognized as a highly polyphyletic clade and *Zinowiewia* is nested in Celastroideae. We register here the first record of *Zinowiewia* in the Brazilian flora, a collection of *Z. australis* was located after taxonomic studies were carried out by the authors for Celastraceae in several herbaria. The specimen *G.T. Prance 10015* (F [1772295], INPA [27148], K [001137341], M [s.n.], MG [41717], P [05493140], U [260544]) was collected in the Roraima State, in Serra do Surucutus, NE of Mission station, 1000-1400 m elevation, in a forest at foot of red sandstone cliff, on 17 February 1969. This species is also known by collections from Venezuela, Colombia, Ecuador, Peru and Bolivia, but it was not previously registered for Brazil. With this addition, Celastraceae is now represented in Brazil by 20 genera (eight of them from the Celastroideae subfamily) and 142 species. Several genera of Neotropical Celastroideae, especially those with a small number of species, e.g. *Crossopetalum*, *Gyminda*, *Haydenoxylon*, *Quetzalia*, *Schaefferia*, *Wimmeria*, and *Zinowiewia* have not been the subject of consistent taxonomic studies or these studies have become outdated. Probably new records of occurrence, and even undescribed species, will be registered when more taxonomic studies are carried out for them. (FAPESP - Fundação de Amparo à Pesquisa do Estado de São Paulo # 2011/21879-5 and 2014/22093-3).

Evolution of floral structure in the transition to pentapetalae (eudicotyledoneae) derived from total evidence analysis of extant and fossil taxa

Andrea Lopez-Martínez[1], *Hervé Sauquet*[2], *Susana Magallón*[3]

1. Posgrado en Ciencias Biológicas, Universidad Nacional Autónoma de México

2. Laboratoire Écologie, Systématique, Évolution, Université Paris-Sud
3. Instituto de Biología, Universidad Nacional Autónoma de México

The Eudicotyledoneae (eudicots) is a solidly recognized clade that contains approximately 75% of all angiosperm species, and includes a wide diversity of floral morphology. Phylogenetic results have consistently identified a grade of independent lineages at the onset of eudicot diversification, corresponding to orders Ranunculales, Proteales, Trochodendrales, Buxales, and Gunnerales, which are successive sister taxa to a species-rich, Pentapetalae. Each of the lineages of the early-diverging eudicot grade includes a small to moderate number of species, and together, they encompass substantial floral structural diversity, including, for example, spiral and whorled phyllotaxy, variable and fixed merosity; and different degrees of fusion among floral organs. In contrast, most of the flowers of Pentapetalae are structurally stable, displaying whorled phyllotaxy, fixed merosity with usually 5 (or 4) organs per whorl in the perianth and androecium, and a two-whorled perianth differentiated into calyx and corolla. In this study, we investigate the evolution of floral structure in the transition between the early-diverging eudicot grade and the initial diversification of Pentapetalae, with a special focus on the establishment of the fixed meristic pattern and bipartite perianth of Pentapetalae. To conduct this study, we combined nucleotide sequences of three plastid markers (*atp*B, *rbc*L, *mat*K) of extant species, and 79 floral morphological characters for 54 extant and 16 three-dimensionally preserved fossil flowers. We estimated phylogenetic relationships among extant and fossil taxa with maximum likelihood and Bayesian phylogenetic inference. The temporal context of floral evolution was then investigated by two different means of fossil calibration. First, we conducted a conventional node-calibrated molecular dating analysis under bayesian relaxed clock models, using only on extant taxa as terminals and incorporating the identified phylogenetic placement of fossils to calibrate internal phylogenetic nodes. We conducted a total evidence 'tip-dating' analysis in which fossils were included as terminals with fixed age, together with extant species. Based on the resulting timetrees, we investigated the evolution of floral structure during the transition to Pentapetalae by estimating the ancestral condition and character state shifts of perianth differentiation and floral merosity. Our results confirm previously suggested affinities of most fossils, but in a few instances, a new phylogenetic placement was obtained. Stochastic mapping for floral characters indicates numerous structural changes in the early eudicot grade, and suggest that merosity was variable in the most recent common ancestor of Pentapetalae.

Highly efficient pollination system in *Aeschynanthus acuminatus* (Gesneriaceae) reveals the potential role of generalized passerines in floral evolution of East Asia

Jing-Yi Lu, *Kai-Hsiu Chen, Chun-Neng Wang*
National Taiwan University

Background and aims: The interaction between angiosperms and their pollinators is regarded as a major driving force leading to the evolution of diverse floral characters. Pollinator assemblages, thus, exert selective pressures on pollination syndromes and affect the species composition among different geographic regions. A well-known example is the extremely low diversity of nectar-specialized avian in East Asia northern of the Himalayans, which gave rise to the long belief of lacking plant-bird relationships with only few detailed investigated cases. *Aeschynanthus*, a Gesneriaceae genus with more than 160 species in subtropical SE Asia, has red and tubular flowers associated with sunbird pollination syndrome. Inhabiting in the northern edge of *Aeschynanthus* distribution where the putatively specific pollinator sunbird is absent, *A. acuminatus* has changed to reddish green flower and widely opened corolla tube in Taiwan. We thus investigated the pollination biology of *A. acuminatus* to increase our understandings on extremely rare observation of ornithophily in Asia, north of Himalayas region. Methods: Pollination efficiency was quantified as natural fruit set and conspecific pollen transfer rate on stigmas. Floral morphology of co-flowering species sharing the same pollinators as *A. acuminatus* were compared to evaluate the effect of interspecific pollen placement. The reflectance spectra of flowers were measured and nectar properties were recorded with nectar sugar composition further obtained by high performance anion-exchange chromatography (HPAEC). *Results:* Two species of passerines, *Yuhina brunneiceps* and *Alcippe morrisonia*, were observed effectively visiting *A. acuminatus*. The high natural fruit set (60%) and conspecific pollen transfer rate (95%) indicate high reproductive success which appears to be the result of accurate pollen placement on the pollinators. In addition, the existence of a major peak in long-wavelength (red) spectrum of floral reflectance and the copious (58.7 μl) and diluted (6.8%) nectar with abundant hexose sugars are consistent to generalized-bird pollination syndromes. *Conclusion:* The complement of generalized-passerines as pollinators in *A. acuminatus* with high pollination efficiency appears to play an important role in successful colonization to Taiwan as we discovered its pollination syndromes are closely matching the generalized-bird pollination syndromes. *Discussion:* In comparison with other members of *Aeschynanthus*, the distinct pollination syndromes of *A. acuminatus* relate to the different avian pollinator assemblage in East Asia; Ecologically, co-flowering species of this generalized-passerine pollination system with different floral morphology could co-exist with high efficiency by pollen placement, reaching higher species diversity in the community. Our research reveals the successful adaptation of generalized-passerine pollination system, which provides a direction of future studies on pollination in East Asia, the potential role of generalized-bird pollination interactions in driving the evolution of species and diverse floral traits.

The vast temperate desert in Arid Central Asia, as an ancient Silk

Road, bred splendid human civilization, provided an important channel for economic and cultural exchanges between East and West. The coupling relationship between human existence and the dynamic change of desert ecosystem in this region is a hotspot concerned by governments and scientific communities. However, lacking of a pollen spectrum about the dominant and indicative taxa within temperate desert vegetation and a corresponding relation between pollen assemblages and specific desert vegetation types prevents us from further understanding the formation and maintain of this desert ecosystem. Here we depict and establish a pollen spectrum of dominated plants in desert vegetation, covering 14 families, 36 genera, 56 dominant and indicative species in eastern Arid Central Asia, and provide a key for identifying the dominant and indicative taxa, and recognize four main temperate desert vegetation types, i.e., semi-dwarf arbor desert, shrubby desert, semi-shrub and dwarf semi-shrub desert and cushion dwarf semi-shrub desert based on the characteristics of pollen assemblages. The present study gives an important reference on distinguishing pollen grains from surface and sub-surface samples in this region, and has a great potential applying for tracing the past change of desert vegetation succession and pattern formation.

Insights into genome structure of two pentaploid dogroses (*Rosa* sect. *Caninae*) harbouring a unique asymmetrical meiotic system

Jana Lunerová[1], *Veit Herklotz*[2], *Christiane M. Ritz*[2], *Aleš Kovařík*[1]

1. Department of Molecular Epigenetics, Institute of Biophysics of the CAS v.v.i., Czech republic

2. Department of Botany, Senckenberg Museum of Natural History, Germany

Members of genus *Rosa* section *Caninae* (also known dogroses) are multihybrids harbouring variable ploidy levels ranging from four to six. All dogroses evolved an unusual matroclinal meiotic system characterised by asymmetrical distribution of genetic material between the female and male gametes: In pentaploid dogroses, (2n=5x=35), the pollen transmits one basic genome (x=7) derived from the seven segregating bivalents, whereas the egg transmits four basic genomes (4x=28) one set derived from the segregation of seven bivalents and three sets of univalent-forming chromosomes. In this study, we explored the genomes of two pentaploid dogrose species, *Rosa canina* and *R. inodora,* which belong to different subsections and are abundant shrubs in central Europe. We sequenced their genomes by Illumina technology and analysed the genomic and chromosomal composition using bioinformatic, molecular and cytogenetic approaches. The clustering analysis using RepeatExplorer revealed that the repeatom (sum of satellite repeats, RNA and DNA transposons, simple repeats and rDNA) is similar between the species with little variation in repeat copy number. We cloned a major satellite called CANR4 which constitutes 1.5 and 2.7% of *R. canina* and *R. inodora* genomes, respectively. Fluorescent *in situ* hybridisation (FISH) revealed its mostly pericentromeric location on several chromosomes in both species. FISH in meiotic pollen mother cells showed that the bivalent-forming chromosomes are relatively deficient in CANR4 in *R. canina*, at least. Additionally, we reconstituted chloroplast genomes of *R. canina* and *R. inodora* revealing specific SNPs and haplotypes. We hypothesize that *R. canina* and *R. inodora* formed from independent hybridisation events involving common closely related progenitors. Thus, unusual asymmetrical meiosis arose at least twice in evolution of Caninae dogroses.

The evolution of genetic diversity hotspot: Adaptation and ongoing speciation in a mangrove tree, *Avicennia Marina*

Haomin Lyu, *Zhengzhen Wang, Xinnian Li, Ziwen He, Lishi Huang, Suhua Shi*

Sun Yat-sen University

Geographical changes have been considered one of the most important factors to account for both demographic history and adaptation. Documenting the admixture events and positive selection can clarify the role of geographic features in speciation. Three varietas of *Avicennia marina*, inhabiting across the Indo-West-Pacific (IWP) region, provide a good example to insight how coastal and marine organisms in the biodiversity hotspots evolve and adapt during environmental changes. Here we present the global patterns of genetic diversity by the resequencing of 13 populations from all the three varietas. The results show that the intermediate varietas (*A. marina* var. *eucalyptifolia*) bears much more genetic variations than the others. The integrative inference of admixture history demonstrates that this pattern is almost independent from the admixture among varietas. The high-frequency transformations between opens and closes of Torres Strait during sea level fluctuations may cause the cycles of migrations and isolations in the interval of 1.806 ~ 5.96 million years ago, suggestive of the accumulation of genetic variations. The demographic model and phylogenetic discordance of loci under selection indicate that these accumulated variations could contribute to the rapid adaptation and high divergence among three varietas and different populations. We also infer the genetic basis of adaptive evolution and differentiation in *A. marina* var. *australasica*, such as the genes regulating the photoperiod and the flowering time, while the differentiation of *A. marina* var. *marina* might be attribute to more complicated geography and isolations. Although the standing genetic variations facilitate the adaptation to changing environments, the accumulation of genetic variations almost halts, and effective population size persistently reduces during the repeated glaciation in Pleistocene. However, following the acceleration of global warming and sea level rising, the mangroves, even other marine and coastal organisms in IWP region, would face unprecedented hardship.

Reduction of transposable element load when hosts invade stressful habitats: A common preemptive strategy in mangroves

Haomin Lyu[1], *Zhengzhen Wang*[1], *Ziwen He*[1], *Zhou Renchao*[1], *Lishi Huang*[1], *Jianhua Ouyang*[1], *Zixiao Guo*[1], *Cairong Zhong*[2], *David Boufford*[3], *Chung-I Wu*[1,4], *Suhua Shi*[1]

1. Sun Yat-sen University

2. Hainan Dongzhai Harbor National Nature Reserve

3. Harvard University Herbaria
4. University of Chicago

Transposable elements (TEs) are generally known to be parasitic and deleterious to the host. Evolution of TE load as hosts invade stressful habitats should shed light on genomic consequences of adaptation to new environments. Woody plants living at the interface between land and sea, collectively referred to as mangroves, are excellent examples of invasion of inhospitable habitats. TEs are also the most common components of the genomes of woody plants. We took advantage of mangrove genomes recently generated by our group to examine TE evolution in plants. The birth vs. death rate of LTR-RTs can be estimated because the death of retrotransposons would leave a trace in the form of solo-LTRs or truncated LTR-RTs. We found that (i) all lineages of mangroves in our study independently and massively reduced their TE load in comparison to their non-mangrove relatives; (ii) genome size reduction has happened in all six true mangrove lineages; (iii) the TE load reduction in all examined true mangroves can largely be attributed to the paucity of young TEs; (iv) the rarity of young TEs is a consequence of the reduction in new TE birth, rather than a death rate increase. Finally, we conclude that many mangroves employ a common strategy of TE load reduction and repressing proliferation when adapting to a new environment.

Peristome patters and spore morphology of *Bryum* Hedw. (Bryaceae) from the Altun Mountain National Nature Reserve in Xinjiang, China

Sulayman Mamtimin[1], *Sabiram Esrayi*[1], *Atigul Molla*[1], *Yong-Ying Liu*[2]
1. College of Life Science and Technology, Xinjiang University, Urumqi 830046, China
2. Department of Biology, Jiaozuo Teachers College, Jiaozuo 454001, Henan, China

The Altun Mountain National Nature Reserve is located in the Kumukule Basin of East Kunlun Mountain, south of Xinjiang Uyghur Autonomous Region, China. The area is the first built, having the largest range for protected plateau desert ecosystem. It was regarded as one of the rare gene banks of plateau species by International Union for Conservation of Nature (IUCN) and World Wildlife Fund (WWF). Unique geographic position and natural conditions of the Altun Mountains cause bryophyte of the area can bear bitter cold on highland. Bryophyte is one of the important roles in the vegetation of the area. Moss flora of the Altun Mountains has an important position in China, attract the attention of many bryologists in the world. More than twenty species of genus *Bryum* Hedw. have been recorded in the area during our studying of bryophyte diversity, it is about 2/3 of Xinjiang. The paper aims to figure out the taxonomic value of the peristomial structures and spore morphology in *Bryum*, to discuss the relationship between the natural environmental condition and the diversity of *Bryum* at the Altun Mountain National Nature Reserve. Morphological characters of peristome and spores from 18 species of the genus *Bryum* in the area were observed by the scanning electronic microscope (SEM). The results showed that: (1) The characters, such as, the exostomial teeth shape, pattern of exostomial dorsal suface, width of perforation on the endostomial segments, the length of the endostomial basal membrane, development of the cilia and exine ornamentation of the spore, are different among the taxa in *Bryum*, and they are stable for each species in the genus. So their presence often is considered highly diagnostic and taxonomically in infrageneric classification combining with other sporophyte characteristics and/or gametophyte characteristics. (2) When most highly developed or perfect peristome, it consists of longer exostome teeth, a high endostomial basal membrane, broad segments and appendiculate cilia. Otherwise, modified or reduced peristome has shorter exostome teeth, lower endostomial basal membrane, narrower segments and shorter and fewer cilia or absent. (3) It seems that the rich diversity of *Bryum* in the Altun Mountain National Nature Reserve is related with the peristomial structures and spore morphology being adaptive for spores dispersing in dry environment.

Morphometrics of the giant sedges of *Carex* section *Rhynchocystis* (Cyperaceae): Overlooked vs. overvalued characters and unnoticed species

Mónica Míguez[1], *Berit Gehrke*[2], ***Santiago Martín-Bravo***[1], *Pedro Jiménez-Mejías*[3]
1. Universidad Pablo de Olavide
2. Johannes Gutenberg-Universität
3. New York Botanical Garden

Carex section *Rhyncocystis* (Cyperaceae) is a group of five species of giant sedges disjunctly distributed in the Western Palearctic (*C. microcarpa* and *C. pendula*) and sub-Saharan Africa (*C. bequaertii*, *C. mossii*, *C. penduliformis*). Recent phylogenetic studies revealed that *C. bequaertii* and *C. mossii* are not mutually monophyletic, and that *C. pendula*, despite monophyletic, actually embraces two strongly differentiated lineages. In order to objectively assess the morphological limits and taxonomic circumscription of the species and lineages, we performed a morphometric study of macromorphological characters based on 109 herbarium vouchers, as well as a nomenclatural survey. Micromorphology of achenes was also studied. Our results suggest the existence of five species, of which only *C. microcarpa* and *C. penduliformis* were supported in their traditional circumscriptions. The two *Carex pendula* lineages were found to correspond to two morphologically distinct, mostly allopatric taxa: one from Western Europe (*C. pendula* s.s.), and another from Central and Eastern Europe, to which the long neglected 18th century name *C. agastachys* should apply. On the contrary, *C. bequaertii* and *C. mossii* were found to be weakly morphologically differentiated and thus better treated within a single species with two subspecies (*C. bequaertii* ssp. *bequaertii* and ssp. *mossii*). Our analyses revealed clear-cut diagnostic characters neglected by the traditional taxonomy of the group, whereas we found that other characters have been overvalued and are not diagnostic. This study illustrates that even within a relatively well-studied area as Europe, plant taxonomy may benefit from objective and careful revaluations.

New fossil flora from Colombia, a window to the Eocene climate and biogeography in the Neotropics

Camila Martinez[1], *William Crepet*[1], *Carlos Jaramillo*[2]
1. Cornell University
2. Smithsonian Tropical Research Institute

An important step in the evolution of our modern glacial climate state occurred during the middle Eocene to early Oligocene, when the global temperature cooled, and the first Antarctica ice sheet appeared. This dramatic climate change caused a significant global turnover in marine and terrestrial biotas, however, more evidence from tropical regions is still needed to document these changes at low latitudes. A new macroflora from the Esmeraldas Formation of Colombia provide plant fossil evidence to understand some of the biotic changes that could have occurred in tropical regions. The Esmeraldas Flora has been collected from two localities and has more than six hundred specimens that include compressions and impressions of leaves mostly, but also seeds, fruits and seldom flowers. Detailed stratigraphic data shows that the Flora was deposited in floodplains of braided and meandering rivers. The age of the Esmeraldas Formation ranges from middle to late Eocene. Here, we present results of paleoclimatic analyses based on leaf fossil material from the Esmeraldas Formation. The obtained data are suggesting drier conditions during deposition compared to those from the present. Leaf cuticle analyses that include anatomical features and isotopic values? ^{13}C are also being performed to provide estimates of atmospheric CO_2 concentration for the Esmeraldas Formation. Finally, we propose taxonomic affinities of some fossil leaves, flowers, fruits and seeds, that suggest the presence of families like Fabaceae, Malvaceae, Menispermaceae, Myrtaceae, Passifloraceae, Rhamnaceae and Solanaceae. Our preliminary results are showing that the Esmeraldas Flora exhibit a great diversity, a predominance of microphyll leaf sizes and a great preservation of cuticles, that in general are suggesting that the Esmeraldas Flora could have represented a dry tropical ecosystem.

Polyphyly of Japanese *Carex* section *Mitratae* and its chromosome evolution based on nuclear and chloroplast DNA sequences

Tomomi Masaki[1], *Takuji Hoshino*[1], *Chun-Kuei Liao*[2], *Marcia Waterway*[3]
1. Okayama University of Science
2. Da-Yeh University
3. McGill University

Genus *Carex* L. has 2,000 species in the world and the largest number in Cyperaceae (Reznicek, 1990). About 493 taxa and 26 genera were reported in the Japanese Cyperaceae, and Japanese *Carex* comprises 311 taxa and 53 sections (Hoshino and Masaki, 2011). Section *Mitratae* is the largest section in Japanese *Carex* and adjacent regions of Japan (Oh, 2006, Dai *et al.,* 2010), containing 80 taxa, 53 taxa is endemic to Japan (Hoshino and Masaki, 2011). This section has separate staminate and pistillate spikes, the width of leaves 0.2-15 mm, and style base of achenes annulated. Akiyama (1955) separated this section into six subsections including adjacent regions of Japan, subsects. *Cryptostachydeae* (Franch.) Ohwi, *Lageniformes* Ohwi, *Nervatae* Akiyama, *Leucochlorae* Akiyama, *Pisiformes* Akiyama, and *Foliosissimae* Akiyama. The chromosome numbers of the species of this section were reported 2n=30-94 (Tanaka, 1948; Okuno, 1940; Hoshino, 1981; Ohkawa et al., 1998; 2000; Yano *et al.*, 2007a; 2007b; 2008; 2010). In this study, we focused on the phylogenetic relationships among the species of section *Mitratae*. We analyzed ITS, ETS-1f, *trn*L intron, and *trn*L-*trn*F intergenic spacer regions for 143 species in 46 sections of Core *Carex* clade (subgenera *Carex* and *Vigneastra*). Our results showed that the Japanese species of section *Mitratae* do not form a monophyletic group. Three major clades were found in section *Mitratae*: 1) *C. breviscapa* (subsect. *Lageniformes*) and *C. pudica* (subsect. *Nervatae*), 2) subsects. *Lageniformes*, *Nervatae* and *Leucochlorae*, and 3) subsects. *Foliosissimae* and *Pisiformes*, sensu Akiyama (1955). Subsects. *Lageniformes*, *Nervatae*, and *Leucochlorae* had characteristic insertions in ETS-1f region. Subsects. *Pisiformes* and *Foliosissimae* clade were divided into two groups, and showed the same tendency in the chromosome numbers.

P0518
Reinterpretation of *Cynara baetica* based on a principle of integrative species delimitation

Sergi Massó[1,2], *Jordi López-Pujol*[1], *Roser Vilatersana*[1]
1. Botanic Institute of Barcelona (IBB-CSIC- ICUB)
2. BioC-GReB, Laboratori de Botànica, Facultat de Farmàcia, Universitat de Barcelona

Cynara is a Mediterranean genus from the family Compositae that currently includes nine species. One of them is *Cynara baetica*, a diploid (2*n* = 34) perennial herb distributed in both sides of Strait of Gibraltar (the gateway between Atlantic Ocean and Mediterranean Sea). Historically, it was described as two different species: (1) *Cynara alba*, that grows in open areas in deep and nitrogenous soils on calcareous bedrocks at altitudes between 500 and 1700 m in southern Spain, and (2) *Cynara hystrix*, that occurs in roadside ditches and open areas under the same soil conditions at somewhat higher altitudes (from 900 to 2100 m) in northern Morocco. In 1992, a morphologic study carried out by A. Wiklund merged these two species in one (*Cynara baetica*) although separated into two subspecies: *C. baetica* subsp. *baetica*, for the Spanish populations; and *C. baetica* subsp. *marocanna,* for the Moroccan ones. The aims of the present study are to: (i) analyse the genetic diversity within and between *Cynara baetica* populations, including samples from the two subspecies (subsp. *baetica* and subsp. *maroccana*); (ii) infer the phylogeographic pattern of *C. baetica* and the role of Strait of Gibraltar as a barrier; (iii) test whether there are morphologic, genetic and/or ecological differences between both subspecies; and (iv) provide conservation guidelines. To achieve these goals, and following the most recent approximations on species delimitation, phylogenetic and population genetic analyses (based on both nuclear—three AFLP primer combinations—and plastid—two cpDNA regions—DNA markers) were combined with ecological niche modelling (ENM) and morphologic studies.

Results obtained showed a clear genetic, morphological and ecological differentiation between the two subspecies. According to these results the current taxonomic treatment is modified and the conservation guidelines are proposed according this taxonomical change.

Morphological studies of trichomes in the family Malvaceae

Rubeena Mattummal
University of Calicut

Plants may have hairs on their axial surfaces, superficially similar to the hairs of human body. They are called trichomes. Trichomes affect the plant in number of ways. There are mainly two types of trichomes: Glandular and non-glandular. Glandular trichomes contain or secrete a mixture of chemicals that have been found to have an enormous array and can be used as pesticides, pharmaceuticals, *etc*. Some trichomes may give resistance to plant growth. Trichomes are small protrusions of epidermal origin on the surfaces of leaves and other organs many plants. They range in size, shape, number of cells and morphology, as well as composition, from long cotton fibers, which are seed trichomes, to tiny bumps onthe surface of a leaf. Trichomes are well known to humans, even those who do not normally think about plant morphology and biochemistry. This is because they give many plants their distinctive look and smell: anyone familiar with the smell released when you handle the leaf of a tomato plant, crush fresh or dried herbs such as basil, mint or thyme, or who notices the stickiness or fuzziness of plant leaves or stems has experienced the impact of trichomes on our everyday perception of plants. They exhibit tremendous diversity, be it in their shape or the compounds they secrete. This diversity is expressed between species but also within species or even individual plants. The industrial uses of some trichome secretions and their potential as a defense barrier, for example against arthropod pests, has spurred research into the biosynthesis pathways that lead to these specialized metabolites. Because complete biosynthesis pathways take place in the secretory cells, the establishment of trichome-specific expressed sequence tag libraries has greatly accelerated their elucidation.The family Malvaceae is notable due to their higher economic importance and also due to the presence of mucilage. To know the variant distribution of trichomes on them 10 different species were selected and the study was conducted. The plant for the present study are collected from different localities, in and around the campus of farook college. The morphology of trichomes on various parts of the selected members of the family, malvaceae are observed. Identification and morphological study of the different types of trichomes are done using light microscope and taxonomic keys. Cleared photographs of the various types of tricomes on different parts of the plants are taken. The plants selected for the work are: 1. *Abelmoschus esculentus* (L.) Moench; 2. *Hibiscus lanarifolius* Willd.; 3. *Hibiscus mutabilis* L.; 4. *Hibiscus rosasinensis var. rosasinensis* L.; 5. *Hibiscus rosasinensis var. schizopetalus* Dyer, Gard; 6. *Malvaviscus penduliflorus* DC.; 7. *Sida acuta* Burn.; 8. *Sida alnifolia* L.; 9. *Sida cordata* (Burn.f.) Bross.; 10. *Urena lobata* L.

Biogeography and chromosome number evolution of tribe Polygonateae (Asparagaceae: Nolinoideae)

Ying Meng[1]*, Jia-Jian Wang*[1]*, Yong-Ping Yang*[2]*, Hang Sun*[2]*, Jun Wen*[3]*, Ze-Long Nie*[1]
1. Jishou university
2. Kunming Institute of Botany, Chinese Academy of Sciences
3. National Museum of Natural History, Smithsonian Institution

Polygonateae is a tribe of monocots (Asparagaceae: Nolinoideae) characterized by a sympodial rhizome, an elongated aerial stem and fleshy berries. The tribe includes four genus and ca. 100 species distributed worldwide in the Northern Hemisphere, but mainly from subtropic to temperate areas. The monophyly of the tribe has been supported by most molecular studies and usually two groups are recognized in Polygonatae: one including *Polygonatum* Mill., *Disporopsis* Hance and *Heteropolygonatum* M.N. Tamura & Ogisu and the other comprising *Maianthemum* Wigg. s.l. (including *Smilacina* Desf.). The tribe is one of the few lineages in Asparagaceae with classic disjunctions in Asia, Europe and North America and a wide variation of chromosome numbers and therefore is an ideal group to investigate the timing and origin of the disjunctions associated with chromosome evolution in the Northern Hemisphere. Here we first provide a phylogenetic framework of the evolutionary relationships among species of Polygonateae by analyzing DNA sequences from five loci: ITS, *rbc*L, *trn*K, *psb*A–*trn*H and *trn*C–*pet*N. The resulting phylogenetic hypothesis is then used to infer divergence times and historical biogeography of the tribe, as well as the chromosome number evolution. Temporal evolution in Polygonateae was estimated using a Bayesian divergence time analysis (BEAST) with fossil calibrations reported from literatures. Biogeographical patterns are explored using a dispersal – extinction – cladogenesis (DEC) model in Lagrange & RASP based on a maximum likelihood method. The evolution of chromosome numbers is investigated using likelihood method for tracking the pattern of chromosome number change along a phylogeny using ChromEvol. The origin of the two lineages within Polygonateae is inferred to have a tropical affinity from the late Oligocene to early Miocene during a time frame coinciding with paleoclimatic events in the Northern Hemisphere. Different biogeographic patterns are found between the two clades in the tribe. The early divergence of the *Maianthemum* clade is estimated in the middle Miocene with possible origin in the tropical America, while the *Polygonatum – Heteropolygonatum – Disporopsis* clade is suggested in the early to middle Miocene with possible ancestral area in the tropical to subtropical Asia. Our biogeographic results also reveal that the modern distribution of the tribe was shaped by multiple recent migrations/exchanges among areas of eastern Asia, Europe (including central Asia), and North America from the late Miocene to the Pliocene. Analyses of chromosome number evolution suggested that $x = 18$ as the ancestral base number for Polygonateae. The chromosome number evolution of the tribe is dominantly on the diploidy level with both trends of descending and ascending chromosome numbers and it seems that dysploidy has played an important role in the evolution of Polygonateae, especially in *Polygonatum*. Polyploids are found in all genera in Polygonateae, except for *Disporopsis*, but most polyploidization events are associated with infraspecific diploidy. Our results suggest that polyploids seems to be less and recent in the tribe and there is no obvious correlation between the frequency of polyploidy and their biogeographic distributions.

P0521

Cetrarioid lichens (Parmeliaceae) from India

Gaurav Kumar Mishra, *Dalip Kumar Upreti*
CSIR-National Botanical Research Institute, Rana Pratap Marg, Lucknow-22001

Among the different plant groups in India lichens exhibit their rich diversity as both macrolichens (foliose and fruticose growth form) and microlichens (crustose and squamulose growth form) are found growing luxuriantly in different habitats. Based on the type of growth forms, habitat, location and type of fruiting bodies and secondary metabolites present in thallus, lichens can be categorized in different communities/groups. Among the macrolichens together with Parmelioid, Cyanolichens and Cetrarioid are the most common group of lichens in India. Cetrarioid lichens are characterized by an erect foliose or subfruticose growth form of the thallus being loosely attached to the substrate, presence of marginal apothecia and pycnidia. A total of 149 species and 25 genera of the group are reported from the world, out of which 46 species belonging to 11 genera are known from India. *Cetreliopsis hypotrachyna* (Müll. Arg.) Randlane & Saag, *Nephromopsis isidioidea* (Räsänen) Randlane & Saag, *Parmotrema subthomsonii* (D.D. Awasthi) A. Crespo, Divakar & Elix and *Nephromopsis sikkimensis* (Divakar & Upreti) Randlane & Saag are endemic to India. *Nephromopsis* with 12 species is the most dominant genera of cetrarioid lichens followed by *Cetrelia* and *Cetraria* with 10 and 7 species respectively in India. *Cetrelia cetrarioides* (Delise ex Duby) W.L. Culb. & C.F. Culb., *Parmotrema thomsonii* (Stirt.) A. Crespo, Divakar & Elix, *Cetrelia braunsiana* (Müll. Arg.) W.L. Culb. & C.F. Culb., *Nephromopsis pallescens* (Schaer.) Park and *N. stracheyi* (C. Bab.) Müll. Arg., are the most widely distributed species of this group. Among the Indian states, the state of Sikkim exhibit maximum diversity of cetrarioid lichens represented by 38 species followed by Uttarakhand with 29 species. A more intensive survey in the Indian Himalayan region will definitely add few more species to the present list as some of the difficult terrain of the area are still not explored systematically for collection of lichens.

P0522

Phylogenetic reconsideration of family Phrymaceae and its relatives (Lamiales)

Hye-Kyoung Moon, *Suk-Pyo Hong*
Kyung Hee University

The family Phrymaceae had been traditionally known as a monotypic family. Recent phylogenetic studies, however, have extended its delimitation with inclusion of 12 genera (*ca.* 200 species) transferred from former Scrophulariaceae and showed the close link with Paulowniaceae and Mazaceae. Nevertheless, phylogenetic relationships between those genera in redefined Phrymaceae and with other families in Lamiales remain to be resolved. In this study, we conducted phylogenetic analyses using the sequence data of multiple genes (nuclear ITS, plastid *mat*K, *ndh*F, *rbc*L, *rps*16 and *trn*L-F) collected extensively across Lamiales to resolve their relationships. Our preliminary results from multiple genes consistently indicated that Phrymaceae is a monophyletic group in Lamiales with Paulowniaceae to be a close sister group. However, the number of major clades within the family and phylogenetic position of Mazaceae in Lamiales may differ according to the markers and sample size applied. Overall, our results support the delimitation of the current Phrymaceae, albeit Paulowniaceae required to be reevaluated. We will further discuss the phylogenetic consistency among the phylogenetic trees generated differently by respective genetic markers and their combination (NRF-2014R1A1A2058195).

The phylogenetic potential of pollen and orbicules in Lamiaceae

Hye-Kyoung Moon
Kyung Hee University

Study on pollen diversity has improved our understanding on the evolution of flowering plants since pollen variation connote phylogenetic history. However, the phylogenetic potential of palynological data should be reevaluated because the traditional classification of angiosperms has been significantly changed with molecular phylogeny. Here, I revisit the phylogenetic potential of palynological information in Lamiaceae, delimitation of which has been greatly expanded as with the inclusion of many genera from Verbenaceae. As a result, I will present pollen morphological data and the presence of orbicules among representative taxa of newly proposed Lamiaceae and will discuss their phylogenetic significance (NRF-2016R1D1A1B04934156).

2. Universidade Federal de Pernambuco
3. University of Memphis

Chresta encompasses 18 species of Compositae, mostly distributed in the Brazilian *Cerrado* and *Caatinga*. Plants of this genus present great morphological diversity, both in vegetative and reproductive structures, despite a relative small number of species. Species of *Chresta* are herbs to shrubs, usually with well-developed underground structures, occurring in a number of environments: rock outcrops, savannahs, quartzitic soils, riverbanks, wet soils and in disturbed areas. The heads are always fused in syncephalia, which can be spherical, with strongly fused capitula, or hemispherical, with the heads loosely grouped. In three species the secondary heads present indeterminate growth of their axis, a highly unusual feature within the Vernonieae. Two of the *Cerrado* species present red flowers and are hummingbird-pollinated, another rare character in the tribe. The *Caatinga* species have deeply lobed leaves, silver-green in most of the species. Palynological analysis has shown that there are three different pollen types in the genus, relative to *Vernonia* types A, C and F. This morphological diversity lead to the controverted taxonomic history of the genus, which either has been considered part of *Eremanthus*, due to the secondary heads, or split up into five different genera, namely *Argyrovernonia, Chresta, Glaziovianthus, Pithecoseris* and *Pycnocephalum*. A previous phylogenetic analysis, based on 3 molecular markers and a morphological dataset including 10 *Chresta* species, recovered the monophyly of *Chresta,* but did not present enough support to understand relationships within the genus, neither brought new insights on how morphological diversity evolved. In this work we used target capture combined with high-throughput sequencing, with a previously developed set of 1,000 nuclear markers, to recover the relationships within *Chresta,* aiming to achieve a better understanding of its morphological diversity. The obtained matrix contains ca. 600,000 characters for each terminal. Parsimony analysis was run in TNT, generating one tree, with maximum bootstrap support in 1,000 replicates. Maximum likelihood analysis used RAxML, with 1,000 bootstrap replicates. Both analyses recovered the same topology for internal relations in *Chresta,* with maximum bootstrap support at all nodes, except for one. *Chresta martii* is sister to all other species, which are grouped in two clades, representing *Caatinga* and *Cerrado* species, both of which are composed by two clades each. The ancestral syncephalium type appears to be hemispherical, with loosely joined capitula, with the spherical, tightly joined capitula type arising twice, once in each clade. The two red-flowered species are separated in two different clades, indicating that this character evolved twice in the group history, as well as the pollen type A that is exclusive from these two species. The clades obtained loosely follow the generic divisions previously proposed by other authors, with the important distinction that *Argyrovernonia* and *Glaziovianthus* would not be monophyletic.

Taxonomic study of *Pedicularis* ser. *Verticillatae* (Orobanchaceae) in Taiwan and Japan

Kaori Murayama[1], *Richard H. Ree*[2], *Kuo-Fang Chung*[3], *Chih-Chieh Yu*[4], *Noriyuki Fujii*[1]
1. Kumamoto University
2. Chicago Field Museum
3. Academic Sinica
4. Taiwan University

Pedicularis ser. *Verticillatae* in Taiwan (Taiwanese populations) has often been classified as *P. verticillata* L. However in Flora of China, the Taiwanese populations are classified as *P. transmorrisonensis* Hayata., otherwise they are classified as *P. refracta* var. *transmorrisonensis* (Hayata) Hurus. by Hurusawa (1948). To taxonomically reexamine the Taiwanese populations, we performed molecular phylogenetic analysis using the internal transcribed spacer (ITS) regions of nuclear ribosomal DNA and the trnK-matK region of chloroplast DNA. We also compared nine characteristics to determine morphological differences among the Taiwanese populations, *P. verticillata* and *P. refracta*. In both ITS and cpDNA trees, the Taiwanese populations were not included in the clade of so-called *P. verticillata*, and instead formed a clade at high bootstrap probabilities (95-100%) with *P. refracta* (Maxim.) Maxim., which is an endemic species of Kyushu, Japan. Furthermore, in the morphological analysis, significant differences were observed between the Taiwanese populations and *P. verticillata* in the following characteristics: angle of the apex of the galea (upper lip of the corolla), corolla length (excluding the calyx tube), width between rachis and sinus of the pinnae and width between rachis and longest pinna *etc.* On the other hand, there were two significant differences were observed between the Taiwanese populations and *P. refracta.* They were the corolla length (the Taiwanese populations = approximately 9 mm, *P. refracta* = approximately 13 mm) and the plant length (the Taiwanese populations = approximately 18.3 cm, *P. refracta* = approximately 31.4 cm). These results suggest that the Taiwanese populations are not *P. verticillata* but are very closely related to *P. refracta*. However there were also significant morphological differences between the Taiwanese populations and *P. refracta*, and their habitat were also different. The Taiwanese populations occur in the alpine zone of high mountains (alt. approximately 3000-3500m) but *P. refracta* occur at grassland habitat of lower mountains (alt. approximately 400-800 m). Therefore, we concluded that *P.* ser. *Verticillatae* in Taiwan (the Taiwanese populations) should be treated as *P. transmorrisonensis* Hayata, as described by Bunzo Hayata in 1915 (Icones Plantarum Formosanarumosa). *P. transmorrisonensis* is an endemic species in Taiwan closely related to *P. refracta*.

Phylogeny of the *Bouteloua repens* complex (Poaceae: Chloridoideae): A preliminary study based on nuclear ribosomal internal transcribed spacer and chloroplast *trn*T-L-F sequences.

Geraldine Murillo-Pérez[1], *María-Elena Siqueiros-Delgado*[1], *Gilberto Ocampo-Acosta*[1], *J. Travis Columbus*[2]
1. Universidad Autónoma de Aguascalientes
2. Rancho Santa Ana Botanic Garden

The *Bouteloua repens* complex (Poaceae: Chloridoideae) has been treated as a group of five species distributed from south USA to Brazil. Due to considerable morphological variation, putative hybridization, polyploidy, and apomixis, circumscription and relationships among taxa have been uncertain. To infer the phylogeny of this complex, two non-coding regions –the chloroplast *trn*T-L, *trn*L-F intergenic spacers, and *trn*L intron, and the nuclear ribosomal internal transcribed spacer (ITS1+5.8S+ITS2), were sequenced and analyzed by Bayesian inference method. The ITS phylogeny was used to carry out a character state reconstruction analysis to test the utility of morphological characters used for species circumscription, and to reconstruct the historical biogeography. Nuclear and plastid data revealed similar phylogenetic patterns. Both support the monophyly of the *Bouteloua repens* complex, but not the species monophyly, except for *B. americana* and *B. repens*, which form a strongly supported clades in the ITS, *trn*T-L-F and combined results. ITS and combined phylogenies show the *B. alamosana* samples from north and south in different clades. However, the *trn*T-L-F hypothesis resolves it as monophyletic. The character-state reconstruction, shows that all characters used as diagnostic are homoplastic, except the shape of the upper floret, which could be the synapomorphy of the *B. americana* clade, since is the only species showing an upper floret reduced to a column. According to the results of historical biogeography, the *B. repens* complex originated in central Mexico, and it was later dispersed until it acquire its current distribution.

Classification and phylogeny of the genus *Dianella* (Asphodelaceae)

Karen Muscat
The University Of Melbourne

The genus *Dianella* (the flax lilies) is a group of petaloid monocots (c.60 taxa) that mostly occur in Australia (more than half of the taxa), throughout South-East Asia, the Pacific (east to Hawaii) to New Zealand and across to the Indian Ocean to Madagascar. Current infrageneric and species-level classification is based on morphology without detailed molecular phylogenetic analyses. The first detailed global phylogeny will be presented with closely related genera using chloroplast and nuclear markers. Sampling includes the majority of Australian *Dianella* and extra Australian species from New Zealand, New Caledonia, New Guinea, Norfolk Island, Lord Howe Island, Hawaiian islands, Japan, Taiwan, Brunei, Malaysia, Bangladesh, Madagascar and Mauritius. Results show a good correlation between morphological patterns and molecular relationships. Biogeographic patterns across the global range and within Australia are identified, indicating an early divergence between Eastern and Western Australian lineages. The study also confirmed numerous new species for Australian and extra Australian *Dianella*.

Multiple-biomineralization in trichomes of Boraginales

Adeel Mustafa*, Hans-Jürgen Ensikat, Maximilian Weigend*
Nees-Institut für Biodiversität der Pflanzen, Universität Bonn

Biomineral deposits are widely prevalent in various types of trichomes of higher plants. The occurrence of mineralized trichomes on plant surfaces is considered to be crucial for plant-environment interactions, particularly to deter herbivores and mitigate irradiation and water stress. Our recent study has demonstrated the presence of calcium phosphate in trichomes of Loasaceae. The present study investigates biomineralization in the trichomes of a range of different, closely allied plant groups in the order Boraginales (Boraginaceae; Codonaceae; Hydrophyllaceae; Namaceae). Scanning Electron Microscope (SEM) and Energy Dispersive X-ray (EDX) analyses were employed for that purpose. The trichome tips were found to consist of either silica or calcium phosphate in high concentrations, providing sharpness, hardness, stiffness and toughness. The basal part of the trichome cells can contain relatively high concentrations of silica or calcium phosphate, whereas the median part, the shaft, is mainly mineralized with calcium carbonate; calcium phosphate and silica occur are here only found as a minor components. Calcium phosphate tips were found in several plant families of Boraginales, but not in Boraginaceae themselves. The process and complex patterns of biomineralization in the trichomes of Boraginales provide a new way of looking at trichomes in the light of systematic relationships and also regarding their functionality.

Phylogeny and taxonomy of *Leptopetalum biflorum* (Rubiaceae)

Akiyo Naiki[1]*, Kensei Akai*[2]*, Hidetoshi Kato*[3]*, Yoshiteru Komaki*[4]*, Keiko Mizunashi*[4]*, Tetsuo Ohi-Toma*[4]
1. Tropical Biosphere Research Center, University of the Ryukyus
2. Okinawa Churashima Research Center
3. Graduate School of Science and Engineering, Tokyo Metropolitan University
4. Botanical Gardens, Graduate School of Science, The University of Tokyo

The genus *Leptopetalum* (Rubiaceae), recently re-circumscribed and divided from *Hedyotis* s.l., comprises three herb and four shrub species. The herb species (*L. biflorum*, *L. pteritrum*, and *L. strigulosum*) are widely distributed in Asia, Southeast Asia, and Pacific islands, whereas the shrub species (*L. foetidum*, *L. grayi*, *L. mexicanum*, and *L. pachyphyllum*) are limited in some oceanic islands of Japan (the Bonin Islands), Marianas, and the West Pacific regions. One of the herb species, *L. biflorum*, has large variation in plant shape and size, and habitat. We recognized at least two morphological types of the plants. One [type A] has thick coriaceous leaves and is well-branched and procumbent on coastal limestone rocks. The other [type B] has chartaceous leaves and is few-branched and erect in inland open habitat. The present molecular phylogenetic analyses using nucleotide sequences of nuclear ribosomal ITS and ETS regions, and chloroplast *rps16* intron and *petB*-*petD* region indicated that the shrub species formed one clade and were nested into herb species lineages, and that plants of *L. biflorum* are divided into two polyphyletic clades, which correspond to the type A and B. These two types can be treated as different species. Characteristics of type B plants correspond to those of the type specimen of *L. biflorum*. Type A plants should be treated as another species based on *Hedyotis albido-punctata*, *H. paniculata*, *H. racemosa*, or *H. taiwanense*, or as a new species.

The family Gesneriaceae in India- An overview

Santhosh Nampy*, Janeesha A P*
Department of Botany, University of Calicut, Kerala

Gesneriaceae Rich. & Juss. in DC., with ca 3400 species, has roughly an equal distribution in the Neotropics and Paleotropics. The plants are mostly perennial herbs with conspicuous showy flowers. The family is easily distinguished by opposite deccusate (sometimes anisophyllous or alternate) leaves, pair-flowered cymes, pentamerous bisexual flowers with zygomorphic corolla, usually four or two stamens, presence of an annular or a one-sided disc and 1-locular ovary with parietal placentation. The Indian

Gesneriaceae belongs to the subfamily Didymocarpoideae and its two tribes, Epithemateae and Trichosporeae. The family is represented by 22 genera and 109 species in India. Since 2007, and essentially based on molecular data, many genera have been redefined, several new genera established and a considerable number of genera sunk into synonymy and a number of additional taxa has been described or recorded. The present paper discusses the diversity, distribution and endemism of the family in India.

Origin and evolutionary history of freshwater Rhodophyta: Further insights based on phylogenomic evidence

***Fangru Nan**, Jia Feng, Junping Lv, Qi Liu, Kunpeng Fang, Chaoyan Gong, Shulian Xie*
Shanxi University

Freshwater representatives of Rhodophyta were sampled and the complete chloroplast and mitochondrial genomes were determined. Characteristics of the chloroplast and mitochondrial genomes were analyzed and phylogenetic relationship of marine and freshwater Rhodophyta were reconstructed based on the organelle genomes. The freshwater member *Compsopogon caeruleus* was determined for the largest chloroplast genome among multicellular Rhodophyta up to now. Expansion and subsequent reduction of both the genome size and GC content were observed in the Rhodophyta except for the freshwater *Compsopogon caeruleus*. It was inferred that the freshwater members of Rhodophyta occurred through diverse origins based on evidence of genome size, GC-content, phylogenomic analysis and divergence time estimation. The freshwater species *Compsopogon caeruleus* and *Hildenbrandia rivularis* originated and evolved independently at the inland water, whereas the *Bangia atropurpurea*, *Batrachospermum arcuatum* and *Thorea hispida* are derived from the marine relatives. The typical freshwater representatives Thoreales and Batrachospermales are probably derived from the marine relative *Palmaria palmata* at approximately 415-484 MYA. When comparing the organelle genome content, it was discovered that *trx* and *grx* genes in chloroplast genome probably involved in the polysaccharides synthesis of Rhodophyta. Gene group substitution rates analysis showed that the ribosomal protein (*rps*), RNA polymerase (*rpo*) and ATPase (*atp*) genes in chloroplast, ATPase (*atp*) and succinate dehydrogenase (*sdh*) genes in the mitochondria were substantially elevated. The primary inference on the origin and evolutionary history of freshwater Rhodophyta proposed in this study needs to be testified with more organelle genome sequences and wider global sampling.

Family Commelinaceae in India: New taxa, infraspecific taxa and new additions

***Mayur Nandikar**[1], Rajaram Gurav[2]*
1. Naoroji Godrej Centre for Plant Research (NGCPR), Shirwal, Satara, Maharashtra, INDIA 412801
2. Department of Botany, Shivaji University, Kolhapur, Maharashtra, INDIA

Since last decade authors are working on family Commelinaceae in India. In the journey we screened thousands of live populations, made consultation of herbaria in search of different taxa in the family. It is a noble experience, resulted in documentation of about 15 genera and about 95 species. While revisiting family, numbers of taxa show so much variation that it has not been possible to divide them satisfactorily into new taxa or infraspecific taxa. However, some are consistent in their characters and have been recognized as a distinct species or variety. Authors described three new taxa in the genus *Murdannia* viz. *M. brownii*, *M. saddlepeakensis*, *M. ugemugei* and one variety *M. spirata* var. *flavanthera*. New reports have been made for Sri Lankan taxa *M. striatipetala* and *M. spirata* var. *parviflora*. Likewise, a new species has been added in the genus *Commelina*, i.e. *Commelina badamica*. Besides, four new taxa are being proposed and communicated. The present paper highlighted all these additions and a note on their distinctness.

Divergence times of *Onosma* L. (Boraginaceae) inferred from nrDNA ITS and two cpDNAs, *trn*H-*psb*A and *rpl32*-*trn*L $_{\text{(UAG)}}$ sequences data

Fatemeh Nasrollahi
Tarbiat Modares University

Onosma L. a taxonomically difficult group consisting of some 150 species is the largest genus of the tribe Lithospermeae. The Asia and Mediterranean regions particularly Iran and Turkey are the main centers of diversity of the genus. They usually grow in open, sunny habitats, and are well adapted to dry and rocky soils and steppes. The name onosma is derived from a Latin word “osma” originated from a Greek “osmê” (smell) and Stearn reported that *onosma* is treated as feminine gender. They have scorpioid inflorescence and tubular corolla. Hair characters has major taxonomic importance in *Onosma*. Corolla colour, shape and size are used as taxonomic characters in this genus. Divergence times were estimated from Bayesian Inference (BI) analysis using BEAST ver. 1.7 [Bayesian Evolutionary Analysis Sampling Trees]. We applied the substitution model selected by the AIC for each gene and a Relaxed Clock. Bayesian and Maximum Likelihood phylogenetics analysis applied to nrDNA ITS and *rpl32*-*trn*L $_{\text{(UAG)}}$ and *trn*H-*psb*A sequences for 42 species (40 ingroups and *Echium italicum*, *E. amoenum* were selected as outgroup). Our result showed that *Onosma* forms a monophyletic group. Since there are no reliable fossils of *Onosma*, the clock was calibrated using the estimate of mean age 30 Mya for a node, encompassing from *Echium* through *Onosma*. BEAST chronogram is congruent with those resulting from Bayesian analyses. The timing of diversification events is demonstrated by a chronogram derived from the all-compatible Bayesian consensus tree with dates for selected nodes constrained to the mean of penalized likelihood estimates obtained from sub-sampling of 1,000 trees from the posterior distribution of the Bayesian MCMC tree search. Our results illustrated that mean nodal Bayesian divergence time estimates indicated that stem–node (the root) is estimated to be middle Oligocene, ~30 Mya. The overall estimated mean ages and mean rates of evolution were obtained.

Disentangling complex evolutionary relationships in the sun orchids (*Thelymitra*, Orchidaceae)

Lars Nauheimer[1], *Mark Clements*[2], *Rowan Schley*[3], *Katharina Schulte*[1,4]

1. Australian Tropical Herbarium
2. Centre for Australian National Biodiversity Research (CANBR)
3. Imperial College London
4. CSIRO National Collections and Marine Infrasructure

Thelymitra is a genus of terrestrial orchids in the tribe Diurideae, which comprises over 118 species occurring in Australasia, with the majority of species in Australia. Despite considerable taxonomic work over the past two decades, evolutionary relationships and species delimitation within *Thelymitra* are still poorly understood. This is mainly due to the high degree of morphological variation found within the genus and complex evolutionary relationships due to past hybridization events. For a first assessment of the infrageneric relationships and the degree of genetic diversity within *Thelymitra*, we conducted a molecular phylogenetic study based on one nuclear and three plastid loci including the majority of the genus' species. This traditional sequencing approach resolved major clades, which in part corresponded well with prominent morphological features, e.g., of the column. Nevertheless, relationships between these major clades or between closely related species remained largely unclear due to lack of phylogenetic signal. Furthermore, incongruences between the plastid and nuclear phylogenies were detected that indicate hybridization events in recent times as well as in the early evolution of the genus. Thus, our four loci study provided the first molecular phylogenetic insights into relationships within *Thelymitra,* albeit with limited resolution. We have now embarked on applying high-throughput sequencing on an Illumina platform combined with target enrichment using target capture probes. Nuclear genes for probe development were selected based on transcriptome sequences across the tribe Diurideae, including Thelymitrinae. This wide sampling was chosen to ensure future combinability of data sets across the tribe. The plastid genes for the development of target capture probes were selected based on whole plastome sequences of Thelymitrinae generated via shotgun high-throughput sequencing. This approach will yield high numbers of nuclear and plastid regions and allow the reconstruction of phylogenetic relationships at finer scales, including the assessment of species delimitation in different species complexes. The increased phylogenetic resolution will then allow us to reconstruct ancestral-character states, to carry out divergence time estimations and ancestral range reconstructions, and thus will increase our understanding of the spatial and temporal evolution of this iconic group of Australasian orchids.

Phylogenomics of *Dichanthelium* (Paniceae: Poaceae): Biogeography and the problem of high sympatry

Kurt Neubig[1], *Lucas Majure*[2], *Robert Naczi*[3], *J. Richard Abbott*[3], *Walter Judd*[4], *W. Mark Whitten*[4]

1. Southern Illinois University Carbondale, Plant Biology, Carbondale, IL, 62901
2. Desert Botanical Garden, Department of Research, Conservation, and Collections, Phoenix, AZ, 85008
3. The New York Botanical Garden, Bronx, NY, 10458
4. University of Florida, Florida

Dichanthelium is distributed throughout the Americas and Hawaii, with its highest species diversity in the eastern United States. Species delimitation within the genus is contentious, with most floristic treatments differing drastically in the number and circumscription of species. Low levels of sequence divergence with conventional molecular markers result in poor resolution at deep phylogenetic levels. Therefore, we used a "genome skimming" approach to reconstruct phylogenetic relationships in *Dichanthelium* for over 80 different samples. *Dichanthelium* is monophyletic and although many deep phylogenetic relationships are highly resolved with these data, many species in eastern North America show very little DNA sequence divergence. Hawaiian *Dichanthelium* species form a clade and one species there is of hybrid origin. However, despite high sympatry, clear hybrids are very rare in *Dichanthelium* of North America. Many complex nomenclatural problems are ameliorated with these phylogenetic data, but new problems of polyphyly have arisen, such as in *D. commutatum*. Using ultrametric analyses, the timing of major biogeographic patterns will be discussed.

Convergent recruitment of new pollinators triggered by independent hybridization events in *Narcissus*

Isabel Marques[1,2], *Andreas Jürgens*[3,4], *Javier Fuertes-Aguilar*[5], ***Gonzalo Nieto Feliner***[5]

1. High Polytechnic School of Huesca, University of Zaragoza
2. University of British Columbia
3. University of KwaZulu-Natal
4. Technische Universität Darmstadt
5. Real Jardín Botánico, CSIC. Madrid

Hybridization is recognized as an important pathway to generate new diversity in plants. But hybrids need to achieve isolation to prevent gene flow and avoid assimilation into the parental gene pool. The recruitment of novel pollinators by hybrids has been hypothesized to be one way in which such reproductive isolation can be achieved. We tested whether pollinators contributed to isolation between two natural *Narcissus* hybrids and their progenitors using pollination experiments, observations, plus morphological and floral-volatile measurements. These hybrids share the same maternal but different paternal progenitors. We found that only the hybrids were visited by ants whereas the progenitors whereas the progenitors were pollinated by butterflies and bees, respectively. The two hybrids exceeded their progenitors in floral-tube aperture size and nectar production. The emission of floral volatiles by hybrid plants was not only equal to or higher than the progenitor species, but also contained some new compounds not produced by the progenitors. The recruitment of ants as novel pollinators in the hybrids involved the combination of increased nectar secretion and the production of novel floral scent compounds. A breakdown of chemical defense against ants may also be involved. This study provides support for the hypothesis that the recruitment of novel pollinators can contribute to reproductive isolation between hybrids and their progenitors.

P0537
When ribosomal loci go mad in *Anacyclus* (Asteraceae, Anthemideae): High levels of 45S rDNA site-number diversity in a diploid plant genus

Marcela Rosato[1], *Inés Alvarez*[2], *Gonzalo Nieto Feliner*[2], ***Josep Antoni Rosselló***[1,3]
1. Jardín Botánico, ICBIBE-Unidad Asociada CSIC, Universidad de Valencia
2. Real Jardín Botánico, CSIC, Madrid
3. Marimurtra Botanical Garden, Blanes

Indications that ribosomal DNA (rDNA) plays a more important role in cell machinery than classically acknowledged have raised interest in understanding all aspects of this family of repetitive DNA. One of these aspects is the structure of rDNA within the genome. The number of rDNA sites and their distribution has been assessed in a significant sample of angiosperms revealing clear regularities but also intra-specific variation, particularly in polyploid and cultivated plants. We aim to test if the structure of the 45S rDNA has been affected by intense contemporary hybridisation in a mostly weedy, Mediterranean genus. The number and location of rDNA 45S sites was assessed in 196 individuals from 47 populations, belonging to all nine species in the genus *Anacyclus*. We used fluorescence in situ hybridization and karyotype analysis. The number of 45S rDNA sites ranged from 4 to 11. This along with the chromosomal location (terminal or interstitial) and other features allowed the recognition of 14 different karyological ribosomal phenotypes that were arranged in a network to facilitate the inference of patterns of cytogenetic evolution. The variation (and inferred dynamism) of rDNA sites found in *Anacyclus* is outstanding: (1) The range of variation for rDNA sites spans a large part of the total range found per diploid complement across all angiosperms. At the Asteraceae level, *Anacyclus* shows (2) the largest range of 45S rDNA site-number variation and the highest number of rDNA sites per diploid chromosome complement. The distribution of karyological phenotypes across species suggests that the main factor in the dynamism found in *Anacyclus* is genomic shock effects resulting from contemporary hybridization.

T2
P0538
Phylogeography of *Orostachys spinosa* (L.) C.A. Mey (Crassulaceae) based on chloroplast DNA markers

Arthur Nikulin, *Andrey Gontcharov*
Federal Scientific Center of the East Asia Terrestrial Biodiversity FEB RAS

We used the sequence data of *trn*H-*psb*A, *trn*Q-*rps*16 and *rpl*32-*trn*L cpDNA intergenic spacers to investigate genetic differentiation within and among populations of *O. spinosa*, crassulacean species characterized by a wide distribution range, spanning from the Siberia's Pacific coasts to the Southern Urals, to analyze the genealogical relationships between haplotypes, and to reconstruct the possible ways of the species range extension. This study provides the first molecular data of the subsection *Appendiculatae* for a better understanding of the evolutionary history of the Far-Eastern crassulacean floras. A total of 621 sequences of three cpDNA loci were obtained from 207 plants representing 25 populations. The length of alignment was 2,345 bp, (ca. 1,4–1,6% of the plastid genome). A number of structural autapomorphies and synapomorphies (indels and inversions) were observed in the data set. Nucleotide substitutions and indel variations revealed 86 haplotypes. Most of these (59; 68%) were found in a single specimen (private haplotypes) and no haplotype sharing between populations was detected. The highest diversity was observed in populations from Altai Mts. yielding 32 haplotipes: almost each individual here carried a private haplotype. Somewhat increased haplotype diversity was also noted in populations from the south-western shore of Lake Baikal and the Tatar Strait shore. The median-joining network revealed two groups of haplotypes, Eastern and Western, separated by 11 mutation steps, of these 2 mutations were "synapomorphic". The Eastern group comprised 27 haplotypes (92 accessions) from populations of the south-eastern part of *O. spinosa* range. The Western group included a comparable number of accessions (115) but was characterized by a significantly higher number of haplotypes (59). Analysis of molecular variance showed that 76.36% of the genetic variation was due to differences between populations. For the among groups analysis, only 21.6% of the total genetic variance resided within populations of one group. The majority of molecular variance was attributable to differences among populations within groups (62.12% of the total), and those differences were significant again. Based on cpDNA, the genetic structure of *O. spinosa* was characterized by relatively low genetic variation within and high genetic differentiation between populations suggesting a restricted gene flow between the populations. The high genetic diversity and differentiation observed in our study is likely a result of isolation of *O. spinosa* populations. Despite quite extensive distribution range the species is characterized by an "island" distribution pattern because its populations are restricted to discontinuously scattered rock crevices, dry slopes and similar mostly xeric habitats. The high levels of genetic diversity parameters of the Altai populations suggest that they have a long evolutionary history. We hypothesize that the South Siberian Mountains is a likely center of *O. spinosa* origin from which the species was spreading in several directions: westwards to the Southern Urals and to the east by several lines: to the lake Baikal area; north-east Asia (Yakutia, Magadan, *etc.*), and the south-east (China and Primorsky Territory). This research was supported by the Russian Foundation for Basic Research grants (16-34-00176 and 15-29-0250515).

P0539
Assessment of phylogenetic relationships between *Sedum* L. and related genera (Sempervivoideae, Crassulaceae) by ITS rDNA sequence comparisons

Vyacheslav Nikulin, *Andrey Gontcharov*
Federal Scientific Center of the East Asia Terrestrial Biodiversity FEB RAS

Phylogenetic relationships in the most species-rich and taxonomically complex crasulacean genus *Sedum* and related genera were analyzed using 223 ITS rDNA sequences. To identify positional homology between divergent sequences, secondary structure models were generated for each sequence by mfold web server (http://mfold.rna.albany.edu) and used to guide the alignment. Our putative model of the ITS1 and ITS2 secondary structures generated with the thermodynamic-based folding conformed models predicted for other plant groups. Our molecular phylogenetic data corroborated results of previous studies based on other markers and limited datasets and supported the monophyly of the tribes Aeonieae, Semperviveae, and Sedeae. In the tree species were grouped into four clades/clusters: Acre, Leucosedum, Sempervivum and Aeonium. Sedeae accommodated majority of *Sedum* species either in the robust Acre clade or paraphyletic Leucosedum cluster. Besides *Sedum*, these lineages comprised a number of genera that were mostly embedded among *Sedum* taxa. Our study established only a few significant subclades in Leucosedum, and neither a morphological nor a lucid biogeographical pattern could be inferred from the phylogenetic pattern. Nevertheless, the extended taxon sampling confirmed the affinity of the North American genus *Dudleya* to Leucosedum and revealed its close relationship with *Sedum* subgen. *Gormania* members from the same continent. This affinity was supported not only by bootstrap and posterior probability thresholds, but also by a molecular synapomorphy in ITS rDNA sequence secondary structure. In the most species- (> 500 spp.) and phenotypes-rich *Acre* clade ITS rDNA data provided support for a sister relationship between Eurasian and American taxa forming respective lineages. Placement of *S. nudum* and *S. bressemoretii* from Madeira in the American subclade was the only exception suggesting either long-distance dispersal of these species from America to Macaronesia or Macaronesian ancestry of the American subclade in *Acre*. The Eurasian subclade of *Acre* was the only large lineage in the tree that accommodated no other genera except *Sedum* and predominantly distributed in Asia species. We revealed two subclades (A1 and A2) comprising taxa co-occurring in East China, Taiwan, Korea, and Japan, but despite largely overlapping distribution, there was no indication of their common ancestry. The presence of species occurring in the Himalayas and adjacent regions in the A2 subclade traces its origin to these territories, while the A1 subclade currently includes only East-Asian taxa. Complex relationships between *Sedum* spp. and other genera in the American subclade of Acre, within Leucosedum and Aeonium clades highlight the inadequate genus concept in the tribes Aeonieae and Sedeae. In the former, this problem relates only to a few distinct species occupying a deviant phylogenetic position that strongly suggests their alternative generic assignment. In the otherwise monophyletic Sedeae, *Sedum* represents a grade of clades/lineages with at least 10 genera embedded into it and often also being para- or polyphyletic. This pattern of relationship calls for re-evaluation of the genus concept in the family Crassulaceae and the tribe Sedeae in particular. This research was partially supported by the Russian Foundation for Basic Research grants (16-34-00176 and 15-29-0250515).

Ecotypic adaptation to serpentine soil and acidic wetland in *Aster rugulosus*

Takako Nishino[1], *Shota Sakaguchi*[2], *Naoko Ishikawa*[3], *Keitaro Fukushima*[4], *Yuji Isagi*[2], *Motomi Ito*[3]

1. Osaka Prefecture University
2. Kyoto University
3. The University of Tokyo
4. Tokyo Metropolitan University

Ecotypic adaptation to edaphic environment has promoted the study of speciation and many reports revealed that rapid physiological response was followed by gradual ecological differentiation. Serpentine soils contain toxic metals and poor basic nutrition for plants, so that serpentine areas restrict novices from entering. *Aster rugulosus* is a perennial species endemic to Japan, which has insect-pollinated flowers and disperses achenes with pappus. It is thought to be an endangered or a vulnerable herb in several districts due to abrupt decrease in habitats. *A. rugulosus* populations are growing in two contrastive edaphic conditions: non-serpentine, acidic wetland with clay and fine sand in lowland, and low mountainous regions with dry and fragile serpentine soils. All populations have some rhizomes in autumn in the swamp zone, whereas only a few populations localized in narrow serpentine zone near the Shizuoka-Aichi border, the central part of Japan, do not develop their rhizomes in the crumbly serpentine soils. Here, we studied phenotypic differences between locally adapted serpentine and wetland populations of *A. rugulosus*. Some life-history traits, especially related to reproduction were measured in natural populations and germination properties were tested under controlled artificial conditions. Furthermore plants from serpentine and non-serpentine sites were grown in reciprocal soil transplant experiments within a common nursery. The present study also examined the relationship of genetic diversity between serpentine and non-serpentine 20 populations using of allozyme and microsatellite polymorphism. The minimum size for flowering of serpentine populations was smaller than that of non-serpentine ones. The entities inhabiting serpentine sites bore achenes with the larger body and shorter pappus so that seed dispersal occurs near their mother plants surrounded by vacant germination sites. This strategy of life history in serpentine populations could compensate for rhizome loss and adapt to physical disturbance of the crumbly serpentine soils. Seed germination was indicative of variation in serpentine tolerance. On serpentine soils, the germination rate, the subsequent growth and the seedling survival in non-serpentine populations was much inferior to which of the serpentine populations. 50% individuals of non-serpentine were survived after transplanting to serpentine soils. It would be suggested that non-serpentine *A. rugulosus* with potential tolerance to serpentine succeeded in entering the serpentine area. Genetic diversity peculiar to serpentine populations has not occurred yet so that lapses of time from establishment of the serpentine ones would be similarly situated to the local non-serpentine ones. So each of the serpentine populations would be originated from the neighbor non-serpentine ones by seed dispersal and as the generations go by, the survivors with serpentine tolerance succeed in ecological adaptation, especially life history traits.

Allelopathy as a biochemical marker: allelopathic effect of the Egyptian *Marrubium* L. Species extracts on seed germination and seedling growth of *Raphanus sativus* L.

Salama El-Darier, Ream Marzouk, Sania Kamal, ***Iman Nour***
Botany and Microbiology Department, Faculty of Science, Alexandria University, Alexandria, Egypt

A numerical study were carried out to investigate the allelopathic potential of two *Marrubium* species (donor species); *M. alysson* L. and *M. vulgare* L. distributed in 11 locations along the western Mediterranean coastal region of Egypt. Aqueous extracts with different concentrations were tested on *Raphanus sativus* L. (recipient species). The results obtained were subjected to numerical analysis to discriminate among the eleven locations. The use of the germination characters such as plumule (PL) and radicle (RL) lengths, plumule (PGR) and radicle (RGR) growth rates and radicle/ plumule (RL/PL) ratio demonstrated a reliable dendrogram. *M. vulgare* samples were separated in a major group, whereas, the other major group containing *M. alysson* samples were further distinguished into four groups. The performed cluster analysis finally supported the obtained dendrogram from SDS-PAGE protein pattern and RAPD-PCR. Subsequently, the allelochemical compounds belonging to a class of secondary metabolites may be served as chemotaxonomic markers at both inter- and intraspecific levels which indicated the presence of particular biosynthetic pathways that conserved among them.

Evaluation of repetitive-DNA-sequence-based PCR fingerprinting for discriminating of two *Nostoc* strains

Bahareh Nowruzi
Department of Biology, Science and Research Branch, Islamic Azad University, Tehran, Iran

The identification and taxonomy of cyanobacteria species is still problematic and confusing, often being based on current morphological and physiological studies, which generates confusing classification systems based on plastic characters that vary with the environmental and cultural conditions. The present research aimed to investigate through a polyphasic approach, the differences in morphological and genotypic features of two cyanobacteria strains isolated from paddy fields of Iran, belonging to the family Nostocaceae (subsection IV. I). Challenges arose when the two *Nostoc* strains could not be discriminated by cloned 16S rRNA and ITS genes sequencing. As a result, the PCR-based techniques based especially on fingerprinting of repetitive DNA fragments such as Highly iterated palindromes (HIP1) has been used for assessing better resolution amongst closely related two *Nostoc* species. Interestingly, the DNA fingerprints generated using four HIP markers viz. HIP-AT, HIP-CA, HIP-GC, and HIP-TG showed 100% polymorphism in two *Nostoc* strains and each marker produced unique and strain-specific banding pattern. This study highlights the efficiency of DNA fingerprinting technique for assessing proximity of small number of strains, but probably for larger number of strains belonging to very closely related orders, the inclusion of DNA fingerprints in conjunction with other molecular tools would be necessary for better resolution of genetic diversity, genetic proximity, and taxonomic affiliation.

Taxonomic studies of the genus *Indigofera* Linn., in Nigeria

Onyebuchi Ephraim Nwankwo
Ebonyi State University, Abakaliki, Nigeria

Taxonomic studies were carried out on the macro-morphology, foliar anatomy and palynology of ten species of the genus *Indigofera* Linn., in Nigeria. The ten species have odd-pinnate compound leaves except *I. nummulariifolia* and *I. subulata* with simple and trifoliate leaves respectively. The leaflets' surfaces are pubescent in *I. hirsuta* and glabrous in other species studied. The leaflets' size ranged from 0.7×0.3 cm^2 in *I. geminata* to 3.2×1.7 cm^2 in *I. macrophylla*. The epidermal cell shapes are mostly irregular on both surfaces of all the species studied except in *I. capitata*, *I. nummulariifolia* and *I. oblongifolia* in which they are polygonal. Sizes of the pollen grains ranged from 22.9×20.5 μm^2 in *I. subulata* to 35.2×28.5 μm^2 in *I. nummulariifolia* while the mean of exine thickness ranged from 0.9 µm in *I. congolensis* to 4.4 µm in *I. capitata*. The grains are tricolpate and tricolporate, subprolate and spheroidal except in *I. spicata* in which it is prolate. Marked variation exists in the number of leaflets per petiole and pollen grain aperture in *I. macrophylla* collected from two different locations. The leaf type and arrangement, number of leaflets per petiole, flower colour, stomatal type and epidermal cell shapes are significant in the taxonomy of the genus *Indigofera*. A distributional map showing the diversity of the species in Nigeria is provided.

P0544
Patterns of hybridization in sympatric populations in *Goodyera* (Orchidaceae)

Sang-Wook Han, Seon Won Seo, ***Sang-Hun Oh***
Daejeon University

Goodyera is a relatively small genus in Orchidaceae with about 40 species distributed worldwide and characterized by creeping rhizomes, rosette leaves with often marked lines, and single anthers with two sectile pollinia. In Korea, six species (*G. schlechtendaliana*, *G. biflora*, *G. repens*, *G. rosulacea*, *G. maximowicziana*, and *G. velutina*) and one hybrid, *G.* x *tamnaensis*, are distributed. All of these species, except for *G. rosulacea*, occur on Jeju Island, and some of which grow together at one site, forming sympatric populations. As part of comprehensive systematic study of *Goodyera*, we located sympatric populations of *G. maximowicziana* and *G. velutina* on Jeju Island. To understand patterns of morphological variation between the species, we examined diagnostic characters for *G. velutina* and *G. maximowicziana* such as stem color, leaf venation, color, and margin, and flower color in 53 individuals of six species. We found that at least three intermediate forms occurred in sympatric populations of *G. velutina* and *G. maximowicziana* on Jeju Island, suggesting hybridization may have played a role in generating morphological diversity within populations. Phylogenetic analysis using both nuclear and chloroplast DNA sequences suggests that the hybridization events associated with *G. velutina*, and *G. maximowicziana*.

Phylogenetic and biogeographic perspectives on pollination systems in the Apocynaceae: An update

Jeff Ollerton[1], *Sigrid Liede-Schumann*[2], *Ulrich Meve*[2], *Mary Endress*[3], *Adam Shuttleworth*[4]
1. University of Northampton
2. University of Bayreuth
3. University of Zurich
4. University of KwaZulu-Natal

The Apocynaceae is a large, diverse family of more than 5,000 species in at least 360 genera, distributed from temperate to tropical environments. The family has representatives in every major biome except arctic tundra, and is particularly species rich in the dry and wet tropics, though there are some subtropical centres of diversity such as the upland grasslands of eastern South Africa. The family received early attention because of the highly derived pollination mechanisms of some subfamilies, particularly the Asclepiadoideae and these asclepiads remain the best studied members of the family. In many ways the asclepiads parallel the orchids in the complexity of their floral structure and the presentation of pollen as packaged pollinia. Unlike the Orchidaceae, however, life forms in the Apocynaceae cover almost the whole spectrum of plant types, including vines, robust (high-climbing) lianas, herbs, tubers, epiphytes, stem and leaf succulents, shrubs, and trees. The pollination ecology of the family is equally diverse and some groups have been relatively well studied, in depth if not in breadth, e.g. North American *Asclepias*. Since the last review of pollination systems within the subfamily Asclepiadoideae (Ollerton & Liede 1997 - *Biological Journal of the Linnean Society* 62: 593-610) our knowledge of other asclepiad genera and other Apocynaceae subfamilies has greatly increased, with important papers published on genera such as *Angadenia*, *Apocynum*, *Ceropegia*, *Mandevilla*, *Oxypetalum*, *Pachycarpus*, *Periploca*, *Tylophora* and *Vincetoxicum*. However, there are still major groups of Apocynaceae that are only beginning to be studied, and there are whole clades for which we have no published data on their pollination ecology. In this presentation we review what is currently known about pollination systems in the family, using recent advances in our understanding of the major phylogenetic relationships as a framework for interpreting evolutionary patterns and answering questions about ecological, biogeographic, and evolutionary patterns and processes within the Apocynaceae.

Monophyly of the Philippine endemic myrmecophytic *Neonauclea* Merr. (Rubiaceae) species including the description of two novel species

Jorge Anton Ordas
University of Santo Tomas

The Rubiaceous genus *Neonauclea* comprises 70 species of diverse trees and shrubs predominantly distributed across Southeast Asia. The genus is the largest within tribe Naucleeae and is well regarded for its extensive radiation of myrmecophytic species, with 19 recorded species and four are found in the Philippine archipelago. With no Philippine representative species investigated in previous molecular studies, this presents a large dearth on phylogenetic data on the genus itself. In this study, we performed a combined Bayesian and Maximum Likelihood analysis of myrmecophytic samples collected from different localities in the Philippines using ITS, *rbc*L, and *trn*T-F datasets to test the monophyly of the myrmecophytic *Neonauclea* species from the Philippines. In contrast to the independent acquisition of myrmecophytism of Bornean myrmecophytic *Neonauclea*, our results suggest a monophyletic ancestry for these Philippine myrmecophytes, exclusively distributed in the Visayas and Mindanao island groups of the archipelago, demonstrated by a strongly supported clade (BS=100; PP=1.00) in the phylogenetic analysis. In addition, two new endemic species are described and illustrated in this study, namely *Neonauclea connicalycina* and *N. viridiflora*, both are closely allied with the endemic *N. formicaria*. A taxonomic key and a map for these species' distribution is also included in the study.

A new delimitation of the species *Chionoloma bombayense* (Müll. Hal.) P. Sollman (Pottiaceae, Bryophyte) based on molecular and morphological data

Marta Alonso, Juan Antonio Jiménez, ***Jose David Orgaz****, María Jesús Cano*
Universidad de Murcia

Chionoloma bombayense (Müll. Hal.) P. Sollman is a moss belonging to the family Pottiaceae. According to Sollman (2000, 2005), it is extremely variable and, for many years, it was considered the only species of the genus *Pseudosymblepharis* Broth., and later *Chionoloma* Dixon (Sollman 2,001). All the species of these two genera in Asia and Africa were regarded as conspecific with *C. bombayense*. It was justified by the extensive plasticity shown by the morphological characters, implying that the different recognized morphospecies were connected by intermediate specimens. In the last years, we have been focus on the revision of *Chionoloma.* The phylogenetic study carried out included many species considered as synonyms of *C. bombayense*, such as *C. angustatum* (Mitt.) M. Menzel, *C. crassicostatus* (D.H. Norris & T.J. Kop.) M. Alonso, M.J. Cano & J.A. Jiménez, *C. dubium* (Thér.) M. Alonso, M.J. Cano & J.A. Jiménez, *C. duriuscula* (Mitt.) M. Menzel and *C. induratum* Dixon (Alonso *et al.,* 2016). However, these species were not grouped together in the phylogenetic tree but, they appeared in different clades, suggesting independent lineages. Although the current results are not sufficient to estimate the number of species in this genus, they do strongly suggest that more than one species should be recognized. Moreover, collections of *C. bombayense* s. str. share some morphological synapomorphies that allow their recognition as a separate species. They are characterized by unbordered and short leaves, the percurrent leaf costa with two stereid bands, with the dorsal band larger than the ventral band, and the basal laminal cells forming a differentiated area like an inverted "U", and not extending up along the margins to form a V-shaped transition to the upper cells. Therefore, based on molecular and morphological data, the concept of *C. bombayense* is here redefined. A complete description of the species is present, its distribution is updated, and the principal distinctive characters that separate it from the nearest species of *Chionoloma* are analyzed and illustrated.

P0548
The genus *Sciuro-hypnum* (Hampe) Hampe (Brachytheciaceae, Bryophyta) in Japan

Jose David Orgaz[1], *Tomio Yamaguchi*[2], *Juan Guerra*[1]
1. Universidad de Murcia
2. Hiroshima University

Sciuro-hypnum (Hampe) Hampe is a widespread moss genus distributed mainly in temperate and boreal regions. Even thought our knowledge about *Sciuro-hypnum* has increased since Ignatov and Huttunen (2002) published the circumscription and nomenclature of this genus within the Brachytheciaceae, the taxonomy of this genus remains poorly understood, especially in East Asia. In Japan, the circumscription of this genus has not been properly studied since Takaki (1955) obviously included all the current *Sciuro-hypnum* species under *Brachythecium* Schimp. Based on the revision of more than 2000 herbarium specimens and different fieldtrips taken out during 2014 and 2015 in order to collect fresh samples, we can conclude that 13 species of *Sciuro-hypnum* are present in Japan. Main taxonomical characters to distinguish the different species are discussed. For each species, we also provided microphotographs as well as distribution maps in order to a better circumscription of the species.

P0549
The taxonomy and geography of Russian Pinaceae

Larisa V. Orlova
Komarov Botanical Institute RAS

The family *Pinaceae* - is the largest amongst gymnosperms, it includes about 230 species in 10 genera, of them in Russia 27-29 wild species (Orlova, 2012). During 2009-2016 complex comparative systematic, morphological and molecular investigations in LE, MW, SVER, NSK, VLA, BP, C, E, K, KRAM, PE, PR, W, Z *etc.*) and in nature – Far East (Kamtschatka, South Primorie), Eastern and Western Siberia, Ural, Murmansk region, Karelia *etc.*) were done. Our investigation allowed to reveal new important features of reproductive (the morphology and sizes of bract scales, the ratio of its length and seed scales) and vegetative organs: terminal buds and its scales – the shape, sizes, color, presence of white waxy coating and pubescence, the ratio of length of profills (thickened basal scales at the base) and bud; annual and older shoots – its thickness, color and pubescence, the sizes and morphology of pulvini; needles – sizes, color, shape of needles and its apex; arrangement, color and the number of stomatal lines and white wax coating on its sides. For *Larix* also – the shape of epidermal cells, the structure of cuticle and wax touch (Orlova *et al.,* 2014) and for *Pinus* –sizes and morphology of sheaths of brachyblasts, its scales, and also the profills at its base (Orlova, 2001; Orlova, 2012). Our research has allowed to clarify the taxonomic status and the geographical distribution of some critical taxa, such as *Pinus funebris* Kom., *P. friesiana* Wichura, *P. sosnowskyi* Nakai, *Abies gracilis* Kom., *A. semenovii* B. Fedsch., *L. olgensis* A. Henry, *L. cajanderi* Mayr, *L. dahurica* Laws., *L. komarovii* Kolesn., *L. kamtschatica* (Rupr.) Carr., *L. archangelica* Laws., *Picea fennica* (Regel) Kom. *etc.* (Orlova, 2006; Orlova, Egorov, 2011; Orlova, 2012; Orlova *et al.,* 2016 *etc.*). Determined that in the Southern Urals two morphologically different groups of *Picea obovata*, confined, apparently, to a certain altitude zones, that confirmed the results of molecular genetic studies by Z.H. Shigapov (2005) and his conclusion about the existence of several genetically distinct populations in this territory. In the Southern Primorye (Russian Far East) have established the availability of a wide strip of contacts of *L. olgensis* and close *L. komarovii*, within which there are hybrid individuals (*L. olgensis* x *L. komarovii*). Microsatellite analysis of 78 samples of *L. olgensis* and *L. komarovii* compared with *L. czekanowskii* samples and *L. cajanderi* of Eastern Siberia, has allowed to establish population-genetic differentiation of *L. olgensis* and *L. komarovii*, as well as to identify possible hybrid forms. In natural populations of Western Siberia – the Yamalo-Nenets Autonomous Okrug and Republic of Komi (Vorkuta) – near Salekhard, Nadym, Pangody *etc.*, we discovered new hybrid larch *L. archangelica* Laws. x *L. dahurica* Laws., with combine features of *L. archangelica* Laws. and *L. dahurica* Laws. Such hybrids are common here, while a typical *L. archangelica* Laws. found to be rarer. Further investigations confirmed the distribution of this hybrid larch in Western Siberia to the south up to the boundary with the Khanty-Mansiysk Autonomous Okrug (village Uvat, Tyumen region) (Lebedeva, Orlova, 2014; Orlova *et al.,* 2014). Now we are working to establish the exact boundaries of the distribution of different *Pinaceae* taxa to be uploaded into an electronic database and electronic maps of distribution to be created.

Phylogeography, ecological paleodistribution and morphological divergence in *Pinus patula*

Alfredo Ortiz Martínez[1], *David A. Moo Llanes*[2], *Juan P. Jaramillo Correa*[3], *Lev O. Jardon Barbolla*[4], *Xitlali A. Aguirre Dugua*[5], *Eduardo Ruiz Sanchez*[6], *David Gernandt S.*[5]
1. Posgrado en Ciencias Biológicas, Universidad Nacional Autónoma de México
2. Facultad de Medicina, Universidad Nacional Autónoma de México
3. Instituto de Ecología, Universidad Nacional Autónoma de México
4. Centro de Investigaciones Interdisciplinarias en Ciencias y Humanidades, Universidad Nacional Autónoma de México
5. Instituto de Biología, Universidad Nacional Autónoma de México
6. Departamento de Botánica, Universidad de Guadalajara

In Mexico, little is known over diversification processes in Pinus due to their large genome with highly repetitive elements, large effective population sizes, weak reproductive barriers and the recent origin of the species. Mexico harbors 49 species and is considered a center of diversification of the genus, especially due to complex geological and climatic history. The aim of this study was to evaluate the morphological divergence, geographical delimitation and phylogeographic history of *P. patula*. Our results indicate that this taxón is indeed formed by two lineages, which are traditionally recognized as varieties based on morphological characters is supported by multivariate analyses (analysis of principal components, discriminant analysis and analysis of grouping). Most morphological variation was found within *P. patula* var. *patula*, which is distributed in the Sierra Madre Oriental, the most ancient mountains range from Mexico (540 million years). Ecologically, the paleodistribution shaped from bioclimatic variables indicates that these two lineages have incurred in expansions and contractions since the Pleistocene to present, being most noteworthy their expansions from the mid-Holocene to the present. The genomic information shows a more complex history than was expected, a number 123 of Single Nucleotide Polymorphisms correlated with morphology and ecological differentiation, but without showing a clear genetic or phylogeographic structure. The cold conditions during glacial periods favored the processes of historical demography and the configuration of the architecture of the genetic variation of the populations. The study of morphology, environmental differentiation, genetic structure and inference of past climatic scenarios, are useful for understanding, how historical processes have molded the structure of the genetic variation of *P. patula* in Mexico.

Phylogenetic relationships of *Gomphrena* and related genera (Amaranthaceae)

Teresa Ortuño[1], *Thomas Borsch*[2]
1. Museo Nacional de Historia Natural (MNHN) - Herbario Nacional de Bolivia (LPB),
2. Botanischer Garten und Botanisches Museum Berlin

The phylogenetic relationships of the subfamily Gomphrenoideae using *rpl16* and *trn*LF*;* Reveal that Gomphrena is a polyphyletic group with species that belong to different ancestral lineages. One of these lineages binds Gomphrena globosa (*Gomphrena* type str.) To the genus *Blutaparon*, *Lithophila*, and *Gossypianthus*. To elucidate the generic limits of Gomphrena s. Str., And its close relationship with these allied genera, we present a phylogenetic reconstruction with a broad sampling of taxa and characters. The matrix includes combined sequences of the chloroplastdial regions *mat*K-*trn*K and + *trn*L-F and rpl16, core sequences (nrITS), and morphological characters of 29 species. In addition to the analysis of a matrix close to 80 samples based on matK-trnK and nrITS regions to represent the high diversity of *Gomphrena* in the Neotropics, with emphasis in Bolivia, where it is the most diverse genus of the Amaranthaceae family. These sequences were analyzed with parsimonic (MP), maximum likelihood (ML) and Bayesian inference (BI) methods. We also analyzed the evolution of 20 macro and micro morphological characters and the C3 and C4 photosynthesis pathway of the species included in the molecular analysis. The results confirm the systematic position of the species of the genus *Blutaparon*, *Lithophila* and *Gossypianthus* within *Gomphrena* str. The relationship between the coastal species of *Blutaparon* and *Litophila* with the species of Gomphrena of Australia. Gomphrena species with C3 photosynthesis of the cerrado (G. *mollis*, *G. rupestris*) have a position as a sister group to the rest of the species of the *Gomphrenas* lineage. Tr. Which have a C4 metabolic pathway including Blutaparon, Litophila and Gossypianthus. Phylogenetic reconstruction shows different lineages in the tropical South Andes within Gomphrena s.tr. Where some clades include new species. We review the nomenclature to elaborate a new circumscription of the genus Gomphrena based on a monophyletic concept.

P0552

Disentangling putative inflorescence and floral homoplasies between New World and Old World Loranthaceae.

Favio González[1], *Natalia Pabon-Mora*[2]
1. Universidad Nacional de Colombia, Facultad de Ciencias, Instituto de Ciencias Naturales, Bogotá
2. Universidad de Antioquia, Facultad de Ciencias Exactas y Naturales, Instituto de Biologia

With c 77 genera and 950 hemiparasitic species, the Loranthaceae is the most successful and diversified family of the order Santalales. Flowers in the family are exceedingly variable in terms of ground plan, shape, size and pollination syndromes. Recent phylogenetic analyses based on molecular data have shown high degrees of putative morphological homoplasies especially among Old World and New World clades. The aim of this study is to explore in detail the developmental and morphological traits of several New World (NW) taxa that appear at first glance as homoplasic with Old World (OW) lineages. These traits are: the reduction of dichasia to single flowers conforming racemes (e.g. NW *Peristethium* and *Tristerix* versus OW *Dendrophthoe*); the acquisition of unisexual flowers (e.g. NW *Passovia* and *Peristethium* versus OW *Loranthus*); the reduction of floral size associated with shifts in pollinators (e.g. NW insect pollinated *Passovia* and bird pollinated *Psittacanthus* versus OW insect pollinated *Loranthus* and bird pollinated *Lepeostegeres*); the fenestrate corolla anthesis (e.g. NW *Tristerix* versus OW *Actinanthella*); the ligulate petals (e.g. NW *Psittacanthus* and *Ligaria* versus OW *Plicosepalus*); the polysporangiate anthers (e.g. NW *Aetanthus* versus OW *Amyema*); and the cleistogamy (e.g. NW *Aetanthus* versus OW *Helixanthera*). Our results indicate that, although superficially similar, most of these putatively homoplasious features exhibit differences in terms of developmental pathways or morphoanatomical characters.

P0554

Comparative genomics and transcriptomics of representative holoparasitic species of Apodanthaceae in the Americas

Natalia Pabon-Mora[1], *Juan Fernando Alzate*[2], *Laura Marcela Arias Agudelo*[2], *Sebastian Guzman*[3], ***Favio González***[3]
1. Universidad de Antioquia, Facultad de Ciencias Exactas y Naturales, Instituto de Biologia
2. Universidad de Antioquia, Facultad de Medicina
3. Universidad Nacional de Colombia, Facultad de Ciencias Exactas, Instituto de Ciencias Naturales, Bogotá

With two genera and thirteen species, the Apodanthaceae are the only parasitic lineage within the order Cucurbitales. Species of both genera (*Apodanthes* and *Pilostyles*), exhibit an achlorophyllous, holoparasitic lifestyle, with a micellium-like endophyte, and gregarious, sessile flowers that emerge from the parasitized stems.

Whereas the monotypic *Apodanthes* is restricted to the Americas and parasitizes preferentially Salicaceae, *Pilostyles* is distributed worldwide and grows parasitizing several legumes. With the aim to compare genome evolution across Apodanthaceae, we have generated and assembled the first plastome of *P. boyacensis,* a species from the Andes of Colombia. Phylogenetic analyses indicate that *P. boyacensis* is more closely related to *P. thurberi* from Southern United States and Mexico, than to the widely distributed *P. blanchetti,* from Panama to Argentina, Brazil and Chile. Such relationship appears to be driven by the *Dalea* host specificity rather than to the geographic proximity between species, as *P. boyacensis* is the only South American species that parasitized Dalea. MiSeq Illumina DNA sequencing from *P. boyacensis* flowers resulted in 8,515,547 paired end reads. Data processing was followed by extensive merging using FLASH and assembly by Newbler v2.9 where a subset of 1,000,000 filtered representative reads resulted in two contigs. Further reassembly by Newbler 30x resulted in a single contig that was then compared with the available plastomes of the African *P. aethiopica* (11 Kb) and the Australian *P. hamiltonii* (15 kb). De novo contig re-assembly by selecting two different reference points indicates that *P. boyacensis* has a circular plastome of 12 Kb. Despite maintaining some synteny with the reported plastomes of *P. aethiopica* and *P. hamiltonii*, mutation rates outside coding sequences are extremely high finding virtually no match in the three species. Comparative annotation shows that the *P. boyacensis* plastome maintains seven functional genes, namely, *rrn16*, *rrn23*, *accD*, *rps3*, *rps12*, *rpl2* and a putative oxidoreductase (*PbOX*). RNA-seq data generated in parallel from flowers and fruits of *P. boyacensis* show transcriptional activity for all genes and indicate that *PbOX* has five functional alternative transcripts. By comparison with the other two species of *Pilostyles*, the plastome of *P. boyacensis* lacks an ORF for *rps4*, while maintaining functional loci for *rpl2* and the Oxidoreductase. Our results point to independent gene loss and differential selection during the past 23-33 Myr in the three species inhabiting different continents. Our data further shows that while the plastome is extremely reduced, the mitogenome and the nuclear genomes have not experienced the same reduction. Our preliminary data on the mitogenome size yields a 2.0 Mb estimate similar to the *Cucumis sativus* mitogenome estimated in 1.7Mb. Although nuclear genome estimates are still under investigation, we generated a preliminary search for the key regulatory network of nuclear encoded transcription factors involved in flower development. Our results show an intact network of ABCDE *MADS*-box genes with two interesting trends: (1) there are fewer active copies of A-class and E-class genes than typically found in other core eudicots and (2) there are alternative spliced transcripts for the B, C and D-class genes.

T2

Phylogeny of the *Bouteloua barbata* complex based on molecular data

Pacheco-Jimenez Marisol[1], *Maria Elena Siqueiros-Delgado*[1], *Rosa Cerros-Tlatilpa*[2], *Amanda Fisher*[3], *Ernesto Flores-Ancira*[1]

1. Universidad Autonoma de Aguascalientes

2. Universidad Autonoma del Estado de Morelos

3. California State University, Long Beach

Bouteloua barbata complex is a group integrated by *B. barbata* var. *barbata*, *B. barbata* var. *rothrockii*, *B. barbata* var. *sonorae*, *B. parryi* var. *parryi*, *B. parryi* var. *gentryi*, *B. elata*, *B. ramosa* and *B. breviseta*. Even though the phylogenetic relationships of the genus *Bouteloua* has been studied due to its high forage value and wide distribution, the evolutionary relationships between the species of the *Bouteloua barbata* complex had been poorly explored, and the monophyly of their taxa and the evolution of their morphological characters are still unknown. The objectives of this study were (1) to estimate the monophyly of the species complex, (2) to define the diagnostic morphological characters that allow the species circumscription, and (3) to define the morphological apomorphic and plesiomorphic characters of the group. Specimens were obtained through field and herbarium collections, covering their whole distribution range from the United States, Mexico and Argentina. Nuclear and chloroplast DNA sequences were used to infer the complex phylogeny. Maximum parsimony (MP) and maximum likelihood (ML) analysis, of individual and combined data, were performed to estimate phylogeny, and the bootstrap was used to get statistical support. To estimate the evolution of the morphological characters used in species circumscription, samples with the highest variation were selected, analyzed and reconstructed using the MP hypothesis in Mesquite software.

Diversity, evolution and biosystematics of Legumes of U.P. India

Vaibhav S Pandey

Ddu Gorakhpur University

Plants came on this plant about 450-500 million years ago. Legumes came on this planet about 60 million years ago and developed symbiotic association about 58 million years ago. Non-nodulation remains common in Caesalpinioideae, with smaller numbers in Mimosoideae and Papilionoideae These plants revolutionized the mother earth planet for fixing the nitrogen and established natural nitrogen fixing industry on this planet. These plants are natural asset for our biological system and govern all biofunctions, distribution, and biodiversity climate link of the world. Legumes belongs to family Fabaceae or Leguminosae. These plants have specific biofunctional quality and growing in different Biospecific regions (BRs) and commonly known as Biospecific regions plants (BRPs). Legumes are live telecast of mother earth planet growing naturally as well as cultivated in different parts of the world since ancient times. India and Indian sub-continent have green and lush vegetation with natural biological industry, with their great biological supporting system to vegetation. Legumes are a significant source of protein, dietary fiber, carbohydrates and dietary minerals. In India, Uttar Pradesh is the largest state, comprises many legumes with their biological industry. Considering these facts diversity of legumes was explored for their documentation and distribution in Uttar Pradesh. The legumes of Caesalpinioideae, Mimosoideae and Papilionoideae were explored. Maximum number of plants were recorded in Papilionoideae followed Mimosoideae and Caesalpinioideae. The diversity, evolution and biosystematics of these Legumes were recorded and discussed.

Bryophytes gemmae biodiversity and related environmental adaptability studies in different vegetation communities of dolomite subtropical

Jia Peng Pang[1], *Zhi Hui Wang*[1], *Zhao Hui Zhang*[2]
1. School of Life Sciences, Guizhou Normal University
2. Key Laboratory for Information System of Mountainous Area and Protection of Ecological Environment of Guizhou Province, Guizhou Normal University

From October 2015 to April 2016 biodiversity of bryophytes gemmae and study on the adaptability to the environment by sampling method and field investigation method on Guiyang Luchongguan Forest Park dolomite subtropical in different vegetation communities. The results show that 100 samples were collected from sampling sites, and 7 families, 16 genera and 30 species were identified, Among them had 6 families, 15 genera and 29 species of Musci, Hepaticae only had *Marchantia polymorpha* L., Barbula and Brachymenium is the dominant families of bryophytes is the number of species in bryophytes indicated arbor and shrubs community>lianas, boscage and climbing shrubs community>boscage and low shrubs community>bryophytes community on bare dolomite. Species diversity and evenness index of arbor and shrubs community community is the highest, the lowest is exposed bryophytes community on bare dolomite, nevertheless the dominance index was contrary. Among them have 2 families 7 genera and 9 species had gemmae, accounting for 30% of the total, which belongs to the Pottiaceae and Bryaceae, The differences of gemmae from size and number, morphological structure, insertion position, frequency of occurrence, special construction. *Barbula ditrichoides* Broth. And *Trichostomum barbuloides* (Broth.) Chen were common bryophytes with gemmae. Common with all vegetation communities, arbor and shrubs community, but the highest frequencies of bryophytes with gemmae were boscage and low shrubs community. Diversity analysis indicated that the bryophytes communities were significant to vegetation communities, coverage, and vegetation communities and coverage, the variance was significant; For bryophytes with gemmae, the groups were extremely significant among humidity. This research can be used as a basis that the environmental adaptive reproductive strategy of bryophytes.

Morphological variation in Australian and Papua New Guinean *Polyosma* Blume (Escalloniaceae)

Oliver K. Paul
PNG Forest Research Institute

The morphological variation within and between species of *Polyosma* Blume from Australia and Papua New Guinea (PNG) was investigated. The taxonomic usefulness of morphological characters was determined. A total of 161 Operational Taxonomic Units (OTU) of *Polyosma*, comprising 35 known species, three undescribed taxa and nine un-identified herbarium specimens were assessed by the use of 30 characters. Of these characters, 20 were qualitative (non-overlapping) and 10 were quantitative (overlapping). The variability within these morphological characters proved to be useful for circumscribing the currently recognised species. In the analysis, two main groups were obtained based on whether the characters were hairy or glabrous, which were further down had resolved into thirteen groups. Twenty four species were recognised from Papua New Guinea. Three un-published names were discovered. Of these, two species grouped well with published names where as one was significantly different to the published named species it was seen grouped with. Australia has six species, with a possible new species from Mt. Spurgeon, Queensland. More materials are required to analysis the Mt. Spurgeon species. The characters and character-states used were consistent within the entire taxon. In future, few more characters will be included and a molecular phylogeny to compliment this morphology study of the taxon in the two study areas.

Ancient geographical barriers drive differentiation among *Sonneratia caseolaris* populations and recent divergence from *S. lanceolata*

Yuchen Yang[1], *Norman C. Duke*[2], ***Fangfang Peng***[1]
1. State Key Laboratory of Biocontrol and Guangdong Provincial Key Laboratory of Plant Resources, Sun Yat-Sen University
2. Trop WATER, James Cook University, Townsville, QLD

Glacial vicariance is thought to influence population dynamics and speciation of many marine organisms. Mangroves, a plant group inhabiting intertidal zones, were also profoundly influenced by Pleistocene glaciations. In this study, we investigated phylogeographic patterns of a widespread mangrove species *Sonneratia caseolaris* and a narrowly distributed, closely related species *S. lanceolata* to infer their divergence histories and related it to historical geological events. We sequenced two chloroplast fragments and five nuclear genes for one population of *S. lanceolata* and 12 populations of *S. caseolaris* across the Indo-West Pacific (IWP) region to evaluate genetic differentiation and divergence time among them. Phylogenetic analysis based on sequences of nuclear ribosomal internal transcribed spacer and a nuclear gene *rpl9* for all *Sonneratia* species indicate that *S. lanceolata* individuals are nested within *S. caseolaris*. We found strong genetic structure among geographic regions (South China Sea, the Indian Ocean, and eastern Australia) inhabited by *S. caseolaris*. We estimated that divergence between the Indo-Malesia and Australasia populations occurred 4.035 million years ago (MYA), prior to the onset of Pleistocene. BARRIERS analysis suggested that complex geographic features in the IWP region had largely shaped the phylogeographic patterns of *S. caseolaris*. Furthermore, haplotype analyses provided convincing evidence for secondary contact of the South China Sea and the Indian Ocean lineages at the Indo-Pacific boundary. Demographic history inference under isolation and migration (IM) model detected substantial gene flow from the Sri Lanka populations to the populations in the Java Island. Moreover, multi-locus sequence analysis indicated that *S. lanceolata* was most closely related to the Indian Ocean populations of *S. caseolaris* and the divergence time between them was 2.057 MYA, coinciding with the onset of the Pleistocene glaciation. Our results suggest that geographic isolation driven by the Pleistocene ice age resulted in the recent origin of *S. lanceolata*.

Natural hybridization and adaptive introgression in New-World red mangroves (*Rhizophora*)

Zixiao Guo[1], **Fangfang Peng**[1], Norman C. Duke[2]
1. State Key Laboratory of Biocontrol and Guangdong Provincial Key Laboratory of Plant Resources, Sun Yat-Sen University
2. Trop WATER, James Cook University, Townsville, QLD

Hybridization in plants can result in adaptive introgression between species and thus contribute to rapid adaptive evolution. It is generally considered that the New World red mangrove genus (*Rhizophora*) consists of two species (*R. mangle* and *R. racemosa)* and a natural hybrid between them (*R. × harrisonii*). Another taxon, *R. samonensis*, is regarded as a synonym of *R. mangle.* To test if there is adaptive introgression between the two species and clarify the taxonomic status of *R. samonensis*, here we collected 119 samples of *Rhizophora* of these taxa across the Atlantic-East Pacific (AEP) region by sequencing seven nuclear genes (SBE2, 23056, C49, 22274, 22454, 23777 and 23714) and one chloroplast DNA spacer (*trn*L-*trn*F). Our results showed that *R. mangle* and *R. racemosa* diverged by 1.11%-5.00% at these nuclear genes. The individuals assigned as the hybrid *R. × harrisonii* are heterozygous at each of these nuclear genes, with one allele matching the haplotype of *R. mangle* and the other *R. racemosa*, confirming their hybrid status. Chloroplast *trn*L-*trn*F sequencing indicated unidirectional hybridization, with *R. mangle* being the maternal parent. Moreover, *R. samonensis* collected in Peru was found to be close to but slightly divergent from *R. mangle*. (Atlantic, except for Hawaii). Although *R. racemosa* and *R. × harrisonii* show morphological variation (two forms were found for each taxon), little genetic differentiation was detected between the two forms of each taxon. Strikingly, about half of the *R. mangle* samples collected in Nigeria are homozygous with the same haplotype of *R. racemosa* in the gene 23777*,* while there was no signal of introgression at all other six nuclear genes, which suggests adaptive introgression from *R. racemosa* to *R. mangle* at this gene. Our study clarifies the taxonomic problems in the New World *Rhizophora* and provides convincing evidence for adaptive introgression in mangroves for the first time.

P0562
The phylogeny of *Youniga* based on plastid and nuclear loci

Yulan Peng
Chengdu Institute of Biology

The genus *Youngia* Cass. is estimated to contain about 35 species distributed in eastern Asian. Previous molecular studies were based on showed that *Youngia* is polyphyletic. In the present study, DNA sequences of three plastid and one nuclear locus from 520 accessions representing approximately 30 species of *Youngia* worldwide were used to infer a phylogeny using maximum likelihood, Bayesian inference and maximum parsimony methods. The study identifies strongly supported major clades and well resolves relationships among them. Major results include: (i) two deep-level clades are discovered representing the deep splits of *Youngia*; and (ii)four major clades representing four major evolutionary lineages are identified.

New records on orchid pollen vectors and visitors from the tropical lowland forests of Mexico and Panama

Oscar Alejandro Pérez-Escobar[1], *David Roubik*[2], *Günter Gerlach*[3]
1. Royal Botanic Gardens, Kew
2. Smithsonian Tropical Research Institute
3. Botanischer Garten München

Orchids are one of the most megadiverse, prominent and endangered components of the Neotropical flora. The Neotropical Orchidaceae have evolved an astounding array of interactions with a diverse set of organisms, upon which they entirely rely essential biological services. This is particularly true for pollination, which is predominantly carried out by insects. Despite the importance of pollination success on orchid population survival, very little is still known about the pollinator identity of Neotropical orchids. In this study, we observed and sampled *in-situ* visitors to flowers and pollen vectors of seven orchid species (*Cycnoches guttulatum, C. dianae*, *Mormodes* sp., *Gongora truncata*, *G. unicolor*, *Sarcoglottis sceptrodes*, and *Trichopilia* sp.) distributed in the lowland tropical forests of Southern Mexico and Panama. These taxa exhibit adaptations for euglossine pollination (e.g. production of volatile compounds, complicate mechanisms for pollen package emplacement). We collected additional data on orchid pollen vectors by using chemical baits known to attract a wide range of male euglossine bees. Morphological comparisons, DNA sequencing, and BLAST searches allowed a reliable identification of pollinia recovered from bees captured on flowers and chemical baits. Visitors of four orchid taxa were recorded for the first time, and pollen vectors of four orchid species were further reported. Five bee species were identified as orchid pollen vectors, namely *E. cyanura, E. obtusa, E. villosa,* and *Eulaema polychroma*. Strikingly, *E. cyanura* appears to be a shared pollen vector of *C. guttultum* and *C. dianae*, two morphologically distinctive taxa that share the same distribution range (i.e. lowland wet forests of Panama). Our study contributes to the knowledge of Neotropical orchid-insect interactions and opens interesting questions regarding the role of fragrance profile specificity as an isolative barrier in male euglossine-bee pollinated orchids.

Systematics studies on the Hymenaea clade (Leguminosae)

Rafael Pinto[1], *Vidal Mansano*[2], *Giulia Serbin*[1], *Boris Domenech*[3], *Makeli Lusa*[4], *Juliana Mayer*[1], *Benjamin Torke*[5], *Anne Bruneau*[3], *Eliana Forni-Martins*[1], *Ana Tozzi*[1]
1. Universidade Estadual de Campinas (UNICAMP)
2. Jardim Botânico do Rio de Janeiro (JBRJ)
3. Université de Montréal
4. Universidade Federal de Santa Catarina (UFSC)
5. The New York Botanical Garden

The Hymenaea clade is included in the resin-producing clade of

subfamily Detarioideae (Leguminosae). It is composed of three genera distributed mainly in tropical regions of Africa and South America: *Guibourtia* (15 species, two in the Neotropics and 13 in Africa), *Hymenaea* (16 species in the Neotropics and one in Africa) and *Peltogyne* (21 Neotropical species). These genera share an arborescent habit (few species of *Hymenaea* are predominately shrubs – *H. eriogyne*, *H. rubriflora* and *H. travassii*) and bifoliolate leaves but differ morphologically in the presence of a corolla (absent in *Guibourtia*), stamen length (heteromorphic in *Peltogyne*) and fruit dehiscence (indehiscent in *Hymenaea*). The goal of this study was to test the monophyly of these three genera and to provide an updated taxonomic treatment, supported by phylogenetic, morphological, cytogenetic and anatomic investigations. Preliminary molecular phylogenetic analysis is based on two informative markers - ITS (nuclear) and *trn*K (plastid) - suggest that both *Hymenaea* and *Peltogyne* are monophyletic, although some species, such as *H. courbaril* and *P. paniculata* appear to comprise multiple lineages with separate origins. *Guibourtia* is resolved as paraphyletic and is composed of at least two distinct lineages, one containing only African species, the other both African and Neotropical species. In contrast to the widely held view that Neotropical *Guibourtia* comprise a single species, our taxonomic studies support the recognition of two species, corresponding to Cuban (*G. hymenaefolia*) and South American populations (*G. chodatiana*). We also found that species diversity in *Hymenaea* was underestimated, and we an in the process of describing three new species several new combinations in the genus. Anatomical studies corroborate previous findings of glandular cavities in leaflets of most species of *Hymenaea*, and for the first time document the presence of these cavities in *Guibourtia* and most species of *Peltogyne*. However, such cavities were not found in *H. velutina* and *P. catingae*. Morpho-anatomical characterization of the midrib and internerval region of leaflets and histochemical analyses of the epidermis proved useful in delimiting species in the three genera. The marginal position of the cavities in the leaflet lamina was found to be useful for differentiating the three genera of this clade from other representatives of subfamily Detarioideae. Cytogenetic analyses have shown that most taxa of the Hymenaea clade have predominantly $2n=24$, the most common condition in subfamily Detarioideae. Exceptions are *G. coleosperma* ($2n=48$) and *G. chodatiana* ($2n=12$). Both *Hymenaea* and *Peltogyne* have two pairs of CMA$^+$ sites, while the species of *Guibourtia* analyzed have just one pair. FISH analyses are still being conducted, and results for species of *Guibourtia* and *Hymenaea* show one pair of 18S and one pair of 5S rDNA sites while *P. pauciflora* presented two pairs of 5S rDNA sites.

The biodiversity hotspot as evolutionary hot-bed: Spectacular radiation of *Erica* in the Cape Floristic Region

Michael Pirie[1,2], *E.G.H. Oliver*[2], *Ana Mugrabi De Kuppler*[3], *Berit Gehrke*[1], *Nicholas Le Maitre*[2], *Martha Kandziora*[1], *Dirk Bellstedt*[2]
1. Johannes Gutenberg-Universität, Mainz
2. University of Stellenbosch
3. Rheinische Friedrich-Wilhelms-Universität Bonn

The disproportionate species richness of the world's biodiversity hotspots could be explained by low extinction (the evolutionary "museum") and/or high speciation (the "hot-bed") models. We test these models using the largest of the species rich plant groups that characterise the botanically diverse Cape Floristic Region (CFR): the genus *Erica* L. We generate a novel phylogenetic hypothesis informed by nuclear and plastid DNA sequences of c. 60% of the c. 800 *Erica* species (of which 690 are endemic to the CFR), and use this to estimate clade ages (using RELTIME; BEAST), net diversification rates (GEIGER), and shifts in rates of diversification in different areas (BAMM; MuSSE). The diversity of *Erica* species in the CFR is the result of a single radiation within the last c. 15 million years. Compared to ancestral lineages in the Palearctic, the rate of speciation accelerated across Africa and Madagascar, with a further burst of speciation within the CFR that also exceeds the net diversification rates of other Cape clades. *Erica* exemplifies the "hotbed" model of assemblage through recent speciation, implying that with the advent of the modern Cape a multitude of new niches opened and were successively occupied through local species diversification.

Targeted NGS for species level phylogenomics: "Made to measure" or "one size fits all"?

Malvina Kadlec[1], *Dirk Bellstedt*[2], *Nicholas Le Maitre*[2], ***Michael Pirie***[1,2]
1. Johannes Gutenberg-Universität, Mainz
2. University of Stellenbosch

Targeted high-throughput sequencing using hybrid-enrichment offers a promising source of data for inferring multiple, meaningfully resolved, independent gene trees suitable to address challenging phylogenetic problems such as in species complexes and rapid radiations. The targets in question can either be adopted directly from more or less universal tools (e.g. "Anchored Hybrid Enrichment"), or custom made for particular clades at considerably greater effort. We applied custom made scripts to select sets of homologous sequence markers from transcriptome and WGS data for use in the flowering plant genus *Erica* (Ericaceae). We tested the resulting targets by obtaining an empirical dataset, and compared them to those that would be selected both using different available tools (Hyb-Seq; MarkerMiner), and when optimising for broader clades of more distantly related taxa (Ericales; eudicots). Approaches comparing more divergent genomes (including MarkerMiner) delivered fewer, shorter potential targets than those targeted for *Erica*. The latter may nevertheless be effective across the wider family Ericaceae. We would conclude that rather than searching for "one size fits all" universal markers, we should be improving and making more accessible the tools necessary for developing our own "made to measure" ones.

Female gametophyte and ovule ultrastructure in apomictic and sexual members of Asteraceae (genera: *Taraxacum*, *Hieracium* and *Pilosella*)

Bartosz Jan Płachno[1], *Piotr Świątek*[2]
1. Jagiellonian University in Kraków

2. University of Silesia

In apomictic plants there is an evolutionary tendency to reduce “unnecessary costs” associated with the sexual reproduction of their amphimictic ancestors (e.g. lack of pollen grains production), which may result in greater reproductive success. Thus, it can be assumed that a cost reduction may also take place in the development of an unreduced female gametophyte and also in ovule tissues which are responsible for the attraction and growth of the pollen tubes. The aim of our studies were to compare: both the egg apparatus and the micropyle structure and also general ovule anatomy and ultrastructure in amphimictic and apomictic species from Asteraceae family (genera: *Taraxacum*, *Hieracium* and *Pilosella*). We found that ultrastructural characters of egg apparatus were similar in both amphimictic and apomictic species. Structural reduction of ovular transmitting tissue was also not observed in apomicts. The only difference between amphimictic and apomictic species (*Taraxacum*), which we found, is that both synergids persisted for a long time without any degeneration. We propose that the persistent synergids in apomicts may play a role in the transport of nutrients to the developing embryo. It seems that there are some evolutionary benefits of retaining the functionality of all of the necessary structures such as synergids and transmitting tissue that are connected with pollination and fertilization in apomicts. Another explanation is that studied taxa are so (too evolutionary young and the reduction of “unnecessary costs ” has not occurred yet. Acknowledgements: This study was funded by National Science Centre, Poland. Contract grant number: DEC-2013/09/B/NZ8/03308.

P0568
Phylogeny and revision of the Neotropical *Adiantum raddianum* group (Pteridaceae)

Regina Yoshie Hirai, ***Jefferson Prado***
Instituto de Botanica

With more than 200 species, the maidenhair fern genus *Adiantum* is among the top ten most diverse fern genera. *Adiantum* is pantropical in distribution and, due to the presence of a unique synapomorphy (sporangia borne on indusia rather than laminae), perhaps the most easily recognized fern genus. Many of its members, including numerous cultivars derived from *A. raddianum*, are grown as ornamentals. Because of its size, a comprehensive taxonomic study of *Adiantum* is difficult and the genus is perhaps better approached through a series of narrower studies. Here, we focus specifically on *A. raddianum* and putative allies. We find a newly defined *A. raddianum* group to be strongly supported as monophyletic and segregated from other maidenhair ferns on the basis of genetic as well as morphological characteristics. Bayesian inference and maximum likelihood analyses of plastid *atp*A, *chl*L, *chl*N, *rbc*L, and *rpo*A sequences support the *A. raddianum* clade as sister to *A. poiretii* and its allies. We identify round-reniform indusia to be a characteristic of the *A. raddianum* group (vs. lunate in the *A. poiretii* group). Additionally, we find species in the *A. poiretii* group to differ in having a unique deletion of 66 nucleotides in our *chl*N gene alignment. For the Neotropical *A. raddianum* group 16 species were recognized. Some of them are widely distributed and one was recently described (*A. alan-smithii*).

Phylogeny of *Osbeckia* (Melastomataceae) in India

Prashob Pulpra Prashob Pulpra, *Sibichen M. Thomas Sibichen M. Thomas*
Plant Systematics Division, Department of Botany, St. Joseph’s College (Autonomous), Devagiri, Calicut 673008, Kerala

The genus *Osbeckia*, endemic to the North Eastern Himalayas and Western Ghats, comprises twenty five species in India. The present work is an attempt to unveil the phylogenetic relationship among the species of the genus and to establish the circumscription of the genus. Morphological and molecular database have been used separately as well as combined for phylogenetic analysis. The nuclear DNA (internal transcribed spacer, ITS) and-morphological characters were considered for the analysis. The study revealed the character evolution of the clade and also supported its monophyletic origin.

P0570
Trends in peristome architecture in the Dicranales (Dicranidae)

Amanda Guerreiro[1], ***Michelle J. Price***[2]
1. University of Geneva
2. Conservatory and Botanical Garden of the City of Geneva

The Dicranidae, a well-supported monophyletic group of mosses, are thought to have undergone rapid diversification after the evolution of the haplolepidous peristome (a single ring of articulate teeth surrounding the capsule mouth that is derived from the inner peristome layer during the developmental sequence). Based on early observations of moss capsules at various stages of development, and specifically of mature capsules at the capsule mouth, by Georg Boyung Scato Lantzius-Beninga (1815-1871), we recently established protocols for observing and comparing taxa with the aim of testing his theory that peristome architecture, seen in longitudinal section, may hold information of taxonomic-systematic interest in the peristomate mosses. By comparing peristome architecture of the capsule mouth – peristome teeth junction region (the peristome attachment region) in 82 samples representing 19 species from 13 genera in 5 families of the Dicranales (Dicranaceae, Ditrichaceae, Fissidentaceae, Leucobryaceae, Rhabdoweisiaceae), and *Grimmia pulvinata* (Hedw.) Sm. (Grimmiaceae, Grimmiales) used as an comparative outgroup, some specific areas or traits were identified that are potentially relevant in taxon discrimination (the form and thickness of the exothecium, form and thickness of the connective tissue, connection between the peristome base and teeth, cell wall thickening patterns), but also in the tooth insertion position, features of the capsule wall and mouth shape, as revealed in longitudinal sections. Clear and often quantifiable differences in the composition and the architecture of the peristome attachment region were observed between the 2 different orders as well as between each of the different families studied, and in some cases also between genera and/or species. Our findings also supported several recent observations on the phylogenetic placement of species included in the analysis (for example, *Paraleucobryum longifolium* shares more peristome architectural features in common with the Dicranaceae seen in the study than the other members of the Leucobryaceae included). Our preliminary investigations form a solid foundation for further exploratory research on peristome architecture within the Dicranales, with the aim of identifying, describing and defining taxonomic unit specific traits using traditional methodologies (hand sectioning and SEM) combined with the application of new and innovative methods for observing whole structures and their three-dimensional composition and form.

Techniques for exploring peristome architecture in haplolepidous mosses: Reviving old innovations

Amanda Guerreiro[1], ***Michelle J. Price***[2]
1. University of Geneva
2. Conservatory and Botanical Garden of the City of Geneva

The peristome of the arthrodontous mosses is an evolutionarily conserved structure composed of a concentric ring or rings of articulate teeth that surround the mouth of the capsule (sporophyte generation). The peristome plays a key role in spore release and dispersion, and is unique to this group of plants. Peristomes have long fascinated bryologists and have been used, at various different taxonomic levels, in the classification of this group of plants. In the 18th Century, the German botanist, Georg Boyung Scato Lantzius-Beninga (1815-1871), investigated the developmental anatomy of moss sporophytes, including of the peristome. Using comparisons of longitudinal sections of moss capsules from mature, but not dehisced, capsules from a selection of peristomate species he also affirmed that species are distinguishable by their unique peristome architecture. His observations of the capsule mouth – peristome teeth junction region of the capsule revealed that taxonomic information can be found within this region based on variations in the developmental patterns of the specific structures, layers or cells that constitute the peristome teeth themselves (cell wall deposition, orientation of the deposition, trabeculae development, *etc.*). His early findings have obvious implications for moss systematics but, likely due to a lack of explanations on the techniques in the original text combined with the complexities involved with sectioning small objects and an incomplete vocabulary associated with the original observations, his theory has not been widely tested within the mosses. Here we give details on simple protocols for specimen treatment, handling and sectioning as well as for specimen observation, illustration and description. Our technique of image preparation is also outlined with the aim of providing baseline information for researchers interested in exploring peristome architecture using traditional techniques that may subsequently reveal some innovative findings in specific groups of mosses.

Juncus quartinianus A.Rich. (Juncaceae, sect. *Ozophyllum*), a Neglected Species from Ethiopia, Eritrea and Somalia

Anna Faltyn[1], *Anna Jakubska-Busse*[2], *Paweł Jarzembowski*[2], ***Jarosław Proćków***[1]
1. Institute of Biology, Wrocław University of Environmental and Life Sciences
2. Institute of Environmental Biology, University of Wrocław

Juncus quartinianus was described by A. Richard in 1851 from Ethiopia. Type specimens were collected by R. Quartin-Dillon and A. Petit in Chiré (Ethiopia) in July 1844. Richard distinguished this species on the basis of the following features: sessile, lateral single head, lanceolate, acute, subcastaneous tepals, and the inner ones slightly longer than the outer, six stamens one-third as long as the tepals and pyramidal capsules longer than the perianth. Later authors have treated this taxon as a synonym of *J. fontanesii* J.Gay ex Laharpe or *J. oxycarpus* E.Mey. ex Kunth. According to the latest available monograph of the Juncaceae family, specimens of *J. oxycarpus* from Ethiopia and Eritrea, that were initially classified as *J. fontanesii*, have longer capsules and are similar to *J. fontanesii* subsp. *pyramidatus* (Laharpe) Snogerup. Indeed, in the course of studying the herbarium material of *J. oxycarpus* and *J. fontanesii* subsp. *pyramidatus*, we found some unusual specimens from Ethiopia, Eritrea and Somalia. These were previously identified mainly as *J. oxycarpus*, but differ in their capsules that are longer than the perianth and their quite different seed coat surface. Some specimens were initially classified as *J. fontanesii*; however, we found that they do not belong to the latter species as their anthers are shorter than the filaments or rarely, the anthers and filaments are equally sized (anthers of *J. fontanesii* are distinctly longer than filaments). Our detailed morphological analyses of flowers, fruit and seeds show that these specimens represent a distinct species from both these taxa. After careful analysis of the literature and herbarium material, it was found that this species was named *Juncus quartinianus* A.Rich., 1851 and thus we proposed to restore this name. In addition, revision of the herbarium material revealed that Richard's description of this species is inaccurate and it has been corrected. “The project was supported by the Leading National Research Centre (KNOW) programme of the Wrocław Center of Biotechnology for years 2014-2018”

Epitypification of the J. E. Smith's Name *Epipactis purpurata* (Orchidaceae, Neottieae)

Anna Jakubska-Busse[1], *Elżbieta Żołubak*[1], ***Jarosław Proćków***[2]
1. Institute of Environmental Biology, University of Wrocław
2. Institute of Biology, Wrocław University of Environmental and Life Sciences

The identity of the holotype of *Epipactis purpurata* Sm. is shown to be demonstrably ambiguous. The specimen is not representative for identification because all its flowers are at the budding stage (pre-anthesis) – thus it is not possible to identify the specimen (holotype) to species based on the recently analyzed features (i.e. gynostemium and floral segments morphology, especially details of the lip). The taxon has been misidentified many times due to its resemblance to some forms of morphologically variable *E. helleborine* (L.) Crantz, which we discovered based on the analysis of herbarium materials from different herbaria (BR, BRNU, FR, G, KTU, M, MA, S, STU, WRSL, ZT, Z). Many plants of *E. helleborine* can have similar combinations of features like the holotype of *E. purpurata* (i.e., robust stem even in the inflorescence and a small leaves). Considering this ambiguity, an epitype for the name is proposed (M 257866) in order to enable its precise taxonomic interpretation. The proposed epitype is composed of two ramets (two shoots) at the full flowering stage. The flowers are wide open, which allows to perform biometric measurements or to look at the details of sepal and petal morphology as well as the lip. *Epipactis purpurata* is the important James Edward Smith's name because the orchid is widely distributed in western and central Europe. "The project was supported by the Leading National Research Centre (KNOW) programme of the Wrocław Center of Biotechnology for years 2014-2018".

New characters useful in determination of *Epipactis purpurata* Sm. s.str. (Orchidaceae, Neottieae) based on the analysis of herbarium material and field research data

Anna Jakubska-Busse[1], *Elżbieta Żołubak*[1], *Paweł Jarzembowski*[1], ***Jarosław Proćków***[2]
1. Institute of Environmental Biology, University of Wrocław
2. Institute of Biology, Wrocław University of Environmental and Life Sciences

The genus *Epipactis* is a difficult and controversial taxon due to its wide but poorly recognized range of phenotypic variability (particularly ontogenetic), which impedes proper identification of the species. The available determination keys do not allow to identify the plants in the pre-flowering and fruiting stages, but only in open flowers. New reports on describing new species of the *Epipactis* genus, e.g. from Iberian Peninsula or Crimea made us undertake studies on revision of the range of variability of *Epipactis purpurata* Sm. Our detailed analysis of the herbarium collections on loan (BR, C, FR, G, K, KTU, M, S, STU, Z, ZT) and field investigations (Poland, Czech Republic and Slovakia) showed that they still contain numerous erroneously identified specimens. An important character in identification of *E. purpurata* is the colour of the shoot, dark-green to magenta in nature, sometimes purplish, rarely green. It must be, however, remembered that the drying method may influence the retention of colour. The aim of our project was to demonstrate full variability of *E. purpurata* Sm. *sensu stricto* and compare it with previous studies. We established new ranges of morphological character variability for the taxon, including diagnostically significant features. The variability refers to flower features, i.e. the shape and pigmentation of the lip, sepals and petals, also the shape and size of the gynostemium as well as the size, shape and colouration of leaves, which, in turn, makes it difficult to determine the diagnostic features for the species. The detailed morphological and anatomical studies of leaf characters, including the shape and size of papillae, confirmed that this feature should be carefully considered in taxa identification as we present different types of papillae in examined specimens. "The project was supported by the Leading National Research Centre (KNOW) programme of the Wrocław Center of Biotechnology for years 2014-2018"

An overview of the genus *Radula* subgenus *Amentuloradula* Devos *et al.* (Radulaceae, Marchantiophyta)

Chatchaba Promma[1], *Matt A. M. Renner*[2], *Rui-Liang Zhu*[1]
1. East China Normal University
2. Royal Botanic Gardens and Domain Trust

The genus *Radula* Dumort., is an isolated genus belonging to family Radulaceae, with about 250 currently accepted species and mainly distributed in tropical and subtropical regions. Subg. *Amentuloradula* Devos *et al.,* is accepted in this genus together with other six subgenera. Most of the species in this subgenus are well characterized by having the microphyllous branches and/or amentulose branches, single lobular hyaline papilla located on the apex of the leaf-lobule, ovoid capsule, spores comparatively large with echinate with brachiate tip ornamented. The preliminary study of subg. *Amentuloradula* is presented and twenty-six species are enumerated, based on available literature, field surveys and specimens examination from various herbaria. This subgenus is mainly distributed in Australasia, most of the species are greatly restricted distribution in Australia, New Caledonia, and New Zealand. Japan and South China seem to be its northernmost limit. The majority of the species are epiphytes on tree trunks, branches and twigs occurring from near sea level to over 4,000 m in elevation.

Taxonomic revision and phylogeny of the genus *Leucas* s.str (Lamiaceae: Lamioideae)

Sunojkumar Purayidath Kandy
Department of Botany, University of Calicut

The genus *Leucas* R.Br. is considered in the strict sense here. Species included in the genus are characterised by the dorsal side of calyx exceeding or equalling the ventral side, anterior corolla lip longer than posterior lip and absence of glands on ovaries. Species previously included in the genus from Africa and Arabia are omitted as they are paraphyletic (Scheen and Albert, 2009). *Leucas s.str*., thus, form an Asian genus, distributed in India, south east Asia up to Australia. Taxonomic revision based on fresh specimen and herbarium data identified 41 species and 9 infraspecific variants. Almost 63% of the species are found as endemic to India with a high diversity and endemism in Westrn Ghats area. Main characters at species level are the nature of calyx mouth, teeth, shape of lower lip of corolla and nature of bracteoles. All species are described with regard to distribution, flowering season and habitat. Comparative morphology identified 3 infra generic sections with *Leucas* s.str. High level of morphological plasticity and small flowers led different views on the infrageneric relationship within the genus. Phylogenetic analysis of the morphospecies using combined sequence data from four plastid regions (*trn*L–*trn*F, *trn*S–*trn*G*, mat*K and *rps16* intron) were conducted. Maximum likelihood and Bayesian approaches were used to assess phylogeny of multi accessions of 37 species and several infraspecific variants. African *Leucas* and related genera were used as outgroups. These approaches proved highly informative in delimiting relationships among species of *Leucas*. Phylogenetic studies confirmed monophyly of *Leucas s.str*. Three well supported clades, corresponds well with the three infrageneric sections recognised by classical taxonomists (Bentham, 1830) are noticed. Clade 1 consists of perennials with ovate leaves and axillary loose inflorescence. Clade 2 consists of perennials with oblong-lanceolate leaves, terminal compact inflorescence and the dorsal side of calyx equalling the ventral side. Clade 3 consists of annual herbs with linear-lanceolate leaves and oblique calyx mouth. A fourth clade consists of two herbaceous species with axillary inflorescence are also found. Clade one corresponds to the primitive section Leucas Benth.; clade 2 to section Astrodon Benth. and clade 3 corresponds to the advanced sect. Plagiostoma Benth. Clade 4 is a new section recognised in this genus. Infrageneric relationships are indicated in the trees provided.

Comparative transcriptomics of strawberries (*Fragaria* spp.) provides insights into evolutionary patterns

Qin Qiao[1], *Jiajun Lei*[2], *Ticao Zhang*[3]
1. School of Agriculture, Yunnan University, Kunming
2. College of Horticulture, Shenyang Agricultural University, Shenyang
3. Key Laboratory for Plant Diversity and Biogeography of East Asia, Kunming Institute of Botany, Chinese Academy of Sciences

Multiple closely related species with genomic sequences provide an ideal system for studies on comparative and evolutionary genomics, as well as the mechanism of speciation. The whole genome sequences of six strawberry species (*Fragaria*) have been released, which provide one of the richest genomic resources of any plant genus. In this study, we first generated seven transcriptome sequences of *Fragaria* species de novo, with a total of 48,557–82,537 unigenes per species. Combined with 13 other species genomes in Rosales, we reconstructed a phylogenetic tree at the genomic level. The phylogenic tree shows that *Fragaria* closed grouped with Rubus and the *Fragaria* clade is divided into three subclades. East Asian species appeared in every subclade, suggesting that the genus originated in this area at ~7.99 Mya. Four species found in mountains of Southwest China originated at ~3.98 Mya, suggesting that rapid speciation occurred to adapt to changing environments following the uplift of the Qinghai–Tibet Plateau. Moreover, we identified 510 very significantly positively selected genes in the cultivated species *F.* × *ananassa* genome. This set of genes was enriched in functions related to specific agronomic traits, such as carbon metabolism and plant hormone signal transduction processes, which are directly related to fruit quality and flavor. These findings illustrate comprehensive evolutionary patterns in *Fragaria* and the genetic basis of fruit domestication of cultivated strawberry at the genomic/transcriptomic level.

Supplementary descriptions of flowers for four species of *Bambusa* (Poaceae: Bambusoideae)

Qiaomei Qin[1,2], *Jingbo Ni*[3], *Rushun Lin*[3], *Nianhe Xia*[1]
1. South China Botanical Garden, the Chinese Academy of Sciences
2. University of the Chinese Academy of Sciences
3. South China Botanical Garden

The morphology of reproductive organs is very important to the modern plant taxonomy. The flowering habit of bamboo is very special. The flowering of bamboo is an intriguing phenomenon because it is a unique and very rare occurrence. Most bamboos flower once every 60-130 years. And as a result, there are rather a percentage of documented bamboo species which were validly published based on the vegetative characters. The genus *Bambusa* is a big genus of Bambusoideae (Poaceae). More than 30 species documented in *Flora of China* are still without descriptions of flowers in this genus. Here, supplementary descriptions of flowers for *Bambusa subtruncata* L. C. Chia & H. L. Fung, *B. contracta* L. C. Chia & H. L. Fung, *B. corniculata* L. C. Chia & H. L. Fung and *B. cornigera* McClure are given, according to the fresh specimens collected from the bamboo garden in South China Botanical Garden. Photographs and illustrations of flowers for these four species are presented. *B. subtruncata*: one spikelet containing 9-10 florets, the intermediate 4-7 florets perfect; prophylls about 3 mm long, 2-keeled; rachilla segments flat, inflated and ciliolate at apex; empty glume 1-3, oblong; lemmas oblong-lanceolate, 11-14 mm long, glabrous; paleas lanceolate, 10-12 mm long, 2 keeled, sparsely ciliolate towards tips of keels; lodicules 3; stamens 6, anthers yellow to purple, 5-6 mm long; ovary obconiform, style 3, stigmas 3 (4), plumose. Caryopsis obconiform when young. *B. contracta*: one spikelet containing 4-5 florets, the intermediate 2-3 florets perfect; rachilla segments flat and glabrous, inflated at apex; empty glume1-3, oblong; lemmas oblong, 5-9 mm long, glabrous; paleas lanceolate, 6-8 mm long, 2 keeled, glabrous; lodicules 3; stamens 6, anthers yellow to purple, 3.5-5 mm long; ovary obelliptic, style 3, stigmas 3, plumose. Caryopsis obelliptic when young. *B. corniculata*: one spikelet containing 6-7 florets, the intermediate 2-5 florets perfect; prophylls about 1mm long, 2-keeled; rachilla segments flat and glabrous, exceedingly inflated at apex; empty glume 2-3, ovate-oblong; lemmas broadly elliptic, 8-12 mm long, glabrous; paleas lanceolate, 8-12 mm long, 2-keeled, glabrous; lodicules 3; stamens 6, anthers yellow to purple; ovary obelliptic, style 3, stigmas 3, plumose. Caryopsis obelliptic when young. *B. cornigera*: one spikelet containing 5-12 florets, the intermediate 5-7 florets perfect; rachilla segments flat and glabrous, exceedingly inflated and ciliolate at apex; empty glume 1-2, oblong; lemmas broadly elliptic, 10-12 mm long, glabrous; paleas lanceolate, 8-11mm long, 2-keeled, ciliolate towards tips of keels; lodicules 3; stamens 6, anthers yellow, 4-8 mm long; ovary very broadly ovoid, style single, stigmas 3, plumose. Caryopsis very broadly ovoid when young.

Sub-localization of paralogous genes duplicated from alternatively-spliced, dual-targeting single-copy genes

Yichun Qiu[1], *Yii Van Tay*[1], *Yuan Ruan*[2], *Keith Adams*[1]
1. University of British Columbia
2. California Institute of Technology

As a major contributor to the angiosperm genomes, gene duplication can lead to the divergence of gene expression patterns and functions. Among all possible fates of duplicated genes, subfunctionalization refers to that duplicates take on different parts of the pre-duplicated function, and this partitioning event could be reflected by subcellular localization of the protein products.

Sub-localization happens after gene duplication when the original gene was localized to two subcellular locations and the duplicates are each localized to one of those locations. Alternative splicing is one mechanism by which the products of a single gene can be localized to two subcellular compartment, as the peptides from alternative spliced transcripts may vary in signals. After duplication of an alternatively spliced, dual targeting gene, one potential type of subfunctionalization is partitioning of the alternatively spliced forms between the duplicates, such that the product of each duplicate is localized to one of the original locations. Here we report the ascorbate peroxidase (APX) genes in land plants, which experienced more than ten lineage-specific sub-localization events.

Plant pollinator networks and evolution of floral traits in Ipomoea

Martin Santiago-Hernandez[1], *Silvana Marten-Rodriguez*[1], *Martha Lopezaraiza*[2], *Francisco Parraguirre*[1], *Ken Oyama*[1], ***Mauricio Quesada***[1]

1. Universidad Nacional Autonoma de Mexico

2. Universidad Autonoma de Guerrero

The interactions between plants and pollinators have been important drivers of Angiosperm diversification. Network analysis has provided a comprehensive tool to understand the role of plant-pollinator interactions at the community level; however, most studies have analyzed this biotic interaction in terms of floral visitation and at specific times of the year. To understand how community-level interactions and phenology may influence floral evolution, it is important to assess how pollinators influence plant fitness on particular plant lineages throught the year. This is the first study that evaluates plant-pollinator networks, phenology and plant reproductive success on a group of coexisting congeners that exhibit different pollination syndromes including ornitophily, melitophily, sphingophily and chiropterophily. To evaluate the role of floral visitors on plant fitness, we conducted different network analyses of an *Ipomoea* community in the Pacific coast of Mexico, including: (1) all flower visitors, (2) visitors that contact the reproductive organs, (3) visitors that deposit pollen on stigmas, and (4) visitors that effect fruit and seed production. We conducted a series of pollination exclusion experiments to test the effectiveness of pollinators and also determined the anthesis and flowering phenology of the Ipomoea species studied. Results show the following: (1) floral visitors of most Ipomoea species included the pollinator functional group that corresponded to the floral syndrome as well as other visitors; (2) effective pollinators, in terms of pollen deposition on stigmas and fruit and seed production, corresponded to the floral syndromes and were the most frequent visitors in all cases; (3) secondary pollinators were also present in most syndromes; (4) coexisting Ipomoeas species sharing the same floral syndrome have staggered flowering phenology or different patterns of anthesis. In conclusion, the fitness network of plant-pollinators of Ipomoea is determined by the floral syndrome, providing strong support for Stebbins Principle that most frequent and effective floral visitors are the primary drivers of the evolution of floral traits. Furthermore, flowering phenology determines pollination network dynamics suggesting avoidance for competition in plants with the same pollination syndrome.

KNOX genes and differences in shoot development between monocots and eudicots: A hypothesis

Geeta R

University of Delhi

Shoot developmental featurs such as indeterminate growth are conserved across vascular plants. However, other features may differ among vascular plant lineages. Differences between monocots and eudicots include leaf initiation and node formation, early leaf development, internode identity and elongation, stem widening and vascularization. Early emphasis in 'Evo-Devo' was to identify genetic mechanisms underlying conserved traits; the role of *KNOTTED*-like homeobox (*KNOX*) genes in regulating indeterminate growth of shoot apices across angiosperms is such an instance. It has been only relatively recently that attention was turned to investigation of differences. Here, I review known morphological and anatomical differences in shoot development between grasses and eudicots; interpret known variation in expression patterns and functions of the Class 1 group (*KNOX1* genes) and suggest that differences in their expression may be implicated in differences in shoot development (specifically, primary thickening and vascularization) between grasses and eudicots. A comparative phylogenetic analysis of this variation helps to identify taxa that may provide suitable systems to test the hypotheses posed here.

Genetic consequences of geological and ecological factors in the Qinghai-Tibet Plateau: Three closely related *Primula* species as a case study based on RAD sequencing

Guangpeng Ren

University of Lausanne

The mechanisms of the interplay between geological and ecological factors in driving speciation, population divergence and shaping current distributions remains poorly understood, especially for species-rich radiations inhabiting the world's biodiversity hotspots. The toolbox of population genomics holds great promise for addressing these key issues, especially if genomic data are analysed within a spatially and ecologically explicit context. We used three closely related *Primula* species (*Primula nutans, P. tibetica* and *P. fasciculata*) that mainly occur in the Himalayas, the Hengduan Mountains and Northeast Qinghai-Tibet Plateau (QTP), respectively, to investigate the genetic consequences of past geological and climatic events in the QTP. Genomic data were obtained for 770 samples of the three species using restriction site-associated DNA (RAD) sequencing. We used a combination approach of population structure analyses, approximate Bayesian computation (ABC) modeling, Bayesian generalized linear mixed modeling (GLMM) and species distribution modeling (SDM) to examine the effects of past geological and climatic events on the three species. The ABC results indicate that the three species originated in the Himalayas and diverged from each other following the uplifts of the Hengduan Mountains and the Northern QTP during the Pliocene. After a long period of divergence, all the three species have retreated to different glacial refugia and expanded their distributions during the Quaternary glacial cycles as shown in the SDMs. For *P. nutans*, GLMM reveals that geographic distance is the major factor in driving population divergence, while for the other two species, geographical distances, climatic variables, pairwise altitude differences among populations and/or edaphic variables are involved in driving genetic variation of different genomic fractions (i.e. negative, neutral and positive genomic regions). Higher population differentiation and more distinct lineages were identified in *P. tibetica* and *P. fasciculata* than in *P. nutans*. The divergence times of these distinct lineages estimated by ABC modeling coincide well with the past glacial and interglacial periods, indicating that past climatic events were the major factors in shaping their large-scale spatial genetic structure. Furthermore, the response to climatic changes of populations of a species depends on its specific ecological preferences, which may show different ways of response to climatic changes compared with the ancestral populations as shown in *P. tibetica*. These results illustrate how geographical and ecological factors affected the evolutionary history of alpine plants. Our findings highlight the significance of combining the use of population genomics with environmental data when evaluating the effects of past geological and climatic events.

Historical biogeography of endemic seed plant genera in the caribbean

Maria Esther Nieto-Blazquez[1], *Alexandre Antonelli*[2], ***Julissa Roncal***[1]
1. Memorial University of Newfoundland
2. University of Göteborg

The aim of this study was to better understand the historical assembly and evolution of endemic seed plant genera in the Caribbean, by first determining divergence times of endemic genera to test whether the GAARlandia landbridge played a role in the archipelago colonization, and second by testing South America as the main colonization source as expected by the position of landmasses and recent evidence of an asymmetrical biotic interchange. To accomplish this we gathered DNA sequences from four loci (18S rDNA, *atp*B, *mat*K and *rbc*L) for 610 species, including 41 seed plant genera endemic to the Caribbean (out of 180 in total). We reconstructed a dated molecular phylogeny using Bayesian inference and ten calibrations. To estimate the range of the ancestors of endemic genera we performed a model selection between a null and a more complex biogeographical model that included timeframes based on geological information and dispersal probabilities among regions. Divergence times for endemic genera ranged from Early Eocene (53.1 Ma) to Late Pliocene (3.4 Ma). Only the origin of four endemic genera occurred within the GAARlandia timeframe (35 to 33 Mya), whose ancestors were already present in the Antilles or derived from the Old World. For the entire data set, Central America appeared as the main source of colonization for endemic seed plant genera. Only two genera had a South American origin. In contrast with recent patterns shown for vertebrates and other organisms, GAARlandia did not act as a main colonization route for plants between South America and the Antilles. Divergence of endemic genera occurred mostly during the Miocene, i.e. after the proposed existence of GAARlandia. Contrary to expectations, Central America was the main colonization source, outplaying South America. A species-level synthesis on Caribbean plant dispersal will be required to reveal finer-scale patterns and mechanisms.

P0584
Biogeographic patterns of *Haplopappus* (Asteraceae, Astereae), a genus of shrubs of the Arid Diagonal of Southern South America.

Marcelo Rosas, *Pablo Guerrero*
Universidad de Concepcion

The biogeographic patterns and historical processes of endemic arid plants in South America are scarcely known. In this study we used a genus of endemic shrubs, *Haplopappus* (Asteraceae, Astereae), which includes 68 species from the Arid Diagonal of the Southern Cone. Our goals were: i) to describe the distribution patterns, ii) to test ecological hypotheses of distribution patterns, iii) identify areas of high endemism, iv) to explore temperature and precipitation as explanatory variables of species richness. We used a list of 1058 specimens with taxonomic and geographic validation, from 21° S to 50° S and from 8 to 4103 m.a.s.l., the data were grouped in bands of 1° latitude and in bands of 200 m of altitude. Latitudinal and altitudinal richness gradients were evaluated according to the adjustment to nonlinear models. The latitudinal structure patterns were assessed using a similarity profile routine using a resemblance matrix, and a cluster analysis. The Mid Domain effect, the Rapoport's rule, and the source-sink dynamic were also tested. A Bayesian analysis of Endemicity (BAE) was used to evaluate hierarchical relationships of endemism between different latitudinal bands. The climatic drivers of species richness were evaluated using spatial regressions. Latitudinal and altitudinal pattern fit Gaussian distribution. The BAE indicated two areas of endemism: (1) the northern area between 21° S - 31° S, and (2) the southern area between 32° S- 50° S. The Mid Domain showed an important effect, except in the central part of the humpback curve and in Patagonia. The nesting analysis showed a significantly nested matrix, which can relate to a source-sink dynamic. The explanatory variables were temperature seasonality and mean temperature of wettest quarter. Our results support the existence of non-random pattern of richness gradients in *Haplopappus*, an integrative hypotesis derived from our results suggest that the genus diversification may be molded by climatic variables related to mediterrean biome and the expansion of some species to colder steppe-like habitats.

Generic delimitation and biogeographic history of the complex *Carthamus* - *Carduncellus* (Cardueae, Compositae).

Roser Vilatersana[1], *Juan Antonio Calleja*[2], *Núria Garcia-Jacas*[1], *Alfonso Susanna*[1]
1. Institut Botànic de Barcelona (IBB – CSIC – ICUB)

2. Unitat de Botànica, Dept. Biologia Animal, Biologia Vegetal i Ecologia, Facultat de Biociències, Universidad Autónoma de Barcelona

The complex *Carthamus-Carduncellus* (Cardueae, Compositae) is formed by aproximally 60 taxa widely distributed throughout the Mediterranenan basin and western Asia. Generic delineation in the complex has been always controversial. The three main taxonomical proposals are (1) the complex is formed by a single genus *Carthamus*, as suggested by Greuter (2003), (2) two genera, *Carduncellus* and *Carthamus*, as proposed by López González (2012); and (3) four genera, *Carduncellus*, *Carthamus*, *Femeniasia* and *Phonus*, by Vilatersana *et al.,* (2000). Our major aim is to provide a robust and comprehensive systematic proposal for the complex *Carthamus-Carduncellus*. To do so, we face the specific goals: (1) to build nuclear and plastid phylogenies encompassing most of the richness of all the putative genera; (2) to propose and test the generic delimitation of the complex and, (3) to infer the biogeographic history of the complex by estimating divergence times and ancestral distribution areas and lineages. To address these issues, we constructed a phylogeny with a nearly-complete taxon sampling based on two nuclear regions (ITS and 3'ETS) and four plastid regions (5´*trn*T-*trn*L r*pl32*-*trn*L, *trn*H-*psb*A, and 3'*ndh*F). For the generic delimitation, we used both cpDNA and nrDNA datasets, we discussed the incongruence between both datasets, and we tested the three hypothesis on the systematic of the complex *Carthamus-Carduncellus* by using the "taxa delimitations" tool implemented in Beast. We used the nrDNA dataset because of its greater resolution for dating and biogeographic analysis performed with BEAST and BioGeoBears. The discussion is complemented with morphological and kariological data.

Lineage divergence of a temperate forest species in eastern Asia, *Smilax sieboldii* (Smilacaceae): Vicariance vs. adaptive divergence

Yalu Ru[1,2], *Ruijing Cheng*[1,3], *Hanyang Lin*[1,2], *Yunpeng Zhao*[1,2], *Pan Li*[1,2], *Chengxin Fu*[1,2]
1. The Key Laboratory of Conservation Biology for Endangered Wildlife of the Ministry of Education, College of Life Sciences, Zhejiang University
2. Laboratory of Systematic & Evolutionary Botany and Biodiversity, Institute of Ecology and Conservation Center for Gene Resources of Endangered Wildlife, Zhejiang University
3. College of Agriculture & Biotechnology, Zhejiang University

Elucidating how various evolutionary factors interact to affect speciation is an essential theme in evolutionary biology. Insights of incipient speciation can be gained from studying lineage divergence. Eastern Asia harbors world richest temperate flora. The mechanisms generating such a rich species and genetic diversity have been fascinating evolutionary biologists for decades while considerable gaps remain in particular whether adaptive divergence also plays a role and its importance relative to vicariance. *Smilax sieboldii* is a typical woody climbing plant inhabiting temperate forests in eastern Asia with a disjunct distribution in mainland China and Taiwan, Japanese Archipelago and Korean Peninsula, providing us an ideal study system to test the relative role of vicariance and adaptive divergence. We employed three data sets including plastid genomes of 12 haplotypes previously suggested by two cpDNA fragments, EST-SSRs for 400 individuals from 38 populations, and RADseq tags for 45 representative individuals (one accession per population). Multiple data sets will be analyzed to confirm geographic lineages, to reconstruct their phylogenetic relationships and demographic histories, e.g., divergence times, dynamics of population sizes and gene flow. We will test competing hypotheses explaining the lineage divergence in relation to historical climate oscillation, sea level fluctuation, emergence and submergence of East China Sea Landbridge, and range shifts. Finally, canonical correlation and redundancy analysis will be utilized to compare the relative contribution of environment and geography to genetic divergence of the focal species. Our findings will imply the evolutionary process of *S. sieboldii* and indicate the relative role of geographical isolation and differential selection which shaped the diversity and phylogeographic structure of temperate forests plants in eastern Asian.

P0587
A taxonomic revision of genus *Ceratostylis* (Orchidaceae) in Thailand

Wirata Rujichaipimon[1,2, 3], *Santi Watthana*[4], *Paweena Traiperm*[2]
1. Master of Science Program in Plant Science, Faculty of Graduate Studies, Mahidol University, Bangkok
2. Department of Plant Science, Faculty of Science, Mahidol University, Bangkok
3. Department of Pharmaceutical Botany, Faculty of Pharmacy, Mahidol University, Bangkok
4. School of Biology, Institute of Science, Suranaree University of Technology, Nakhon Ratchasima

Ceratostylis is a genus in the orchid family (Orchidaceae) distributes from tropical and subtropical Asia to western pacific with approximately 153 species. The aim of this study was to revise the species of this genus found in Thailand. We collected and gathered the data from previous literatures, as well as studied the voucher specimens held at the main herbaria in Thailand and Europe including BCU, BK, BKF, BM, C, K, L, QBG and PSU. In addition, the type specimens were examined and compared from the herbaria where visited, as well as consulted the digitized specimens that are available online. In Thailand, six *Ceratostylis* spp. have been recorded i.e., *C. ampullacea* Kraenzl., *C. pleurothallis* (C.S.P. Parish & Rchb.f.) Seidenf., *C. radiata* J.J. Sm., *C. siamensis* Rolfe ex Downie, *C. subulata* Blume and *C. thailandica* Seidenf. Among these six species, *C. siamensis* and *C. thailandica* are endemic to Thailand. All species are dense tuft plant and exhibit only epiphytic form, except *C. subulata* which having both epiphytic and lithophytic habits. A key to species is provided together with descriptions, illustrations, photos, ecological data and notes.

Phytogeography, endemism and conservation of the genus *Sonerila* Roxb. (Melastomataceae) in Western Ghats

Resmi S, *Santhosh Nampy*
Department of Botany, University of Calicut, Kerala

Sonerila Roxb. (Melastomataceae - tribe Sonerileae) with about 175 species is distributed from Sri Lanka and southern India to the Indo-Pacific region. The genus is easily distinguished in having uniparous (scorpioid) cymes and trimerous flowers. The members are caulescent/acaulescent herbs of shady habitat, often with basal rosettes of large, turgescent leaves, sometimes with tubers and mostly seen in moist rocky crevices. The genus is represented by 51 species and two varieties in India. Western Ghats has the highest species diversity with about 41 species and 2 varieties (81%). Most of them are endemic. Considerable work was conducted in the Sonerilas of neighbouring countries by various authors. However, no similar attempt is so far initiated in this group in India. In spite of greater diversity and endemism, the genus has been largely neglected taxonomically in India. The present paper discusses the diversity, distribution, endemism, conservation and status of the genus in Western Ghats.

Multi-gene phylogenetic analysis reveals the multiple origin and evolution of mangrove physiological traits through exaptation

Sunil Kumar Sahu[1], *Kathiresan Kandasamy*[2]
1. Sun Yat-sen University
2. Centre of Advanced study in Marine Biology, Annamalai University

Mangroves are taxonomically diverse group of salt-tolerant, mainly arboreal, flowering plants that grow in tropical and sub-tropical regions and have adapted themselves to thrive in such obdurate surroundings. While evolution is often understood exclusively in terms of adaptation, innovation often begins when a feature adapted for one function is co-opted for a different purpose and the co-opted features are called exaptations. Thus, one of the fundamental issues is what features of mangroves have evolved through exaptation. We attempt to address these questions through molecular phylogenetic approach using chloroplast and nuclear markers. First, we determined if these mangroves specific traits have evolved multiple times in the phylogeny. Once the multiple origins were established, we then looked at related non-mangrove species for characters that could have been co-opted by mangrove species. We also assessed the efficacy of these molecular sequences in distinguishing mangroves at the species level. In addition by using the AFLP, chloroplast and nuclear markers we resolved the taxonomical controversy between *Rhizophora* hybrids *R.* × *annamalayana* and *R.* × *lamarckii*. This study revealed the multiple origin of mangroves and shed light on the ancestral characters that might have led certain lineages of plants to adapt to estuarine conditions and also traces the evolutionary history of mangroves and hitherto unexplained theory that mangroves traits (aerial roots and viviparous propagules) evolved as a result of exaptation rather than adaptation to saline habitats.

DNA barcoding of *Hippophae*

Saloni Malik[1], *Soom N. Raina*[2], *Shashi B. Babbar*[1]
1. Department of Botany University of Delhi
2. Amity Institute of Biotechnology Amity University

Species of *Hippophae,* reported to inhabit high altitudes of Himalayas across Jammu and Kashmir (J&K), Himachal Pradesh (HP), Uttarakhand (UK) and Sikkim (SK) states in India, are *H. rhamnoides* subsp. *turkestanica, H. tibetana* and *H. salicifolia*. It is difficult to identify these species correctly if available in vegetative state. The present investigation was undertaken to see if DNA barcodes distinguish these species. A total of 56 accessions of *Hippophae* collected with tentative identifications as *H. salicifolia*, *H. rhamnoides* ssp. *turkestanica*, and *H. tibetana* from the states listed and 24 accessions of *H. rhamnoides* subsp. *carpatica*, *H. rhamnoides* subsp. *mongolica*, *H. rhamnoides* subsp. *rhamnoides* procured from Ukraine, Russia, Germany and Finland were analyzed. The loci used for DNA barcoding were ITS, *mat*K, *rbc*L and *rpoC1* and the number of their sequences obtained were 72,75,80 and 79, respectively. In the neighbor joining (NJ) trees of all the tested loci, accessions of *H. rhamnoides* subsp. *turkestanica* from UK, co-segragated with *H. salicifolia* from HP, UK and SK. Likewise, accessions of *H. salicifolia* from Kinnaur (HP) grouped with *H. rhamnoides* subspecies *turkestanica* and four of *H. tibetana* from HP co-segregated with *H. salicifolia* collected from HP, UK and SK. These observations raised doubts about the identification of some of accessions of *H. salicifolia* (HP), *H. rhamnoides* subspecies *turkestanica* (UK) and *H. tibetana* (HP). Therefore, sequences of all the loci were BLAST searched on NCBI and BOLD (only *mat*K and *rbc*L). BLAST1 analysis revealed that the accessions collected as *H. rhamnoides* subspecies *turkestanica* from UK were, in fact, *H. salicifolia*. Likewise, the accessions collected as *H. salicifolia* from HP turned out to be *H. rhamnoides* and the correct identity of four accessions collected from HP as *H. tibetana* was *H. salicifolia*. To reveal the inter-relationships among species, NJ trees were constructed again. ITS NJ tree had two main clades, one comprising only *H. tibetana*, while the other included *H. salicifolia* and all sub-species of *H. rhamnoides.* The latter clade futher segregated in two groups, one of which was represented by *H. rhamnoides* ssp. *turkestanica* and the other comprised rest of the sub-species *of H. rhamnoides*. NJ tree based on *matK* too revealed two clades. However, in this tree, *H. tibetana* clustered with *H. salicifolia* in one clade, but in two distinct sub-clades. The other clade too had two sub-clades, one of which had all accessions of *H. rhamnoides* subsp. *turkestanica* along with four of eight accessions of *H. rhamnoides* subsp. *rhamnoides* from Germany. The other sub-clade included rest of the sub-species of *H. rhamnoides*. In the *rbc*L NJ tree, there was no clear-cut segregation of species as well as sub-species of *H. rhamnoides*. The three species could be easily distinguished on the basis *rpoC1* sequences. However, no distinction could be made among the sub-species of *H. rhamnoides.* The study highlights the power of DNA barcoding for identification of *Hippophae* species and also points towards the distinctive nature of *H. rhamnoides* subsp. *turkestanica*, which could possibly be raised to the species level.

The Zingiberaceae in the Flora of Peninsular Malaysia

Yen Yen Sam

Forest Research Institute Malaysia

Peninsular Malaysia has an exceptionally rich ginger flora with a total of 21 genera and close to 190 species recorded so far. The warm and humid climate plus the wide range of habitats in the evergreen tropical rainforest contributed to the high diversity and endemism observed in the family. Though located in the Malesian region, its ginger flora is very distinct from the neighbouring floristic regions where approximately 60% of the species are endemic to the peninsula. Peninsular Malaysia has a long history in the documentation and taxonomic study of the ginger species. However, there are still many new discoveries in recent times, e.g. three new genera and 32 new species are described in the last 15 years. The Flora of Peninsular Malaysia project currently undertaken by the Forest Research Institute Malaysia has amassed a great amount of herbarium collections for a comprehensive revision of the family. Based on the experiences of the current and past Flora projects, the collaboration and contribution from both local and foreign experts are very crucial in revising such big family which is estimated to exceed 200 species when the treatment is completed.

P0592

Diversification correlates of Neotropical plants biodiversity

***Andrea Sanchez Meseguer**, Frederic Delsuc, Fabien Condamine*
CNRS

Due to its unique geological history and tropical ecology, the South American biota bears many of the known biodiversity hotspots in the world, including the richest (the Tropical Andes, where many rapid radiations have occurred). The establishment of complex riverine systems, the uplift of the Andes, and Cenozoic climatic changes have all influenced Neotropical plant diversity, but the historical causes and regional determinants remain debated. The ensuing question '*What gave rise to the Neotropical staggering biodiversity?'* is one of the most debated topics in evolutionary ecology. Despite an increasing number of evolutionary studies on Neotropical groups, the relative contribution of different factor in Neotropical diversification is still poorly understood. Most studies in the field focus to detect changes in diversification trajectories that have occurred through time and/or across clades. If rate variation is detected, the potential impact of different factors on the observed pattern is generally discussed based on temporal congruence between diversification changes and the potential factor. The recent development of environment-explicit phylogenetic birth-death models now allows explicitly testing the relative contribution of various factors on Neotropical diversification. Here, we present a meta-analysis of diversification correlates for more than 45 Neotropical plant clades, including angiosperm (e.g. orchids, palms, grasses) and gymnosperm lineages (cycads), that span different taxonomic levels (families, tribes, genera, sections), ages of origin (from the Eocene to the present), as well as Neotropical regions (e.g. Andes, Amazonia, Central America). The global plant dataset is further classified according to the main distribution of lineages (Andean-centered vs. Amazonian-centered), and altitude (lowland, montane or highland). According to this division, we evaluate the relative contribution of Andean orogeny and Cenozoic climate change on diversification trajectories of Neotropical plants. We compare the fit of a series of diversification models that incorporate mountain building and/or climate change, against other constant and time variable null models. The overall pattern from our analyses is that, in more than 50% of the phylogenies, temperature-dependent models fit the data better than other time- or altitude-dependent models. Most lowland and Amazonian clades show positive correlation with temperature (i.e. speciation rates decrease over time), while mountain-highland clades present a mixed pattern: some clades are positively correlated while others are negatively correlated with temperature (i.e. speciation increases with climate cooling). Mountain building appears to have directly influenced diversification of lowland Neotropical taxa form the Andes and the Amazonian regions, generally towards increasing diversification. Unexpectedly, the effect of mountain uplift over other montane-highland clades is less pronounced, which are mostly influenced by changing temperatures. For less than 20% of the phylogenies, time-dependent models fit the data better than the other environmental-dependent models, which might suggest that other factors not considered in this study are at play. These results suggest that Cenozoic climate cooling had differential effects on Neotropical diversity, promoting diversification for some clades but hampering diversification for others, while the Andean orogeny has always spurred Neotropical species richness.

New insights on the floral evolution in the Gomphrenoideae (Amaranthaceae), based on molecular phylogenetics and floral morphological and developmental data

***Ivonne Sánchez-Del Pino**[1], Alexander Vrijdaghs[2]*
1. Centro de Investigación Científica de Yucatán, A.C. (CICY)
2. Ecology, Evolution and Biodiversity Conservation KU Leuven

Androecium and gynoecium are key characters in the systematics of Gomphrenoideae (Amaranthaceae). SEM and LM based floral ontogenetic and morphological studies provide new insights in the evolution of the flower in Gomphrenoideae. A sampling of 37 species was studied for morphology of gynoecium, androecium and pollen characters whereas ontogenetic development was observed for 13 species. Character optimization was conducted in a parsimony tree using Mesquite software. Seventeen characters were optimized, of which eight were related to androecium, three to stigmas, and six to pollen. In this study we aimed to perform homology assessments for the androecial tube and its appendages of Gomphrenoideae; to test Eliasson´s hypothesis for the evolution of the androecium appendages; to re-evaluate pollen and gynoecial characters in a phylogenetic context.Two types of androecial appendages, not homologous, and hypothesized to be de novo organs were characterized. Based on these findings, we can suggest that none of Eliasson´s hypothesis can be supported. Four pollen characters support major clades within Gomphrenoideae. A peryginous hypanthium appears twice in Amaranthaceae sensu lato and it is here for the first time well documented. At early development stages, a central ovule primordium slightly fixed at one side to the annular ovary wall, and dome-shaped flower receptacles are hypothesized to be synapomorphies for respectively Amaranthaceae sensu lato and Gomphrenoideae.

Genetic diversity analysis of *Curcuma* by Random Amplified Polymorphic DNA (RAPD)

Pattamon Sangin, *Pranee Nangngam, Audsharaporn Jai-Eun*
Naresuan University

Genetic diversity analysis of *Curcuma* and intraspecific level of *Curcuma longa* was studied using RAPD technique. One out of ten primers (MI1) was found to give polymorphic DNA patterns. A total of 49 bands were scored with the size of 0.30-3.0 Kb. Genetic similarity was estimated by the Jaccard coefficient from NTSYSpc 2.20e version which ranged between 0.612-1.000. A dendrogram was also constructed by using Unweighted Pair Group Method with Arithmetic Mean (UPGMA) which divided *Curcuma* into two major clusters. First group comprised all *C. longa* L. 11 accessions, which *C. longa* L. (Cu19) and *C. longa* L. (Cu20) were grouped together with the high similarity index (1.000). The second clade was 8 samples of *Curcuma*; *C. manga* Valeton & Zijp (Cu10), *C. amada* Roxb. (Cu11, Cu12 and Cu15), *C. rubescens* Roxb. (Cu17), *C. aromatica* Salisb. (Cu14), and *Curcuma sp*. (Cu3 and Cu16).

Phylogenetic relationship of *Jatropha curcas* using *atp*B – *rbc*L intergenic spacer

Pattamon Sangin, *Sudarat Kasemcholathan*
Naresuan University

The plants in genus *Jatroph*a belong to the family Euphorbiaceae, which are distributed in tropical and subtropical region around the world. There are only 5 species of *Jatropha* in Thailand; *J. curcas*, *J. gossypiifolia*, *J. multifida*, *J. podagrica* and *J. integerrima*. However, *J. curcas* is the only one which is attracted as an alternative to biodiesel. It is widely distributed in many areas in Thailand, which is difficult to identify by morphological properties because their characteristics are similar. Therefore, in this research, DNA sequences data from *atp*B–*rbc*L intergenic spacer were used to elucidate the evolutionary relationship in 15 accessions of *J. curcas*. The result showed that the length of of *atp*B-*rbc*L was 857 to 873 bp. The phylogenetic tree was reconstructed by maximum likelihood method revealed that *J. curcas* accessions were divided into 2 groups as *J. curcas* (11) was closely related to *J. curcas* (8). Furthermore, *J. multifida*, *J. podagrica* and *J. gossypiifolia* revealed a close phylogenetic relationship.

Genetic diversity analysis of *Jatropha* by Random Amplified Polymorphic DNA (RAPD)

Pattamon Sangin, *Sagaoduen Moungyu*
Department of Biology, Faculty of Science, Naresuan University

Genetic diversity analysis of *Jatropha* and intraspecific level of *J. curcas* was studied using RAPD technique. Six out of one hundred and seven primers (2075 2391 2393 2777 OPA4 and OPA18) were found to give polymorphic DNA patterns. A total of 144 bands were scored with the size of 0.25-3.0 Kb. Genetic similarity was estimated by the Jaccard coefficient from NTSYSpc 2.20e version which ranged between 0.46-1.000. A dendrogram was also constructed by using Unweighted Pair Group Method with Arithmetic Mean (UPGMA) which divided *Jatropha* into two major clusters. First group comprised all *J. curcas* 18 accessions which Hongsa, Lumpang and Jomthong were grouped together with the high similarity index (1.000) as well as Mukdahan and India also clustered together. The second clade was 5 samples of *Jatropha*; *J. gossypifolia*, *J. podagrica*, *J. multifida*, *J. integerrima* (1) and *J. integerrima* (2) which *J. integerrima* (1) and *J. integerrima* (2) were clustered together with the genetic similarity value of 0.792 according to morphological character.

Pollen morphology of some entomophilous trees from Terai – Dooars region of west Bengal, India

Baishakhi Sarkar[1]*, Subir Bera*[2]*, Abhaya Prasad Das*[1]
1. University of North Bengal
2. University of Calcutta

The sub-Himalayan West Bengal, also known as the Terai-Dooars region is a part of the Himalaya Biodiversity hotspot and is well-known for its floristic and faunal diversity. Documentation and identification of floristic elements involves the collection and preservation of plant parts of which pollens provide very comfortable option using little space but exposing numerous but quite useful characters those can be used for identification as well as for phylogenetic analysis. The flowering plants have evolved different modes of pollination mechanisms to facilitate the fertilization process. Although the morphology of the grains is not always directly affected by the mode of pollination, but it reflects the environmental and ecological conditions. Present study deals with pollen morphology of 100 randomly selected entomophilous tree species comprising 77 genera under 39 families from Terai and Dooars regions of West Bengal, India and portrays diversification of pollen characters. Although the grains were mainly in monad condition, tetrads and polyads were also found especially in Mimosoideae. The extremely diversified exine patterns like granulate, bacculate, rugulate, verrucate, scrabrate, various types of reticulation and also psilate tends to be characteristic to not only at the family level but also can be species specific. Other morphological characters showed distinct variations. The shape varied from oblate (*Moringa olieferae, Erythrina* sp.) to perprolate (*Tecoma stans, Combretum* sp.*)*. The size also varied from very small grains of *Syzygium operculatum* (8.78 μm) to very big grains of *Bauhinia acuminata* (117 μm). Although the dominant aperturate condition was tricolporate type, other apertures like tricolpate, triporate, polycolpate, polyporate, polycolporate can also be noticed. Using these morphological characters the phylogenetic relationship of the taxa were examined. This study may help in establishing the insect plant relationships and tends to be important as it lays the basic foundation for future investigation of the late quaternary vegetation and climatic condition of the area along with other palynological aspects like pollination ecology, pollen biology, melissopalynology and aeropalynology.

Evolutionary and systematic studies in south American endemic genus *Tristagma* (Amaryllidaceae)

Agostina Sassone
Instituto de Botánica Darwinion

Subfamily Allioideae is one of three within family Amaryllidaceae (Chase *et al.,* 2009), and of great economic importance. The closest relatives of *Allium* L. in South America are represented by the endemic genera of the tribes Gilliesieae and Leucocoryneae. The tribe Leucocoryneae includes 6 genera exclusively distributed in South America, except of *Nothoscordum* Kunth, which is widespread in South America with one species occurring in North America. Most of the genera have a controversial taxonomy, species and genus delimitation has been considered problematic. *Tristagma* was described by Poeppig (1833: 369) with *Tristagma nivale* Poepp. as type species. Circumscription of *Tristagma* species has been a source of confusion for various reasons; e.g., generic concepts, nomenclatural inconsistencies, and doubtful species. The aim of this research is to present a multidisciplinary study of *Tristagma*, in order to define the number of species, contributing to a better knowledge of the subfamily Allioideae in South America. Morphological, phylogenetic, a complete bibliographic, taxonomic revision, and geographical distribution analyses were conducted. Phenetic analyses were performed including 200 specimens of *Tristagma* on the base of 60 vegetative and reproductive morphological characters. Through multivariate analyses 3 complexes of species and diagnostic morphological characters are identified.Fifty-seven specimens representing species of *Tristagma* and allied genera were examined. Three molecular markers (ITS, *mat*k and *ndh*F) were sequenced and analyzed with Parsimony and Bayesian inference analyses, to elucidate relationships within *Tristagma* and related groups. Exploring molecular marker ITS, *Tristagma* resulted monophyletic, when analyzing cpDNA phylogenetic hypothesis the position of *Tristagma* was not defined. The combined analysis supports *Tristagma as* paraphyletic being necessary the inclusion of *Ipheion* to be considered as a monophyletic genus. Also, the optimization of DNA content shows genome size variation among Leucocoryneae genera and within *Tristagma*. As a result of the bibliographic compilation, the identification of different species with fresh material and the study of available herbaria specimens, it is concluded that *Tristagma* is composed by 12 species. The genus *Tristagma* can be characterized by uni or plurifloral inflorescences, flowers with fused tepals forming a tube, and staminal filaments disposed in two series. Also, preliminary biogeographic studies were conducted in order to define the environmental requirements of the different species of *Tristagma*. Available pecimens of all species, covering the entire range of distribution of the genus, where georeferenced. Bioclimatic variables and altitude from the WorldClim dataset were associated with each locality of the studied specimens. By the correlation of climatic and geographical information it is concluded that precipitation and the mean temperature of the winter are the most influencing variables of the actual distribution of *Tristagma* species.

Taxonomical identity of *Encalypta* species with gemmae and genetic diversity in Japan

Takumi Sato, *Tomio Yamaguchi*
Hiroshima University

The genus *Encalypta* Hedw. (Encalyptaceae, Bryophyta) includes 36 species worldwide, and is mainly characterized by the markedly thickened transverse walls of the basal laminal cells and the campanulate calyptrae completely covering the capsules. The genus is predominantly recorded in montane and arctic regions throughout the world, and the species are approximately restricted to alpine regions in Japan. Seven species have been reported from Japan: *E. alpina* Sm., *E. asperifolia* Mitt., *E. ciliata* Hedw., *E. microstoma* Bals.-Criv. & De Not., *E. rhaptocarpa* Schwaegr., *E. streptocarpa* Hedw. and *E. trachymitria* Ripart. However, it has been discussed about taxonomical identity of Japanese plants of *Encalypta* with gemmae. The Japanese plants bearing gemmae was firstly identified as *Merceya serratinervis* Takaki by Takai in 1951, but later Takaki (1958) recognized it to be *Encalypta streptocarpa*. Horton (1983) concluded that Japanese plants previously identified as *E. streptocarpa* were misidentifications of *E. procera*, and she recognized *E. streptocarpa* to be restricted to Europe in her revision of *Encalypta* from North America. Iwatsuki (2008) re-examined all specimens collected from Japan and identified as either *E. streptocarpa* or *E. procera* focusing on gametophyte morphology and concluded that only *E. streptocarpa* is present in Japan. In the present study, molecular analyses were performed for the first time to reveal the taxonomic identity of Japanese specimens previously identified as *E. streptocarpa* in Japan. Phylogenetic analyses based on *trn*L-F and *ITS* support the monophyly of each Japanese *Encalypta* species and revealed that all Japanese samples bearing gemmae were nested within *E. streptocarpa* clade. We also provided the genetic diversity of *E. streptocarpa* from Japan based on haplotype network analyses.

The preliminary study of the genus *Alysicarpus* (Desmodieae, Fabaceae) in Thailand

Jiratthi Satthaphorn, *Charan Leeratiwong*
Department of Biology, Faculty of Science, Prince of Songkla University

The preliminary study of the genus *Alysicarpus* (Desmodieae, Fabaceae) in Thailand was studied between May 2016 and January 2017 based on field surveys and herbarium specimens especially from Thailand. A total of three species of Thai *Alysicarpus* were found namely *A. bupleurifolius* (L.) DC., *A. rugosus* (Willd.) DC. and *A. vaginalis* (L.) DC. The genus is significantly characterized by leaflet shapes, stipules, calyx lobes, corolla colors and legume indumentums. Morphological descriptions, distribution, ecological aspects and taxonomic treatments of the genus are provided.

T2

P0601

Phylogeny of the grass subtribe Rottboelliinae (Poaceae):

Why such a rotten mess?

Tanya Scharaschkin, *Melodina Fabillo*
Queensland University of Technology

Rottboelliinae is one of six subtribes in the grass tribe Andropogoneae. The number of genera recognized varies with taxonomic treatments, ranging from 10 to 18. *Coelorachis, Hackelochloa, Heteropholis, Ratzeburgia* and *Rottboellia* were synonymized with *Mnesithea* on the basis of morphological characters. Recent molecular phylogenetic studies partially support this decision, but results do not concur. Some authors recognise *Heteropholis, Ratzeburgia* and *Rottboellia* as separate from *Mnesithea* whilst others suggest that these three genera should remain synonymised with *Mnesithea* but *Hackelochloa* be recognised as a distinct genus. The genera *Elionus* and *Ophiuros* are included in the subtribe by some authors but not others. Taxonomic instability in the subtribe appears to be due to overlapping variability in gross morphological characters used to delimit genera and the lack of comprehensive taxonomic sampling in previous phylogenetic studies. In Australia, Rottboelliinae is represented by ~20 species in six genera that occur mainly in mesic eucalypt woodlands and savannahs. Seven of these species are endemic to Australia and two are rare. *Hemarthria uncinata* var. *uncinata* and *H. uncinata* var. *spathacea* show great morphological diversity, raising the question as to whether *H. uncinata* includes cryptic species or is a single variable species. Morphological characteristics of species of *Eremochloa* in Australia do not consistently agree with taxonomic descriptions and identification using published keys is problematic. The primary objective of this study was to test previous hypotheses of relationships and taxonomic decisions regarding the number of genera included in the subtribe Rottboelliinae. A secondary objective was to determine the phylogenetic position of the Australian taxa belonging to this subtribe. In order to resolve taxonomic issues, the following strategies were used: comprehensive and extensive taxon sampling, multi-gene sequencing, inclusion of morphological characters and careful examination of vouchers. Preliminary phylogenetic results based on separate and combined analyses of chloroplast sequence data (*atp*B-*rbc*L spacer, partial *mat*K gene, partial *ndh*F gene, *trn*L-F intron and intergenic spacer) using Bayesian inference, maximum likelihood and parsimony provide some interesting results. The genera *Eremochloa*, *Elionuros, Glyphochloa* and *Thaumastochloa* appear to be monophyletic. The genus *Mnesithea* is polyphyletic and previous recommendations of synonymy are not fully supported. The genus *Hemarthria* is not monophyletic. One possible cause for conflicting molecular phylogenetic results leading to contradictory recommendations for taxonomic decisions appears to be incorrect identification of species. The importance of careful examination of vouchers and re-examination of vouchers for Genbank sequence data cannot be overstated. This is the first comprehensive phylogenetic study of Rottboelliinae at a global and Australian level.

Comparative diversification analyses of Hydrangeaceae and Loasaceae: The role of continental dispersal in generating species diversity

John Schenk[1], *Sarah Jacobs*[2], *Larry Hufford*[3]

1. Georgia Southern University
2. University of Idaho
3. Washington State University

Hydrangeaceae and Loasaceae are sister clades that likely originated in arid regions of Mesoamerica but subsequently experienced different biogeographic and speciation histories. Hydrangeaceae became particularly diverse in Asia, with additional centers of diversity in western and eastern North America. Loasaceae, in contrast, has two centers of diversity, one in western North America and a second in the South American Andes Mountains. We tested the hypothesis that these clades share a common origin in Mesoamerica, and then compared how they diversified along both biogeographic and phylogenetic axes. Because these lineages experienced different biogeographic transitions that expanded their ranges into novel continental areas, we were able to examine and compare the consequences of colonization to ecological opportunity. Under an ecological opportunity model, we predicted that clades will experience an increase in speciation rates following the first colonization of new continental areas. We constructed a time-calibrated, phylogenetic hypothesis consisting of approximately 64% of the species diversity, and then applied the phylogeny to diversification and historical biogeographic analyses. The Hydrangeaceae-Loasaceae split occurred at least 95.34–72.94 mybp. Speciation rates were approximately constant from that time until about 18 mybp, after which they sharply increased. Historical biogeographic analyses supported a Mesoamerican origin of Loasaceae and Hydrangeaceae, followed by numerous biogeographic transitions in both clades. Lineages of Hydrangeaceae diversified early into Asia from western North America, followed by colonizations into eastern North America. A significant diversification rate increase was identified in the *Philadelphus* clade, associated with its initial colonization of Eurasia. A second increased diversification rate shift, not associated with a geographic change, was identified in the so-called Hydrangea-2 clade. Loasaceae experienced greater early lineage diversification in western North America than Hydrangeaceae, followed by a biogeographic transition into South America at the origin of Loasoideae. The latter range expansion into South America was not associated with a significant increased diversification rate; however, increased diversification was inferred in the *Cajophora* clade of Loasoideae, a change likely tied to ecological opportunities created with the uplift of the Andes. Two increased shifts were associated within the genus *Mentzelia*: one in *Mentzelia* section *Trachyphytum* and a second in *Mentzelia* section *Bartonia*. Neither of the two *Mentzelia* shifts were associated with continental-scale biogeographic transitions. We conclude that geographic range expansions have been important in generating species diversity in both families, but climate change, including aridification of the American West during the Miocene and glaciations during the Pleistocene, may have been equally important in accelerating cladogenesis in *Mentzelia*.

P0603

Nomenclatural novelties for *Mimosa* subseries *Obstrigosae* from South America

Fernanda Schmidt Silveira, Silvia T.S. Miotto, ***João R. V. Iganci***

Universidade Federal do Rio Grande do Sul (UFRGS)

Brazil is a center of diversity and endemism of *Mimosa* genus, represented by ca. 360 species, particularly on South and Central regions. Nevertheless, only from the last 20 years, we have observed an increasing in taxonomic revisions, Floras and specialists training, especially for Brazil Central. *Mimosa* section is the second in number of species, having circa 180 spp., distributed in three series and 37 subseries. Taxonomy of *Obstrigosae* subseries is considered by specialists of South America really difficult and uncertain. It is commoly find exsicates incorrectly identified. In this context, typification and name validation plays an important role, once these assign the correct application of the name for a species. Regarding this, our goals were: (1) lectotypification of *M. adpressa* Hook. & Arn and *M. obstrigosa* Burkart to the correct use of these names and (2) revalidation of *M. subinermis* Benth. as a distinct species from *M. rupestris* Benth. to allow the evaluation of its conservation status and improvement of the knowledge of *Mimosa* diversity. As lectotypus of *M. adpressa* was chosen the exsiccate from Argentina of the Province of Entre Rios, collected by Tweedie and deposited at Kew herbarium. For *M. obstrigosa*, the chosen exsiccate to be the lectotypus was from Argentina of the Santa Ana city, collected by Rodriguez and deposited at SI herbarium. *Mimosa subinermis* species can be readily distinguished from *M.rupestris* by its habit, presence of aculei, branches sparsely covered with strigose trichomes, paleaceous calyx covering fast half of the corolla length, fruits covered with strigose adpressed trichomes.

Resolving phylogenetic relationships of pantropical Ochnaceae s.l. using targeted sequence capture

***Julio V. Schneider**, Thomas Berberich, Georg Zizka*

Senckenberg Research Institute

Ochnaceae s.l. (including Medusagynaceae and Quiinaceae) is a pantropical family of about 550 species and 32 genera largely distributed in rainforests and savannas. To date, intergeneric relationships could be only partially resolved due to incomplete taxon and molecular sampling as characteristic for many tropical plant families which rely on DNA extraction from poorly preserved herbarium specimens. To overcome limitations of traditional Sanger sequencing, we have chosen a gene capture approach, targeting 660 kbp of the nuclear genome. Here, we present the pipeline from bait development to sequence assembly as well as new insights into the phylogenetic relationships of Ochnaceae.

Names matter: *Fagonia* sp. and breast cancer

***Melanie Schori**[1], Allan Showalter[2]*

1. US Department of Agriculture, Agricultural Research Service
2. Ohio University, Department of Environmental & Plant Biology

Plants are an importance source of many medicines, and researchers around the world continue to investigate traditionally used plants for their therapeutic effects. Collaboration between systematists, taxonomists, and medical researchers is important to ensure that tested material is correctly identified before it is used and to highlight closely related species that might have similar medicinal properties. *Fagonia* is a genus of plants in the caltrop family (Zygophyllaceae) and includes 34 species, many of which were lumped into the species *F. cretica* L. in the 1860s. The name *F. cretica* continues to be widely used in primary, secondary, and tertiary literature, even though Beier revised the genus in 2010. In 2012, an article on cytotoxic properties of an aqueous extract of *Fagonia* from Pakistan on breast cancer cells reported the species as *cretica*, which does not grow in the country. DNA sequencing has since been used to distinguish *Fagonia* species from Pakistan, and the cultivation requirements of the widespread *F. indica* are now being studied. Several other species with limited distribution may also be effective against breast cancer, but their traditional use has not been well documented and they still need to be evaluated in the laboratory. In the future, *Fagonia* may prove to be an important source for breast cancer treatment, and correct identification of the plant material will be essential for ensuring efficacy and conservation of genetic resources.

Atlas Florae Europaeae – the greatest ever effort for mapping floristic diversity in Europe runs across borders and projects

***Alexander Sennikov**[1,2], Arto Kurtto[1], Raino Lampinen[1], Pertti Uotila[1]*

1. University of Helsinki
2. Komarov Botanical Institute

There is a pressing need to accelerate biodiversity research and provide for comprehensive availability of its results because of the rapid degradation of the environment and the high risk of human-induced extinctions in all parts of the world. The development of unified global databases is a major step forward in biodiversity studies and conservation efforts. Whereas taxonomic databases (and electronic database-derived monographs) are becoming commonplace in biodiversity research, databases of distributional data are much less common and are largely limited to countries with lower levels of plant diversity and higher levels of resources. In addition, distributional data derived from taxonomic monographs are fragmented and thus poorly available to the scientific community. *Atlas Florae Europaeae* (AFE) is a long-term programme of mapping the diversity of vascular plants in Europe, aiming at covering the whole flora of Europe with grid maps of species and subspecies distribution. With 16 printed volumes already published, AFE currently covers about 25% of the European flora. To date, the quality of its coverage far exceeds that of the data available from other sources, e.g. GBIF. Established as a supplement to *Flora Europaea* (FE), AFE has surpassed its original purpose of providing the technical background of distributional data to taxonomic treatments in FE. At present, AFE collaborates with Euro+Med PlantBase (EMPB) by contributing some treatments and checklists and by providing map visualisation, hosting and maintenance. To respond to conservation needs, AFE collaborates with IUCN on assessment of European plant species. Based on the AFE database and with input from the AFE staff, the main floristic elements of Europe were defined and the main correlations between plant, mammal, climate and environment data were uncovered. We have identified two main problems with the existing data and its acquisition and handling. Re-mapping of many taxa is required because of historical data deficiency in East Europe and some of the earliest treatments being outdated. Secondly, traditional data-collection is too slow and no longer lives up to the current demand for scientific development. As a solution, AFE is being converted from a static data collection into a live, online database, which allows flexible data additions and corrections and expands taxonomic coverage without limits. The taxonomic checklist of AFE will be largely based on EMPB, with on-demand addition of further preliminarily accepted taxa which makes the checklist more flexible and open to accommodate original research. A revised mapping programme is being developed, operating with distributional information at the level of hierarchical territories, grid squares and precise records, with emphasis on the grid level. Data-collection and processing are to be no longer limited by recognised taxa or events. The next step forward is a direct link enabling further integration of EMPB and AFE, with bi-directional data flow. As well as collaboration and integration with other large-scale projects, AFE aims to embrace an unlimited number of smaller-scale side mapping and taxonomic projects utilising the AFE mapping workflow, offering the possibility of establishing new regional mapping programmes. This will open a pathway for the acceleration of more comprehensive data coverage in Europe.

The diverse leaf division patterns of yarrows are under effects of differential expression patterns of the *NAM* gene

Sha Sha, *Duo Chen, Yanping Guo*
College of Life Sciences, Beijing Normal University

Understanding the genetic mechanisms of phenotype divergence among related species can inspire hypotheses about the process and relevant evolutionary forces of speciation. The leaves of the yarrow species (*Achillea*, Asteraceae) show a great deal of diversity. Pinnate leaves, divided once to three times, are common in this genus, while some species have serrate leaves. Changes to phenotypes among organisms should be mainly attributed to historical signals, or a more appropriate term would be evolutionary processes. In model plants, serrated leaves develop with a program centered by the transcription factor NAM (CUC1/2). Whether such regulatory "tools" also work in yarrows? What makes leaves of the congeneric species different? We isolated orthologs of the *NAM* gene from *Achillea acuminata* and *A. asiatica* characterized by serrated and pinnate leaves, respectively. We verified that the *Achillea NAM* of is functionally equivalent to *AtCUC2* in the development of leaf serrates using VIGS experiments and a complementation assay applied to *Arabidopsis cuc2* mutants. We checked the patterns of expression of this gene by the whole mount *in situ* mRNA hybridization and two quantitative gene expression assays, the droplet digital PCR (ddPCR) and quantitative Real-Time PCR (qPCR). *In situ* hybridization showed *NAM* expression signals at leaf margins of both species, and furthermore, in *A. asiatica* on the margins of the elongated leaf lobes corresponding to the positions of the secondary dissection. Expression signals disappeared when the blades were fully expanded. Both ddPCR and qPCR revealed a continuous decline of *AacNAM* expression from the early to the late developmental stages of a single leaf of *A. acuminata*, whereas, a relatively long maintenance and fluctuation of *AasNAM* expression in a leaf of *A. asiatica*. The leaf transformation between the yarrow species is correlated to the altered expression patterns of the *NAM* gene, especially its differential expression dynamics.

Physiological and biochemical study of *Racomitrium canescens* under extreme high temperature stress

Wei Sha, Man Wang, Meijuan Zhang, ***Tianyi Ma***
Collage of Life Science, Agriculture and Forestry, Qiqihar University, Qiqihar, Heilongjiang

The Bryophytes are well regarded as pioneer terrestrial plants, distributed everywhere all over the world, including many kinds of extreme environmental conditions. So, bryophytes were considered possessing variable stress tolerance. *Racomitrium canescens* is belonging to Grimmiaceae, Grimmiales, Bryatae, Bryophyta, mainly growing on rock surfaces at lower altitudes, thin soil on rock surfaces, sand land, or stone walls and base of trees, distributed over China, North Korean, Japan, Vietnam, southeast of Siberia and Australia. In this study, *R. canescens* was discovered being able to be survived in extreme high temperature stress of 60 ℃ , 80℃ and 100℃ for at least 24 hours in wet condition. Moreover, *R. canescens* can grow normally more than 10 days after being transferred back to regular condition. Physiological and biochemical indexes were determined in different high temperatures and treatment time points. Changes of proline contents, soluble sugar contents, soluble protein contents and malondialdehyde contents of *R. canescens* were found not regularly depending on treatment temperature and time. However, chlorophyll contents, net photosynthesis rates and transpiration rates were in the same tendency under 60 ℃ and 80 ℃ stress, but performed differently under 100℃ treatment, supposing different responding mechanisms will play roles when *R. canescens* suffers to different high temperature stresses. This study provides theoretical proofs for researches of plants in response to extreme high temperature stress.

A systematic study of the southern African endemic genus *Sisyranthus* (Apocynaceae: Asclepiadoideae–Ceropegieae)

Khanyisile Shabangu[1], *Stoffel Petrus Bester*[2], *Michelle Van Der Bank*[3]
1. African center for DNA barcoding, University of Johannesburg
2. National Herbarium (PRE), South African National Biodiversity Institute
3. African center for DNA barcoding, University of Johannesburg

Sisyranthus E.Mey. species are placed in the tribe Ceropegieae, subtribe Anisotominae (Apocynaceae–Asclepiadoideae). Plants have their fertile parts hidden in the tube of the flowers, and are cryptic in both their habit and small flower size making it difficult to find them in the wild. The genus was first described by Meyer in 1837 and last revised in Flora Capensis (1908) with only one new species described since then. Currently the genus comprises

13 recognised species found in the grasslands of southern Africa, with one species restricted to Zimbabwe. Many of the species are range-restricted and poorly known. The existing key is difficult to use thus leading to confusing identifications. In existing DNA phylogenies, the subtribe Anisotominae has been under sampled and a broader sampling of the southern African taxa is required in order to resolve relationships within and between *Sisyranthus* and its close allies. A revision will lead to a better understanding of the group and its affinities. The aims of this study was: (1) to produce a molecular phylogeny for *Sisyranthus* and its close relatives using sequence data from two nuclear markers (ITS and ETS) and five plastid regions (*mat*K, *ndh*F, *rbcLa, trn*L-F, and *ycf1*); (2) to map morphological characters onto the resulting phylogeny; (3) to revise the genus; and to (4) produce a key to properly identify the species. Preliminary results will be discussed.

Biosystematic study of *Tamarix* L. species in Semnan Province, Iran

Tahmineh Shagholi[1], *Maryam Keshavarzi*[2], *Masoud Sheidai*[3]
1. Alzahra University
2. Alzahra University
3. Shahid Beheshti University

Tamarix L. with approximately 54 Species is the largest genus of the Tamaricaceae (Baum, 1978). This genus consists of shrubs and semi-shrubs which grow in dry and temperate coastal areas. Iran as one of the major centers of the speciation of this genus has 25 species which are distributed in different Regions of the country (Mobayen, 1996). In this research *Tamarix* species of Semanan province has been studied. Totally, 16 populations of 8 species were gathered through 2015 to 2016. Studied species were: *T. arceuthoides*, *T. mascatensis*, *T. ramosissima*, *T. chinensis* (previously were only reported from China, Mongolia and Japan (Gaskin & Shaal, 2003)), *T. szowitsiana*, *T. meyeri*, *T. androssowii* and *T. aucheriana*. In order to clarify the identifications of the studied species ITS phylogenetic marker and blasting the DNA sequences with NCBI accessions were used, in addition to morphological characters. Using phylogenetic analysis, Maximum Likelihood, UPGMA, Neighbor Joining and HGT tree of species relationships and their gene flow were analyzed. Based on results of present study, morphological and molecular were not in concordant and agreement. Morphological and molecular variation of 6 populations of two species as *T. szowitsiana* and *T. androssowii* were studied using ISSR marker. The result of each primer after PCR and differentiation on agarose based on presence or absence of band, were numbered on 0 and 1. UPGMA cluster analysis and MDS shows the absence of a clear limit between accessions of these two species and their high gene flow. Species relationship has been discussed.

Studies on seed morphometry in some Epidendroideae (Orchidaceae)

Mahammad Khasim Shaik
Acharya Nagarjuna University

SEM (Scanning Electron Microscope) studies on seed morphometry of nine orchids, such as *Malaxis densiflora* (A.Rich.) O.Kuntze, *Oberonia arnottiana* Wight., *O.ensiformis* Lindl., *Calanthe triplicata* Lindl., *Acampe praemorsa* Blatt.&Mc. C., *A.rigida* Lindl., *Luisia zeylanica* Lindl., *Vanda testaceae* (Ldl.) Reich. F., *V.tessellata* Hk. F. have been carried out. The quantitative data related to the length and width of the seed and embryo, seed and embryo volume, percentage of air space, and numbers of testa cells were presented here. The seed truncation character can be used to differentiate between species in the genera such as *Calanthe, Malaxis, Oberonia, Vanda, Acampe* and *Lussia*. This data indicate that the seeds of *Calanthe* species are more truncated than that of the other studied taxa. Seeds with higher ratio of seed volume/embryo volume (more than 2.2) especially in *C. triplicata, V. tessallata, V. testaceae* are expected to be more buoyant than those with a lower ratio of seed volume/embryo volume. These are widely spread out species in Western Ghats of south India. The buoyancy of seeds could be attributed to the dispersal of seeds to vast areas as well as widely distribution of the species.

P0612

Taxonomic study of the genus *Populus* L. from Pan-Himalaya

Ce Shang, *Limei Zhang, Zhixiang Zhang*
Laboratory of Systematic Evolution and Biogeography of Woody Plants, College of Nature Conservation, Beijing Forestry University

Plants of *Populus* are distributed and cultivated worldwide, but some taxonomic problems remain unsolved within this genus. The considerable morphological variation both within and among populations have posed challenging obstacles in species delimitation and classification. In the Himalayas and adjacent regions, 57 species and varieties have been recorded, mostly from China. Based on herbarium specimens and field observation among populations, we have performed morphological character analysis for species circumscription. Number of capsule valves was found to be a key character to differentiate taxa. Triploidy *P. davidiana* Dode, which leaves are quite similar to those of *P. rotundifolia* Griff., was found using flow cytometry, suggesting the independence of both the species. Phylogenetic relationship between sections was discussed on the basis of chloroplast genomes. In this work, 22 species, 3 hybrid and 1 variety are recognized in four sections; Sect. *Tacamahaca* Spach is reduced to be a synonymy of Sect. *Aigeiros* Duby; 3 new combination and 27 new synonymy are proposed.

Evolutionary developmental genetics of capitulum architecture variation in Asteraceae

Chuze Shen[1], *Jie Chen*[1], *Yanping Guo*[2], *Guangyuan Rao*[1]
1. School of Life Sciences, Peking University
2. College of Life Sciences, Beijing Normal University

The rich morphs of angiosperm flowers and inflorescences are intimately linked to their efficiency of reproduction and modes of speciation. In the large daisy family, Asteraceae, many florets assemble into a head-like inflorescence called capitulum that functionally acts as a flower. The formation of such a pseudanthium has helped the composite plants gain an increased fitness and thus an evolutionary radiation. There are a variety of types of capitulum differing in the morph, number and arrangement of ray florets. *CYC2* members are involved in the formation of the rays. We have identified a new *CYC2* member (*CYC2g*) in the more derivative lineages of the daisy family and confirmed a set of nested gene duplications across the Asterales. Thereinto, the *CYC2c* and *CYC2g* appear to be ray-specific and express alternatively in different lineages/species. To test whether these two genes have similar phenotypic effects on ray morphogenesis, we have developed *Chrysanthemum lavandulifolium* as a model system. Overexpression of *ClCYC2g* can significantly increase the number of rays in a flower head as *HaCYC2c* does in the sunflower mutants. Whilst ectopic expression of *ClCYC2d* severely inhibits the petal growth of ray flowers and make the corolla tube split at the adaxial side. Altogether, our data clarified the evolutionary trajectory of the *CYC2* genes across Asterales and put forward an evolutionary developmental mode of ray evolution and variation in Asteraceae.

Stipe anatomy of Thelypteridaceae, new insight for the classification

Kuanyu Shen[1], *Zhaorong He*[2], *Yuehong Yan*[3], *Yeachen Liu*[1,4]

1. Department of Biological Resources, National Chiayi University, Chiayi

2. Institute of Plant Science, School of Life Science, Yunnan University, Kunming

3. Shanghai Chenshan Plant Science Research Center, Chinese Academy of Sciences, Shanghai Botanical Garden, Shanghai

4. Author for corresponding

Thelypteridaceae is one of the largest families in Eupolypods II. This family is certainly confirmed as monophyly, however, several genera of Thelypteridaceae are paraphyly or polyphyly. In the past, these genera were recognized as taxonomic units by pinna shape, venation, position and morphology of trichomes. These chosen characteristics might be affected by convergence evolution or improper weighting, cause several taxonomic units to be unnatural. Otherwise, some separated taxa should be recognized as a clump in the view of molecular phylogenetic study. Anatomical structures reveal important new insights of classification and evolution of ferns. The amounts, shapes of vascular bundles and xylem bundles morphology could be applied to the characters for specific taxa, thus the similarities and differences between the taxa are the clues for the evolution. Unfortunately, very few monographs discuss about these anatomical characters in the classification of Thelypteridaceae. In the present study, 50 more species represented 17 genera have been studied. The fresh materials had been fixed in the 70% alcohol and slicing by microtomes with paraffin and free-hand methods. The measurement of cell size, the xylem and phloem cells arrangement in the vascular bundles, existence of fiber and circumendodermal band (CB) between the genera, leaf size and habitat types are also considered as water usage strategy of each species. The results show CB is absent in *Macrothelypteris pro parte*., *Phegopteris, Pseudphegopteris pro parte.*, *Metathelypteris*, *Parathelypteris pro parte., Christella pro parte.* and *Pronephrium*. The thicken types of CB cell walls, the diameter of xylem cells, channels embedded in the vascular bundles are assumed relating to habitat and leaf size.

Diversity, vertical distribution patterns and drivers of epiphytic bryophytes in tropical and subtropical forests, SW China

Shen Ting[1], *Corlett Richard*[1], *Guo Xinlei*[2], *Song Liang*[1]

1. Xishuangbanna tropical botanical garden

2. Northwest Institute of Eco-Environment and Resources

Epiphytic bryophytes play significant roles in forest ecosystems, including water retention, nutrient cycling, interaction with epiphytic vascular plants, and providing habitat for a variety of small animals. Their diversity and distribution patterns in forest canopies are little known because of access problems. However, with the innovation of canopy techniques—from telescopes, ladders, single rope techniques, canopy walkways, hot-air balloons, and inflatable rafts, to canopy cranes— forest canopy studies have broken through the previous barrier of easy access to the different positions in the canopy. This study surveys the diversity patterns and species distributions of epiphytic bryophyte communities along a vertical gradient in the tropical rain forest in Xishuangbanna and the subtropical montane moist forest in Ailao Shan, both in Yunnan, China, using canopy cranes. We will investigate how the differences between the two sites in elevation, climate, and forest type influence their bryophyte communities, and how microclimate factors (relative humidity, PAR, mean temperature) and host characteristics (tree diameter, bark pH, bark roughness, water holding capacity of bark) influence the vertical distribution of epiphytic bryophytes at each site. The results of this study will help us to understand how bryophyte diversity is maintained in three-dimensional space and to assess the conservation significance of these patterns. This project is the first to explore canopy epiphytes in China, so it will provide fundamental data for the Chinese forest biodiversity monitoring network as well as contributing to international cooperation in the forest canopy.

P0618

Phylogeny and systematics of *Prunus* L. subgenus *Cerasus* (Mill.) A. Gray (Rosaceae)

Shuo Shi[1,2], *Yu-Xin Li*[2], *Jin-Lu Li*[1], *Jia-Hui Sun*[1], *Jing Yu*[1], *Shi-Liang Zhou*[1], *De-Yuan Hong*[1]
1. Institute of Botany, the Chinese Academy of Sciences
2. Hebei Normal University

Subdivision of *Prunus s. l.* (Rosaceae) has been a conundrum for about 300 years. The purpose of this study was to solve this problem with a special emphasis on taxonomy of true cherries by integrating both morphological and molecular evidence. The first step was taken to reconstruct the phylogeny of *Prunus s. l.,* and the subsequent subdivisions of *Prunus s. l.* were based on the phylogeny. By doing so the circumscription of true cherries was followed and phylogeny of true cherries was built. Taxonomic treatments of true cherries were provided. In total, fifteen DNA fragments, including twelve chloroplast fragments (*atp*B-*rbc*L, *mat*K, *ndh*F, *psb*A-*trn*H, *rbc*L, *rp*L16, *rpo*C1, *rps*16, *trn*S-G, *trn*L, *trn*L-F and *ycf1*) and three nuclear genes (ITS, *s6pdh* and *SbeI*) were used to reconstruct the phylogeny of seventy-seven species of *Prunus s. l.* representing all 10 entities of the genus in broad sense. The molecular marker *ycf1* was used for the first time for the genus, and *SbeI* was developed for the genus. The resulting phylogeny indicated that *Prunus s. l.* is a monophyletic group that has diverged into three clades. Considering close relationships among the species belonging to the three clades, we treat *Prunus s. l.* as one genus, *Prunus*. The genus was subdivided into three subgenera, subgenus *Padus* (Mill.) Petem., subgenus *Cerasus* (Mill.) A. Gray and subgenus *Prunus,* which correspond to the three clades. The subgenus *Prunus* were further subdivided into seven sections based on the phylogeny, namely, section *Amygdalus*, section *Armeniaca*, section *Emplectocladus*, section *Microcerasus*, section *Persicae*, section *Prunocerasus* and section *Prunus*. Phylogeny of thirty-five species of the subgenus *Cerasus* were reconstructed using three chloroplast fragments (*atp*H-*atp*I, *pet*A-*psb*J and *pet*N-*psb*M) and the nuclear *SbeI-a*. The topologies created by the maximum parsimony, maximum likelihood and Bayesian inference were nearly identical. Exclusion of section *Microcerasus* from the subgenus and inclusion of *P. mahaleb* L., *P. maackii* Rupr. within the subgenus were confirmed. After literature verification, specimen examination and living plants observation, taxonomic treatments of subgenus *Cerasus* of China were made. *Prunus tianshanica* (Pojarkov) S. Shi., comb. nov. and *Prunus* L. subgenus *Prunus* section *Persicae* (T. T. Yü & L. T. Lu) S. L. Zhou were proposed.

A revision of the phylogeny of the Thermopsideae: Data from *cp*DNA and ITS markers

Wei Shi[1], *Peiliang Liu*[2], *Borong Pan*[1], *Zhihao Su*[1]
1. Xinjiang Institute of Ecology and Geography, CAS
2. Northwest Agriculture and Forestry University

In this paper we resolved conflict in the phylogeny of the clade Thermopsideae, using internal transcribed spacer (ITS) and four chloroplast intergenic spacer (*mart*K, *trn*H–*psb*A, *trn*L–*trn*F and *rpc*L) marker data. We genotyped 110 individuals, including six distinct haplotypes of individuals in the genus *Ammopiptanthus,* as well as 85 individuals from other key genera in the Thermopsideae. Traditionally, the Thermopsideae were not considered monophyletic group, and the wider Thermopsideae were divided into two subclades. However, we report that molecular data indicates that species in the genus *Sophora* are nested within *Ammopiptanthus* and thus form an isolated clade. Furthermore, we found that the genera *Piptanthus* and *Baptisia* are monophyletic, while the genus *Thermopsis* is not. *Piptanthus*, *Anagyris*, *Baptisia,* and *Thermopsis* are clustered together into an uncontested clade, during which North American *Thermopsis* spp. form a side branch within which *Baptisia* is nested. *Thermopsis* show a geographical division between Old World and New World populations. Our results can either strength to just the four 'core genera' in Thermopsideae with *Ammopiptanthus* excluded, or confirm the sister group relationship between *Sophoreae* and *Ammopiptanthus*.

Observation of flower development and chromosome analysis of *Osmanthus fragrans*

Yaya Shi, *Xiaojuan Wang*
Shanghai Sceince and Technology Museum

Osmanthus fragrans is an evergreen small tree which originated from Asia, and 75% of the varieties of *O. fragrans* are distributed in China. *O. fragrans* has unique flower development and the rare breeding system of androdioecy (coexistence of males and hermaphroties). It has been reported that in hermaphrodites flowers, two carpel primordia can heal up gradually and form a normal pistil, however in male flowers, two carpel primordia can not heal up and ultimately form bractlike degenerated pistil, through paraffin section assay. In our researches, the male and hermaphrodites flower buds of *O. fragrans* were gathered separately from the end of July until the end of October, the whole process of male and hermaphrodites flower buds' development were analyzed by scanning electron microscopy assay, the different development process of carpel primordia in hermaphrodites and male flowers were observed. The chromosome of *O. fragrans* was also analyzed to reveal the mechanism of sex determination mechanism. Because the androdioecious phenomenon is very rare in nature (about 3%), It has been predicted to be a intergradations from bisexual to unisexual flower. Our research on the development and differentiation of *O. fragrans* sexual organs can be used not only to understand the mechanism of flower differentiation of this species, but also the evolution of flower sexual differentiation.

Molecular phylogenetics and character evolution in Vochysiaceae

Gustavo Shimizu[1], *Deise Gonçalves*[2], *Amy Litt*[3], *Kikyo Yamamoto*[1], *André Simões*[1]
1. University of Campinas (Unicamp)
2. The University of Texas at Austin
3. University of California, Riverside

Vochysiaceae is a small family within the order Myrtales, comprising eight genera and about 240 species. This study presents the largest molecular dataset to date for this group, using both plastid (*ndh*F gene) and nuclear (ITS1) DNA sequence data. One hundred and sixty new sequences and eight others retrieved from GenBank were analyzed using maximum parsimony and Bayesian inference. The combined analyses with seven genera and 64 species of Vochysiaceae aimed to test the monophyly of its tribes and genera, as well as start to unravel infrageneric relationships, and to find morphological synapomorphies for major clades. Three main clades were obtained: Erismeae (*Erisma* and *Erismadelphus*), QRC (*Qualea*, *Ruizterania* and *Callisthene*) and VS (*Vochysia* and *Salvertia*), but there is no strong resolution in their relationships. *Erisma* is sister to *Erismadelphus*, *Callisthene* is uncertain, *Qualea* and *Ruizterania* lineages form a polytomy, and *Salvertia* is sister to *Vochysia*. *Ruizterania* is considered a synonym under *Qualea*. Several of the morphology-based infrageneric categories were corroborated as monophyletic by the molecular data, and some intriguing taxa, like *V. discolor* Warm. and *V. pseudopumila* Rizzini & Heringer, had their placement clarified. Among the morphological traits mapped, four have states represented as potential synapomorphies for the family: absence of translucid glands in the leaves, presence of spur or bursiform prominence in the fourth sepal, erect stamen in the flower bud and only one fertile stamen. Other nine character states are also potential synapomorphies for major clades. New in-depth questions inside some groups can be driven based on the present results, but efforts to better resolve the backbone of the family will continue as well.

Phylogeny of Plantagineae (Plantaginaceae, Lamiales)

Alexey Shipunov[1], *José Luis Fernández Alonso*[2], *Gustavo Hassemer*[3]
1. Minot State University
2. Real Jardín Botánico CSIC
3. University of Copenhagen

Plantagineae (Plantaginaceae, Lamiales) consist of well-known, worldwide distributed plantains (Plantago), small aquatic Littorella and Andean páramo shrubs Aragoa. This assemblage is unusual in many ways. First, it is a clear example of evolutionary reduction. Second, Plantago exhibits amazingly high diversification rates. Third, the worldwide distribution of plantains raises numerous questions related to vicariance and dispersal. In addition, there is a striking contrast between morphological disparity of these three genera. Frequent hybridization in Aragoa is also an important aspect of this genus evolution. Here we present the most complete draft phylogeny of the group and discuss its evolutionary, morphological and biogeographical implications.

Udaria – A new liverwort genus of Lophocoleaceae from Eastern Himalaya, India

Devendra Kumar Singh Devendra Kumar Singh, ***Shuvadeep Majumdar Shuvadeep Majumdar***, *Devendra Singh Devendra Singh*
Botanical Survey of India

The family Lophocoleaceae currently includes 21 genera in the world, 10 of which are monotypic, with the taxonomic circumscription of the genera yet not fully resolved. In India the family is represented by 30 species and infraspecific taxa, belonging to genera *Chiloscyphus* Corda (06 species), *Heteroscyphus* Schiffn. (14 species) and *Lophocolea* (Dumort.) Dumort. (09 species and 01 variety), mostly distributed in the Indian Himalayan region. Nine species, or 30 per cent of the hitherto recorded taxa, are endemic to the country. The taxonomy of the family in India is well understood. The Eastern Himalaya, which is the most species rich bryogeographical region in India, exhibits the maximum diversity of the family with 26 taxa known from this territory, followed by Western Himalaya and the Western Ghats with 16 taxa each, Central India (06 species), Eastern Ghats & the Deccan Plateau (03 species) and the Andaman & Nicobar Islands (02 species). While, some taxa are restricted to their respective bryogeographical region in Indian bryoflora, a number of them are common to one or more than one of the above territories. During our on-going studies on the liverworts of the Eastern Himalaya, we came across some interesting plants from Arunachal Pradesh and Sikkim which, in the presence of undifferentiated stem; 2-lobed, sub-transverse to succubous leaves with thin-walled cells; 2-lobed underleaves with 1–2-dentate margin, occasionally with additional tooth along the inner margin of the lobe; rhizoids fascicled at underleaf base; gynoecia on the main shoot; large female bracteoles more or less equal to the female bracts, and long exserted, oblong trigonous perianth with dorsal third keel and 3-lobed mouth, are referable to the family Lophocoleaceae. The plants with 1–2-celled or linear multicellular gemmae, female bracts and bracteoles larger than leaves and underleaves respectively and long exserted, symmetrically trigonous perianth with 3-lobed mouth show closer affinity with Lophocoleoid elements of the family. However, in the presence of longitudinal, 1–12 cells high lamelliform strips on stem surface; striolate – rugulose leaf cuticle; gynoecia with 1–2 sub-floral innovations and gemmiparous female bracts, these plants are remarkably distinct from hitherto all the known genera of the family, and hence described here as new genus *Udaria* D.K.Singh, S.Majumdar & D.Singh, *gen. nov.* The new genus, at present, is monotypic and represented by *Udaria lamellicaulis* D.K.Singh, S.Majumdar & D.Singh, described here as new species. The paper provides detailed description and illustration of the new taxon and discusses features underlining its taxonomic delimitation.

A novel phylogenetic classification for *Schinus* L. (Anacardiaceae) and insigths into biogeographic patterns in southern South America

Cíntia Silva-Luz[1], *José Rubens Pirani*[1], *John D. Mitchell*[2], *Douglas Daly*[2], *Susan K. Pell*[3], *Gregory M. Plunkett*[2]
1. São Paulo University
2. The New York Botanical Garden
3. United States Botanic Garden

Schinus belongs to the Anacardiaceae and comprises about 33 species mostly restricted to southern South America. Species are divided into two subgenera defined using a combination of characters that is not always consistent, and species delimitations, especially in *Schinus* subg. *Duvaua* remain controversial. In South America, *Schinus* represents the richest genus and its species can be found in a great diversity of habitat as Patagonia, Chaco, *Monte*, Seasonally Dry Tropical Forest, *Yungas, Prepuna*, Chilean Sclerophyll Forest and Atlantic Forest. Phylogenetic studies in Anacardiaceae are still scarce, especially for South America. A phylogenetic study of *Schinus,* combined with analysis of Anacardiaceae fossil records might provide a deeper understanding of the biogeographic history of the genus. Moreover, these biogeographic hypotheses can increase our knowledge of South America biogeography, since *Schinus* is a remarkable element from vegetation formations of this region. In order to obtain a more thorough understanding of infrageneric relationships of the genus, we sampled 47 *Schinus* taxa, and 13 genera of Anacardiaceae as outgroup. We performed phylogenetic analyses from DNA sequences using plastid (*trn*L-*trn*F and *rps16*) and nuclear (*ETS*, *ITS*, AT2G44760 and AT2G20790) regions. Bayesian and ML analyses supported the monophyly of *Schinus* (BPP: 1.00, BS: 100%). According to phylogenetic analyses, characters traditionally used in the genus circumscriptions probably evolved multiple times or they are plesiomorfic. For example, *S. terebinthifolia, S. weinmanniifolia, S. molle* and *S. lentiscifolia*, compound leaved species, were the first lineages to branch out. However these taxa were placed in *S.* subg. *Schinus* they appeared in our phylogenetic reconstruction as a basal grade. Therefore, this subgenus might not be considered as monophyletic, and compound leaves are probably a plesiomorfic character. *Schinus lentiscifolia* is sister to a clade comprising all simple leaved species. Our results suggested that sections of *Schinus* subg. *Duvaua* need new circumscription and diagnostic characters, since spine-ending branches character probably evolved multiple times, and therefore it is not suitable to define the sections proposed by Barkley. Phylogenetic reconstruction showed interspecific relationships in *Schinus* that had never been demonstrated before. Besides, it also suggested possible cryptic species within some clades, in which was not evidenced by morphological studies. In addition, our analysis showed five well supported clades within simple leaved species: 1 - *Yungas Clade,* 2 - *Sclerophyll Forest - Patagonian Alliance,* 3 - *Patagonian - Prepuna Alliance,* 4 - *Arid Areas Clade,* and 5 - *Atlantic Forest Clade.* These biogeographical patterns are similar to other studies for southern South America biota. For instance, relationship between species from "clade 2" provides strong evidence for past floristic connections because it may have resulted from dispersal events between Central Chile subregion and the northern part of the Subantarctic subregion. Previous study suggested a possible association between climatic niche evolution and diversification because sister species or sister clades in Anacardiaceae share the same geographic region but inhabit different climatic niches. Our analyses also highlight that some sister clades in *Schinus* phylogeny presented similar pattern of climatic niche evolution, and this may be associated with relatively great diversity in *Schinus*.

Polyploidy as a factor in the evolution of the *Bouteloua curtipendula* complex (Poaceae: Chloridoideae)

María Elena Siqueiros Delgado[1], *Amanda Fisher E.*[2], *J. Travis Columbus*[3]
1. Universidad Autónoma de Aguascalientes
2. Department of Biological Sciences
3. Rancho Santa Ana Botanic Garden and Claremont Graduate University

In this paper we assess the impact of polyploidy and hybridization in the *Bouteloua curtipendula* species complex (BCC). The BCC is a monophyletic group of perennial grasses in the Chloridoideae subfamily. We tested for evolutionary signatures of hybridization and polyploidy in the BCC by obtaining 77 chromosome counts from anther mother cells (2n = 20 to >100) and comparing the phylogenetic pattern of diploids and polyploids in nuclear and chloroplast trees. We sequenced ITS and *trn*T-L-F regions for 96 and 70 individuals, respectively, resulting in 150 nuclear ribosomal ITS sequences, including 54 cloned sequences. We found no evidence for recombination between ITS sequences with a PHI test. Maximum parsimony and Bayesian analyses were used to estimate the ITS phylogeny. Diploid samples were found in all clades, while most of the polyploid samples were concentrated in a single clade. Cloned diploids contained 1-3 copies of ITS with >99% sequence similarity. The tetraploids *B. purpurea* and some *B. curtipendula* samples had a low amount of variation among ITS copies, while the cloned polyploids possessed several highly divergent ITS copies. Pollen size correlates with ploidy-level in the BCC, but is not a clear indicator of genome size. We found evidence that the BCC lineage has a complicated evolutionary history that has included autopolyploidy and allopolyploidy.

Ultra structural characters of calcium oxalate (CaOx) crystals and Idioblasts of some selected angiospermic taxa of the

family Araceae from India: A systematic approach.

Imam Saadi Sk Md Abu
Department of Botany and Forestry, Vidyasagar University, West Bengal

Crystallization is a common phenomenon in many plant groups. In Angiosperms, only the family Araceae, CaOx crystals are very abundantly present in their different plant parts (leaf, petiole, stem/storage organ, roots) within parenchyma/aerenchyma cells to form crystals idioblast. These crystals idioblast contain the composition of calcium and oxalic acid to form different crystal diversity like- prismatics, crystal sands, druses and raphides. Present study divided raphide on the basis of their termination like- SWC, SWP1, SWP2, ThTT, and TnTT and other different micro-morphological characters (shapes of barbs, length of bridge and grooves, idioblast morphology and their arrangement within cell). These characters may apply in taximetrics to solve the taxonomic problems in the different levels viz. families, genus, and species.

Different ways to obtain similar results. The development of the corolla and epipetaly in temperate and tropical herbaceous *Rubioideae* (*Rubiaceae*)

Alexander Vrijdaghs[1,2, 3]*, Petra De Block*[2]*,* ***Erik Smets***[1,3]
1. Naturalis Biodiversity Center
2. Botanic Garden Meise
3. KU Leuven

It is commonly assumed that flowers in *Rubiaceae*, one of the largest angiosperm families after *Asteraceae*, *Fabaceae* and *Orchidaceae*, have a calyx with basally fused lobes and a tubular corolla with epipetalous stamens. In several, but not all, tropical *Rubiaceae* species studied in literature, floral developmental investigations revealed that the corolla is early sympetalous, developing a stamen corolla tube from an annular primordium. Other species showed late sympetaly with a rudimentary or absent stamen corolla tube. Consequently, the stamens are inserted at the very base of the corolla tube or in the hypanthium. Payer observed in herbaceous European *Rubioideae* that the corolla originates from individual petal primordia. Later in the development, the petals and the basal part of the filaments fuse postgenitally, forming together a floral cup with only the distal parts of the filaments remaining free. In this study, we want to test the hypothesis that rubioid tubular corollas are developmentally compound floral cups resulting from three processes; 1) the development of a stamen-corolla tube from a common annular primordium, 2) the development of a corolla tube sensu stricto from an annular intercalary meristem, and 3) postgenital fusion of petals or petal lobes. Following Goethes “*Prinzip der variablen Proportionen*” we hypothesize that these processes are differently expressed in the species studied. We investigated the development of the perianth and androecium in temperate (European) and tropical herbaceous species within Rubioideae. Our observations on temperate *Asperula*, *Galium* and *Rubia* species confirm those of Payer. In these cases the floral cup results from postgenital fusion of initially free petals and filaments. In the temperate *Phuopsis* and tropical *Richardia* species studied, a stamen-corolla tube is formed, resulting in a corolla tube with epipetalous stamens. In *Phuopsis*, the stamens are inserted halfway between the base of the corolla tube and the corolla lobes, due to the development of a corolla tube sensu stricto, which is absent or rudimentary in *Richardia*. The developmental patterns in these species concur with our hypothesis. In contrast, the developmental patterns in *Asperula*, *Galium* and *Rubia* differ due to the absence of a stamen-corolla tube and corolla tube sensu stricto. Moreover, the tubular corolla-like structure results from postgenital fusion between filaments and petals. Consequently, the tube is a compound structure composed of the fused parts of filaments and petals and the observed epipetaly is actually a pseudo-epipetaly.

Biodiversity, distributions, and adaptations of epiphytic bryophytes in the context of global changes in Yunnan, SW China

Liang Song[1]*, Xian-Meng Shi*[1]*, Xi Chen*[1]*, Wen-Yao Liu*[1]*, Wen-Zhang Ma*[2]
1. Xishuangbanna Tropical Botanical Garden, Chinese Academy of Sciences
2. Kunming Institute of Botany, Chinese Academy of Sciences

Yunnan Province, Southwest China, an high-elevation and low-latitude inland province, covers a territory with complex terrain and diversified climate zones and functions as refugia for diverse and unique nature resources. Unfortunately, species composition and distribution patterns of epiphytic bryophytes at multiple scales and their links to environmental changes remain poorly studied. Three investigations had been carried out to address biodiversity and distributions of epiphytic bryophytes in Yunnan, while ecophysiological measurements and manipulation experiments had been conducted to assess adaptations of epiphytic bryophytes and their fates in a changing world. The three protected forests in Yunnan harbored 226 epiphytic bryophyte species belonging to 101 genera, 46 families. The subtropical montane cloud forest located in the Ailao Mountain National Nature Reserve of Southwest China, which is generally characterized by persistent and frequent cloud cover at the canopy level, is especially rich in epiphytic bryophytes. In total, 176 epiphytic bryophyte species have been recorded and the total biomass of the epiphytic bryophytes is 6.7 tons per hectare. Bole epiphytic bryophytes adapt to the shady understorey microhabitats through a series of correlations and trade-offs between functional traits. However, even slight changes in climate resulted in remarkably reduced rates of growth and detrimental effects on the health of the transplanted epiphytic bryophyte species over 2 years. The low water retention capacity and high dependence of net photosynthesis to water content of epiphytic bryophytes implied high risks of imbalance of carbon budget for them under the increasing severity of drought. Epiphytic bryophytes could take up N from the bark and wet deposition in both organic and inorganic N forms. The process of carbon metabolism and the chemical stability of epiphytic bryophytes are strongly influenced by N addition levels, and presenting strong correlations with the bryophytes loss. In addition, a general decline in community heterogeneity and biomass production of bryophytes induced by high N loads can be expected, which will probably alter the C and N cycles of subtropical montane forest ecosystems and arising their risk of the function and structure stability under intensive climate changes.

Host–hemiparasite–arbuscular mycorrhizal fungi interactions vary with different host plants

__Xiao-Lin Sui__, Ai-Rong Li, Kai-Yun Guan, Yan Chen
Kunming Institute of Botany, Chinese Academy of Sciences

Although arbuscular mycorrhizal fungi (AMF) are ubiquitous and well known for improving plant growth and regulating plant-plant interactions, their roles in regulating interactions between root hemiparasitic plants and their host plants remain less known. Leguminous and gramineous plants are both considered good hosts for root hemiparasitic plants, showing robust growth promoting effects once attached. However, the two functional groups tend to have different responses to AMF inoculation, with leguminous plants often showing positive responses while gramineous plants showing little or even negative responses. We therefore hypothesized that AMF inoculation might have different effects on the host-hemiparasite interactions between a leguminous host and a gramineous one. We conducted greenhouse pot cultivation experiments to test effects of *Glomus mosseae* on the growth and photosynthesis of gramineous (*Elymus nutans*) and leguminous (*Trifolium repens*) parasitized by a root hemiparasite *Pedicularis kansuensis*. The results showed that shoot and root dry weights (DWs) of both hosts were significantly reduced when parasitized by *P. kansuensis*. The ETR (electron transport rate) of *E. nutans* was significantly reduced, whereas that of *T. repens* was significantly improved when parasitized by *P. kansuensis*. For hosts parasitized by *P. kansuensis*, inoculation with *G. mosseae* significantly increased shoot and root DWs, ETR and chlorophyll content, decreased N:P ratio of *T. repens*. In contrast, inoculation with *G. mosseae* only increased the root DW, decrease ETR and chlorophyll content of parasitized gramineous plants. These results show that the effect of AMF on regulating the relationship between hosts and hemiparasite varies in different host species.

A phylogeny of *Mastigolejeunea* (Marchantiophyta: Lejeuneaceae) -- Evidence for reduction of *Mastigolejeunea* to subgeneric rank in *Thysananthus* and transferring *M. florea* to *Spruceanthus*

__Phiangphak Sukkharak__[1], Robbert Gradstein[2]
1. Department of Biology, Faculty of Science, Burapha University, Thailand
2. Dept. Systématique et Evolution, Muséum National d'Histoire Naturelle, France

The pantropical *Mastigolejeunea* is morphologically close to *Thysananthus* and the separation of these two genera has long been controversial. The relationship between *Mastigolejeunea* and *Thysananthus* is assessed based on Bayesian inference and maximum likelihood analyses of plastid *psb*A-*trn*H, *trn*G and *trn*L-F, and nuclear ITS. *Mastigolejeunea* was resolved as monophyletic and sister to *Thysananthu*s with moderate support, but *M. calcarata* was nested in *Thysananthus* subsect. *Anguiformes* and *M. florea* was resolved in *Spruceanthus*. The molecular evidence strengthens the intermediate position of the subsect. *Anguiformes*, a group largely restricted to New Zealand and New Caledonia, between *Thysananthus* and *Mastigolejeunea*. The results underline the morphological overlap of *Mastigolejeunea* and *Thysananthus* and indicate that the two groups do not merit recognition as separate genera. *Mastigolejeunea* is thus reduced to subgeneric rank under *Thysananthus.* The latter genus becomes the second largest genus of Lejeuneaceae subfam. Ptychanthoideae with 30 species, and is one of the largest genera of liverworts that has been monographed worldwide.

Species delimitation in the Norway-Siberian spruce complex (*Picea*: Pinaceae) using genome-wide data

__Alexis Sullivan,__ Xiao-Ru Wang
Umeå Plant Science Centre, Department of Ecology and Environmental Science, Umeå University

The combined ranges of Siberian (*Picea obovata* Ledeb.) and Norway spruce (*P. abies* (L.) Karst.) cover a vast expanse of Eurasia from the Atlantic to the Pacific coasts. Although relatively well-studied among plants, the species boundary between Norway and Siberian spruce is still unclear. Recent studies have shown Fennoscandian *P. abies* populations have chloroplast and mitochondrial genomes more closely related to Siberian spruce than to continental European populations of *P. abies*. Because the organelle genomes are differentially inherited from the seed and pollen parent in *Picea*, this result could indicate the deep population structure observed in Norway spruce is not due to glacial subdivision but rather represents two separate species. However, organelle genomes may also be polyphyletic due to organelle capture or incomplete lineage sorting and nuclear microsatellite data gives little indication of a polyphyletic Norway spruce. To more conclusively address species limits within the Norway-Siberian species complex, we are using exome capture data from 40,000 probes to infer coalescent phylogenies and implement Bayes Factor species delimitation tests. We genotyped 35 Norway-Siberian spruce individuals evenly distributed across the entire range of the complex. In addition, we genotyped 15 *Picea* species representing the phylogenetic breadth of the genus to test the hypothesis that Norway and Siberian spruce are sister species. After stringent filtering to minimize sequencing errors and paralogous loci, we obtained ~50,000 high-quality SNPs. Our first results from coalescent species trees do not support the commonly-assumed sister relationship between *P. abies* and *P. obovata*. Second, we find that both mitochondrial and chloroplast genomes are discordant with nuclear loci: most Fennoscandian Norway spruce populations are more closely related to their southerly conspecifics than to Siberian spruce. Third, we detected a lineage in extreme northern Fennoscandia most closely related to Siberian spruce. Ongoing analyses are testing if this extreme northern lineage represents a distinct species or if genomic data have confirmed the presence of Siberian spruce ~2,000 km further east than its described distribution.

A new case on bio-exchange between Eurasia and India subcontinent

Bin Sun
Institute of Botany, Chinese Academy of Sciences

The bio exchange between Gondwana and Laurasia happened after the collision and docking between the Indian subcontinent and Eurasia. The uplift of Tibet had profoundly affected this bio exchange process. Today, Indian Tertiary floras increasingly show that tropical elements in the subcontinent originated in the southern hemisphere, whereas the origin of those temperate elements in northeast India is still unclear. Based on fossil records, a former biogeographic hypothesis suggested that the temperate elements in Northeast India came from southwest China, and migrated westward across southern Tibet in the middle Miocene before the Himalayas arose, then entered India through Kashmir in the late Pliocene to Pleistocene before spreading eastwards along the southern slope of the Himalayas. Here we provide a new potential migration route of temperate plant, *Berberis*, from eastern Asia to India subcontinent based on a new fossil link. The find, differing from the former hypothesis, suggests that the northern Tibet, but not the southern Tibet, had play the role as the pathway when it was not so high (ca. 2,000 m a. s. l.) as to block any migration of temperate elements between two continents.

Comparative genomic in situ hybridization between sweetpotato (*Ipomoea batatas* (L.) Lam) and its wild related species

Jianying Sun, *Zongyun Li*
School of Life Science, Jiangsu NormalUniversity

Sweetpotato (*Ipomoea batatas* (L.) Lam) is the world’s food security bottom line crop, and it is also an important feed and industrial raw material crops, while plays an important role in China’s energy security. Sweetpotato is highly heterozygous in heredity, and there is a wide range of cross incompatibility in interspecies, which restricts its breeding. As a result, the genetic diversity of cultivars is reduced, which seriously restricts the genetic improvement of sweetpotato varieties. The wild relatives of sweetpotato are one of the important sources of new genes for disease resistance, quality and stress resistance in cultivar breeding. They have very rich genetic background and carry a large number of excellent trait genes. The introduction of these excellent traits can be carried out to solve the narrow genetic basis of sweetpotato. Therefore, understanding the genome structure and genetic diversity of hexaploid sweetpotato and its related wild species is important for us. In this study, comparative genomic *in situ* hybridization (cGISH) technique was used to find the relationships between *I. batatas* and its related species. The hybridization signals reflect the degree of homology of the repeats. Suggested by previous researches, 13 species were considered. The wild species genome were made into probes to study the homology between *I. batatas* cultivar ‘Xushu 18’ and wild species with FISH. According to the signals, the 13 wild species were divided into 4 groups. The genome of the first group of species have strong signals on all mitosis chromosomes of cultivated sweetpotato with only several weak signals. In some species, there genome have no signals on 8-15 chromosomes, while on the others the signals are strong. *I. umbraticola* is grouped into the third, and the hybridization signals looks wildly exists but weak. The last group contains only one species named *I. grandfolia*, it shows the furthest relationship with cultivar with only a few signals. In all FISH between wild species and cultivar, the signals were concentrated in the middle or the end of the chromosomes. It indicated that the *I. batatas* has different degrees of repeat sequences with these related species. Suggested by the results presented here, *I. tabascana* is very close to the sweetpotato in addition to the previously thought that *I. trifida* and *I. triloba* had the most relatively relationship with the sweetpotato.

Using fluidigm amplification and NGS sequencing data to explore biodiversity across an ancient floristic disjunction

Miao Sun[1,2], *W. Mark Whitten*[1], *Matthew A. Gitzendanner*[1,2,3], *Douglas E. Soltis*[1,2,3], ***Pamela S. Solits***[1,3]
1. Florida Museum of Natural History, University of Florida
2. Department of Biology, University of Florida
3. Genetics Institute, University of Florida

The multidimensional biodiversity of the forests in eastern Asia (EA) and eastern North America (ENA) has fascinated scholars and researchers worldwide for decades. Advances in high-throughput sequencing (HTS) have offered an excellent opportunity to re-evaluate these two anciently connected forest communities with a shared evolutionary and ecological history, exploring the drivers of biodiversity across geographic space and through evolutionary time. The Fluidigm Access Array System uses sets of PCR primers, simultaneously amplifying 48 target regions across 48 samples (or 192 loci x 24 samples in a new configuration) using microfluidic amplification reactions, incorporating sample-specific barcodes and HTS adapters. Based on this system, here we present an efficient workflow from DNA sample quantification, primer design, PCR validation, and primer-pooling to sequence data assembly and bioinformatics pipeline. We designed 143 universal microfluidic PCR primer pairs to amplify the most variable regions of the plastome, as well as commonly sequenced mitochondrial (*atp1*, *rps3*, *nad5* and *mat*R) and nuclear rDNA loci, generating a large phylogenetically informative multi-locus dataset across all disjunct genera between EA and ENA sites. This promising approach permits us to compare the disjunct forests of EA and ENA through reconstruction of species-level community phylogenies at multiple sampling locations in both regions with maximal genomic-scale data and hundreds of samples per site.

Exploring the phylogeny and diversification of rosids through a supermatrix approach with limited sampling

Miao Sun[1,2], *Charlotte Germain-Aubrey*[2], *Stephen A. Smith*[3], *Pamela S. Soltis*[2,4], *Zhiduan Chen*[5], ***Douglas E. Soltis***[1,2,4]
1. Department of Biology, University of Florida
2. Florida Museum of Natural History, University of Florida

3. Ecology and Evolutionary Biology, University of Michigan
4. Genetics Institute, University of Florida
5. Institute of Botany, the Chinese Academy of Sciences

Molecular phylogenetics relies on adequate and representative sampling of taxa and genes, although what constitutes adequate sampling may not always be clear. Biased or incomplete sampling may result in the estimation of a strongly supported but incorrect topology. Perhaps no major clade of angiosperms plays a more significant role in many modern terrestrial ecosystems than rosids, an enormous clade of ~90,000 species, representing approximately 25% of all angiosperms and exhibiting tremendous overall diversity in morphology, habit, reproductive strategy, and life history. However, our knowledge of this clade is remarkably limited along any metric. With our bioinformatics pipeline, we have found that less than 34% of all named rosid species have DNA sequences usable for phylogeny reconstruction, and these sampled data are highly biased toward specific subclades. Here we use the rosid clade as an exemplar to explore and evaluate how the analyses of phylogeny and diversification are influenced by limited gene and taxon sampling. We employed two supermatrices: 1) a 9,300-species, four-gene (*atp*B, *rbc*L, *mat*K, and *mat*R) matrix; and 2) a 5-gene 20,974-taxon matrix assembled from five widely used genes (*atp*B, *rbc*L, *mat*K, *mat*R, and ITS) with maximum coverage of all rosid species deposited in GenBank. Our results generally agree with previous estimates of rosid phylogeny, but with a few significant differences. Comparisons of rosid diversification analyses based on the two supermatrices show that rosids have undergone two diversification rate shifts, confirming that other lineages (ants, amphibians, fungi, ferns) radiated in response to the rise of rosids. However, the downstream analyses are relatively limited when the molecuar data for phylogenetic analyses are limited, and when other biological data for species and all other traits are limited, especially for such a big clade.

R. M. Schuster's theory on the origin and biogeography of liverworts tested

Yu Sun
Botany Unit, Finnish Museum of Natural History, University of Helsinki

Inferring the age and origin of liverworts as a whole and their major lineages is greatly hampered by the scarcity of the fossil records and the poor state of preservation of most of the early fossils. The long-lasting and most influential theory on the origin and biogeography of liverworts was that of R.M. Schuster in the early 1980s, who assumed that liverworts originated in the Gondwana and the patterns of biogeography across most taxonomic groups were resulted from tectonic events and stepwise dispersals. These interpretations have been greatly challenged by the recent studies based on molecular data, and currently both fossil data and reconstructed phylogenies suggest that liverworts are the earliest diverged lineage of land plants that possibly dates back to the Ordovician. In the present study, a broad sampling of a multigene data was compiled to test the origin and biogeographical patterns of liverworts. This includes 300 samplings from three chloroplast genes (*rbc*L, *rps*4 and *trn*L-F), including 287 species of liverworts as ingroup and 13 species mosses as outgroup. A time-calibrated, molecular-based phylogenetic analysis and different approaches for ancestral range inference were conducted. Nine biogeographic areas were defined according to palaeogeographic history: Africa (AF), Australasia (AU), southern South America (SSA), Neotropics (NE), Europe (EU), North America (NA), East Asia (EA), India (IN) and Southeast Asia (SEA). The results show that liverworts likely originated from Australasia in the early Ordovician. Totally, 60 dispersal events were detected throughout the tree. Most of the dispersal events (43 dispersals) occurred after 100 MA, only 4 dispersal events occurred before 200 MA and 13 dispersal events occurred between 200 MA to 100 MA. During the Paleozoic Era, liverworts dispersed from AU to EA twice and formed the Haplomitriopsida and Marchantiopsida, and dispersed from AU to NE which is the ancestor of Frullaniaceae, Jubulaceae and Lejeuneaceae. Subsequently, liverworts dispersed to EU and NA from both EA and AU before Cretaceous, and distributed rapidly all over the world during Cretaceous. It supports the Gondwanan origin of the group, but instead of the previously assumed continental drift and stepwise dispersal, long-distance dispersal has played an important role in resulting the distribution patterns of liverworts. The frequent dispersal events since Cretaceous may well have been conditioned by the evolution and diversification of angiosperms.

Molecular phylogenetics of two new species related to southwestern China buckwheat based on nuclear and plastid DNA sequences

Zhanmin Sun[1], *Yu Tang*[2], *Yanmin Wu*[1], *Yixiong Tang*[1], *Jirong Shao*[3], *Meiliang Zhou*[1]
1. Biotechnology Research Institute, Chinese Academy of Agricultural Sciences
2. Department of Food Science, Sichuan Tourism Universit
3. School of Life Sciences, Sichuan Agricultural University

During the 2004-2010, our research group investigated the wild buckwheat distributed throughout the Sichuan Province, in the southwest of China. During, last 10 years, *Fagopyrum pugense*, *F. crispatifolium*, *F. qiangcai*, *F.wenchuanense, F. luojishanense* and *F. hailuogouense* are discovered as new species in fagopyrum by our group. Here, phylogenetic analysis of two recently identified *Fagopyrum* wild species, *F.luojishanense* and *F.hailuogouense*, related to southwestern China buckwheat was examined using the sequence of internal transcribed spacers (ITSs) and the *maturase K* (*matK*) gene. 14 *Fagopyrum* species including the 2 new speicies were chosed to build the evolutionary tree, The neighbor-joining (NJ) and maximum-likelihood (ML) trees were almostly congruent with each other, and in all analyses, *Fagopyrum* species except *F. hailuogouense* and *F. luojishanese*were divided into the cymosum group and urophyllum group, agree with the previous study. Interestingly, *F. luojishanese* belonged to cymosum group in *matK* trees while belonged to urophyllum group in ITS trees, which suggested that it was a transitional type of two groups. As for *F. hailuogouense*, it had a separate cluster in both ITSs and *matK* trees, showing a far genetic distance with others, this recent data may provide a new way to inference the classification of *Fa-*

gopyrum. Our results provide a framework for investigating the patterns of morphological evolution and geographical distribution of the *Fagopyrum* genus and a better understanding of evolutionary mechanisms and genetic relationships of 2 new species related to southwestern China *Fagopyrum* sepecies.

A preliminary study of the genus *Calymperes* Sw. (Calymperaceae, Bryophyta) in Thailand

Orawanya Suwanmala, *Sahut Chantanaorrapint*
Prince of Songkla university

A review of genus *Calymperes* in Thailand is presented based on field surveys, herbarium specimens, and data from previous publications. Twenty taxa have been recorded. Most species are corticolous epiphytes growing on tree trunks, but are also found on decaying wood, soil and rocks, including limestone and sandstone. They are found in various forest types, from dry to moist deciduous or evergreen forests, i.e. coastal, mangrove, spring, lowland evergreen and montane forests, from sea level to over 1500 m alt. The southern part of the country exhibits great diversity of species with 19 taxa, followed by 13 species in the southern-eastern region. The most common species of *Calymperes* in Thailand is *C. afzelii* Sw., distributed in 5 floristic regions including northern, eastern, southern-western, southern-eastern and peninsula.

Actinomorphic flower: A rare autapomorphic case in Zingiberales

Sasivimon Chomchalow Swangpol, *Wandee Inta*
Department of Plant Science, Faculty of Science, Mahidol University

The Zingiberales order is described as having bilaterally symmetric (zygomorphic) flowers with five stamens or less. In the banana family (Musaceae), which is considered the most primitive taxon in the order, the perianth typically appears as two whorls of three outer tepals and two inner ones united into a compound tepal and the third inner tepal free with five free stamens. However, a new species, *Musa nanensis*, recently found in northern Thailand near the Thai-Laos border, possesses a vastly unique floral structure of two united whorls of tepals composed of three outer and three inner tepals. The similar shapes, though different sizes, of these tepals indicates that the merging of both whorls is not only a simple fusion of a compound tepal and a distinct free tepal, but an exceptional floral structural change. Six fertile stamens fused at base also do not indicate an infrequent structural aberration. Although molecular data and chromosome number do not support the separation of this taxon from *Musa*, its distinctive floral morphology adds new description to the genus and family. Modification from zygomorphic to actinomorphic flowers, and from five to six stamens, indicates a unique reversal event in the Zingiberales approaching basal monocotyledons and may have been influenced by pollinator shifts. In order to understand this uncommon autapomorphy, further parallel investigations on pollination biology, floral development and regulation of floral homeotic genes of *M. nanensis* are being further studied.

Research of flower color diversity in Taiwan, seen through the eyes of bee pollinators

King-Chun Tai[1], *En-Cheng Yang*[2], *Chun-Neng Wang*[1,3]
1. Department of Life Science, National Taiwan University, Taiwan
2. Department and Graduate Institute of Entomology, National Taiwan University, Taiwan
3. Institute of Ecology and Evolutionary Biology, National Taiwan University, Taiwan

There are more than 4,000 angiosperm species native to Taiwan, at least 60% of them are speculated to be insect pollinated. Color signal plays a major role in attraction and decision making of insect pollinators. But experimental data about the flower color diversity of Taiwan plants in color vision of honeybee, the most important pollinator worldwide, remains unknown. We conducted large scale measurements on flower reflectance spectrum and summarized them into bee color hexagon followed by best discrimination fit analysis, in order to answer following two questions: (1) How colorful are flowers native to Taiwan, in the eyes of honeybee? (2) Would color diversity of subtropical Taiwan flora emerge specific patterns, compared to the results of well-studied region, such as Australia and Israel? Mapping of 824 spectrum data collected from 584 Taiwanese native flowers, the result showed that loci of the flower colors form two obvious clusters in uv region and blue-green region, where 57% of the loci makes up a distinct ‘White Arm’ pointing to 60°. It seems plausible that the dominance of bee pollinators in Taiwan and their innate preferences led to such a tight clustering. And the best discrimination fit analysis showed that the frequency of slope midpoints in long wavelength is also much lower in Taiwan than that of Australia and Israel, which revealed that few pollinators in Taiwan can detect flower color with rapid spectral changes in long wavelength region. In conclusion, we suggested that specific pattern of flower color diversity in Taiwan comparing to Australia and Israel. This may result from the adaption of flower color of plants to different pollinator composition, especially the fact that almost none avian pollinators were documented in Taiwan island. This is also the first color diversity research in East Asia with bee color space analyzed. Our successful approach shall be beneficial to many studies follow on.

Evolutionary history of Series *Sakawanum* (genus *Asarum*: Aristolochiaceae) showing interspecific clinal variation of calyx lobe lengths

Daiki Takahashi[1], *Tsutomu Teramine*[2], *Shota Sakaguchi*[1], *Hiroaki Setoguchi*[1]
1. Kyoto university
2. Kochi Gakuen College

Clines, the gradual variation in measurable traits along a geographic axis, play major roles in organism evolution. Series

Sakawanum (genus *Asarum*; Aristolochiaceae) shows a typical interspecific cline in floral morphology. This series comprises three species (*A. minamitanianum*, *A. sakawanum*, and *A. costatum*) and all species are parapatrically distributed in southern Japan. Within the series, the lengths of the calyx lobes increases gradually among the species inhabiting regions from east to west in southern Japan. *A. minamitaniaum*, which distributed in western-most extent of the range has the longest calyx lobe lengths (50-150 mm), and *A. costatum*, which distributed in eastern-most extent has the shortest lengths (8-20 mm). *A. sakawanum*, which distributed between *A. minamitaniaum* and *A. costatum* has the intermediate length (20-40 mm) between the other species. As clinal variation can be formed by the neutral processes (e.g. isolation by distance, range expansion and secondary contact), to infer the evolutionary history of this series would be very useful for considering the formation of clinal variation in this series. In this study, we used 17 EST-SSR markers with approximately Bayesian computation (ABC) and ecological niche modeling to infer the evolutionary history of series *Sakawanum*. Our ABC analysis showed the secondary contact with gene flow model was more probable model than other tested models (blanching models and radiation models) under the all examined tolerance rates. Following the model, *A. sakawanum* (morphologically intermediate species) would be originated by the results of secondary contact of *A. minamitanianum* and *A. costatum* after the Last Glacial Maximum period. We considered that this secondary contact and subsequent gene flow would likely have formed the intermediate morphology of *A. sakawanum* and interspecific clinal variation of this series.

Monograph of the *Daphniphyllum* (Daphniphyllaceae)

Mo Shih Tang[1], *Yuen-Po Yang*[2], *Chiou-Rong Sheue*[3]
1. Chung Hwa University of Medical Technology, Tainan, Taiwan
2. National Sun Yat-sen University, Kaohsiung, Taiwan
3. National Chung Hsing University, Taichung, Taiwan

Daphniphyllum is a small-sized monogenus of the Daphniphyllaceae distribution from Himalayas toJapanand from Central China toNew Guinea, including south of India and Sri Lanka. The plants of *Daphniphyllum* have limited morphological features, especially leaf and fruit that strictly constraints the identification of the genus. Based on the examination of more than 4500 specimens and the comparative study of leaf anatomy and pistillate flower, this genus comprises 28 species, including 4 varieties. *D. lanyuense stat. nov.* was described and mapped.

Effective application of next-generation sequencing (NGS) approaches in biogeography and population genetics: Case study in *Abies alba*

Anass Terrab[1], *Francisco Balao*[1], *Juan Luis García Castaño*[1], *María Teresa Lorenzo*[1], *Jose Manuel Sánchez Robles*[1], *Paun Ovidiu*[2]
1. University of Seville
2. University of Vienna

Abies (Pinaceae) is a widely distributed monophyletic genus of Northern Hemisphere conifers (firs) comprising around 50 species, being the silver fir (*Abies alba*) the widespread species in Europe. Many molecular phylogenetic researches were conducted for *Abies alba*. All of these studies used only data from few markers. Here we present the molecular phylogeography of the species, using Next-generation sequencing (RADseq) from populations belonging to 13 countries. The application of NGS by RADseq method in this study has provided great information for the relationship and evolution of *Abies alba* in Europe. The evolutionary history of the European silver fir is discussed in the context of the paleogeological and postglacial history of the region.

Floral morphology of Sabiaceae:

Contribution to understanding floral diversity and evolution in Proteales

Pakkapol Thaowetsuwan[1], *Dietmar Quandt*[2], *Herve Sauquet*[3], *Louis Ronse De Craene*[1]
1. Royal Botanic Garden Edinburgh
2. University of Bonn
3. Universite Paris-Sud

Recent floral developmental and anatomical studies have provided detailed information about all three genera of Sabiaceae, i.e., *Meliosma*, *Ophiocaryon* and *Sabia*. The family presents several unusual floral traits among angiosperms, e.g., flowers with sepals opposite petals and stamens, and unusual disporangiate monothecal anthers. Within the family, *Meliosma* and *Ophiocaryon* were found to be more closely related with the presence of two fertile stamens and three staminodes contrary to the five fertile stamens in *Sabia* and this was supported by recent molecular phylogenetic studies. Earlier classifications mostly assigned Sabiaceae to Sapindales/Rutales, and a few suggested an affinity with Ranunculales. Molecular phylogenetic studies have confirmed a position of Sabiaceae within the basal eudicots grade close to Ranunculales and Proteales. Sabiaceae show several unique characters that are unusual among the grade, e.g., pentamery, a bipartite perianth, disporangiate monothecal stamens, tricolporate pollen grains, a receptacular nectary and a syncarpous gynoecium with two carpels. However, there are conflicts in determining the exact position of Sabiaceae on the phylogeny with some studies suggesting a secondary branching from Ranunculales or a close relationship to Proteales, a thesis mostly accepted nowadays (e.g. APG IV). This conflict encouraged our team to further investigate morphology and development of this family, including the study of the third lesser known genus *Ophiocaryon*. Earlier studies in *Meliosma* and *Sabia* found that Sabiaceae share many common characters with trimerous Ranunculales, e.g., Menispermaceae and Lardizabalaceae, and three hypotheses have been presented to interpret the origin of pentamery in Sabiaceae either from spiral, trimerous or dimerous precursors. However, comparison of flowers of all four families of Proteales, viz., Sabiaceae, Nelumbonaceae, Platanaceae, and Proteaceae, is difficult because of their historic divergence and highly different pollination systems. The results from a comparative study of the three genera of Sabiaceae with other families in Ranunculales and Proteales has revealed several morphological characters that are potential synapomorphies of all Proteales, e.g., a (nectar) disk, a tanniferous cell layer in the ovary wall and orthotropous ovules. Molecular phylogenies using fossil calibration suggested that Proteales is a very old clade that appeared more than 100 million year ago; therefore, the great diversity of floral morphologies may be due to the early separation of all four families. More extensive floral morphological investigations in Proteaceae and the distinctive *Platanus kerrii* should be done to gain more information about floral evolution and diversity within Proteales.

P0646

A preliminary study on the phylogeny of the Chinese Vaccinieae (Ericaceae)

Yi Hua Tong, *Nian He Xia*
South China Botanical Garden, Chinese Academy of Sciences

Vaccinieae is the largest tribe of Vaccinioideae, which consists of about 1,250 species of 34 genera distributed all over the world but concentrated in the tropical regions of Asia and America. There are few phylogenetic studies on the generic relationships of blueberry tribe, so the boundary of many genera is very unclear. *Vaccinium* is one of the most complex genera of this tribe, with 400 species widely distributed in the world, and close to *Agapetes*, *Gaylussacia*, *Orthaea*, *Notopora*, *Costera*, *etc.* According to the recent preliminary phylogenetic analyses of Vaccinieae using nuclear and chloroplast DNA sequence data, *Vaccinium* was found to be polyphyletic. Many sections recognized within *Vaccinium* are considered more distinct than some genera. Chinese Vaccineae represents by only two genera, *Vaccinium* and *Agapetes*, with 91 species and 54 species respectively. At present, some evidence showed that *Agapetes* is close to some Asian sections of *Vaccinium*. Some researchers even merged *Agapetes* into *Vaccinium*, which created a more complicated *Vaccinium*. However, due to lack of samples from East Asia, which sections of *Vaccinium* are closest to *Agapetes* is unknown and whether it is appropriate to treat these two genera as one also lack of convincing evidence. Thus, to figure out the relationships of *Agapetes* and *Vaccinium*, we conducted a preliminary phylogenetic analyses with nuclear ribosomal ITS, and plastid *mat*K and *rbc*L as markers, using a sampling of 62 *Vaccinium* species (covering 20 sections) and 28 species of *Agapetes* species. The results showed that both *Agapetes* and *Vaccinium* are not monophyletic. The studied *Agapetes* species contains three groups: (1) The monotypic section *A.* sect. *Pseudagapetes* Airy Shaw, i. e. *A. scortechinii* (King et Gamble) Sleumer, a species endemic to Malay Peninsula. The phylogenetic analyses revealed that it is distantly related to other *Agapetes* species and should be excluded from the genus. However, which genera it should be positioned in has not been resolved yet. (2) *Agapetes bracteata*. Evidence from molecular systematics also showed that rather than the species of the same series, *A. bracteata* is closely related to those of *V.* sect. *Conchophyllum*. Thus, it seems to be the best treatment to transfer it to *Vaccinium* for now. (3) The core *Agapetes* group. Including most species of the genus, the core *Agapetes* group in phylogenetic relationship is near with four sections of *Vaccinium*, i. e. sect. *Epigynium*, sect. *Aëthopus*, sect. *Calcicolus* and sect. *Monanthos*. However, there will be still much work to be done to clarify the relationship between the core *Agapetes* group and its affinities. In addition, our molecular systematic study indicates that many currently circumscribed sections of *Vaccinium* are not monophyletic, such as sect. *Epigynium*, sect. *Aëthopus*, sect. *Calcicolus*, sect. *Conchophyllum*, sect. *Bracteata*, sect. *Eococcus*, *etc.*

Discovery and description of two new species using DNA barcoding

Hironori Toyama, *Tetsukazu Yahara*
Department of Biology, Faculty of Science, Kyushu University

Tropical forests contain over 90% of the world's tree diversity, where we are still finding many new species by recent floral surveys. However, traditional procedures of new species description require us a well-trained skill of taxonomy based on morphological observations. Additionally, the number of taxonomists well-trained for tropical plants are declining and thus we need to develop a more efficient way to discover and describe new species. DNA barcoding can provide such an efficient way of taxonomic discovery. Here, we show two examples for discovery and description of new species using DNA barcoding. *Eustigma* is a small genus of Hamamelidaceae, distinguished from the other genera by small auriculate petals and greatly enlarged stigma. Previously, only three species have been known from China, Laos, Taiwan and Vietnam: *E. balansae* Oliv., *E. lenticellatum* C.Y.Wu and *E. oblongifolium* Gardner & Champ. During our DNA barcoding studies on sterile collections of trees from Hon Ba Nature Reserve in South Vietnam, we found a new species, *Eustigma honbaense* H.Toyama, Tagane & V.S.Dang. The *matK* sequences between *E. honbaense* and *E. oblongifolium* differed in 6 bases of the 781 total. The *rbcL* and *matK* sequences between *E. honbaense* and *E. balansae* differed in 1 base of the 517 total and 5 bases of the 761 total, respectively. Another example is a new species, *Euphorbia bokorensis* H.Toyama & Tagane (Euphorbiaceae), we found in Bokor National Park, Cambodia. It has very unique morphological features including subsucculent stems, gland-like stipules and conspicuous cyathophylls and we could not confidently identify its genus by morphology. Phylogenetic analyses using *mat*K, *ndh*F and ITS regions revealed that it is a member of *Euphorbia* subgenus *Euphorbia* exhibiting the greatest diversity in both species richness and growth forms among the four subgenera of *Euphorbia*. Previously, 21 sections were recognized in this subgenus, but *E. bokorensis* was not included in any of them. Thus, we described a new section *Bokorenses* H.Toyama & Tagane. Bayesian phylogeny showed that it is sister to the Malagasy clade, including sections *Denisophorbia*, *Deuterocalli* and *Goniostema*, and also to the northeastern African clade, including sect. *Rubellae*. While standard cpDNA barcodes (*rbc*L and *mat*K) are useful for species discrimination within relatively old clades like *Eustigma*, barcodes of the nuclear Internal Transcribed Spacer (ITS) are useful for species discrimination among closely related species like *Euphorbia*. Although relatively fewer efforts of DNA barcoding have been made for plants of Southeast Asia, our study showed that it provides an efficient way of discovery and description of new species. Further efforts of DNA barcoding for Southeast Asian plants will enable us to efficiently document undescribed diversity of species in tropical forests that is under threats of rapid loss.

The role of long distance dispersal syndromes in the diversification and biogeography of the hyperdiverse Cynoglossoideae (Boraginaceae)

Ana Otero[1], *Pedro Jiménez-Mejías*[2], ***Virginia Valcárcel***[3], *Pablo Vargas*[4]

1. Real Jardín Botánico de Madrid, Consejo Superior de Investigaciones Científicas
2. National Museum of Natural History, Smithsonian Institution
3. Universidad Autónoma de MAdrid
4. Real Jardín Botánico de Madrid, Consejo Superior de Investigaciones Científicas

Long distance dispersal syndromes (LDD), especially endozoochory, have been hypothesized to facilitate plant colonization boosting diversification. However, few studies have analyzed the influence of epizoochorous fruits in diversification rates and biogeography. We evaluate the effect of epizoochory in the diversification patterns of cosmopolitan Boraginaceae (Cynoglossoideae). Phylogenetic reconstructions of 57 genera (227 spp.) and estimates of divergence times are used to infer evolutionary pathways. We employed trait-dependent diversification analysis (HiSSE) and a biogeographic reconstruction approach (Lagrange). The geographical range of Cynoglossoideae lineages is not necessarily related to fruit structures. Differentiation of Cynoglossoideae lineages in the Paleocene reveals an origin in eastern Paleartic and that epizoochorous traits (glochids) have been long-term maintained through different groups from an ancestral condition. This supports the idea that complex traits are not necessarily derived and do not necessarily imply the endpoint of fruit differentiation. Two events of diversification rate increases occurred in two major epizoochorous lineages at approximately the same place (eastern Palearctic) and same time (16-36 myr). However, there are four epizoochorous lineages with an unexpected lower diversification rate, which is revealing a hidden effect. These results suggest that the diversification of Cynoglossoideae has been driven by many different variables rather than the effect of one key innovation.

Independent placements of temperate genera across the phylogeny of the tropical Asian Palmate group (Araliaceae) since its early evolution

Virginia Valcárcel[1], *Rong Li*[2], *Jun Wen*[3]

1. Department of Biology, Universidad Autónoma de Madrid
2. Kunming Institute of Botany, Chinese Academy of Sciences
3. National Museum of Natural History, Smithsonian Institution

The Asian Palmate group is one of the main clades of the Araliaceae. It gathers 50% of the diversity of the family with 21 generic-lineages and nearly 1,500 species. The diversity center of the group has been located in SE Asia, with 19 generic lineages occurring in Asia (13 in SE Asia) plus three in the neotropics. The Asian Palmate clade is a heterogeneous group in terms of morphology, diversification patterns and niche affinity. On one hand it includes both moderately to highly diversified generic lineages (e.g. *Dendropanax*, c. 85 spp.; Neotropical *Schefflera*, c. 200 spp.; Asian *Schefflera*, c. 350 spp.) and scarcely diversified to monotypic genera (e.g. *Chengiospanax,* 2 spp.; *Gamblea,* 4 spp.; *Kalopanax,* 1 sp.; *Sinopanax,* 1 sp.; *Tetrapanax*, 1 sp.). On the other hand, while most of its generic lineages are tropical or subtropical, seven of them display temperate affinity. Interestingly, five of the seven temperate genera are scarcely diversified (*Chengiopanax,* 2 spp.; *Gamblea,* 4 spp.; *Kalopanax,* 1 sp.; *Oplopanax,* 3 spp.; *Tetrapanax*, 1 sp.). In this study we analyse the complete plastome of 20 generic lineages of the Asian Palmate group to investigate the role of niche shifts in the evolution of the group. Our results indicate that the diversification of the Asian Palmate group took place in Asia during the late Cretaceous and the Paleocene, with the emergence of all generic lineages before the Oligocene. The temperate taxa appear scattered across the Asian Palmate plastome tree, right from the root of the tree, as inferred from the basal placement of *Oplopanax*. Long branches and early divergence from tropical closest relatives also characterize the evolution of the temperate genera. Also, the temperate lineages display less diversification than their tropical sister-groups; except for the *Hedera-Merrilliopanax* pair where the temperate *Hedera* is more diversified (12 spp.) than the tropical *Merrilliopanax* (4 spp.). These results may challenge the idea that temperate taxa derived from tropical counterparts in the Asian Palmate group and raises the question of whether the temperate affinity constitutes an evolutionary dead-end in the Asian Palmate group or a diversification driving force.

Gregor Mendel's constant hybrids

Peter Van Dijk
Keygene N.V.

Gregor Mendel's (1822-1884) crossing experiments in *Hieracium* (hawkweed) are not well-known compared to his experiments in *Pisum*, although they continued for seven years. Geneticists generally assume that they were intended to verify his *Pisum* findings. Because most *Hieracium* species are apomictic, this would be doomed to fail. Therefore the *Hieracium* studies are considered as a frustrating failure. In contrast, historians of science generally assume that Mendel's main interest was not the inheritance of traits, but the formation of new species by hybridization. In this view, the *Hieracium* experiments were more important than the *Pisum* experiments. However, after careful analysis of the surviving letters of the correspondence between Mendel and Carl Nägeli, it becomes obvious that Mendel was looking for 'constant hybrids', in other words apomicts, in *Hieracium*. Mendel was the first to show the inheritance of apomixis in crosses between sexual and apomictic *Hieracium*. The misunderstanding that *Hieracium* was chosen to confirm the *Pisum* results is probably caused by a missing page in one of Mendel's letters to Nägeli. We could not find support for the interpretation of the historians of science. On the contrary, Mendel's later pollen competition experiments suggest that Mendel was above all a geneticist.

Population genetics and phylogeography of the tropical African tree *Staudtia kamerunensis* using newly developed microsatellite markers.

Samuel Vanden Abeele[1], *Steven Janssens*[1], *Franck Monthe*[2], *Armel Donkpegan*[2], *Olivier Hardy*[2]
1. Botanic Garden Meise
2. Université Libre de Bruxelles

Despite the high levels of tree biodiversity in African rainforests, current logging is mainly focused on a selected number of tree species, which causes these species to be under high pressure. To facilitate the conservation and regeneration of these valuable timber species, knowledge on the genetic population structure is extremely valuable. In the current study, the genetic structure of *Staudtia kamerunensis* populations from Central Africa was analyzed with a set of newly developed microsatellite markers. Both variants of the species were included to verify if there is a genetical component underlying the morphological differences. The software QDD v2.1 was used to detect microsatellite loci of interest and to select suitable primers from a microsatellite enriched genomic library of *Staudtia kamerunensis*. Selected primers were then tested with different PCR conditions to ensure DNA amplification and readability after which polymorphic loci were retained and combined in multiplexed reactions using Multiplex Manager 1.2. Multiplexed reactions were carried out on populations from Cameroon, Gabon, Republic of the Congo and Democratic Republic of the Congo. Allele lengths of the different loci were analyzed with Peak Scanner Software 2 and Geneious 9.1.6. Heterozygosity levels, allele frequencies and the number of alleles were then used to assess genetic diversity within and between populations and clustering analyses were carried out with Structure 2.3.4 and the *adegenet* package for the R software. Finally, these results were discussed in a historic climatological and biogeographical context.

Phylogenomics of the phaseoloid and millettioid legumes using a target enrichment approach

Mohammad Vatanparast[1], *Adrian Powell*[2], *Sue Sherman-Broyles*[2], *Jeff J. Doyle*[2], *Ashley N. Egan*[1]
1. Smithsonian Institution
2. Cornell University

The legume family (Leguminosae) is the third largest family of flowering plants and is the second most important family in economic value. The phaseoloid (ca. 2,070 species in 112 genera) and millettioid (ca. 1,100 species in 56 genera) legumes form a single large clade of the papilionoid subfamily and include various important crops such as soybean, common bean, cowpea, pigeon pea and winged bean. The majority of taxa in this clade correspond to the Phaseoleae sens. lat. and Millettioid sens. stric. subclades; however, in spite of multiple molecular phylogenetic studies, relationships within this clade remain unresolved or with low statistical support, particularly along the backbone. To understand the evolutionary history of these legumes, we used transcriptomes of 24 taxa from this group as well as six outgroup legume genera to develop thousands of hybridization probes. Our probes include representatives of all subtribes and major, delineated clades determined in previous studies within the millettioid clade. We obtained sequences for hundreds of genes to build a robust phylogenetic tree encompassing phaseoloid and millettioid legumes. Our results reveal robust phylogenetic relationships of multiple clades and subclades within the millettioid clade and provide well-supported phylogenetic evidence useful for the classification within this important legume clade.

Assembling Brazilian subtropical highland vegetation over space and time

João R. V. Iganci[1], *Josimar Kulkamp*[1], *Cássia Plá*[1], *Mariane Dornelles*[1], *Tiina Sarkinen*[3], *Gustavo Heiden*[2]
1. Universidade Federal do Rio Grande do Sul
2. Embrapa Clima Temperado
3. Royal Botanic Garden Edinburgh

A high number of endemic species is being reported for the Brazilian subtropical highland grassland and mixed forest biomes. Both formations occur in highland areas mainly in Southern Brazil, under similar climate and environmental conditions. Bayesian inference on biogeography using multiple lineages have being proving to be a good approach for assembling biomes evolution over space and time. Here we apply this method to assemble both subtropical highland grassland and mixed forest evolution. The subtropical highland grasslands are a species rich formation found over basalt rocky outcrops and peatlands, while the mixed forest is an Ombrophilous Forest dominated by the gymnosperm *Araucaria angustifolia*. Both formations behave as continental vegetation islands, and encompasses tropical and temperate lineages, sharing species with other sourrounding biomes. Dominant and endemic species from each formation were mapped and their distribution as comunities were modeled to identify the most suitable areas for both grasslands and mixed forests. Specific lineages represented by species rich taxa in each formation were chosen to compose the Bayesian analyses. Each biome represents a complex history of niche evolution represented by lineages reaching new habitats or local especiation events.

Polyploids on islands: A NGS study of Macaronesian endemic *Lavatera acerifolia* (Malvaceae)

Irene Villa-Machío, *Gonzalo Nieto Feliner, Javier Fuertes Aguilar*
Real Jardín Botánico

By increasing dramatically the sampling of genomes, Next Generation Sequencing (NGS) techniques opened a wide avenue towards reconstructing species evolutionary histories thus representing a crucial source of information for phylogeography. However, polyploidy --a very common process among vascular plants— is a major challenge for the NGS techniques due to difficulties in genotyping individuals resulting from the existence of multiple paralogous loci, which is even more complex in plants without a reference genome. In addition, population-base studies require a highly reliable set of homologous fragments and SNPs. Plant evolution in oceanic islands provides a suitable framework where genetic groups can be directly related to discrete geographic areas. *Lavatera acerifolia* (2n=44) is one of the two endemic entomophilous species of *Malvaceae* family occurring in the Canary Islands, sister to *Lavatera maritima*, also polyploid (2n=44) and distributed along the West Mediterranean basin, including SW Morocco. Our study applies GBS to reconstruct the origin and evolution of *L. acerifolia* in the Canary Islands. To overcome the complexity derived from the polyploid condition of this species we have done sensitivity analyses comparing different settings in critical steps of the filtering process. Specifically, de-novo assembly and mock-reference workflows to SNP discovery have been performed and compared. Our analyses group populations into 2-4 genetic groups with a clear geographic structure that is consistent with an east-west colonization complex pattern. Methodologically, we confirm the critical influence of missing data, paralog filtering and multiple heterozygous loci, when analyzing data under phylogenetic approaches.

Long-term evolutionary effect of climate change explored by combining micro and macroevolutionary levels

Tamara Villaverde[1], *Lisa Pokorny*[2], *Ricarda Riina*[1], *Sanna Olsson*[1], *Isabel Sanmartin*[1]
1. Real Jardín Botánico, CSIC
2. Royal Botanic Gardens, Kew

To understand the long-term evolutionary effect of climate change, an approach that combines the micro and macroevolutionary levels, from within populations to across species, is needed. Bridging this gap is difficult because it requires the integration of many disciplines and analytical approaches, but it has become recently feasible through the advent of Next Generation Sequencing techniques (e.g. target enrichment with genome skimming, i.e. HybSeq) by scaling up the molecular data available. We focused on Africa, a continent that has received relatively little attention in the global biodiversity research effort. We chose two non-tropical lineages exhibiting a common disjunct distribution known as Rand Flora to explore if high extinction rates were associated to historical and ongoing drought. This enigmatic floristic disjunct pattern occurs in unrelated plant lineages with similar large-range disjunct distributions across the continental margins of Africa and adjacent islands (Macaronesia-northwest Africa, Horn of Africa-Southern Arabia and Southern Africa). Although Rand Flora lineages belong to different angiosperm families and exhibit different life-history traits and climatic preferences (from sub-humid to semi-xeric affinities), they share the tropical lowlands of Central Africa and the Saharo-Arabic deserts areas in the north as effective climatic barriers to the dispersal and persistence of populations. To explore the effect of extinction at micro (populations) and macro (species) levels, we reconstructed the phylogenetic relationships in *Euphorbia* section *Balsamis* and in the genus *Camptoloma* using nuclear and chloroplast molecular data. We inferred speciation and extinction rates as well as possible declines in population size. Our preliminary results in *Euphorbia* show phylogenetic resolution for the section and within species and a biogeographic structure that might indicate dispersal from the African continent to Canary Islands, which is related to climatic aridification waves in Africa.

Taxonomy, nomenclature and endemism in genus *Ipomoea* (Convolvulaceae) from India

Vinod Shimpale
Department of Botany, The New College, Kolhapur, 416 012 (MS) India. Affiliated to Shivaji University, Kolhapur

India is one of the 12 mega diversity regions of the world. As India shows wide and richest floristic composition there are many large and diverse families of Angiosperms of which the family Convolvulaceae is one of them. There are about 55 genera and 1,600 species of the family Convolvulacae throughout the world, while in India the family is represented by about 20 genera and 180 species. The genus *Ipomoea* is one of the larger genera of family Convolvulaceae. It comprises near about 650 species distributed throughout the world mainly in tropical and warm temperate region. As per the previous Indian literature in India the genus *Ipomoea* is represented by 60 species. Among the Indian Convolvulaceae the genus *Ipomoea* is the dominant with high number of species followed by *Argyreia*, *Convolvulus etc.* During revisionary studies on the genus *Ipomoea* it is observed that according to ICN few species needs typifications, few are not collected after type locality and few are not hitherto reported for Indian flora. During present investigation about 40 species of genus *Ipomoea* are collected from different phytogeographical regions of the India. All the aspect regarding endemism, nomenclature, distribution and taxonomy are discussed in present work.

Be (e)ing with blossoms in the Outer Himalaya: Using pantraps as floral functional units to explore patterns in bee-plant interactions across land uses in Doon Valley, Uttarakhand, India.

Preeti Virkar[1,2], *V. P. Uniyal*[1], *Qamar Qureshi*[1]
1. Wildlife Institute of India
2. Navdanya Trust

Currently, human use of land and its intensification is regarded one of the most significant threats to species, including wild pollinators. Alteration of habitat (not just loss) can also modify network structure emphasizing a landscape approach for pollinator conservation. Besides, pollinators, chiefly bees respond to commonly found floral colours, which is associated with the rewards they offer. However, traditional plant-bee interactions are assessed with active methods that are either phytocentric (observing flowers for pollinator visitations) or zoocentric (investigating pollen loads from bees), which requires skilled surveyors. Constraints of funds and time, furthermore, result in low and incomplete sampling, indicating an inability of active methods to record maximum interactions. Declining pollinator populations worldwide, insist future investigations should approach the mutualistic interactions with attention to the “species functional groups”. For the first time, we use the passive method of pantrap captured bee samples to build interaction matrices with floral functional units based on (pantrap) colours. Considering the robustness of plant-bee interactions in different habitats should vary depending on the availability of diverse floral functional groups, we tested in agroecosystems and forests of Doon Valley, (1) whether real mutualistic (bee-plant communities) interactions varied compared with three randomized networks (using null models), and (2) how bee interactions with floral functional groups affect network attributes in different selected habitats. Network attributes viz. connectance, interaction evenness, linkage density and nestedness were selected to assess their patterns and ecological implications across agroecosystems and forests habitats in Doon Valley. Real plant-bee interactions varied from null models. Highest bee interactions were seen in the white floral functional groups (n = 236), and the least were in blue floral functional groups (n = 75). Bee families showed differential floral colour preferences in forests and agroecosystems. Plant-bee communities were more robust in forests than agroecosystmes. Network attributes such as weighted linkage density and weighted nestedness confirmed benefits of quantitative data over only presence-absence records for the conservation of mutualistic interaction. A detailed investigation into the types of forests revealed riverine habitats were robust to invasive species than Sal forests, indicating forest managers to take appropriate steps in vegetation management. Network interactions in agroecosystems indicated to agriculturists adopt a polyculture approach to cultivation to maintain robust mutualistic interactions for better productivity in crops. The study also highlighted that pantraps could be reliably used by numerous unskilled surveyors, in different areas simultaneously for long-term investigation and monitoring of plant-bee interactions.

Pollination of two sympatric species of *Balanophora*: *B. fungosa* and *B. harlandii*.

Nikolay Vislobokov
M.V. Lomonosov Moscow State University, Biological faculty, Department of Higher Plants.

Balanophora is a genus of holoparasitic plants, which inhabit mainly in tropical regions of Asia. The genus divided to two subgenera (subgen. *Balanophora* and subgen. *Balania*) by merism of male flowers, while its female flowers are simplified to filiform structures. Species of the both subgenera inhabit the same territory (sympatric). In addition to morphological, ecological differences between the sympatric species are expectable, e.g. different system of pollination. Pollination biology of some species from subgen. *Balanophora* was investigated earlier. It was showed that *B. abbreviata* is pollinated by bees. Pyralid moths were recognized as pollinators of *B. kuroiwai*. Data on pollination of species from subgen. *Balania* are poor: ants and cockroaches were noted as visitors of *B. tobiracola*. The present research is dedicated to flowering biology of two species of *Balanophora* from different subgenera. *Balanophora fungosa* (subgen. *Balanophora*) and *B. harlandii* (subgen. *Balania*) were investigated in the same season and habitat in northern Vietnam. Inflorescences of the both species open acropetally. Within an inflorescence of *B. harlandii*, 8–16 flowers can be anthetic simultaneously; each flower remains anthetic for 1 day. Within an inflorescence of *B. fungosa*, 10–20 flowers can be anthetic simultaneously; each flower remains anthetic for 2–5 days. Inflorescences of both species were visited in daytime by flies (Calliphoridae, Drosophilidae, Syrphidae), wasps (*Vespa sp*.), ants (Formicidae, Mirmicidae), harvestmen (Phalangidae) and others. Drosophilid flies were the most frequent visitors of *B. fungosa*, while *B. harlandii* was visited predominantly by the wasps. Pollen grains of *Balanophora* were found at the bodies of the drosophilid flies and the wasps. On average, 102 pollen grains of *Balanophora* were found on the body of each wasp, while only 2 pollen grains were found on the body of each fly. Drosophilid flies visit male inflorescences of *B. fungosa* on average 433 times per day and visit female inflorescences 144 times per day. Wasps visit male inflorescences of *B. harlandii* on average 62 times per day and visit female inflorescences 18 times per day. It can be concluded, that drosophilid flies are the main pollinators of *B. fungosa* and wasps are the main pollinators of *B. harlandii*. However drosophilid flies can take minor part in pollination of *B. harlandii* as well as wasps can pollinate *B. fungosa*. The flies carry far less pollen than the wasps, but higher frequency of visits offsets this difference. As a result, sufficient effectiveness of pollination is ensured for the both species. Mechanism of plant-pollinator interaction is somewhat similar for *B. fungosa* and *B. harlandii*: sweet smell attracts insects and they feed on nectar as a reward. Probably, some differences in chemical composition of volatiles led to situation, when flies prefer one species but wasps prefer another one. Chemical change of volatiles and followed change of pollinators range can served as factors of divergence of this species during sympatric evolution. This study was funded by the Russian Foundation for Basic Research (project 16-34-00330).

Dynamic evolutionary history of the East Asian Tertiary relict *Platycarya* (Juglandaceae) based on species distribution models and genetic data

Qiuchi Wan[1,2], *Zhuo Zheng*[1], *Marta Benito-Garzón*[2], *Kangyou Huang*[1], *Erwan Guichoux*[2], *Rémy Petit*[2]
1. Sun Yat-sen University
2. BIOGECO, INRA, Univ. Bordeaux

Subtropical East Asia harbours a large plant diversity and was an important glacial refugia for plant species throughout Quaternary glacial-interglacial cycles. However, the impact of past climate change on the dynamics of tree species in this region remains poorly understood. Here we use observations of *Platycarya*, a widespread subtropical Asian tree genus currently treated as monotypic (although two species have been formerly described), to explore the consequences of past climate change on species' evolutionary and population demographic history in subtropical China. We relied on species distribution models (SDMs) and genetic data (two cpDNA intergenic spacers, nuclear internal transcribed spacer regions and random genomic single nucleotide polymorphisms). By compiling distribution data and performing SDMs, we found that the two putative species, *P. strobilacea* and *P. longipes*, are sympatric over part of southern China and have similar climatic envelopes. Their past distributions as inferred by mapping their climatic envelopes at the Last Glacial Maximum did not differ much from their current distributions. Using nuclear genetic markers, we found interspecific genetic divergence matching well with previously recognized taxa and geographically structured intraspecific variation. Using cpDNA markers, we also found geographically structured intraspecific variation. Nevertheless, we also detected several cases of interspecific and intraspecific genetic admixture in southwest China. Integrating SDMs with phylogeographic studies suggests that *Platycarya* populations in subtropical China did not undergo significant range contraction during glacial episodes, allowing allopatric divergence, but the limited amount of range expansion resulted in secondary contacts and subsequent genetic exchanges across porous barriers. These findings help understand the origin of the large plant diversity found in subtropical China through allopatric speciation as well as stabilization of new hybrid populations. This study is supported by National Natural Science Foundation of China (No 41230101) and by the 7th Framework Program of the EC under the Trees4Future project (No 284181).

Revision of series Gravesiana (*Adiantum* L.) based on morphological characteristics, spores and phylogenetic analyses

Aihua Wang, ***Faguo Wang***
South China Botanical Garden, Chinese Academy of Sciences

Since the adoption of some ambiguous and quantitative characters in Flora Republicae Popularis Sinicae 3 (1), species identifications of the series Gravesiana have been in disarray, requiring clarification. Two hundred and fifty-nine individuals from 47 different populations were collected for the estimation of morphological characters and phylogenetic analyses. Spores of 26 populations were observed through scanning electron microscope. Our results were different from those of previous research: (1) six identifiable species, rather than five species observed previously, were confirmed in the series Gravesiana, they are *A. gravesii*, *A. juxtapositum*, *A. mariesii*, *A. dentatum*, *A. longzhouensis* and *A. obovatum*, of which the latter three are newly recognized species. (2) Thirteen characters were measured and estimated through the program Mesquite v. 2.71. The character whether the pinna stalks were 1/3-1/2 times longer than the pinna was used to distinguish *A. gravesii* and *A. lianxianense* previously and was found to be unreliable here, whereas such characters as the height of the plant (H), pinna aligned forms (FP), number of pinna (NP), pinna margin (M), number of veins flabellate at base (NV), sori number and shape per pinna (NSS), pinna texture (T), and powder-covered or not on the abaxial surface of the pinna (P) are estimated to be stable and reliable characters useful for identification. Descriptions of new species and their retrieve keys are also listed. (3) Surface ornamentations and spore sizes are helpful for us to distinguish species in series Gravesiana.

Phylogeography and integrated taxonomy of *Diabelia* (Caprifoliaceae), a Sino-Japanese disjunct and Asian endemic genus

Hua-Feng Wang[1], *Sven Landrein*[2], *Shota Sakaguchi*[3], *Masayuki Maki*[4], *Zhi-Xin Zhu*[1], *Kun-Kun Zhao*[1]
1. College of Tropical Agriculture and Forest, Hainan University, Haikou 570228, China
2. Xishuangbanna Tropical Botanical Garden, Chinese Academy of Sciences, Menglun 666303, China
3. Graduate School of Human and Environmental Studies, Yoshida-nihonmatsu-cho, Sakyo-ku, Kyoto 606-8501, Japan
4. Botanical Gardens, Tohoku University, Kawauchi 12-2, Aoba, Sendai 980-0862, Japan

Diabelia (Caprifoliaceae) is an Asian endemic genus with a Sino-Japanese disjunct distribution pattern. The genus has potential to be developed and used in the horticulture industry with its diverse flower forms and colors. Furthermore, some taxa within this genus are listed as endangered in China and Japan; studying its genetic diversity would help conservation efforts. However, due to possible inter-specific hybridization and introgression, inter-specific differentiation and/or recent convergent evolution, the species delimitation within the genus is disputed; moreover, the phylogeography within the genus and its speciation processes are not clear. In this study, we collected 37 populations (335 individuals) in the field in Zhejiang (China) and Japan. We studied its morphological characters and sequenced ITS, *trn*L-*rpl32*, *trn*H-*psb*A and Expressed Sequence Tags-Simple Sequence Repeats (EST-SSR) for all individuals. We developed 13 pairs of Tags-Simple Sequence Repeats (EST-SSR) based on transcriptomes. After analyzing the population diversity and population genetic structure, we found 40 haplotypes based on t*rn*L-*rpl32 a*nd *trn*H-*psb*A markers. Japan Ehime (H1), Shiga (H2) and Shimane (H16) population expanded whereas Tokushima population (H13) shrank. Chinese *D. spathulata* was sister to the other haplotypes, Chinese range might represent vicariance, but this was not conclusive as we did not have samples from Kyushu, the closest island to E China. The phylogeny work showed that Chinese haplotypes were embedded within the other Japanese ones, and it was more likely dispersed from Japan to E China based on cpDNA data. Based on molecular dating, we speculated that Diabelia originated in Wenzhou, Zhejiang, China, and then it spread to the west of Hongshu (e.g. Shiga) of Japan ca. 20 Ma ago (e.g. *D. spathulata*). However, cpDNA was prone to introgression, and just represented one gene genealogy. In the future we would use microsatellite markers to have more information on the allele diversity and distribution. Comparing different genetic markers would be much more informative in future.

Comparison of floral morphology and pollinator behavioral pattern among different sexes in *Eurya Japonica* Thunb.

Hui Wang, *Peiming Zheng, Qiang Li, Xiao Liu, Ning Wang, Fenghua Bai, Weihua Guo, Renqing Wang*
Shandong University

As reproductive organ, plant flower can attract the pollinators during pollination process. Generally, morphology of entomophilous flower is different among different sexes, which may attract different pollinators, thus will further affect the reproductive characteristics of different sexual individuals. *Eurya japonica* Thunb. (Pentaphylacaceae) is a subdioecious shrub, and both the female and male reproductive success of hermaphrodite individuals are outperformed by females and males, respectively. This study was conducted to compare the floral morphology and pollinator behavioral pattern among different sexes. The characters of floral morphology, and the species and the number of visiting insects in certain time were observed. The results showed that the flower of different sexes of *E. japonica* have many obvious differences in respect of the floral morphology and flower visiting insects. The flowers colour of different sexes is similar by visual inspection. The flowers amount of male individuals was the highest, while that of hermaphrodites was the least. The male flower is bell-shaped with non-reflexed petals; the female flower is cup-shaped with reflexed petals; while the hermaphrodite flower presents some transitional traits between the male and female flowers. The stigmas number of female flowers and the stamens number of male flowers are more than those of hermaphrodite flowers, respectively. In addition, no difference was found in the flowers nectar volume and sugar content between female and hermaphrodite flowers, whereas male flower has the least nectar volume. The number of visiting insects in male individuals was the highest in certain time. The visiting insects of female flower were mostly Diptera, while those of male and hermaphrodite flowers were Thrips. The floral morphology and pollinator behavior adapt to each other during the evolution. It is also thought that the differences of floral morphology and pollinator behavioral pattern influence the reproductive success of *E. joponica.*

P0663

A systematic revision of pantropical genus of *Caudalejeunea* (Lejeuneaceae, Marchantiophyta)

Wang Jian
East China Normal University

The genus of *Caudalejeunea* (Steph.) Schiffn., with the capacity of the species to reproduce asexually by means of discoid gemmae, is the only frequently epiphyllous genus and abundant in humid tropical regions in Ptychanthoideae. A world-wide revision of the genus leads to the recognition of eleven species. Morphological characters of *Caudalejeunea* are include the presence of gemmiparous branches, trigones cordate and more conspicuous cell-wall thickenings and the homogeneous oil bodies. *Gradsteinianthus* R.L.Zhu & Jian Wang bis gen. nov. is newly described based on molecular and morphological evidence. Based on the distinct important morphological characters, *C. latigynolobula* Jian Wang bis sp. nov. is described new to science. *Caudalejeunea grolleana* Gradst. is transffered to *Acrolejeunea* and a new combination *A. grolleana* (Gradst.) Jian Wang bis is proposed. *Caudalejeunea recurvistipula* (Gottsche) Schiffn. is resurrected as a distinct species and *C. africana* is reduced to a synonym of the species. *Caudalejeunea mauritiana* Horik. is reduced as a synonym of *Dicranolejeunea axillaris* (Nees & Mont.) Schiffn. and *C. acutifolia* Gerola is excluded from the genus. A key to the species of the genus *Caudalejeunea* is provided and each species is fully described and illustrated, with complete synonymy and detailed data on habitat and distribution. *Caudalejeunea* is pantropical in distribution; the centre of diversity of the genus is tropical Africa with highest endemics, and some species exhibit intercontinental disjunctions between tropical regions of Africa, America, Asia and Oceania. To understand the reason of bryophytes with intercontinental disjunctions and, we analyse the patterns of beta diversity of tropical bryophytes to determine if they possess high dispersal capacities based on the distributions of tropical bryophyte species.

Five species newly recorded herbaceous plants of Metachlamydeae in Northeast China

Meng Wang, *Shu-Mei Zhang*
Dalian Natural History Museum

Northeast of China, located in the East of Eurasia, is vast in territory, and has varieties of plants species, a total of 164 families, 928 genera and 3,103 species of vascular bundle plants. It is an important region for the origin, evolution and development of flora. Based on the results of field investigation and related data, five species newly recorded herbaceous plants of metachlamydeae are reported (*Cynanchum hancockianum* (Maxim.) Al. Iljinski*, Lamium amplexicaule* Linn*, Mentha sachalinensis* (Briq.) Kudo*, Solanum photeinocarpum* N. et O*, Pedicularis artselaeri* Maxim). As newly recorded species plants in Northeast China, *Cynanchum hancockianum* (Maxim.) Al. Iljinski is distributed in Zhuanghe, Dalian. *Lamium amplexicaule* Linn is distributed in Dalian. *Mentha sachalinensis* (Briq.) Kudo is distributed in Liaoning. *Solanum photeinocarpum* N. et O is distributed in Jinzhou, Dalian. *Pedicularis artselaeri* Maxim is distributed in Lingyuan, Chaoyang. The finding of many newly recorded plants distributed in Liaoning confirms that the plants in Liaoning province have obvious features of transitional zone between north China flora and northeast China flora and provides new evidences for the relationship between them. The voucher specimens were preserved in the herbarium of Dalian natural history museum. These newly recorded plants have a great significant meaning to study the plant species diversity and provide new materials for investigation of their geographical distributions in China.

Newly recorded herbaceous plants of Archichlamydeae in Northeast China

Meng Wang, *Shu-Mei Zhang*
Dalian Natural History Museum

Northeast of China, located in the East of Eurasia, is vast in territory, and has varieties of plants species, a total of 164 families, 928 genera and 3,103 species of vascular bundle plants. It is an important region for the origin, evolution and development of flora. Based on the results of field investigation and related data, one family (Aizoaceae), three genera (*Mollugo* L., *Achyranthes* L., *Dicranostigma* Hook. f. et Thoms.) and four species newly recorded herbaceous plants of Archichlamydea are reported (*Mollugo stricta* L., *Achyranthes bidentata* Blume, *Dicranostigma leptopodum* (Maxim.) Fedde, *Erodium cicutarium*). As a newly recorded family in Northeast China, aizoaceae is distributed in Tieling. As newly recorded genera in Northeast China, *Mollugo* L. is distributed in Tieling. *Achyranthes* L. is distributed in Dalian and Fengcheng. *Dicranostigma* Hook. f. et Thoms. is distributed in Jinzhou, Dalian. As newly recorded species plants in Northeast China, *Mollugo stricta* L. is distributed in Tieling. *Achyranthes bidentata* Blume is distributed in Dalian and Fengcheng. *Dicranostigma leptopodum* (Maxim.) Fedde is distributed in Jinzhou, Dalian. *Erodium cicutarium* is distributed in Dalian. The finding of many newly recorded plants distributed in Liaoning confirms that the plants in Liaoning province have obvious features of transitional zone between north China flora and northeast China flora and provides new evidences for the relationship between them. The voucher specimens were preserved in the herbarium of Dalian natural history museum. These newly recorded plants have a great significant meaning to study the plant species diversity and provide new materials for investigation of their geographical distributions in China.

Phylogenomics of *Betula* (Betulaeae) species based on RAD-seq

Nian Wang[1,2], *Richard Buggs*[1,3]
1. School of Biological and Chemical Sciences, Queen Mary University of London
2. School of Forestry, Shandong Agricultural University
3. Royal Botanic Gardens Kew

Discordance among molecular phylogenetic trees has been frequently observed and attributed to various factors, such as different evolutionary histories, deep coalescence, hybridisation and introgression or horizontal gene transfer. New approaches have been used to construct accurate phylogenetic trees that take account into the relationships between many separate gene trees and the underling history of species divergence. *Betula* provides an excellent model to study species relationships. In this study, we developed restriction site associated (RAD) markers for most diploid *Betula* species and used a concatenation method and a method based on summary statistics to infer relationships among diploid species of the genus. After filtering and trimming, the total number of reads for each species ranged from 1,065,196 in *B. hainanensis* to 2,560,486 in *B. populifolia* whereas the number of mapped reads was from 904,705 in *Alnus inokumae* to 2,439,447 in *B. populifolia* with the percentage of mapped reads varied from 66.0% in *A. inokumae* to 96.8% in *B. pendula* ssp. *mandshurica*. With a reference genome for mapping, we obtained up to 16,213 reads with a minimal length of 300 bp in *A. inokumae* whereas this figure was 32,977 in *B. maximowicziana*. 4,890 loci with a minimal length of 300bp were used in the analysis. The results show that *B. corylifolia* and *B. michauxii* should be incorporated into subgenus *Aspera* whereas *B. maximowicziana* should be within subgenus *Betula*. Based on our phylogenomic approach, we proposed a new classification of *Betula* of three subgenera and seven sections: subgenera *Acuminata* [section *Acuminatae*], *Aspera* [sections *Asperae* and *Lentae*], and *Betula* [sections *Betula*, *Costatae*, *Dahuricae* and *Maximowiczianae*]). The study shows that RAD-seq is suitable for phylogenomic analysis especially with an available reference genome (albeit fragmented). This dataset will also allow future investigation of the parental origins of polyploid species.

Phylogeography of *Scrophularia incisa* and its close relatives (Scrophulariaece): Revealing the evolutionary history of desert plants in northwestern China

Ruihong Wang[1], *Pan Li*[2], *Zhaoping Yang*[2], *Chengxin Fu*[2]
1. Zhejiang Sci-tech University
2. Zhejiang University

Pleistocene climate oscillations appear to have had an important effect in shaping intra- or inter-specific genetic variation and evolutionary history in many arid-adapted species. To understand the process involved and reveal evolutionary relationships, phylogeographic analysis were examined from *S. incisa*, and two other species also from *Scrophularia* section *Caninae*, including *S. kiriloviana*, *S. dentata*. We collected 522 individuals from 32 populations of the three closet relatives of *Scrophularia incisa* species complex and sequenced two maternally inherited chloroplast (cp) DNA fragments and also the bi-paternally inherited nuclear ribosomal ITS and microsatellite loci. We recovered four major clades in phylogenetic trees reconstructed from cpDNA and internal transcribed spacer (ITS) sequence variation. Most sampled individuals that are distributed in Inner Mongolia, QTP, Tibet and Xinjiang, respectively, comprised monophyletic clades nested within those found in Central Asia. *Scrophularia incisa* in Inner Mongolia and Qinghai-Gansu were paraphyletic, while the placement of *Scrophularia incisa* from Inner Mongolia was in the Xinjiang gene pool revealed in the SSR structure, differing with the ITS and cpDNA phylogenetic trees. Our phylogeographic analysis supported the importance of Pleistocene climate change, in this case the increase of aridification and enlargement of deserts, as a cause of divergence in *Scrophularia incisa* complex as a result of allopatric speciation, hybridization and introgression. These findings highlight the complexity of closest relatives evolutions and the importance of the Pleistocene climate change in shaping the genetic diversity.

Accounting the events on the evolutionary pathway from early land plants to angiosperms

Xin Wang
State Key Laboratory of Palaeobiology and Stratigraphy, Nanjing Institute of Geology and Palaeontology

Ovules are megasporangia that are retained on their mother plants until seed maturation and recruit additional protective parts in the evolution of seed plants. Establishing the correlation between ovules in angiosperms with those in gymnosperms and spores in other vascular plant groups is the foundation for integrated systematic analysis of land plants. Gymnosperms have invented various ways to protect their seeds as seen in the cones of Cycadales and Coniferales. Protection of megasporangia or ovules is initially provided by integuments. This is followed by various laminar structures derived from formerly branches that form the cupular walls in various taxa. This trend is further enhanced to a new level by angiosperms that protect their seeds even before the seeds are born (in ovule stage). Different from their gymnospermous peers, angiosperms have developed ovule-enclosing as a competitive strategy in their survival struggle, ensuing the protection by integuments and cupular walls in various seed plants. Besides ovule-enclosure (angio-ovuly), angiosperms have developed angiocarpy in various taxa independently. Associated with or after these stepwise enhanced protections, stepwise ensured nutritional supply, outcross-enhancing reproductive characteristics, improved fruit and seed dispersing features give angiosperms additional edges in their evolution. Ensurance of plenty of nutrition for the offsprings is a major advantage for plants in their evolution starting from *Rhynia* on. The first step in this direction is the occurrence of heterospory in various taxa, which allocates more resources to the female spores. Following heterospory, megaspores become retained in their mother plants, giving rise to ovules that can absorb extra nutrition from the mother plants for their healthy development. In addition, these changes and advantages are coupled with outcrossing enhancing self-incompatibility. Extended nutritional bond with sporophyte after meiosis is further extended to a new level of vivipary, namely, germination of seeds on the sporophytes. Different extent of megaspore protection and enclosure (angio-spermy) and the spatial relationships between the ovules and their protecting laminar structures define and distinguish various fossil or extant plant groups, including ferns, gymnosperms and angiosperms. As the nutritional and protecting relationships evolve, different fructifications emerge in various plant groups throughout times, and, correspondingly, various gene dispersal and communication mechanisms evolve. The coupling evolution between animals and plant fructifications plays a crucial role in the radiation of angiosperms that accelerates the evolution in both groups.

Genome-wide evidence for sympatric introgression and speciation with gene flow of two *Rhizophora* mangrove species

***Xinfeng Wang**, Zixiao Guo, Suhua Shi*
State Key Laboratory of Biocontrol and Guangdong Provincial Key Laboratory of Plant Resources, Sun Yat-sen University

The two species in the mangroves genus *Rhizophora*, namely *R. mucronata* and *R. stylosa* are very closely-related, estimating as diverging at approximately 0.66 million years ago. Owing to their overlapping distribution in Indo-west Pacific region and observations of inter-species hybridization and gene flow, their independent species status were doubted. We firstly characterized the divergence and gene exchanges between the two species on the whole genome scale by resequencing 26 individuals of *R. mucronata* and 17 individuals of *R. stylosa*. Comprehensive analysis of the 5.4 million single nucleotide polymorphisms (SNPs) obtained by mapping to the reference genome of *R. apiculata* supported their independent species status, while observed dramatically reduced divergence when they are sympatric. The introgression found in sympatric populations in Daintree River, Australia and Tg.piai, Malaysia were proved to exist from ancient to recent time, and further found to be bidirectional in Daintree River and unidirectional from *R. mucronata* to *R. stylosa* in Tg.piai. These findings are useful to study the role of gene flow played in speciation or species maintenance after speciation.

Taxonomic revision on subsect. *Oyama*

***Yaling Wang**[1], Shouzhou Zhang[2]*
1. Xi'an Botancial Garden of Shaanxi Province
2. Laboratory of Southern Subtropical Plant Diversity, Fairylake Botanical Garden, Shenzhen & Chinese Academy of Sciences

Magnolia section *Rhytidospermum* subsection *Oyama* is famous ornamental group for its pure white pendant flowers with showy red or purple androecium. Although they have most wild distribution at latitude (25°32´-41°55´N), longitude (85°20´-119°42´E) and altitude (330-3400m), and quiet similar morphological characters within and among populations, the systematic position and internal classification of this group has still been controversial. In this study, 116 individuals from 12 populations representing 4 taxa in subsect.*Oyama* were studied for the taxonomic revision of sect. *Oyama*. The morphology variation and geographical distribution, as well as molecule data analysis on the combine data of three universal DNA regions (matK, rbcL, trnH-psbA) were conducted to detect the phylogenetic relationships. The results revealed that subsect. *Oyama* include three species and two varieties: *Magnolia globosa* Hook.f. & Thoms., *M. sieboldii* K. Koch, *M. sieboldii* ssp. *japonica* K. Ueda, *M. wilsonii* (Finet. & Gagnep.) Rehder, *M.wilsonii* var. *sinensis* (Rehder & Wilson) Y.L. Wang & S.Z. Zhang.

Systematic studies on the *Umbelopsis*

***Ya-Ning Wang**, Xiao-Yong Liu, Ru-Yong Zheng*
Institute of Microbiology, Chinese Academy of Sciences

The fungi of *Umbelopsis* (Umbelopsidaceae, Mucorales, Mucoromycotina) are saprobes and widely distributed in soils and plant residues. In recent years, some species of this genus have been found to be endophytes. *Umbelopsis* species are important oleaginous fungi due to their high oil contents. Compared with other taxa of the Mucorales, *Umbelopsis* is characterized by forming: 1) velvety and often colored colonies, 2) a low and dense layer of aerial hyphae; 3) sporangiophores which are often arising erectly from the vesicles; and 4) small columellae or not forming at all. *Umbelopsis* is a basal monophyletic group within the Mucorales clade in phylogenetic analyses. A total of 128 *Umbelopsis* strains comprising 121 strains from China and 27 ones from other countries have been studied. Based on the results of morphological characteristics, maximum growth tempearature and multilocus phylogenies (partial 18S and 28S, internal transcribed spacer regions of nuc rDNA, and two protein-coding genes, *act1* and *MCM7*), fourteen species were recognized in the genus *Umbelopsis*. In this study, *U. changbaiensis* was described as a new species; *U. angularis*, *U. dimorpha* and *U. nana* were reported as new record species from China; *U. longicollis* was recombinated from *Mortierella longicollis*; *U. nana*, *U. roseonana* and *U. versiformis* were treated as heterotypic synonyms; *U. ramanniana* and *U. isabellina* were revealed to be heterogenetic and may be two species complexes. In addition, lectotypes and epitypes for *U. longicollis*, *U. nana* and *U. vinacea* were also designated.

Variable architecture of legume plastomes beyond Papilionoids

Yin-Huan Wang[1,2], *Xiao-Jian Qu*[1,2], *Si-Yun Chen*[1], *De-Zhu Li*[1], *Ting-Shuang Yi*[1]
1. Kunming Institute of Botany, Chinese Academy of Sciences
2. University of Chinese Academy of Sciences

It is universally known that legume plastomes experience significant structural and size variation. However, most studies have focused on subfamily Papilionoideae and limited studies on the mimosoid clade. In order to explore structural variation of plastomes beyond Papilionoids, we sequenced plastomes of 20 species from representing genera. Integrated three previously published plastomes with 11 new ones, we firstly addressed the architecture of mimosoid plastomes. The mimosoid plastome presented typical quadripartite structure and contained 111 unique genes. Their IRs (inverted repeats) experienced multiple expansion/contractions. A ca. 13 kb IR expansion into SSC (small single copy) was detected in plastomes of a clade formed by the tribe Ingeae and *Acacia* sensu stricto (s.s.) and to be the synapomorphy of this clade. A ca. 1.7 kb IR expansion into and a ca. 1.9 kb contraction out of LSC (large single copy) were found in *Pithecellobium flexicaule* and *Acacia dealbata*, respectively. Linear regression analysis showed decreased synonymous substitution rates of genes relocating from SSC into IR. A loss of both introns of *clpP* occurred in *A. dealbata* and *Faidherbia albida*, and a duplicated *clpP* copy was detected in *A. dealbata*. Furthermore, a 421 bp inversion that containing *rps18* was found in *A. dealbata*. Size of mimosoid plastomes was found significantly affected by IR-SC boundary shift and also associated with repeat content. Plastomic coding and noncoding regions with variable sequence divergence may supply valuable markers for molecular evolutionary and phylogenetic studies at different taxonomic levels. We have also detected a variety of structural variations in plastomes of seven species from subfamily Cercidoideae except *Adenolobus garipensis* and *Cercis glabra* representing two basal branches of this subfamily. These variations included IR expansion and contraction, gene or intron loss and sequence inversion. Our results would be crucial for further studies on the variation and evolution of legume plastome architecture.

Discrepancy between nuclear and chloroplast DNA variations reveals alpine valleys to be the arena for new species under iterative climate changes

Zimeng Wang
Peking University

Rhodiola (Crassulaceae) has experienced rapid diversification on the Qinghai-Tibet Plateau (QTP) since 21 million years ago. For a better understanding of this evolutionary process, this study took a species pair of *R. stapfii* and *R. prainii* as a miniature, 25 populations were sampled from the whole distribution area of these two species, mainly in the southern part of QTP. 13 nuclear SSR loci and five unique chloroplast sequence markers generated from high-throughput sequencing reads were analyzed as well as traditional markers such as internal transcribed spacer (ITS). SSR analyses show that *R. stapfii* and *R. prainii* have different population structures. Phylogeny based on ITS sequences conflicts severely with that of chloroplast sequences. The cpDNA phylogenetic tree braches are dense but those based on ITS are more dispersed. Tree topology conflicts happens as well, indicating during certain periods some populations were distributed closely so that they had the strong gene flow by pollens, not seeds. Also, niche modeling shows that these two species were sympatric during glacial periods and became parapatric or even allopatric during interglacial periods. Thus, a evolutionary scenario can be expected that during warm periods populations are "pumped out" from their glacial refuges to adjacent regions, while during glacial periods they are squeezed into valleys of Yarlung Zangob River, where their possible incomplete reproductive isolation were challenged by pollen flows. Special landscape along Yarlung Zangob River as well as iterative climate changes in Quaternary period provides an arena for new speciation of the genus *Rhodiola*.

P0674

Systematics and phylogeny of Apiaceae subfamily Apioideae major lineages related to *Angelica*

Jun Wen
Sichuan University

Apiaceae is a large and taxonomically complex family (include more than 3,700 species spread across about 455 genera) of angiosperms that include many economically and medicinally important plant families? The typical representative medicinally genus is *Angelica* L. In the previous study we know that *Angelica* is not a monophyletic group, and it is scattered in four large lineages. However, in the previous study they didn't have got a definite generic boundaries of *Angelica*. Our research will be based on richer sampling, more suitable DNA barcode (including ITS, ETS, some chloroplast genes and low copy nuclear conserved ortholog set (COS) genes or even single copy genes) as well as a clearer morphological analysis, including leaf epidermis micro-morphological fruit anatomy and morphology, pollen morphology and so on) of these four lineages with Apioideae subfamily as the framework to discuss the systematics and phylogeny of *Angelica.* Some species should be reduced to synonyms, and we should define the composition of *Angelica* sensu stricto. In addition, we also expect to solve the problem of some groups of genus *Angelica* at the transcriptome level.

Why don't all flowering plant male gametophytes have extremely fast pollen tube growth rates?

Joseph Williams
University of Tennessee

Pollen tube growth rate (PTGR) is an important aspect of male gametophyte performance because of its central role in the fertilization process. Theory suggests that under intense competition, PTGRs should evolve to be ever faster, especially if PTGR accurately reflects gametophyte quality in the sporophyte generation. A comparative analysis of PTGRs in 457 seed plants revealed a strong phylogenetic signal, even when slow-growing gymnosperms were removed. Species with increasingly faster PTGRs were increasingly nested in many independent groups of angiosperms. Species with the fastest PTGRs (> ~5,000 µm/h) were found in at least 16 independent groups that display a number of convergent features thought to select for rapid PTGR. Similarly, species with exceptionally slow PTGRs (< ~50 µm/h) were restricted to lineages which lack features that promote high levels of pollen competition. Given the basic life history benefits of rapid growth rate (greater competitive ability, shorter lifespan), it is surprising that we still lack a basic understanding of costs and tradeoffs associated with evolving rapid PTGR. Pollen tube growth rate is ultimately determined by how effectively the work of tube construction is translated to elongation (growth and growth rate). Do pollen tubes grow with similar costs and do they grow equally efficiently? I compared the scaling of wall production rate (WPR) to PTGR in three distantly-related water lilies that flower concurrently in the same ponds: *Nymphaea odorata*, *Nuphar advena* and*Brasenia schreberi*. Flowers were pollinated and carpels were collected at two time points. PTGR was calculated as the average increase in tube length over a growth period of about 45 minutes. Tube circumferences (*C*) and wall thicknesses (*W*) were then measured on glycol methacrylate-embedded material collected at the end of that time period. Wall production rate (WPR) was calculated as: mean ($C \times W$) × mean PTGR for each pollination. The ratio of WPR to PTGR is a measure of growth efficiency - efficient growth occurs when wall production rate is low relative to PTGR. Within species, pollen tubes maintained a constant WPR to PTGR ratio over a range temperatures and growth rates. Slow growing tubes were equally efficient as fast-growing tubes. However, fast-growing tubes had significantly thinner walls, but the effect was offset by a nearly opposite pattern for tube diameter. Species had significantly different growth efficiencies, however. Whereas *N. odorata* and *N. advena* had similar PTGRs, for any given PTGR, they had significantly different WPRs. In conclusion, PTGR is a fundamental aspect of plant life histories that can evolve for many reasons. PTGR efficiencies evolve by changes in the volume of wall material used for growth and in how that material is partitioned between lateral and length dimensions. Rapid growth can be achieved by increasing energetic costs and/or by increasing growth efficiency. The economics of pollen tube growth are determined by tube design, which is consequent on tradeoffs between efficient growth and other pollen tube functions.

Relationships of the tribe Metrosidereae and realignment of the tribe Kanieae (Myrtaceae) based on sequence and morphological data

Peter Wilson[1], *Margaret Heslewood*[1], *Myall Tarran*[2]

1. National Herbarium of New South Wales

2. The University of Adelaide

Myrtaceae is a large family of tropical and temperate trees and shrubs currently divided into 2 subfamilies and 17 tribes. The tribe Metrosidereae, which includes the widespread Pacific genus *Metrosideros*, has a strongly southern distribution and is presently the only tribe in subfamily Myrtoideae that is absent from mainland Australia. The tribe Kanieae, as presently constituted includes genera restricted to Australia and Malesia. The tribal classification was based on a phylogenetic analysis of the chloroplast *trn*K intron that showed good support for most tribes but little for any intertribal relationships. Sequence of chloroplast *psb*A–*trn*H and nuclear ribosomal ITS and ETS regions was added for representative species in the tribes Kanieae and Metrosidereae. This included sequence of 3 accessions of the genus *Kania*, type of the tribe Kanieae, that had been represented by one very poor sequence in the previous study. Analyses of this extended dataset now show a strong sister relationship between *Kania* and the tribe Metrosidereae but not with the other genera presently assigned to the Kanieae. This relationship between *Kania* and the tribe Metrosidereae is strongly correlated with a morphological feature, hypanthium vascularisation, that has come to light through recent research on fossil fruits of *Metrosideros*. A consequence of this finding is that a new tribe will be required to accommodate the majority of other genera presently assigned to the Kanieae. Since *Kania* only occurs in Papua New Guinea and the Philippines, there are now 2 sister clades that do not occur naturally on the Australian mainland.

Are we splitting hairs? Resolving infrageneric relationships in the Australian *Plectranthus* (Lamiaceae)

Trevor Wilson[1], *Paul Forster*[2], *Barry Conn*[3], *Maurizio Rosetto*[1], *Murray Henwood*[3]

1. National Herbarium of New South Wales

2. Queensland Herbarium

3. The University of Sydney

Plectranthus (Lamiaceae) is well-known for its use in medicine, agriculture and horticulture. From its highest centre of diversity in Africa, the distribution of the genus extends throughout the old world tropics. Over the past few decades the described number of Australian *Plectranthus* has more than doubled to 48, making eastern Australia another area of high diversity for the genus. Identification of Australian *Plectranthus* can be challenging due to a troublesome combination of delicate macro-morphological characters (e.g. corolla shape) and cryptic micro-morphological characters (e.g. trichomes). Furthermore, phenotypic plasticity and the sympatric distribution of similar-looking species are also common. This combination has assisted with masking the high diversity of Australian *Plectranthus*, and it has continuously facilitated misidentifications. As of yet no quantifiable approach has been implemented to understand the relationships of Australian *Plectranthus*. For the many descriptions of Australian *Plectranthus* currently in the pipeline, this lack of knowledge hampers the provision of useful diagnosable characters. A careful integration of molecular and morphological data is therefore necessary to test the usefulness of current taxonomic characters and institute an understanding of relationships. We describe the preliminary phylogenetic results for Australian *Plectranthus* based on our analysis of chloroplast DNA acquired from high throughput sequencing methods. These results are also combined with data of extra-Australian *Plectranthus* to improve our perspective on relationships and biogeography of the entire genus.

eFlora of New Zealand

Aaron Wilton, *Ilse Breitwieser*

Landcare Research

The eFlora of New Zealand initiative aims to deliver a resource on the wild New Zealand vascular and cryptogrammic flora that is up-to-date and engages a wide range of users both inside and outside the taxonomic community. Development of the eFlora has required implementation of a process that combines important components of traditional floras with an information system that integrates data from a range of sources. For example, this approach combines traditional editorial and review processes with a team approach for managing nomenclatural and taxonomic information. The eFlora currently integrates data from specimen, taxonomic and nomenclatural, descriptive and image systems to deliver a website (http://nzflora.info) and PDFs of treatments. The eFlora system provides a means for authoring new taxonomic treatments – including taxonomic and nomenclatural novelties. Since 2010 over 50 new family level treatments have been published using this method. This new taxonomic content is combined with taxonomic treatments from earlier New Zealand Floras and more recent taxonomic treatments published in journals to publish the web site within which information is provided as different profiles - templates that combine different subsets of information to address differing audience needs. We will present our experiences developing, and future plans for, the eFlora of New Zealand.

Inferring the evolutionary history of *Penstemon* (Plantaginaceae) from phylogenetic analysis of high-throughput sequence data

Andi Wolfe

The Ohio State University, Department of Evolution, Ecology and Organismal Diversity

Penstemon is the largest genus of plants endemic to North America. Its 280+ species are distributed from coast-to-coast and from Alaska to southern Mexico and the highlands of northern Guatemala, excluding most of the Canadian Shield region. Most species occur west of the Rocky Mountains, with the largest diversity of species in the Intermountain Region. The current taxonomy of *Penstemon* circumscribes six subgenera, divided into 12 sections and 23 subsections. Most species are xerophytic, and more than half occur in montane to subalpine habitats. Edaphic endemics are found in all sections of the genus, with many species restricted to calcareous, volcanic, shale, clay, and deep sand substrates. *Penstemon* exhibits considerable morphological diversity. Species may be woody, suffrutescent, or herbaceous, and exhibit extreme variation in vegetative characters, inflorescence architecture, vestiture, and floral morphology. We have used targeted amplicon sequencing for 48 loci to reconstruct the phylogeny of >90% of the species in this large and very diverse genus. Our goals for this phylogenetic study were to: 1) build a robust phylogeny for *Penstemon* that will be used to examine rates of diversification in the context of testing adaptive radiation theory; 2) examine taxonomic relationships in the context of an evolutionary framework; 3) elucidate trends in the evolution of morphological traits; 4) determine if there is a phylogenetic pattern for edaphic specialization; and 5) test biogeographic hypotheses proposed in previous studies of the genus.

Genomic consequences of gene flow between two *Senecio* species on Mount Etna, Sicily

Edgar L.Y. Wong, *Bruno Nevado, Simon J. Hiscock, Dmitry A. Filatov*

Department of Plant Sciences, University of Oxford

S. aethnensis and *S. chrysanthemifolius* are two sister species which range above 2000 m and below 1000 m respectively on Mount Etna, Sicily. It was estimated that the species diverged around 100-150 thousand years ago and the divergence might have been driven by the rise of Mount Etna, which provided novel niches for the morphological and genetic divergence. Ongoing gene flow was found between the two species as they maintain a hybrid zone between their respective ranges. However, some hybrid breakdown was observed to manifest in F_2 hybrids, which suggested that these species have already evolved some degrees of postzygotic isolation. Previous analyses of gene expression have identified a set of differentially expressed genes. Some of the differentially expressed genes are involved in primary amine oxidase activity and magnesium ion binding – functions that are likely important for adaptation to volcanic soils. These genes have been evolving under diversifying selection. This study reports DNA polymorphism and divergence analyses in the differentially expressed genes in order to test whether they have been subject to diversifying selection in the recent past. For this purpose, we sequenced differentially expressed genes from multiple populations at different elevations on Mount Etna. Genomic clines were analysed for these genes to investigate the selective pressures keeping the two species distinct while maintaining a hybrid zone. Overall, this project aims to reveal the evolutionary forces during on-going ecological speciation driven by adaptation to contrasting conditions at high and low altitudes.

Evolution of WRKY transcription factors in Poaceae family

Kangcheng Wu

Fujian Agriculture and Forestry University

WRKY gene family is one of the largest transcription factor families in higher plants, which plays important roles in regulating plant development and resistance. Poaceae is a family covering various economic-valued plants. In this report, a total of 17 Poaceae species, spanning 6 subfamilies, from basal to crown Poaceae, were studied to systemically research the evolution of *WRKY* gene family. Totally, 5 WRKY groups were classified according to their phylogeny, Group I, IIa, IIb, IIc, IId, IIe, III. It was found that the large proportion of Poaceae WRKY was mainly produced by several recent-independent polyploidization events and tandem duplication. In addition to species that experienced recent polyploidization events, other Poaceae also showed various WRKY numbers, such as sugarcane, millet, which were contributed by large tandem duplications of Group III. The analysis of selection pressure indicated that Group III of WRKY evolved faster than other groups. Some genes showed fast evolutionary rate in Group I, IIc and IIe. Positive selections and functional divergence were found in these fast-evolved genes. It was found that there was a branch with fast evolution in the Group I, and specific functions were unknown. The divisions of Poaceae plants were divided into BOP clade, Chloridoideae clade, and PACMAD clade (except the subfamily of Chloridoideae), which were different from previous classifications.

Leaves and seed cones of *Dacrycarpus* (Podocarpaceae) from the Miocene of South China

Xinkai Wu[1], *Xiaoyan Liu*[1], *Tatiana Kodrul*[1,2], *Cheng Quan*[3], *Jianhua Jin*[1]

1. State Key Laboratory of Biocontrol and Guangdong Key Laboratory of Plant Resources, School of Life Sciences, Sun Yat-sen University

2. Geological Institute, Russian Academy of Sciences

3. Research Center of Paleontology and Stratigraphy, Jilin University

Dacrycarpus (Podocarpaceae) has an abundant macrofossil record in southeast Australia, New Zealand and Patagonia, but no record was reported previously in the Northern Hemisphere. In this study, we described a new species of *Dacrycarpus* recovered from the Miocene Erzitang Formation of Guiping Basin, Guangxi, South China. The specimens contain various forms foliage and three-dimensional preserved female cones, with well-preserved cuticles. The new materials have dimorphic foliage including bifacially flattened “adult” leaves on long shoots and bilaterally flattened “juvenile” leaves on short shoots. All foliage have a single midvein and incurved apex, as well as resin ducts. Bilateral leaves are distichous, falcate, straight to slightly apically curved, decurrent, stongly keeled with a single prominently raised vein. Maximum length per shoot is 3.4-7.4 mm. Maximum width per shoot is 0.6-1.1 mm. The ratio of leaf length and width is 4:1-7:1. Short shoot is about 12-26 mm long × 5-10 mm wide. Leaves are amphistomatic, with two longitudinal bands of stomata occurring from leaf base to apex on each surface. Each band contains 2-5 rows of stomata. Stomatal axes parallel to the midvein. Florin rings are well developed, sunken below leaf surface. Stomatal complex is paratetracytic. Polar subsidiary cells usually shared between adjacent stomata of row. Epidermal cell walls are straight, smooth and thin. Bifacial leaves are small, 2-3.5 mm in length, 0.4-0.8 mm in width, awl-shaped, spirally arranged, loosely imbricate, appressed, strongly keeled and amphistomatic. Seed cones are terminal, obovate, 4.2-5.9 mm long, 3.6-5.2 mm wide, deployed singly on a warty receptacle. Based on the architectural features of leaves and seed cones, the present fossils are assigned to the genus of *Dacrycarpus*, showing the most resemblance to *D. imbricatus* (Blume) de Laubenfels, the only extant species in China. The discovery demonstrates that the genus has spread into South China at least by the Miocene, and the migration may have occurred with the collision between the Indian and Eurasian plates. The new species of *Dacrycarpus* builds the first reliable fossil link for this genus between two hemispheres.

P0683

Understanding functional diversity and mechanisms of plant community assembly using non-target metabolite profiling: A test of HPLC-MS method.

Wenbin Zhou, *Sirius Li, Qiu-Yun (Jenny) Xiang*

Department of Plant and Microbial Biology, North Carolina State University, Raleigh, NC 27695-7612, USA.

Secondary metabolite diversity represents a special dimension of biodiversity important to ecological functions and community assembly. However, there have been few studies evaluating secondary metabolite diversity and the relationship between chemical diversity and phylogenetic diversity within and among plant communities. Recent studies have demonstrated the value of analyzing the distribution and variation of functional traits to gain insights into primary ecological processes (niche differentiation or environmental filtering) shaping community assembly. We attempt to characterize the pattern of secondary metabolite variation in the eastern Asian and eastern North American disjunct forests to provide new insights into the biodiversity and community assembly. As a first step, we tested the utility of the HPLC-MS non-target profiling method. A set of 30 leaf samples with various habits from three plant communities including species from distantly related clades of seed plants as well as species from the same family, same genus, or same species for a pilot study. The samples were from the Ordway-Swisher Biological Station, Talladega National Forest, and Mountain Lake Biological Station. Our goal is to see if sufficient data would be obtained from dry leaf extracts and useful for comparative analyses. We obtained 6174 chemical compounds for the 30 species from the profiling using Aglient MassHunter Profinder B.06.00 software. Of which, 27% were rare (present in < 5% of the samples). Data sets shared by 30 species, >25 species, >20 species, >10 species, and >1 species, were constructed and transformed by cube root, normalized by sum, and scaled by mean centering for further analyses. Partial least square (PLS) test revealed significant differences among sites, suggesting the chemical composition is correlated with sites (MANOVA, $F_{(2,27)} = 5.7223$, $P = 2.762*10^{-06} < 0.05$). Fifteen chemical markers were identified to explain most of the patterns distinguishing among sites. Hierarchical cluster analysis (HCA) with ward’s method in R for samples within each site showed samples from the same genus or the same species were clustered together, but not samples from the same family or order. Comparison of phylogenetic diversity measured by *rbc*L-*mat*K trees and chemical diversity will be conducted. Patterns of chemical clustering of species and phylogeny will also be compared within and among sites to gain insights on relationship of chemical diversity to phylogenetic diversity and on processes of community assembly. The preliminary study demonstrated HPLC-MA is useful for the community level analysis of chemical diversity.

P0684

On the generic circumscription of the complex thalloid liverwort family Corsiniaceae (Marchantiophyta) based on molecular and morphological evidence

***You-Liang Xiang**, Lei Shu, Rui-Liang Zhu*

School of Life Sciences, East China Normal University

The most recent classification divided Corsiniaceae into three genera, *Corsinia* Raddi, *Cronisia* Berk. and *Exormotheca* Mitt. A combined molecular phylogenetic analysis of three chloroplast genes (*rbc*L, *atp*B and *psb*A) and one nuclear gene (the ribosomal LSU) was carried out to assess possible alternative treatments of the family, using *Targionia hypophylla* and *Monosolenium tenerum* as outgroups. All the *Exormotheca*, *Corsinia* and *Cronisia* species included in our analyses formed a well-supported clade and all *Exormotheca* species were nested within the other two genera. In combination with morphological data, here we propose to subsume all species in *Cronisia* and *Exormotheca* into the earlier published genus *Corsinia*. *Exormotheca* and *Cronisia* are treated as new synonyms. Eleven new combinations are proposed: *Corsinia bischlerae* (Furuki et Higuchi) R.L.Zhu, Y.L.Xiang & L.Shu comb. nov., *Corsinia brevipedunculata* (Kashyap)R.L.Zhu, Y.L.Xiang & L.Shu, comb. nov., *Corsinia bulbigena* (Bornefeld, O.H.Volk et R.Wolf) R.L.Zhu, Y.L.Xiang & L.Shu, comb. nov., *Corsinia ceylonensis* (Meijer) R.L.Zhu, Y.L.Xiang & L.Shu, comb. nov., *Corsinia fimbriata* (Nees) R.L.Zhu, Y.L.Xiang & L.Shu comb. nov., *Corsinia gollanii (*Steph.) R.L.Zhu, Y.L.Xiang & L.Shu, comb. nov., *Corsinia holstii* (Steph.) R.L.Zhu, Y.L.Xiang & L.Shu, comb. nov., *Corsinia pustulosa* (Mitt.) R.L.Zhu, Y.L.Xiang & L.Shu, comb. nov., *Corsinia tuberifera* (Kashyap) R.L.Zhu, Y.L.Xiang & L.Shu, comb. nov., *Corsinia weddellii* (Mont.) R.L.Zhu, Y.L.Xiang & L.Shu comb. nov., and *Corsinia welwitschii* (Steph.) R.L.Zhu, Y.L.Xiang & L.Shu, comb. nov.

Stable carbon isotope variation in recent and fossil *Liquidambar* leaves as palaeoenvironmental indicator

***Liang Xiao**[1,2], Xiangchuan Li[1,2], Junfeng Guo[1], Nan Sun[1], Xiaoyong Yao[1]*

1. School of Earth Science and Resources, Chang'an University

2. State Key Laboratory of Palaeobiology and Stratigraphy, Nanjing Institute of Geology and Palaeontology, Chinese Academy of Sciences

Quantitative reconstruction of ancient environments and climates has been a major goal for studies in geobiology. Fossil leaves are increasingly used as indicators of palaeoenvironmental parameters such as temperature, atmospherical CO_2 concentration, precipitation. It is demonstrated that the carbon isotope composition of leaf remains can also reveal ecophysiological information on plant's response to past environmental change. In this study, stable isotope compositions of recent *L. formosana* leaves collected in 6 different sites as well as fossil *L. miosinica* leaves sampled from late Miocene Shengxian Formation, Zhejiang Province, China, were obtained. According to variations of stable isotopic discriminations on six recent *L. formosana* leaves with the climates of their living areas, the correlativity between $\Delta^{13}C$ and environmental factors was established. Among all correlativity, three relativities are notable between $\Delta^{13}C$ and annual extremely warmest temperature (EWT), mean annual precipitation (MAP), annual solar radiation hours (SRH). The relativity values are 0.60, 0.75, 0.80, respectively. Thereby, the three regression equations are used to infer palaeoenvironments. The $\Delta^{13}C$ value is measured and then changed as 20.82. When the $\Delta^{13}C$ value is substituted into three regression equations, the EWT, MAP, SRH in the late Miocene, Zhejiang, are counted as 39.2 °C, 1,329 mm, 1,938 hrs, respectively. The ancient SRH is obtained for the first time. Here, the ancient MAP is within the range reconstructed from other methods, such as the coexistence approach (CA), climate analysis of endemic species (CE), which suggests that the palaeoenvironmental results based on $\Delta^{13}C$ of fossil leaves are reliable. In addition, comparing the results to recent environments, it is found that the late Miocene palaeoenvironments of Zhejiang, China are similar to that of the same place. It indicates that the late Miocene climate is warm and moist, which is ascribed into subtropical climate.

P0686

Genetic evidences of Karst-habitat adaptation in genus *Urophysa* (Ranunculaceae): A comprehensive transcriptome analysis

Deng-Feng Xie

Sichuan university

The Karst environment characterized by low soil water content, periodic water deficiency, and poor nutrient availability provides an ideal natural laboratory for studies on adaptive evolution. However, few studies have been conducted on how plants adapt to the Karst habitat. *Urophysa* is a Chinese endemic genus with high degree of Karst-specific distribution, and is hoped to be a new model system to study speciation and ecological adaptation in the special habitat. In this study, we performed transcriptome sequencing of flowers and leaves of *U. henryi* (HF and HL) as well as those of *U. rockii* (RF and RL). A total of 249,191 unigenes were obtained and 54% of which are homologous with sequences in public protein databases (Nr, Swiss-Prot, Pfam-A, GO, and KEGG). The differential gene expression analysis indentified 233 highly expressed genes among *U. rockii* and *U. henryi* transcriptomes, including 97 genes between flowers (HF vs. RF) and 136 genes between leaves (HL vs. RL). After genes annotation, theses differentially expressed genes were enriched in functions involved in photosynthesis, stress response, biological process regulation and metabolism. Our findings indicate that species of *Urophysa* evolved complex strategies for adapting to extreme environments on Karst and provide novel insights into genetic mechanisms of Karst adaptation in plants.

P0687

Floral ontogeny of *Illicium lanceolatum* (Illiciaceae), with emphasis on carpel, ovule and floral apex development

Xin Zhang

College of Forestry, Northwest A&F University

Illiciaceae is a member of the ANITA grade, which has been identified as the most basal among extant angiosperms based on molecular investigations. The family includes a single genus with apocarpous gynoecium, demonstrating various ancestral morphological characteristics especially in terms of carpel, ovule and floral apex. Various aspects of Illiciaceae morphology have been investigated before, however, with the new APG system of flower arising, the details of the carpel, ovule and floral apex of Illiciaceae need to research for understanding of the flower evolution. Here the development of carpels and ovules of *Illicium lanceolatum* were studied using LM and SEM. Based on comparisons with other taxa, the evolutionary implication of a persistent floral apex is an apical meristem residuum of a shoot which is the relic of flowering plants ancestor. The carpel is a leaf like structure that will encircle the ovule and the ovule primordium originates from floral axis in Illiciaceae. The micropyle is formed by both integuments in contrast to previous results and shows the diversity within Illiciaceae can also be used for taxonomic purposes.

P0688

Reconsideration of the carpel in angiosperms

Zhang Xin
Norwest A&F University

Angiosperms distinguish themselves from gymnosperms by their ovules that are enclosed before pollination. However, how the ovules get enclosed in angiosperms remains a mystery, especially for Magnoliaceae. The only key to this mystery is finding a series of carpels transitional from fully closed with enclosed ovules to open with naked ovules.We use routine paraffin section technology, LM, SEM to document the morphology and anatomy of carpel variation in *Michelia figo* (Magnoliaceae). A series of carpel variations within a single flower of *Michelia figo* (Magnoliaceae) are documented, in which the ovules are exposed in atypical carpels. These atypical and typical carpels for the first time demonstrate clearly how the naked ovule get enclosed. Each atypical carpel, with naked ovules subtending foliar part and branches bearing ovules, suggesting that a typical carpel is actually an end-product of the fusion between the ovuliferous branches and subtending foliar parts. The only difference among these carpels is the extent of fusion . This is generalization is in full agreement with the molecular genetic studies on angiosperm flowers. Therefore, the formerly huge gap between angiosperms and gymnosperms appears diminishing.

ITS non-concerted evolution and rampant hybridization in the legume genus *Lespedeza* (Fabaceae)

***Bo Xu*[1], *Xin-Fen Gao*[1], *Li-Bing Zhang*[2]
1. Chengdu Institute of Biology, Chinese Academy of Sciences
2. Missouri Botanical Garden

The internal transcribed spacer (ITS) as one part of nuclear ribosomal DNA is one of the most extensively sequenced molecular markers in plant systematics. The ITS repeats generally exhibit a high level of within-individual homogeneity, though relatively small-scale polymorphism of ITS copies within individuals has often been reported in literature. In this study, we identified large-scale polymorphism of ITS copies within individuals in the legume genus *Lespedeza* (Fabaceae), which suggests incomplete concerted evolution of ITS in *Lespedeza*. Divergent paralogs of ITS sequences, including putative pseudogenes, recombinants, and multiple functional ITS copies were detected in the same individual in our study. Thirty-seven ITS pseudogenes could be easily detected according to nucleotide changes in conserved 5.8S motives, the significantly lower GC contents in at least one of three regions, and the lost ability of 5.8S rDNA sequence to fold into a conserved secondary structure. Two recombinations of ITS are discovered in our putative hybrid species *L. jiangxiensis* and are resolved as basal to the parental lineages, indicating that they may result in the loss of clade resolution in the phylogenetic tree and may obscure the real phylogenetic relationships. Interestingly, the distribution patterns of the putative functional clones were very different between the traditionally recognized two subgenera. Within *L.* subg. *Macrolespedeza*, the ITS clones from most species were mixed together, suggesting low rate of concerted evolution. In contrast, the ITS clones from each species of *L.* subg. *Lespedeza* each formed a monophyletic group or unresolved, implying a higher rate of concerted evolution. This great difference between the resolution patterns of the ITS clones in the two subgenera could be attributed to their different extents/frequencies of hybridization. This inference is further corroborated by the analysis of the single-copy nuclear gene PGK which indicates that rampant hybridization has played a critical role in the evolution of *Lespedeza*, especially in *L.* subg. *Macrolespedeza*. Homogenization of parental polymorphism has been detected in our putative hybrid samples of *L. daurica*/*L. potaninii* and *L. virginica*. Different directions of homogenization are found between *L. daurica*/*L. potaninii* and *L. virginica*. These findings of our study have significant implications in using ITS marker for reconstructing phylogeny and studying hybridization and polyploidy evolution; if not well recognized, ITS data could lead to incorrect tree inference and erroneous estimates of evolutionary relationships.

The symbiotic relationship between *Cypripedium tibeticum* and its specific mycorrhiza Tulasnellaceae along altitudinal gradient

Lingling Xu
Xi'an University

Cypripedium tibeticum, which is an endemic and widespread perennial herb in China, belongs to the family Orchidaceae. *C. tibeticum* forms specific mycorrhizae with Tulasnellaceae. Due to habitat changes and human activities, *C. tibeticum* is threatened with extinction and is listed as national protected plant. In this study, roots of *C. tibeticum* along altitudinal gradient between 3270-3400 m were collected, and two method were used to obtain internal transcribed spacer (ITS) sequences of orchid mycorrhizal fungi. First method, isolated mycorrhizal fungi from the roots of *C. tibeticum*, extracted mycorrhizal DNA fragments and amplified ITS sequences with primer pair ITS5/ITS4. Second method, *C. tibeticum* roots' DNA were extracted and amplified potative orchid mycorrhizal ITS sequences using primer pair ITS1OF/ITS4OF. This primer pair has the advantage that it does not exclude *Tulasnella* species and thus should give an accurate view of orchid associations within the Basidiomycota, representing the vast majority of the mycorrhizae found on orchid species. A threshold of 97% similarity between ITS sequences was applied to circumscribe operational taxonomic units (OTUs) among the mycorrhizal taxa. To identify the different OTUs, representative sequences for each OTU were queried against GenBank by using BLAST. ITS phylogeny of the *C. tibeticum* mycobionts associated with the Tulasnellaceae family were constructed. Correlation analysis were used to reveal the effect of altitudinal gradient on the diversity of orchid mycorrhizal Tulasnellaceae. The result showed that 433 strains were isolated from roots of *C. tibeticum*, of which 107 (106 Tulasnellaceae and one Ceratobasidiaceae) strains were assigned to putatively orchid mycorrhizal OTUs. The 743 high-quality orchid mycorrhizal ITS sequences were obtained straight from roots' DNA of *C. tibeticum*, including 742 Tulasnellacea and one Sebacinaceae. Fifteen different OTUs were distinguished. Only 2 OTUs were shared between orchid mycorrhizal strain-isolating and straight amplifying ITS sequences method. Three OTUs of Tulasnellaceae were observed to show significant patterns of occurrence in relation to altitude. This research will elucidate the symbiotic relationship between *C. tibeticum* and the Tulasnellaceae at altitudinal gradient, and provide theory evidence for resource protection, propagation and sustainable utilization of *C. tibeticum*.

Genome-wide convergence during evolution of mangroves from woody plants

Shaohua Xu[1], *Ziwen He*[1], *Zixiao Guo*[1], *Zhang Zhang*[1], *Gerald Wyckoff*[2], *Anthony Greenberg*[3], *Chung-I Wu*[1,4], *Suhua Shi*[1]
1. Sun Yat-sen University
2. University of Missouri-Kansas City
3. Bayesic Research
4. University of Chicago

When living organisms independently invade a new environment, the evolution of similar phenotypic traits is often observed. An interesting but contentious issue is whether the underlying molecular biology also converges in the new habitat. Independent invasions of tropical intertidal zones by woody plants, collectively referred to as mangrove trees, represent some dramatic examples. The high salinity, hypoxia and other stressors in the new habitat might have affected both genomic features and protein structures. Here, we developed a new method for detecting Convergence at Conservative Sites (CCS) and applied it to the genomic sequences of mangroves. In simulations, the CCS method drastically reduces random convergence at rapidly evolving sites as well as falsely-inferred convergence caused by the mis-inferences of the ancestral character. In mangrove genomes, we estimated ~400 genes that have experienced convergence over the background level of convergence in the non-mangrove relatives. The convergent genes are enriched in pathways related to stress response and embryo development, which could be important for mangroves' adaptation to the new habitat.

Genetic variation and population structure of 'Zangli' pear landraces in Tibet revealed by SSR markers

Lei Xue, *Jun Wu*
Nanjing Agricultural University

Pear (*Pyrus* L.) is one of the most important fruits in temperate regions. Even in the mountainous border region of Tibet, Sichuan, and Yunnan provinces (China), a variety of highly adapted pear landraces were discovered in Tibetan Autonomous Prefecture and were named 'Zangli pears'. Here, we analyzed genetic diversity of 29 genotypes of Zangli distributed in Tibetan region, together with 30 genotypes of sand pear (*P. pyrifolia*) in border regions, and 8 genotypes of *P. ussuriensis* as out groups, using simple sequence repeats (SSR) markers. Twenty-eight SSR markers displayed high polymorphism with a total of 202 alleles. Cluster analysis revealed a close genetic relationship between Zangli and sand pears, while population structure analysis revealed that gene flow between the western and eastern side of the Jin-sha River was restricted by geographic isolation. Diversity statistics for five geographic groups implied a migration event from Sichuan and Yunnan provinces to the border region of western Sichuan, eastern Tibet, and northwestern Yunnan provinces. Six specific genetic alleles in Zangli pear landraces might be related to their adaption to severe environmental conditions.

5. Chiba University

Sea dispersal plants like mangrove plants produce specifically adapted diaspores (mainly seeds and fruits) to sea dispersal and can disperse them over the vast distance by ocean currents. As sea dispersal is often effective for long distance dispersal, many of the sea dispersal plants have extremely wide distribution range in tropics and subtropics worldwide. Distinct spatial genetic structures are common in many mangrove species across apparent geographic barriers (for example, *Bruguiera gymnorhiza* across Malay Peninsula and *Rhizophora mangle* across Central Panama Isthmus), and they are explained in the context of vicariance caused by land barriers that prevented migration of seeds by sea dispersal. However, some recent works on mangroves using genetic markers also reported clear genetic structure within oceanic regions where no apparent geographic barriers exist, which may imply the presence of "Cryptic Barriers". Although these genetic structures may promise to provide new insight into historical biogeography of mangroves, detail studies have not been well performed yet. In this study, we employed a widespread sea dispersal legume *Vigna marina* (Burm.) Merr. as a model species to test the

"Cryptic Barrier" hypothesis in the Pacific. This species distributes in IWP region and has wider distribution range than all other IWP mangroves. We conducted wide-scale phylogeographic analysis to understand detail patterns of population genetic structure using both cpDNA and nuclear microsatellite (SSR) markers for more than 300 individuals collected from 16 countries. Moreover, we employed Approximate Bayesian Computation (ABC) based approaches to infer past demographic history that formed the contemporary genetic structure in the focal region. *CpDNA* sequences showed high levels of genetic diversity and clear population genetic structure within the distribution range. We recognized clear genetic structure divided into three groups; North Pacific (NP), South Pacific (SP) and Indian Ocean (IO), strongly differentiated each other (F'CT=0.954 to 1.000). Although the genetic structure was less distinct for nuclear microsatellite, regional tendency of genetic diversity was similar to the one for cpDNA. These results supported the presence of the "Cryptic Barrier" within the Pacific Ocean. Additionally, ABC analysis estimated the divergence time between NP and SP at last glacial maximum (LGM), which indicates a strong influence of past climatic events on the population genetic structure of sea dispersal species including mangroves. These finding may provide new insight into biogeography and conservation of coastal plants including mangroves.

P0694

Allopolyploid origin in *Rubus* (Rosaceae): Evidence from nuclear Granule-Bound Starch Synthase (*GBSS*I) sequences

Yan Wang[1,2], *Tao Chen*[1,2], *Jing Zhang*[1,2], *Qing Chen*[1], *Bo Sun*[1], *Haoru Tang*[1,2], *Xiaorong Wang**[1,2]

1. College of Horticulture, Sichuan Agricultural University

2. Institute of Pomology and Olericulture, Sichuan Agricultural University

Rubus L. is a large and taxonomically complex genus exhibiting apomixis, polyploidy and frequent hybridization. Most of Chinese *Rubus* are mainly concentrated in two major sections, *Idaeobatus* and *Malachobatus*. Our previous phylogenetics suggested that polyploid sect. *Malachobatus* probably originate from common ancestors, via polyploidization of hybrids between *R. pentagonus* ($2n = 2x = 14$) of sect. *Idaeobatus* and sect. *Cylactis* species. To confirm this hypothesis, we investigate the copy number and subparalog structure of *GBSS*I-1 gene within *Rubus* at different ploidy levels. For diploids, we found *GBSS*I-1α existed in species of subsections *Thyrsidaei*, *Idaeanthi*, *Pileati*, *Stimulantes*, *Pungentes*, and *Wushanenses*, while *GBSS*I-1β existed in sects. *Rosaefolii*, *Leucanthi*, and *Corchorifolii*, respectively. Both *GBSS*I-1α and *GBSS*I-1β were identified in diploid *R. pentagonus* and *R. peltatus*, as well as in majority of *Malachobatus* polyploids. *GBSS*I-1α has a longer intron 4 than that of *GBSS*I-1β. We further constructed the phylogenetic tree and phylogenetic network based on multiple *GBSS*I-1 copies. Based on these results, we confirmed that these sect. *Malachobatus* polyploids are allopolyploidy origin. They had experienced adaptive radiation, resulting species explosion in a short time. In addition, it was evidenced that *R. pentagonus* plays an important role in the speciation from diploids to polyploids in *Rubus*.

P0695

Structural and developmental features of secretory canals in secondary xylem of *Sindora glabra* trunk

Jinchang Yang

Research Institute of Tropical Forestry, Chinese Academy of Forestry

Popularly known as diesel tree in China, *Sindora glabra*, a tropical species of Leguminosae, subfamily Caesalpinioideae, is characterized by the exudation of yellowish oleoresin or amber oil when wounded in the trunk, having a good prospect on producing essential oil, medicine and cosmetics. Despite the multipurpose use of this species, the knowledge on the oleoresin producing mechanism remains inadequate and the information on anatomical feature is very limited. The aim of this study was to describe structural and developmental features of secretory spaces present in the trunk of S. *glabra*, based on the usual techniques of wood anatomy. Three naturally distributed plants with the diameter of 28.6-32.7 cm were selected to study the origin, development and structural features of secretory canals in secondary xylem of *S.glabra* trunk, and variation of density, diameter, ratio of thin-walled and thick-walled epithelial cells in radial direction were analyzed. Only axial secretary canals were observed in the secondary xylem in the trunk, distributed along the marginal parenchyma bands which delimited growth layers and arranged in a tangential direction. They originated in the cambial zone from the initial parenchyma cells derived from fusiform initials or ray initials. The secretory canals were formed by schizolysigenesis and the process of development could be divided into five stages, namely initial, formative, expanding, mature and senescent stage. At the initial stage, 4-8 initials were arranged in a radial direction and had dense cytoplasm and clear visible nucleus. At the formative stage, the canal space appeared after the middle lamella of central cell walls degraded and the initials separated. At the expanding stage, the secretory lumen can be enlarged by the tangential extension and the anticlinal and periclinal division of the living epithelial cells. At the mature stage, secretory canals were constituted by a locally biseriate epithelium, lumen and sheath cells, and had 7-19 epithelial cells, measured 44.55 to 167.07 μm in tangential diameter; the epithelium composed of two-thirds of thin-walled cells and one-third of thick-walled cells. At the senescent stage, partial epithelial cells degraded in their walls, some cells filled with gum in their cavities, or expanded to form the tylosoids by blocking secretory lumen. Within the secondary xylem, the density of secretory canals increased from the close cambium towards the near pith in general, but the tangential diameter of secretory canals and the ratio of thin-walled cells showed the opposite trend. The average diameter and density of secretory canals were 58.83 μm and 6.73 per mm respectively, and the proportion of thin-walled epithelial cells at all developmental stages was above 50%. The initiation of secondary secretory canals and the fusion between two adjacent canals in the trunk resulted from the separation of the initial cells and the adjacent radial cells. The formation and development of secretory canals in secondary xylem gave an important hint to probe the mechanism of oleoresin secretion in the trunk of *S. glabra*, and the high percentage of epithelial cells with thin and unlignified walls might be of value in terms of sustainable exudation of the oleoresin.

P0696
Origin and evolution of *Rubus takesimensis* (Rosaceae) in Ulleung Island, Korea

Jiyoung Yang[1], *Woong Lee*[1], *Jae-Hong Pak*[1], *Seung-Chul Kim*[2]
1. Research Institute for Ulleung-do & Dok-do, Kyungpook National University, 80 Daehak-ro, Bukgu, Daegu, 41566, Korea
2. Department of Biological Sciences, Sungkyunkwan University, 2066 Seobu-ro, Suwon, Gyeonggi-do 16419, Korea

On Ulleung Island, Korea, about 88% or even all endemic species (nearly 40) are considered to be anagenetically derived. However, we are still far from fully understanding the genetic consequences and anagenetic speciation in diverse endemic lineages of vascular plants on Ulleung Island. The family Rosaceae includes the most number of endemic species (i.e., *Cotoneaster wilsonii*, *Potentilla dickinsii* var. *glabrata*, *Prunus takesimensis*, *Rubus takesimensis*, and *Spiraea insularis*), yet the genetic consequences of them rarely exist, hampering generalization of anagenetic speciation in endemic species rich lineage. In this study, we have chosen one of endemic species *Rubus takesimensis* and compared pattern of genetic diversity and population structure with its continental progenitor species *R. crataegifolius*. We extensively sampled the progenitor-derivative pairs, *R. crataegifolius* (212 accessions from 42 populations in Korea, Japan, Russia and China) and *R. takesimensis* (113 accessions from 15 populations) and sequenced five noncoding regions of chloroplast DNA. We found that island endemic *R. takesimensis* was not formed monophyletic taxa and was deeply embedded within the continental progenitor *R. crataegifolius*, making it paraphyletic. In addition, several geographically diverse continental populations were responsible for the origin of *R. takesimensis*; majority of *R. takesimensis* accessions were sister to the clade containing accessions of *R. crataegifolius* primarily from the Korean peninsula, while rare accessions from Dodong, Jeodong and Seok-po shared their common ancestor with the ones from southern part of Korean peninsula, Jeju Island and Japan. There was also an evidence for few accessions from Chusan population originated seperately from the Korean peninsula. Of 129 haplotypes, we found 81 and 48 haplotypes in *R. crataegifolius* and *R. takesimensis*. There were no haplotype sharing between two species and most of haplotype were in low frequency. Higher haplotype diversity found in Korean peninsula populations than Japanese populations. Also, Chusan region that have been observed as bird habitat and Dodong and Jeodong region are located in near a port for passenger ships showed high genetic diversity. The AMOVA results showed very little genetic differentiation between the progenitor-derivative pairs and substantial genetic differentiation among populations in insular endemic *R. takesimensis*. Also, reduction of haplotype diversity found in *R. takesimensis*. Therefore, genetic consequences of *R. takesimensis* showed unusual case of anagenetic speciation that was expected patterns.

A new genus of *Paralysimachia* F. Du, S. Yang & J. Wang gen. nov. and it's new species of *Paralysimachia xueshanensis*, *Primulaceae* in Yunnan Province, China

Fan Du, *Shaoyong Yang*, *Juan Wang*
Southwest Forestry University

A new genus *Paralysimachia* of *Primulaceae* has been identified in Yunnan Province, China. This is the first time to identify a new genus without corolla, most similar to genus *Lysimachia.* The new species of *Paralysimachia xueshanensis* are distributing at the alpine meadow steppe at the alt. of 3,390~3,420 m, on the top of the Big Snow Mountain of Bangdong county in Lincang city, within a habitat of 200-300 square meters area, it's anatomy and taxonomy has been described and illustrated. The differences between *Paralysimachia* and *Lysimachia have been compared and studied.* The rich plant species in Yunnan Province has produced many new species, and the isolated geographical ecology is the important factor to originate new species and genus, such as the new genus *Paralysimachia*, the new species *Paralysimachia xueshanensis* is distributing in a habitat of 200-300 square meters area.

P0698
Genetic diversity and phylogeography of *Gymnocarpos przewalskii* (Caryophyllaceae) based on EST-SSR makers

Zhao-Ping Yang[1,2], *Ma Qing*[1], *Pan Li*[1], *Cheng-Xin Fu*[1]
1. Key Laboratory of Conservation Biology for Endangered Wildlife of the Ministry of Education, College of Life Sciences, Zhejiang University, Hangzhou
2. College of Life Science, Tarim University, Alaer

The genus *Gymnocarpos* (Caryophyllaceae) contains only ten species, ranging across arid and semi-arid regions of Africa and Asia, with the Southern Arabian Peninsula as the estimated ancestral area. *G. przewalskii* Maxim. is an endangered shrub species which is endemic to Northwest China. Due to lack of efficient molecular markers, the genetic diversity and historical demography of this endemic species is poorly understood. In this study, we performed high-throughput transcriptome sequencing of *G. Przewalskii* leaves using the Illumina HiSeqTM 2000 sequencing platform, and generated large transcript sequences for functional characterization and development of gene-associated SSR markers. A total of 92,039 unigenes (mean length 1057 bp) were assembled from about 113.5million reads, and 40,971 (44.51%) of them showed similarity to public databases. From the 92,039 unigenes, 11,752 expressed sequence tag–simple sequence repeats (EST-SSRs) were identified. Mono-nucleotide SSRs were the most abundant motif (46.3%), followed by tri- (29.7%) and di-nucleotide (19.1%) repeats. From the 11,752 EST-SSRs, 3611 primer pairs were designed for marker mining. Among them, 65 pairs were selected randomly for further validation, and twelve of which were identified as polymorphic SSR loci. Then, these twelve EST-SSR markers were applied to study the phylogeography of *G. przewalskii.* We sampled in total 353 individuals of *G. Przewalskii* from 24 populations, which covers the whole range of its distribution in China. The sampling sites were scattrd across the Tarim Basin (eight), the Hami Basin (seven), the Hexi Corridor (seven), Zhongwei (one) and the Urad Rear Banner (one). Nine to fifteen individuals were sampled for each population. Across the twelve

EST-SSR markers surveyed, the range was 2.3–8.4 for mean number of alleles (NA), 2.814–4.203 for mean allelic richness (RS), 0.430–0.612 for mean expected heterozygosity (HE) and 0.428–0.616 for genetic diversity (GD) of 24 populations. These diversity estimates were highest in Yumen of Ganshu and lowest in Luntai of Xinjiang. A Bayesian clustering analysis suggested that the populations of *G. przewalskii* were divided into two genetic clusters, the western and eastern lineages. The former contains all the populations from Tarim basin, and the latter contains the other populations. This is largely congruent with the previous findings revealed by cpDNA sequences. 78.38% of the variations found within populations, whereas, 8.83% are found among populations within linaeages, and only 12.29% are found between lineages. It is likely due to short divergence time of the lineage and long lifespan of shrub species. As a result, the EST-SSR markers developed in our research will be an informative resource for future studies on ecological, evolutionary, and conservation gentics of *G. Przewalskii,* as well as other relatd taxa. It will also help us to improve our understanding of the microevolutionary processes of this endangered species.

Phylogeny and chromosomal evolution of the *Schoenus apogon* complex (Cyperaceae): Evidence for multiple polyploidization

Okihito Yano[1], *Yu Ito*[2], *Hiroshi Ikeda*[3], *Norio Tanaka*[4], *Jeremy Bruhl*[5], *Karen Wilson*[6]
1. Okayama University of Science
2. Xishuangbanna Tropical Botanical Garden
3. The University of Tokyo
4. National Museum of Nature and Science
5. University of New England
6. National Herbarium of New South Wales

A previous phylogenetic study of the genus *Schoenus* (Cyperaceae) discerned a species complex centred on *S. apogon*, comprising five species distributed in Australia, Japan, and New Zealand. Chromosome variations, 2n=8 from New Zealand and 2n=18 from Western Japan, has been observed in the complex, but its correlation with phylogeny has yet to be explored. Here we apply a molecular phylogenetic approach to explore whether and how polyploidy characterizes evolutionary lineages. Our taxon sampling covers three of the five species (*S. apogon*, *S. caespitans*, and *S. yarrabensis*) in the complex from the three biogeographic regions. Our chromosome observations using the sample set confirms and complements both aneuploidy and polyploidy (2n=8 from Australia, Japan (East), New Zealand; 2n=10 from Australia; 2n=16-18 from Japan (West); 2n=20 from Australia). Our analyses of chloroplast (*rbc*L and *trn*L-F) and nuclear (ITS) DNA data sets produced mostly congruent results, in which the 2n=10 cytotype was consistently placed sister to all the rest with strong support. The 2n=16-18 cytotypes from Western Japan and an unknown cytotype from Australia formed a monophyletic clade with moderate support. The morphology of the 2n=16-18 lineage matches that of *S. yarrabensis*. The 2n=20 cytotype from Australia is distantly related to the 2n=16-18 cytotypes in Western Japan, indicating multiple origins of polyploidization, for which different lineages of 2n=8 cytotypes have been involved.

The making of elaborate petals through evolutionary innovation and developmental repatterning

Xu Yao[1,2], *Wengen Zhang*[1,2], *Xiaoshan Duan*[1,2], *Rui Zhang*[1], *Hongyan Shan*[1], *Hongzhi Kong*[1]
1. State Key Laboratory of Systematic and Evolutionary Botany, CAS Center for Excellence in Molecular Plant Sciences, Institute of Botany, Chinese Academy of Sciences
2. University of Chinese Academy of Sciences

As a special type of floral organ, petals show tremendous diversity in shape, structure, color/coloration, and function, and have increasingly been used as a model for studying plant organogenesis and evolution. Petals of *Nigella* (Ranunculaceae) species are of particular interest because they are highly elaborate, bilabiate structures with extensive modifications. To understand how *Nigella* petals become elaborated and diversified, we investigated the morphology, micro-morphology and development of petals in seven representative species (i.e., *N. integrifolia*, *N. nigellastrum*, *N. orientalis*, *N. damascena*, *N. sativa*, *N. hispanica*, and *N. arvensis*). We found that the degree of petal complexity increased gradually during evolution, involving both modification of existing characters (e.g., the elongation of stalk and the alteration of the upper and lower lips in shape) and *de novo* origination of new features (e.g., pseudonectaries, short trichomes, and conical cells). By investigating and comparing the processes of petal morphogenesis in these species, we also demonstrated the duration of important developmental events that led to the diversification of mature petals in gross morphology and micro-morphology. We found that developmental repatterning has played key roles in generating petal complexities during evolution.

P0701

Discrepancy between chloroplast and multiple nuclear sequences signify multiple refugia in *Lindera aggregata* (Lauraceae) in Subtropical China

Jun-Wei Ye
Natural History Research Center of Shanghai Natural History Museum, Shanghai Science & Technology Museum, China

Subtropical evergreen broad-leaved forest (EBLF) is one of the most important vegetation types in East Asia. Palaeo-biome reconstruction (PBR) and predominant phylogeography studies were controversial on range shift history of the EBLF during Last Glacial Maximum (LGM). Recently, few studies on relatively lower altitude distributed plants (ca. < 1,500 m) using a combination of chloroplast DNA (cpDNA) and ecological niche modeling (ENM) show consistent pattern with the PBR. However, maternal inherited marker only is partial in exploring the evolutionary history. Thus, in this study, *Lindera aggregata*, a widespread low altitude distributed (200 - 1,000 m) dominant plant was selected, cpDNA is combined with multiple nuclear sequences to investigate whether it conform to contraction-expansion pattern or not. Nine haplotypes were identified in 131 individuals from 18 populations using four cpDNA fragments. The most recent common ancestor (MRCA) of all haplotypes was around the Pliocene-Pleistocene boundary estimated by second calibrations with four calibration points. No significant phylogeography structure ($N_{ST} = 0.860$, $G_{ST} = 0.833$, $P > 0.05$), widespread haplotype H3 at northern 24°N and star-like network suggest possible postglacial expansion. While, the signal were not detected by mismatch analysis and neutrality test. Private haplotype in Wuyi Mt. may be a result of *in situ* glacial persistence. Meanwhile, three distinct clusters were derived through Bayesian clustering using haplotype of 14 nuclear sequences genotyped by self-developed primers. South cluster located mainly at southern 24°N, two clusters at northern 24°N were roughly located at east (central cluster) and west (north cluster) side of Luoxiao Mt. *BEAST show two northern clusters have a common ancestor, this ancestral population and south cluster have a common ancestor. Central and north clusters, all three clusters were respectively diverged at 0.55 Ma and 0.76 Ma estimated by isolation by migration (IMa). Low migrations among the three clusters indicate long-term isolation. The Extended Bayesian Skyline Plot (EBSP) suggest both central and north cluster experience gradually expansion since 0.1 Ma. Thus, Despite possible northward postglacial expansion indicated by cpDNA, *L. aggregata* populations have multiple refugia and even experienced localized expansion at LGM (ca. 0.02 Ma). ENM of different models also show different patterns. Potential habitat predicted by Model for Interdisciplinary Research on Climate (MIROC) was almost the same as the present, while Community Climate System Model, version 4 (CCSM4) predict contraction to western Nanling Mt. and Wuling Mt. in central China in LGM. Consequently, low altitude distributed plants may also conform to multiple refugia pattern. More informative nuclear genome must be included in future study on controversy of range shift history of the EBLF.

Gaolejeunea, a new genus of subtribe Echinolejeuneinae (Lejeuneaceae, Marchantiophyta) from China

Wen Ye[1], *Rui-Liang Zhu*[2]
1. South China Botanical Garden
2. East China Normal University

Over the past few decades, *Cheilolejeunea gaoi* has always been a peculiar member of Chinses Lejeuneaceae. A narrowly endemic species known only from the type locality in Shangsi Co., Guangxi, it has previously been treated as a species of *Cheilolejeunea*. However, the presence of Allorgella-type denticulations that formed by two adjacent cells on leaf and underleaf margins, the small, ovate leaf lobules without distinct teeth, the ental hyaline papilla, and the finely segmented oil bodies, all suggest somewhere else. Maximum likelihood, maximum parsimony, and Bayesian analyses of a three marker dataset (nrITS, cpDNA *rbc*L and *trn*L-*trn*F) derived from 85 accessions of Lejeuneeae and 15 outgroup species revealed *C. gaoi* belongs to Echinolejeuneinae. Based on the results of phylogenetic analyses, with combination of morphological data, we suggest here that *C. gaoi* should be established as a new genus, *Gaolejeunea*.

Diversification of alpine bamboos since the late Miocene

Xiaying Ye[1,2], *Guoqian Yang*[1,2], *Pengfei Ma*[1], *Dezhu Li*[1]
1. Germplasm Bank of Wild Species, Kunming Institute of Botany, Chinese Academy of Sciences
2. University of Chinese Academy of Sciences

Fargesia and *Yushania* (alpine bamboos), two genera of Arundinarieae which mainly distributed at high elevation of the Hengduan Mt, are the major dominant species of the cloud forest and have ecological importance. However, due to the extremely low level of sequence divergence in plastid genome and low-copy nuclear regions, as well as less sampling, the relationship between species of this group have been proven difficult to elucidate. Here, we adopted ddRAD-seq method, which is a powerful tool for non-model organisms to compare interspecific relationship, to illustrate the phylogenetic relationship for alpine bamboos with widely sampling. We also clarified the cause of complex phylogeny of alpine bamboos, dated the divergence time of major clades for Arundinarieae, particularly the alpine lineages, and explored the correlation between geological events and the diversification of alpine bamboos. Both concatenation (maximum-likelihood) and coalescent (SVDquartets) methods reconstructed a robust topology for alpine bamboos, treated *Yushania* as a monophyletic lineage and *Fargesia* as polyphyletic groups. In this phylogeny, we total received eleven clades and six were new established in our study. The new clades were named after the lineages of plastid topology, including V-Y clade comprising of the *Yushania* genus, four parallel clades V-F1, V-F2, V-F3 and V-F4 which separated from *Fargesia*, and alpine *Bashania* clade (V-S). For *Yushania*, interspecific relationship was basically solved, species with numerous branches per node and high culm grouped at the basal, which is identical to the section division of traditional classification. *Y. crispata*, *Y. violascens*, *Y. puberula* formed a strong support clade and sister to the remainder of *Yushania*. The phylogenetic relationship within and between four clades of *Fargesia* all exhibited substantial bootstrap support, and the distributions for four parallel clades have a trend from low elevation to high elevation in the Hengduan Mt, but no correlation to the traditional classification. According to network and genetic clustering analyses, gene exchange was happened frequent at the initial divergence of alpine bamboos and its relatives, especially between V-F3 clade and the basal group of *Yushania* which had minor difference when altered reconstruction methods. Meantime, alpine bamboos is a recent origin group, its stem age was dated to the late Miocene, c. 7.18 Ma, and experienced a rapid divergence. The crown age of four clades of *Fargesia* – V-F1, V-F2, V-F3 and V-F4 – was 4.01 Ma, 2.8 Ma, 2.63 Ma and 2.73 Ma, respectively. *Yushania* separated from *Fargesia* at 3.31 Ma and diverged into the species-rich subclades in the Pliocene (3.13-0.89 Ma). Owning to recent origin, insufficient information accumulation and gene exchange may be responsible for the intricate phylogenetic relationship of alpine bamboos. Additionally, diversification analyses demonstrated two speciation rate shifts happened along the branch, one shift occurred about 7-8 Ma when the alpine bamboos just origin initially, another one happened at 2-4 Ma which was coincident with the time of alpine bamboos spreading into higher mountains. All the two shift events are related to the putative uplift phase of the Hengduan Mt and indicate mountain uplift trigger the diversification of the alpine bamboos.

An owerview of the genus *Nonea* in Turkey

Yeter Yeşil
Istanbul University

The genus *Nonea* Medik. (Boraginaceae tribe Boragineae Bercht. & J. Presl) includes about 36 taxa. The distribution of the genus ranges from central Asia to the Iberian Peninsula and Morocco. Its main centre of diversity stretches from the Pontic Caucasian mountain system to the Anatolian and Irano-Turanian highlands, while fewer species occur in Europe and in the Mediterranean, especially along the North African coast (Selvi & Bigazzi, 2002; Selvi *et al.,* 2006). Turkey is the richest country, with approximately 23 species representing more than 60% of the whole genus Baytop 1978; Selvi & Bigazzi, 1999; 2001; 2002; Bigazzi *et al.*, 2004; Bilgili *et al.*, 2012; K.rüklü, 2012. In this study morpholgy of Turkish *Nonea* species were examined using light and scanning electron microscopy. The most important characteristics of *Nonea* species such as nutlet shapes and surfaces, and corolla colour and shapes were investigated. Nutlet shapes are reniform and transversely reniform, obliquely erect or transversely ovoid; corolla colour white, yellow, pink, orange-red to violet or dark purple or variegated; corolla shapes are actinomorphic, zigomorphic, infundibular or irregularly infundibular. An identification key is provided according to morphology, especially nutlet and flower characteristics to better evaluate the similarities and relationships between taxa.

An investigation on seed micromorphology of some *Aethionema* R.Br. species (Brassicaceae) grown in Turkey by Scanning Elektron Microscope

Gulden Yilmaz[1], *Mehmet Tekin*[2]
1. Trakya University, Faculty of Science, Department of Biology
2. Cumhuriyet University, Faculty of Pharmacy, Depaertment of Pharmaceutical Botany

Aethionema R.Br. (Brassicaceae) is a taxonomically complex genus and a few macromorphological characters are available for species delimitation. The Turkish flora comprises of about 41 *Aethionema* R.Br. species, of which 20 species are endemic to Turkey. The aims of the present study are to illustrate the utility of derivated seed morphology features in the identification of most of the species considered, and to relate such characters to the systematics of the genus. So, testa micromorphology of *Aethionema membranaceum* (Desv.) DC., *Aethionema schistosum* Boiss. & Kotschy and *Aethionema oppositifolium* (Pers.) Hedge grown around Middle Anatolia in Turkey were given for the first time with this study. Seeds were examined under Zeiss ESEM and SEM micrographs were taken. The results were compared with those from previous studies of different species of the same genus. Micromorphological characters may provide additional taxonomic information in the genus. The importance of ultrastructure of seed surface, as a reliable approach for solving taxonomic problems has been well recognised.

Plastid genomes revealed three lineages of *Ginkgo biloba* diverged in the Mid- to Late-Pleistocene

Wen-Bin Zhou[1], *Ping-Ping Yin*[1], *Chun-Xiang Xie*[1], ***Yun-Peng Zhao***[1], *Marcus Koch*[2], *Cheng-Xin Fu*[1]
1. The Key Laboratory of Conservation Biology for Endangered Wildlife of the Ministry of Education, College of Life Sciences, Zhejiang University
2. Department of Biodiversity and Plant Systematics, Centre for Organismal Studies, University of Heidelberg

Two refugia of *Ginkgo biloba* in China were confirmed by our previous phylogeographic studies using AFLP, nuclear microsatellites and three cpDNA fragments. However, the phylogenetic relationship between the common haplotype occurring across its range and the rest ones, as well as the timing of their divergence, was not resolved due to insufficient informative loci. In the present research, we addressed these two questions using plastid genome data of ten representative cpDNA haplotypes of *G. biloba*. The phylogeny recovered three strongly-supported clades, the widespread haplotype clade (H1 clade), east-specific haplotype clade (E clade) and west-specific haplotype clade (W clade), of which the latter two are sisters. Timing inference in a context of gymnosperm phylogeny with ten fossil calibrations suggested the H1 clade initially diverged at 0.603 mya (95% HPD: 0.043~0.809 mya), followed by the divergence between E and W clades at 0.286 mya (95% HPD: 0.016~0.752 mya). Our results provide a well-estimated temporal hypothesis to be tested using co-occurring species inhabiting warm temperate forests in eastern Asia, and emphasizing the importance of both application of plastid genome data and fully-resolved phylogeny of all recovered genetic lineages to timing estimation.

Topography and climate explain bias of plant diversity in the genera disjunctly distributed in eastern Asia and eastern North America

Xue Yin
Sun Yat-sen University

Disjunct distributions of the same plant clades (e.g. genera) and biogeographic bias in different continents are critical to understand the ecological relationship between plants and environment such as topography and climate. A long-recognized biogeographic mystery is the disjunct plant genera between eastern Asia (EAS) and eastern North America (ENA), first observed by Carl Linnaeus and has puzzled generations of botanists. Although it has been argued that differences in physiography and climate between the two regions are the primary causes of bias in species diversity in these disjunct genera, this hypothesis has not been tested. We compiled data of topography, contemporary and historical climate to quantitatively assess contributions of these factors to the Asian bias of EAS-ENA disjunct plant diversity. We showed that contemporary climate explained 25% of the spatial variation in diversity of the EAS-ENA disjunct genera, 4% more than the variation explained by topography (21%). In contrast, on the species level, topography explained 21% of the variation in species richness while climate only explained 8%. Historical climate (Last Glacial Maximum climate) was highly correlated with current climate and showed no significant effects on diversity at both genus and species levels. We further found that topography accounted for about 29% of the variation in species richness in topographically more heterogeneous EAS but only 5% of that in ENA. We concluded the diversity patterns of EAS-ENA disjunct genera, to a large extent, could be a product of topographic heterogeneity and contemporary climate, although the importance of each factor depends on taxonomic level and region.

The contribution of Neogene plateau uplift and Quaternary climate fluctuations to endemic plant diversity of the Tibetan Plateau

Haibin Yu
Sun Yat-sen University

Aim To test the effects of Neogene plateau uplift and Quaternary climate oscillations on the formation of extant species and phylogenetic diversity. Location Tibetan Plateau (TP). Methods We collated data on endemic species distributions based on county-level mapping from several monographs and online databases. We calculated both species richness and phylogenetic diversity for all species, herbs, shrubs and trees from these data for a 0.5 × 0.5-degree grid covering the TP. We posed eight biogeographic hypotheses associated with plateau uplift or climate fluctuations and quantified. We used partial regression analysis and mixed conditional autoregression (CAR) model to assess the relative contribution of each hypothesis to species diversity. Results Endemic species diversity is concentrated in the southeast part of the plateau and declined from the southeast to northwest. Hypotheses based on plateau uplift independently explained three-times more variance in diversity than Quaternary climate changes. The full CAR model containing all hypotheses explained 35 – 75% of the total variation in diversity, while each predictor explained at least 5% on average, and the montane museum hypothesis explained the most variation averaged across diversity measures and life forms (17%). Main conclusions Extant endemic seed plants diversity is concentrated in the Hengduan and East Himalayan mountains. Both the Neogene TP uplift and Quaternary climate fluctuations had large impacts on current patterns of species diversity, but the influence of plateau uplift seemed to be more important than climate changes. Our study provides insights for explaining the diversity patterns of alpine species and has implications for the conservation of montane species under the context of future climate changes.

Evidence for the involvement of *TEOSINTE BRANCHED1*-Like Genes in the asymmetric floral development of *Canna indica* L.

Qianxia Yu[1,2], *Xueyi Tian*[1,2], *Jingping Liao*[1]
1. South China Botanical Garden
2. University of Chinese Academy of Sciences

Asymmetric flower which lacks any symmetry plane is rare across angiosperm. *Canna indica* (Cannaceae, Zingiberales) has conspicuously asymmetric flowers. In its flower, all the whorls contribute to the floral irregularity, especially the irregular androecial petaloidy which makes the flower more elaborate. In the androecium, a single half of the stamen primordium develops to the fertile anther, while the rest abort or develop to petaloid structures. The *CYCLOIDEA*/*TEOSINTE BRANCHED1* (*CYC*/*TB1*)-Like genes have long been identified as the main factor to control floral symmetry in numerous lineages. They have functions both in aborting stamen and promoting petal growth. In order to test their possible roles in regulating floral symmetry in this species, we analysed the spatio-temporal expression patterns of them. We identified three homologs of *TB1*-Like (*TBL*) genes and named them *CiTBL-1a*, *CiTBL-1b* and *CiTBL-2* according to phylogenetic analysis. RNA *in situ* hybridization analysis showes that *CiTBL-1a* and *CiTBL-1b* have identical expression patterns. In the young inflorescence, both *CiTBL-1*s are expressed in the bracts, the bottom of the floral primordia and the cincinnus primordia. While in the developing flower, their expressions are restricted to the outer two wholes--sepals and petals. In contrast, *CiTBL-2* transcripts are mainly found in the floral primordia and the inflorescence primordia. During floral development, the expression become stronger in the androecium and gynoecium. The expression regions of *CiTBL-2* are exactly complementary to those of *CiTBL-1*s. The expression data indicates that compared with *CiTBL-1*s, *CiTBL-2* possibly plays a more important role in the floral development of *C. indica*. In addition, we have observed that the flower is bilateral symmetric before the differentiation of the petal-stamen common primordia, and the axis of symmetry just passes through the second floral primordia of the cincinnus. This phenomenon indicates that the inflorescence architecture may have impact on the floral symmetry of *C. indica*. However, the expression patterns of *CiTBL*s almost remain unchanged during the process of symmetry shift from bilateral symmetry to asymmetry. Further explorations of their function are needed to explain the irregular floral patterning and origin of androecial petaloidy.

Diversity and ecology of bryophytes in the headwaters region of Urumqi River, Xinjiang, China

Jia-Xing Guo, Wei Sheng, ***Yu-Huan Wu***
Hangzhou Normal University

The headwaters of the Urumqi River is located in the central Tianshan Mountains of Xinjiang, and the elevations of the glacier terminuses are 3,650-3,700 m. Based on the field investigation and specimen collection, 148 species in 70 genera and 32 families of bryophytes are reported. Among them, *Bryum stirtonii* Schimp. and *Jungermannia japonica* Amak. are new to China.*Platydictya subtilis* (Hedw.) Crum, *Anomobryum yasudae* Broth., *Didymodon acutus* (Brid.) Saito and *Dumortiera hirsuta* (Sw.) Reinw. are new to Xinjiang province. One liverwort and 25 arcocarpous mosses are found in the foreland of the reatreating Tianshan No.1 Glacier since since the end of the Little Ice Age. The results supported the hypothesis that arcocarpous mosses are more adapted to harsh environments than pleurocarpous mosses. The way of sexual reproduction is employed by most mosses instead of asexual reproduction. The breed system of mosses in glacier foreland since the end of the Little Ice Age are mainly dioecious (69.23%), much more than those of monoecious (26.92%) and polyoicious (3.85%) indicating the way of unisexual reproductive may be more advantage in extreme climate. Canonical Correspondence Analysis (CCA) was also applied to study the relationships between the bryophytes and their environmental factors. The results showed that the influence of herb coverage, altitude, soil humidity, and tree canopy are the most important factors in distribution pattern of bryophytes.

P0711

Relationships of *Atraphaxis*, *Persepolium* and *Bactria* (*Polygoneae, Polygonaceae*) based on molecular and morphological data, and plastid phylogeny *of Atraphaxis*

Olga V. Yurtseva[1], *Evgeny V. Mavrodiev*[2]
1. M.V. Lomonosov Moscow State University
2. Florida Museum of Natural History

An updated molecular phylogeny of Polygoneae was obtained with Maximum Likelihood (ML) and Bayesian analyses (BI) applied for the DNA sequence data (ITS1&2 regions of nrDNA and combined *trnL* intron $^{(UAA)}$ + *trn*L-F IGS and *rpl*32–*trn*L $^{(UAG)}$ IGS regions of plastid genome). *Knorringia* is an isolated lineage sister to the rest Polygoneae. The clade including *Fallopia, Muehlenbeckia*, and *Reynoutria* is sister to the clade including *Atraphaxis, Duma, Polygonum*, and *Polygonella*. *Duma* is grouped with *Polygonum* and *Polygonella* in plastid topology, and is a separate lineage in ITS-based topology. The clade of *Polygonum* and *Polygonella* is sister to *Atraphaxis* s.l. in which a new genus *Persepolium* (=*Polygonum sect. Avicularia subsect. Spinescentia*) was established forming the clade immediately sister to *Atraphaxis* s.s. Based on molecular and morphological data, a new genus *Bactria* was described as a sister to the clade (*Atraphaxis* s.s. plus *Persepolium*). *Bactria ovczinnikovii* from Pamir and *B. lazkovii* from Tien Shan are grouped in plastid topology, but demonstrate paraphyly in ITS-based topology. The intra-individual ITS1-2 polymorphism and strongly different secondary structure of ITS1 detected in *B. lazkovii* are arguing for the hybrid origin from an unknown *Bactria* species and an unknown donor (donors) of different ITS variants, one of which demonstrates partial pseudogenization. Striking intra-individual polymorphism of sporoderm surface detected in *B. lazkovii* agrees with this suggestion. The standard maximum parsimony (MP) analysis and three-taxon statement analysis (3TA) were applied to the comprehensive morphological dataset of 22 accessions of *Bactria, Persepolium,* and *Atraphaxis*. s.s. In total, 27 characters, including the life history, habitus, morphology of the shoots, leaf blades, ochreas, perianth, achene, the ultrasculpture of perianth and achene surfaces, as well as the pollen morphology were analyzed. All the characters were conceptualized with a certain number of states and treated as unordered. The obtained patterns of the relationships are congruent to the ITS-based topologies resulted from the molecular treatments of the same taxonomical complex. MP reconstructions of perianth and pollen morphology were performed for Polygoneae using topologies that resulted from ML analyses of molecular data sets. MP reconstructions of selected morphological traits were performed for the clade including *Bactria*, *Persepolium*, and *Atraphaxis* s.s., using topologies that resulted from MP analysis of morphological data set. The campanulate perianth of 5 equal-sized segments and microreticulato-perforate sporoderm surface detected in *Bactria* and *Persepolium* are symplesiomorphies. The perianth with accresent inner segments and long filiform tube is an apomorphy appeared in *Atraphaxis* s.s. from the campanulate perianth. Striato-perforate sporoderm surface shared by *Atraphaxis* and *Persepolium dumosum* is treated as a homoplasy. Preliminary molecular phylogeny of *Atraphaxis* was built with ML and BI applied for 65 tips combined plastid matrix based on 3-loci (cpDNA *trn*L $^{(UAA)}$ intron, *trn*L–*trn*F IGS, and *rpl*32–*trn*L $^{(UAG)}$ IGS regions). The section *Atraphaxis* with dimeric flowers forms a distal subclade, the members of sections *Tragopyrum, Physopyrum* with specialized pentamerous perianth and the species with campanulate perianth of 5 equal-sized segments form no subclades. The ITS-based topology is incongruent to combined plastid phylogeny due to probable allopolyploid origin of many species.

T2

P0712

Evolution of Perianth morphology and sporoderm ornamentation in and *Atraphaxis*, *Persepolium* and *Bactria* (*Polygoneae, Polygonaceae*)

Olga V. Yurtseva
M.V. Lomonosov Moscow State University

Atraphaxis, Bactria, and *Persepolium* are close related in phylogenetic reconstructions based on molecular and morphological data. *Atraphaxis* is sister to *Persepolium*, their common clade is sister to *Bactria,* what let to trace evolution of their morphological features. *Bactria* combines two rare endemic shrubs from Pamir and Tian-Shan. They have terminal frondulose thyrses of 5-10 spaced cymes of 2-3 flowers. The campanulate perianth has five equal segments covered adaxially and abaxially with elongate-rectangular sinuate epidermal cells with random cuticular striation. Eight filaments are deeply inserted in receptacle lined with nectar-secreting tissue. These characteristics rather indicate entomophily. *Persepolium* combines five dwarf caespitose undershrubs or shrubs endemic for SW Iran. They have terminal frondose or frondulose thyrses of 10-20 well spaced cymes of 2-3 flowers, urceolate or campanulate perianth divided in 5 equal coriaceous segments densely velutino puberulent. The outer perianth surface is covered with elongate-rectangular epidermal cells forming short trichomes, alternating with stomata. Nectar-secreating tissue lines the receptacle and the bases of filaments inserted deeply in receptacle. These features are usual for self-pollinators. *Atraphaxis* numbered ca 35 shrubs or undershrubs is distributed from SE Europe to South Siberia and China. Atraphaxis has compact bracteose thyrses of 6-20 congested cymes of flowers and diverse perianth which is 1) campanulate with 5 equal segments and short funnel-form tube, 2) specialized with long filiform tube, two or three accrescent inner segments and two outer segment; 3) specialized with short filiform tube, three inner segments spherically surrounding the ovary and two reflected ones. Due to the campanulate perianth with five equal segments and short tube is shared by some *Atraphaxis* species, *Bactria* and *Persepolium,* it can be treated as initial to the other types of perianths in *Atraphaxis*. Dimeric flowers can be treated as the last novelty appeared in *A.* section *Atraphaxis* which formed distal subclade in phylogenetic reconstructions. Showy petaloid perianth of *Atraphaxis* has white or brightly colored segments covered outside and inside with rectangular-elongated cells sinuate in outline, with random cuticular striation. The expanded part of tube is covered with polygonal cells with random cuticular striation. The filiform basal part joint to long pedicel serves for better exhibition of the perianth in compact thyrse. Nectar-secreting tissue lines short receptacle and the inner surface of the filaments, which are inserted at the edge of receptacle to ease exposure of pollen. This morphological complex was formed in Atraphaxis as an adaptation to entomophyly. Pollen grains in all the taxa are prolate to subprolate, spheroidal to oblong-spheroidal, tricolporate, elliptical in equatorial view, trilobed-circular in polar view. *Bactria* has microreticulato-foveolate or foveolate-perforate sporoderm surface. *Persepolium* has foveolate, foveolato-perforate to microreticulato-foveolate sporoderm surface, excepting *P. dumosum* which has striato-perforate sporoderm surface. *Atraphaxis* has striato-perforate sporoderm surface originated from reticulate-perforate surface present in *A. toktogulica* by arranging of lumina in rows, rising of lateral edges of lumina, and emerging of grooves with rows of perforations. Striato-perforate sporoderm surface possibly reduces the weight of pollen and facilitates transfer by pollinators.

Plastid phylogenomics and Ranunculaceae diversification after K-P boundary

Wei Zhai[1], *Xiaoshan Duan*[2], *Rui Zhang*[2], *Chunce Guo*[2], *Lin Li*[2], *Hongzhi Kong*[2], *Yi Ren*[1]

1. College of life sciences, Shaanxi normal University

2. Institute of Botany, CAS

Ranunculaceae is a basal eudicotyledonous family with about 53 genera and 2,500 species. The family has been the focus of systematic studies for centuries for its unstable position in angiosperm phylogeny and its tremendous diversity in vegetative and reproductive structures. Recently, the family is increasingly being used as a model to answer the important evolutionary questions that cannot be easily addressed by using any other existing models species. Yet, because of the uncertainties in the phylogenetic relationships among genera, it has been difficult to infer the evolutionary histories of many characters. Recent molecular phylogenetic studies have shown that the Ranunculaceae, as a monophyletic group, included Glaucidium, Hydrastis and the core Ranunculaceae. *Glaucidium* was the basal most in Ranunculaceae, followed by *Hydrastis* as sister to the core Ranunculaceae. Within the core Ranunculaceae, the Coptideae was the first diverged clade, and the remaining genera were divided into 11 well supported lineages/tribes, namely Isopyreae, Adonideae, Delphinieae, Nigelleae, Helleboreae, Cimicifugeae, Caltheae, Asteropyreae, Callianthemeae, Anemoneae and Ranunculeae. However, the relationships among the 11 clades were unresolved. To figure out the phylogenetic relationship of Ranunculaceae, 81 coding genes (77 protein-coding and 4 RNA-coding sequences) from 37 taxa of this family were used to reconstruct the phylogenetic trees. In the ML (maximum likelihood) tree, all of the relationships were strongly supported, including several internal nodes which are previously weakly supported in different topologies of the family. Glaucidium was resolved as the basal most lineage of the family, followed by Hydrastis and Coptis (Coptideae), confirming several other studies. The remaining genera form 11 strongly supported lineages, each of which corresponds to the tribes recognized by previous studies. Unlike previous studies, the relationships among the 11 lineages, however, are different. Specifically, tribe Adonideae appears to be sister to tribe Isopyreae, and they together are strongly supported as sister to a group containing the remaining 9 tribes. Of the remaining 9 tribes, Ranunculeae is the closest sister of Anemoneae, followed by Helleboreae, Callianthemeae and Cimicifugeae, whereas Asteropyreae, Caltheae and Nigelleae are successive sister of Delphineae. The molecular dating results indicated that the origin of Ranunculaceae is 105.2 Mya (HPD=96.2-116.1); the divergence times for the Glaucidium, Hydrastis, and Coptideae are estimated to be at 89.3 Mya (HPD=75.8-103.4), 83.5 Mya (HPD=69.8-96.3) and 72.6 Mya (HPD=59.8-85.1), respectively. The remaining 11 lineages of core Ranunculaceae began to diversify around the K-P boundary (66.3 Mya; HPD=54.1-78.2), and each ancestor of these 11 lineages have been originated within 15 million years (65-50 Mya). These implied that the extant 11 lineages may split out rapidly within a short period after the K-P boundary. The LTT (lineage-through-time) plot analysis also highlighted a rapid radiation after the K-P boundary, at which the diversification rate has increased substantially.

Implications of speciation as demonstrated by *Magnolia* hybrids

Kevin Parris[1], ***Donglin Zhang***[2]

1. Department of Plant and Environmental Sciences, Clemson University

2. Department of Horticulture, University of Georgia

Controlled crosses *Magnolia sieboldii* K. Koch 'Colossus' (2n=2x=38) × *M. grandiflora* L. 'Kay Parris' (2n = 6x = 114), *M. foveolata* (Merr. Ex Dandy) Figlar 'Shibamichi' (2n=2x=38) × *M. laevifolia* (Law & Y.F. Wu) Noot. 'Gail's Favorite' (2n=2x=38), and *M. sieboldii* 'Colossus' × *M. insignis* Wall. 'Anita Figlar' (2n=2x=38) were performed in 2013, 2010, and 2014, respectively. Genetic variations and assessed inheritance of parents and F1 sibling populations were analyzed using ISSR markers. A total of 35 siblings (9, 11, and 15, respectively), 6 parents, and 5 comparator males were included in the molecular work. 79.3% of bands were polymorphic in the first cross. UPGMA tree revealed that all siblings were closer to their hexaploid pollen parent (*M. grandiflora*) and more distant from their diploid parent (*M. sieboldii*), supporting foliage morphology observations. In the second cross, phenotypic differences in foliage and flower morphology among the siblings were apparent by the second year. Branch lengths in the UPGMA tree revealed greater separation among the siblings and less separation from their Section Michelia parents. In the third cross (intersectional) that was analyzed, phenotypic differences were not yet apparent, but UPGMA tree indicated branch lengths with less separation among the siblings and greater separation from parent species than the previous cross (intrasectional). The implication of speciation from these hybrids was discussed in details with both morphological traits and molecular data. Further studies should include selection of the best individuals for future controlled crosses and determination of their reproductive fecundity.

P0715

Pollinator shift drives floral divergence and reproductive isolation in two close related species of *Cimicifuga* (Ranunculaceae)

Jianqiang Zhang, *Yi Ren*
Shaanxi Normal University

Traditionally the great diversification of animal-pollinated angiosperms has been proposed to be promoted by divergence in pollinators. However, the underlying evolutionary and ecological processes are still poorly understood, in part because most studies have focused on floral diversification and pollination relationships in a phylogenetic context or pollinator-mediated phenotypic selection within populations. Here we report a intriguing case of pollinator shift driving floral divergence and speciation in two close related species *Cimicifuga japonica* and *C. purpurea*. Both species belong to plant family Ranunculaceae, and the former species possess white and radial symmetry with caducous sepals and nectariferous, while the flowers of *C. purpurea* form a monosymmetric feature, the sepals are purple, chartaceous, erect and lately deciduous, the petals (nectary leaf) are yellow, erect and hidden inside of the sepals to hide the nectar in the flower, the stamens have purple filaments and yellow anthers. Through field observations, flower morphological measure and experimental analysis, we found an obvious pollinator shift between the two species. For *C. japonica*, pollen foraging flies are main visitors, among which some large sized flies can touch the anthers and stigma when crawling and collecting pollens on the flowers. Among the visitors of *C. purpurea*, *Vespula rufa rufa* (Linnaeus), the red wasp, has obvious higher visiting frequency and pollen carrying efficiency, thus is the main pollinator for the species. Interestingly, morphological analysis showed that the flower morphology are exactly fitted for *Vespula rufa rufa* pollinator: the purple sepals and yellow anthers of *C. purpurea* color could be easily recognized by the red wasp comparing to *C. japonica*'s white ones. In addition, the purple-yellow color of the inflorescence of *C. purpurea* is similar to the yellow and red-brown stripes of red wasp that might avoid the red wasp to be found and attacked by other predators when sucking the nectar. Besides, the red wasp has larger size and powerful, chewing mouthpart with developed and hard palate can open the wrapped sepals, and its hard palate length with close petal can get the nectar reward. The natural distribution area of *C. japonica* and *C. purpurea* are largely allopatry, which provides alternative drivers for the floral divergence of the two species. Using cpDNA *trn*L-F and *trn*S-G spacers, we detected very low gene flow between the two species. Molecular dating analysis suggested that the two species diverged at ca. 0.3 Mya (Million years ago). Such a shallow divergence should be characterized by extensive gene flow and incomplete lineage sorting, yet not seen in the case of *C. japonica* and *C. purpurea,* suggesting strong selective pressure acting on the divergence of the two species. We thus represent this intriguing case of pollinator shift-driven speciation, and further studies on process and underlying mechanism of this process would greatly strengthen our understanding of pollinator-driven speciation in angiosperms.

P0716

Floral symmetry genes and the development of zygomorphy in Solanaceae

Jingbo Zhang, *Ghadeer Bukhari, Wenheng Zhang*
Department of Biology, Virginia Commonwealth University

In core eudicots, the origins of floral zygomorphy from ancestral actinomorphy in several lineages are always associated with the repeated deployment of *CYCLOIDEA2*-like (*CYC2*-like) genes, which belong to the *CYC/TB1* clade of the TCP gene family. We have sought to characterize the genetic basis of the independent origin of floral zygomorphy in Solanaceae. To this end, we cloned the *CYC2* genes from Solanaceae and Convolvulaceae, and reconstructed the gene phylogeny for these sequences. The differential expressions of the *CYC2* paralogs were examined by qRT-PCR and RNA *in situ* hybridization in plants with three types of floral symmetry: actinomorphic flowers (in *Solanum lycopersicum* L.), zygomorphy in androecium and calyx (in *Nicotiana obtusifolia* Martens & Galeotti), and strong zygomorphy in androecium, corolla, and calyx (in two species of *Schizanthus* Ruiz & Pav.). Differential gene expression was further tested in *Schizanthus* by using RNA-seq. We identified two major sequence types of *CYC2* genes, *CYC2-I* and *CYC2-II,* which resulted from a gene duplication in the common ancestor of Solanaceae. Furthermore, a genus-specific gene duplication identified in *Schizanthus*, which represents the most basal clade of the family, produced two *CYC2-I* paralogs, *scCYC2-Ia* and *scCYC2-Ib*. The expression of *CYC2* genes was detected at both early and late stages during floral development in the tested species. In particular, in *So. lycopersicum, CYC2* genes were broadly expressed early on across the floral meristem. During floral organ initiation, the expression of *soCYC2-I* was concentrated in stamens and ovules, while the expression of *soCYC2-II* was concentrated in sepals. A similar pattern of gene expression was observed in *N. obtusifolia* except for the expression of *niCYC2-II,* which exhibits an asymmetric pattern correlated with its zygomorphic calyx. In *Sc. grahamii* Gill. ex Hooker, the expression of *scCYC2* was detected mainly in zygomorphic androecium and calyx. Specifically, *scCYC2-Ia* was found strongly expressed in the aborted dorsal and ventral stamens, while *scCYC2-Ib* was expressed complementarily in the functional stamens. *scCYC2-II* showed a dorsoventral asymmetrical expression pattern in the zygomorphic calyx. Furthermore, the RNA-seq results obtained with *Sc. pinnatus* Ruiz & Pav. indicated no expression of *CYC2* genes in corolla. Therefore, our results suggest that *CYC2* genes are likely involved in the development of floral zygomorphy in androecium and calyx, but genes other than *CYC2* are involved in the development of zygomorphic corolla in Solanaceae.

A taxonomic revision of *Radula* in china based on molecular and morphological evidence

Li-Na Zhang[1], *Rui-Liang Zhu*[2]
1. Institute of Tropical Agriculture and Forestry, Hainan University, 58 Renmin Road, Haikou 570228, China
2. School of Life Sciences, East China Normal University, 500 Dongchuan Road, Shanghai 200241, China

Radula Dumort., a monotypic genus in Radulaceae with more than 250 currently accepted species, is mainly distributed in subtropical and tropical regions. Over 40 species placed in three subgenera have previously been recognized in China. Although the genus is well delimitated and easily recognized, the infrageneric taxonomy is considered to be very contentious. In the present study, a taxonomic revision of *Radula* in China is presented based on both molecular phylogenetic and morphological-anatomical analyses. The materials used in this research were fresh collections and herbarium specimens collected from all over the country. The morphological investigation focused primarily on three re-evaluated characters (viz., stem cross-section, oil body and papilla). Four chloroplast DNA sequence (*trn*G, *trn*L-F, *rps4* and *atp*B-*rbc*L) data generated from 33 species in China were analyzed applying different phylogenetic approaches including the maximum parsimony, maximum likelihood and Bayesian inference. Our revision confirmed the occurrence of 38 species in six subgenera in China: *Amentuloradula* (2 spp.), *Cladoradula* (4), *Metaradula* (9), *Odontoradula* (5), *Radula* (17), *Volutoradula* (1). Two new species, *R. hainanensis* L.N.Zhang & R.L.Zhu and *R. subacuminata* L.N.Zhang & R.L.Zhu, both belonging to subg. *Metaradula*, were described. Five species, *R. fauriana*, *R. mittenii*, *R. stenocalyx*, *R. tabularis* and *R. ventricosa* are newly reported for China. One species, *R. inouei*, is hitherto known only from China. The highest diversity of species was found in Hainan island with 24 species, and the second in Taiwan with 21 species. Two sections, sect. *Epiphyllae* Castle ex Grolle and sect. *Chinenses* Yamada were proposed to be resurrected. Based on the morphological analyses, we found that oil body and papilla can be divided in three types respectively, and they also play important roles in taxonomy of *Radula*, especially in the infrageneric classification.

A study of *Cryptocarya* (Lauraceae) in southeast Asia based on morphology and phylogeny

Meng Zhang, *Yahara Tetsukazu, Mase Keiko, Tagane Shuichiro*
Center for Asian Conservation Ecology, Kyushu University

The genus *Cryptocarya* within the Lauraceae family is widely distributed throughout the tropic forests including the Southeast Asian region. The total number of *Cryptocarya* is estimated between 200 and 250. However *Cryptocarya* has not been fully studied and still remains difficult to identify. Thus we are carrying on a series field survey of plant biodiversity in Southeast Asia, including Cambodia, Indonesia, Laos, Malaysia, Myanmar, Thailand, and Vietnam. We used both plots survey and general specimen collecting methods at different elevations of the tropical mountains. In addition, we applied the both morphology observation and phylogenetic analysis based on DNA barcode ITS to identify the *Cryptocarya*. As a result, within 83 collecting *Cryptocarya* samples, 20 *Cryptocarya* species were identified and 9 species are remaining for identify including 3 new candidate species, which are *Cryptocarya bokorensis* sp. nov., *Cryptocarya kaengkrachanensis* sp. nov., and *Cryptocarya honbaensis* sp. nov.

Biogeographic history of *Saxifraga* sect. *Irregulares* (Saxifragaceae) disjunct between Eurasia and western North America

Meng-Hua Zhang, *Xiao-Shuang Zhang, Dai-Gui Zhang, Ze-Long Nie*
Jishou University

Saxifraga is the largest genus in Saxifragaceae and a characteristic component of temperate to polar climatic zones and of alpine vegetation belts in mountain ranges of the Northern Hemisphere, especially diversified in high mountains of SW China. Sect. *Irregulares* is a special group in the genus usually characterized by zygomorphic flowers, except for *Saxifraga mertensiana* from North America with actinomorphic flowers. This section includes 15-20 species, most of which are found in eastern Asian and only one species disjunctly distributed in North America. Phylogenetic studies suggested that it is the first early-diverged group in the genus. In order to understand its biogeographic history under a robust phylogeny, we employed both nuclear gene (ITS) and chloroplast DNA regions (*psb*A-*trn*H, *trn*L-F) to reconstruct the species' relationships within sect. *Irregulares*. Biogeographical inferences were based on a Bayesian uncorrelated log-normal relaxed molecular clock together with fossil calibrations and geographical distribution data to address relationships, divergence times, and historical biogeography. Our results indicate that sect. *Irregulares* is monophyletic and composed of three main lineages: (1) Ser. *Stonoliferae*, a group with long-creeping rhizome; (2) *Saxifraga mertensiana* from western North America characterized by actinomorphic instead of the zygomorphic flowers; and (3) the remainder species without stolons were grouped together (ser. *Rufescentes*). Sect. *Irregulares* was estimated to have split with *Saxifraga* at 20.17 Ma (95% HPD: 12.26–28.78 Ma) in the early Miocene, and the split between eastern Asia and North American lineagesat 16.24 Ma (95% HPD: 9.68–23.43 Ma) in the middle Miocene. Our biogeographical and analyses suggested that both Bering land bridge and North Atlantic land bridge are likely to explain the expanding of sect. *Irregulares* from Eurasia towards western North America. In addition, the analyses supported that *Saxifraga kegangii* D. G. Zhang, Z. L. Nie & M. H. Zhang, a new species of *Saxifraga* sect. *Irregulares* from Hunan province of central China. This new species can be easily distinguished from the other related taxa by its leaf shape and disc semiannular around the side of the ovary.

Anther and ovule development in *Camellia japonica* (Naidong) in relation to winter dormancy: Climatic evolution consider-

ations

***Qiang Zhang**, Qing Hao, Xiao Guo, Qinghua Liu, Kuiling Wang*
Landscape and Forestry College, Qingdao Agricultural University

The *Camellia japonica* (Naidong) population in Qingdao, Shandong province is the only one in temperate areas in China. While this population has been present in this area since the tertiary, its has evolved independently after that. To date, there are no reports on its embryology, and no research on the connection between embryology and climate. Here, we studied anther and ovule development of *C. japonica* (Naidong) using light and scanning electron microscopy, in order to determine the characteristics of early flower development, microsporogenesis, microgametogenesis, megasporogenesis and macrogametogenesis in this plant. We observed basic anther wall formation, glandular tapetum and successive microsporocyte cytokinesis. Moreover, microspores tetrads were mostly tetrahedral and occasionally symmetrical, we did not observe pseudopollen grains as previously reported for Camellia. The ovary was superior and presented axial placentation and anatropous, bitegmic ovule, allium type of embryo-sac, integumentary tapetum and hypostate which may provide winter cold temperature resistance. The early flower development sequence placed *C. japonica* (Naidong) in a most primitive branch of the phylogenetic tree compared to other species. The embryo characteristics and the development of *C. japonica* (Naidong) are significant for phylogeny research of Theoideae, as the taxonomy of this family is currently problematic at all levels. Moreover, this information is also useful flowering induction as a possible horticultural application. Flower buds went in dormancy during winter as gametophyte state, a characteristic evolved in *C. japonica* (Naidong) in response to the climates changes.

Diversification of Rosaceae since the Late Cretaceous based on plastid phylogenomics

***Shu-Dong Zhang**[1], Jian-Jun Jin[1], Si-Yun Chen[1], Mark W. Chase[2], Douglas E. Soltis[3], Hong-Tao Li[1], Jun-Bo Yang[1], De-Zhu Li[1], Ting-Shuang Yi[1]*
1. Kunming Institute of Botany, CAS
2. Science Directorate, Royal Botanic Gardens, Kew
3. Florida Museum of Natural History, University of Florida

Phylogenetic relationships in Rosaceae have long been problematic because of frequent hybridization, apomixis and presumed rapid radiation, and their historical diversification hasn't been clarified. With 87 genera representing all subfamilies and tribes of Rosaceae and six of the other eight families of Rosales (outgroups), we analyzed 130 newly sequenced plastomes together with 12 from GenBank in an attempt to reconstruct deep relationships and reveal temporal diversification of this family. Our results highlight the importance of improving sequence alignment and the use of appropriate substitution models in plastid phylogenomics. Three subfamilies and 16 tribes (as previously delimited) were strongly supported as monophyletic, and their relationships were fully resolved and strongly supported at most nodes. Rosaceae were estimated to have originated during the Late Cretaceous with evidence for rapid diversification events during several geological periods. The major lineages rapidly diversified in warm and wet habits during the Late Cretaceous, and the rapid diversification of genera from the early Oligocene onwards occurred in colder and dryer environments. Plastid phylogenomics offers new and important insights into deep phylogenetic relationships and the diversification history of Rosaceae. The robust phylogenetic backbone and time estimates we provide establish a framework for future comparative studies on rosaceous evolution.

DNA barcoding of *Oryza* (Poaceae)

***Wen Zhang**[1,2], Jia Liu[1,4], Chao Xu[1,2], Haifei Zhou[1], Yanlei Liu[1,2], Xun Chen[1,3], Shiliang Zhou[1]*
1. Institute of Botany, the Chinese Academy of Sciences
2. University of Chinese Academy of Sciences
3. Northeast Forestry University
4. Sichuan Agricultural University

Rice (*Oryza sativa*) is one of the most important crops in the world, which supports half of world's population. There are about 24 species in rice genus. The genetic germplasms of rice genus have been collected, conserved in seed banks and utilized in varying degrees. It is not easy to identify seeds of different species and there are a certain proportion of misidentifications of seed materials housed in seed banks. In this study, we used 85 samples representing all species in the genus and evaluated 35 the most variable chloroplast DNA regions to identify rice species using the BLAST method, Best Close Match method, and tree-base method. The combinations of the 35 barcodes provided the highest species discrimination success in BCM method (70.73%) and maximum likelihood tree (62.96%). DNA barcoding provide effective discrimination in most genome types (C, CD, E, F, G, HJ, HK) except species of A, B and BC genome type, which can help differ whole species in five series of Oryza (*Ser. Australianses*, *Ser. Brachyanathae*, *Ser. Meyerianae*, *Ser. Ridleyanae*, *Ser. Schlechterianae*)

How many ferns and lycopods and where are the hotspots in China?

Xian-Chun Zhang
Institute of Botany, Chinese Academy of Sciences

The flora of China is one of the richest in the world, as to the ferns and lycopods the number of species is ranked the first by country. The number of species was 2,742 (including species, infraspecific taxa and hybrids) in the Chinese national flora (Flora Reipublicae Popularis Sinicae), but revised to be 2,270 in the English version Flora of China. Meanwhile the number of recognised families and genera also changed from 63 and 220 to 40 and 178 respectively. The exact number of species of ferns and lycopods is still uncertain. New discoveries and taxonomic revsions do make changes of the species numbers. Especially in some difficult groups, such as *Angiopters*, *Dryopteris*, *Polystichum*, *etc.,* the number of species might be reduced by extensive taxonomic revisions and molecular DNA barcode analysis. Hotspots are biodiversity rich geographical areas where the endemic species and endangered species number are high. Facing the problem of global changes and biodiversity losses in this century, we should pay special attention to the conservation of these hotspots and its biodiversity. Besides the two main biodiversity hotspots in China, the Southwest China Mountains and the East Himalayas, there are smaller "hotspots" across China in many provinces and districts. Here, I analysis the endemic species of ferns and lycopds in each region of China in order to find the hotspots for conservation.

Phylogenomic synteny network analysis reveals an ancient MADS-box transcription factor tandem duplication and lineage-specific transpositions

Tao Zhao[1], *Rens Holmer*[1], *Suzanne De Bruijn*[1], *Harrold A. Van Den Burg*[2], *Eric Schranz*[1]
1. Wageningen University
2. University of Amsterdam

Conserved genomic context (or synteny) provides critical information for comparative evolutionary analysis, such as the inference of ancient polyploidy events, recurrent genomic rearrangements across species and gene ancestry. With the increase of sequenced and assembled plant genomes, we have an opportunity to use synteny to analyze the dynamics of gene family conservation, expansion and transposition across broad phylogenetic groups. Here we present an integrated approach to organize gene synteny networks using *k*-clique percolation. As an example, we analyzed gene synteny networks for the MADS-box transcription factor gene family based on fifty-one completed plant genomes. Several novel evolutionary patterns can be inferred and visualized from our analyses. For example, we identified several lineage-specific gene clusters derived from transposition events including floral morphology (*AP3* and *PI*) and flowering-time (*FLC*) in the Brassicales and root-developmental genes (*AGL12* and *AGL17*) in Poales. We identified two highly connected gene clusters containing many key phenotypic regulatory Type II MADS-box gene clades (*SEP1, SEP1, SQUA, TM8, SEP3, FLC, AGL6 and TM3*). Synteny results support that these genes thus evolved from an ancient tandem gene duplication likely predating the radiation of seed plants, which then expanded by polyploidy events and sub-functionalization. Our phylogenomic synteny network approach can be applied to any group of species to gain new insights into the evolution and dynamics of any set of genes.

Morphological study on the asexual reproduction by deciduous leaves of *Takakia lepidozioides*

Tianxiong Zheng
Graduate School of Sciences, Hiroshima University

The class *Takakiopsida* consisting only two species, *Takakia lepidozioides* and *T. ceratophylla*, represent the earliest lineages within the mosses and has been attracting researchers due to enigmatic morphologies such as, (1) both leafy and leafless rhizomal shoots, (2) cylindrical shape of leaves, (3) the archegonia and the antheridia without protective structure, (4) the absence of rhizoids, (5) Symbiotic fungal hyphae in mucilage hairs on the rhizomal shoots. In Japan, *T. lepidozioides* is known only as female plants and the deciduous leaf seems to serve as a means of asexual reproduction. We observed that the development of leaves at the growing shoot, plant regeneration from detached leaves and the process of reinfection of symbiotic fungi. To detect proliferative region in leaves, we detect DNA synthesis by using 5-ethynyl-deoxyuridine (EdU) detection system. In young leaf primordia on growing shoots, the single apical cell with two cutting faces was observed. Visualization of DNA synthesis by EdU assay indicated that whole cells of young primordia including the apical cell had mitotic activity and the apical cell play an important role for morphogenesis of cylindrical shape of leaf. As the leaves grow, apical cell lost mitotic activity and intercalary region in leaf remain proliferative. In mature leaves, all of cells have no mitotic activity and the apical cell often died. Mature leaves easily detached at base from the shoot by slight mechanical shocks. In our culture stocks, many of regenerated shoots repeatedly arose around the plants. Morphological observation and EdU assay showed that the beak shaped mucilage hairs initially arose on the detached leaf. Subsequently, the apical cell producing strap-like or cylindrical meristematic region was directly regenerated without differentiation of filamentous protonema like other mosses. The mucilage hairs on the detached leaf were hardly distinguishable to those of rhizomal shoots. The cylindrical leaves with a single apical cell of *Takakia* seem to properties resembling individual shoot itself, although it show determinate growth unless detaching from main shoot. Co-culturing of sterilized detached leaf and symbiotic fungi isolated from mucilage hairs showed that the symbiotic fungi immediately enter the inside of the newly formed mucilage hairs through the mucilage pore and established the labyrinth of hyphae in mucilage hairs between the cell wall and cytoplasm. The appearance of mucilage hairs in detached leaves seems to promote the re-establishment of symbiotic relationship with fungi and contribute to survive and grow of regenerated shoots.

Evolution of WRKY transcription factors in Brassicaceae

Qinqin Zhou, *Fei Chen, Yue Hu, Liangsheng Zhang*
Fujian Agriculture and Forestry University

Brassicaceae, containing many edible plants, medicinal plants and the mode plant Arabidopsis, is a highly diverse plant family with vast adaptations. The recently released and various Brassicaceae genomes provide the great resources for understanding the molecular basis for their adaptations. WRKY gene family is one of the largest transcription factor families in higher plants with important roles in regulating plant development and resistance. In this report, a total of 22 Brassicaceae genomes, spanning 10 tribes, from basal to crown Brassicaceae, were studied to systemically analyze the evolution of *WRKY* genes in Brassicaceae. In total, 5 WRKY groups were classified (Group I, IIa, IIb, IIc, IId, IIe, III). By comparing the number of *WRKY*, we found that the large expansion of Brassicaceae *WRKY* was mainly contributed by recent-independent polyploidization events. Except the species with recent polyploidization events, all other core Brassicaceae showed conserved *WRKY* numbers, which did not contribute to the diversity and adaptability of Brassicaceae. By analyzing the selection pressure, we found that the Group III *WRKYs* tended to evolve faster than other groups. However, some genes in Group I, IIc and IIe also showed fast evolutionary rate. Positive selections and functional divergence were found in these fastly evolved genes. By comparing the salt-treated expression of *WRKY*, more Arabidopsis than Thellungiella genes were up-regulated. However, more down-regualed genes were found in Thellungiella compared with Arabidopsis. Both orthologs and paralogs had significant different evolutionary rate and the tissue expression of these genes also showed significant variations, which could explain the diversity and adaptability of Brassicaceae. These results uncovered the characteristics of *WRKY* evolution in Brassicaceae, which were believed to provide not only clues about the diversity and adaptability of Brassicaceae but also a good foundation for studying the diversity and adaptability of other highly adaptive plant lineages such as Asteraceae, Leguminosae, Poaceae and Orchidaceae.

Occurrence of earliest gigantopterid from the basal permian of the North China Block and its bearing on evolution

Weiming Zhou[1], *Jun Wang*[2]
1. Nanjing University
2. Nanjing Institute of Geology and Palaeontology, Chinese Academy of Sciences

Gigantopterids are a morphological group consisting of a number of enigmatic fossil plants with angiosperm–like leaves and reticulate venation that are of uncertain systematic affinity. Gigantopterid plants were abundant and a characteristic floral element in the Late Palaeozoic Cathaysian floras. However, in China, their oldest occurrence was much later than that in North America (Artinskian) and Indonesia (Asselian to Sakmarian). Here we document the gigantopterid *Gigantonoclea* cf. *mira* from basal Permian (Asselian) strata in the North China Block that represents the oldest unequivocal evidence for the gigantopterids. The foliage is characterized by complex venation composed of four orders, small isodiametric meshes and intercalary subsidiary veins arising directly from the rachis, being a distinctive morphological type of leaf venation. In addition, a non–marginal feeding trace is detected on the lamina, extending the earliest record of plant–animal interaction between gigantopterid plants and arthropods to the earliest Permian, and supporting the selective feeding preference of *Gigantonoclea* leaves within Cathaysian gigantopterids. Our new observations show that the venation characters of *Gigantonoclea mira* and *Gigantonoclea* cf. *mira* more closely resemble *Gigantopteris dictyophylloides* than other members of gigantopterids including the evolutionary *Callipteridium* sequence to which it was previously assigned.

Characteristics of vascular-plant diversity of Mt. Kenya, East Africa

Yadong Zhou[1,2,3], *Qingfeng Wang*[1,3]
1. Wuhan Botanical Garden, Chinese Academy of Sciences
2. University of Chinese Academy of Sciences
3. Sino-Africa Joint Research Center, Chinese Academy of Sciences

Mt. Kenya is one of the highest mountains in the tropical regions of the world. The uniqueness of plant compositions and patterns of species diversity at Mt. Kenya has attracted botanists from all over the world to examine and evaluate.In the past 3 years, we had collected and identified about 1,500 plant specimens of Mt. Kenya. Combining our data and other collections of more than 7,000 specimens from herbaria around the world, we concluded that, there were about 1,550 species in total (including exotic plants) at Mt. Kenya, belonging to 726 genera, 157 families. Specifically, 9 lycophytes (belonging to 5 genera, 2 families), 131 ferns (belonging to 55 genera, 20 families), 6 gymnosperms (belonging to 5 genera, 3 families) and 1,404 angiosperms (belonging to 661 genera, 132 families) were classified. We have also identified 3 new species and 75 new records at Mt. Kenya. With regard to life forms, 53.24% of total plant species were herbs, 10.40% woody herbs, 9.25% small trees, 8.34% lycophytes and ferns, 6.42% shrubs, 5.07% trees, 3.40% lianas and 3.04% climbers. More than half of plant species (60.49%) were endemic in Africa, whereas 25.13% cosmopolitan, 9.29% endemic in tropical East Africa, 3.63% endemic in Kenya, and only 1.36% endemic in Mt. Kenya. With the increase of altitude, the plant diversity showed a quadratic pattern with the peak of diversity from 2,000 to 2,600 m a.s.l., which were largely composed of forests (Fa & Fb). However, communities such as the bamboo zone (B, including bamboo-*Hagenia* forest, *Hagenia-Hypericum* forest), heath zone (E), Afromontane vegetaion (A) and Afromontane desert (Ad) have relatively low diversity values.

P0729

Phylogenomics based on RAD-seq and whole chloroplast sequencing recovers ancient hybridization and asymmetric introgression between *Cercidiphyllum japonicum* and *C. magnificum*

Shanshan Zhu[1], *Yonghua Zhang*[2], *Yingxiong Qiu*[1]
1. Zhejiang University
2. Sun Yat-sen University

Chloroplast capture - the apparent introgression of a chloroplast (plastid) genome from one plant species into another, is commonly suggested as an explanation for topological incongruity. However, the cases of incongruence between phylogenetic trees are usually presented based on few nuclear loci and organellar fragments. Chloroplast capture occurred in *Cercidiphyllum* species is of a typical example. With the development of next generation sequencing (NGS), it provides new opportunities to get high quantity and quality data with low cost. Here, we obtained genomic data from 21 samples of *Cercidiphyllum* species to infer the phylogenetic relationships using restriction site-associated DNA sequencing (RAD-seq). Meanwhile, using a combination of reference-based mapping and *de novo* assembly of whole genome Illumina data, we assembled the complete chloroplast genomes of *C. japonicum* (5 individuals respectively from North China, South China, South Japan, Central Japan and North Japan) and one individual of *C. magnificum*. Phylogenetic analyses based on RAD-seq data clearly supported the distinctiveness of two species of *Cercidiphyllum*. By constrast, phylogenetic analyses of the complete chloroplast genome revealed that the *C. japonicum* individuals from certral and north Japan were clustered with *C. magnificum*. Comparative chloroplast genome analyses showed few genetic and structural variation between the *C. magnificum* and *C. japonicum* (from central Japan and north Japan), and the differences were indeed smaller than that with other individuals of *C. japonicum* (from North China, South China, South Japan). This is the first time to confirm the two species of *Ceicidiphyllum* at genome-wide. It also provides the first documentation of chloroplast capture between species of *Cercidiphyllum* based on whole chloroplast genome sequencing.

P0730

Phylogenetic relationships in Chinese *Anaphalis* (Asteraceae), based on chloroplast and nuclear DNA sequences

Xuemin Xu, Zhen Wei, Junyu Gu, ***Shixin Zhu***
Zhengzhou University

Anaphalis is the largest genus in Asian Gnaphalieae tribe (Asteraceae), containing about 110 species. There are about 54 *Anaphalis* species intensively distributing in Hengduan Mountains in China. The Chinese *Anaphalis* is a taxonomically problematic group, especially in the terms of species delimitation. The phylogenetic relationships of *Anaphalis* and its closely related genera in Gnaphalieae, such as *Helichrysum*, *Gnaphalium*and *Pseudognaphalium*, are not clear as well. In this study, three cpDNA sequences, including *psb*A-*trn*H, *trn*L-*trn*F and *rpl32*-*trn*L intergenic spacer, and one nrDNA sequence, ITS, were sequenced for 73 *Anaphalis* taxa representing 25 species. The aim of this study is to provide the phylogenetic relationships within the Chinese *Anaphalis* species, examine the monophyly of the genus and discuss the relationship between *Anaphalis* and closely related genera. The results indicated that two clades within *Anaphalis* are well recognized. One clade involved most *Anaphalis* species, and the other one only included 4 *Anaphalis* species (*A. nepalensis*, *A. margaritacea*, *A. triplinervis* and *A. viridis*). However, all Chinese *Anapalis* species we used are nested with *Helichrysum* in nrDNA phylogenetic tree, while in cpDNA phylogenetic tree *Anaphalis* are nested with *Helichrysum* and *Pseudognaphalium*. Based on nrDNA and cpDNA phylogenetic trees, the current *Anaphalis* is not monophyly and need to be revised. Several important morphological characters were then plotted on the phylogenetic trees and discussed.

P0731

Systematics of East-Mediterranean *Raphanus* L. (Brassicaceae)

Jotham Ziffer-Berger
Herbarium of the Hebrew University of Jerusalem, the National Natural History Collection

An evaluation of the two sections of *Raphanus* (Brassicaceae) *sensu* O.E. Schulz, as given in Engler's *Pflanzenreich,* on the basis of multi-species morphological and ITS data, supported that Raphanus is a polyphyletic group embedded in the Oleracea lineage of the tribe Brassiceae. Section Raphanis, which includes *Raphanus raphanistrum*, *R. pugioniformis* and *R. sativus*, is a strongly supported monophyletic lineage. Section Hesperidopsis is embedded in a different lineage together with *Brassica deflexa* and *B. aucheri* . We propose to reinstate the genus *Quidproquo* in place of *Raphanus* sect. Hesperidopsis, to reflect the polyphyletic origins of the genus *Raphanus* sensu O.E. Schulz.

Research progress on taxonomy of *Xanthium* L.

Liping Yin[1], *Ning Zhang*[1], *Manyu Zou*[2], *Shuiliang Guo*[2]
1. Shanghai Entry-Exit Inspection and Quarantine Bureau
2. Shanghai Normal University

The species of this genus *Xanthium* L.is distributed globally, however are most frequently found in the tropical and sub-tropical regions. Taxonomy of *Xanthium* L.is confused that there have a variety of classification methods. For example, Flora of China and Flora of North America considers that there are two or three species in the world, while Plant List records sixteen accepted names of the species of *Xanthium*. Löve and Dansureau revised the genus *Xanthium* and reduced the number of species to only two. Weaver and Lechowich though there are 20 species belonging to this genus. Caius reported that the genus *Xanthium* includes 25 species. According to lots of diverse literature of *Xanthium*, there is a controversy that whether this genus should split into more species groups, or unit the smaller entities into larger or very large groups. USDA classifies the *Xanthium* L. into two species and three varieties in line with Cronquist's classification method. And Fan reported 17 species of the genus. Predecessors mainly draw on several morphological traits of *Xanthium*, such as the leaf shape, involucre shape, involucre volume, spines length and the density of spines, to classify species. However, there are few type specimens to prove its correctness. Morphological traits are so variable that the taxonomic study of the members of this genus is sometimes difficult. The cytological study showed that the karyotype analysis would provide strong support for authentic taxonomic diversification of some uncommon species of *Xanthium*. It was concluded that chemistry analysis including ultraviolet spectrometry and infrared spectrometry could help classify the species. Molecular markers analysis with the results that the genetic material among several species has a certain difference. As a consequence, morphology, cytology, chemistry and molecular markers study could only differentiate among two or several species. Research progress above help in making a clear understanding on the classification of the genus.

Similar morphology but different origins: Hybrid status of two more semi-creeping taxa of *Melastoma*

Peishan Zou, *Shuqiong Wang, Renchao Zhou*
State Key Laboratory of Biocontrol and Guangdong Provincial Key Laboratory of Plant Resources, School of Life Sciences, Sun Yat-sen University, 510275, Guangzhou, Guangdong, China

Inferring the origins of hybrid taxa based on morphology alone is difficult because morphologically similar hybrids can arise from hybridization between different populations of the same parental species or be produced by hybridization of different parental species. In this study, we investigated the origins of two semi-creeping taxa in *Melastoma*, which are similar to a natural hybrid *M. intermedium*, by sequencing one chloroplast intergenic spacer, nuclear ribosomal internal transcribed spacre (*nr*ITS) and two low-copy nuclear genes (*tpi* and *cam*) in these taxa and their putative parental species. Our sequence analysis results provide compelling evidence for hybrid status of the two semi-creeping taxa. The two hybrids originated from hybridization between *M. dodecandrum* and *M. malabathricum*, and between *M. dodecandrum* and *M. normale*, respectively. Therefore, they have different origins from *M. intermedium* and morphological similarity for the three hybrids might be due to origins from hybridization between the same creeping species *M. dodecandrum* and an erect species in each of the three cases. We also observed low rate of introgression from *M. normale* to *M. dodecandrum*, which may contribute to rapid adaptive evolution of *M. dodecandrum* to different environments. Rare occurrence of these two hybrids may be due to relatively small range overlap between parental species in one case and flowering period differentiation between parental species in the other.

Unraveling the evolutionary dynamics of ancient and recent polypoidization events in *Avena* (Poaceae)

Qing Liu[1], *Lei Lin*[1,2], ***Xiangying Zhou***[1,2], *Paul M. Peterson*[3], *Jun Wen*[3]

1. Key Laboratory of Plant Resources Conservation and Sustainable Utilization, South China Botanical Garden, Chinese Academy of Sciences, Guangzhou 510650, China

2. University of Chinese Academy of Sciences, Beijing 100049, China

3. Department of Botany, National Museum of Natural History, Smithsonian Institution, Washington, DC 20013-7012, USA

Understanding the diversification of polyploid crops in the circum-Mediterranean region is a challenging issue in evolutionary biology. Sequence data of three nuclear genes and three plastid DNA fragments from 109 accessions of *Avena* L. (Poaceae) and the outgroups were used for maximum likelihood and Bayesian analyses. The evolution of cultivated oat (*Avena sativa* L.) and its close relatives was inferred to have involved ancient allotetraploidy and subsequent recent allohexaploidy events. The crown ages of two infrageneric lineages (*Avena* sect. *Ventricosa* Baum ex Romero-Zarco and *Avena* sect. *Avena*) were estimated to be in the early to middle Miocene, and the *A. sativa* lineages were dated to the late Miocene to Pliocene. These periods coincided with the mild seasonal climatic contrasts and the Mediterranean climate established in the Mediterranean Basin. Our results suggest that polyploidy, lineage divergence, and complex reticulate evolution have occurred in *Avena*, exemplifying the long-term persistence of tetraploids and the multiple origins of hexaploids related to paleoclimatic oscillations during the Miocene-Pliocene interval in the circum-Mediterranean region. This newly-resolved infrageneric phylogenetic framework represents a major step forward in understanding the origin of the cultivated oat.

Deep phylogenetic incongruences between plastid and nuclear genomes in a clade of tropical trees

Sophie A. Zwartsenberg[1], *Jenifer C. Lopes*[1], *Rita D. Brandão*[2], *Lars W. Chatrou*[1]

1. Wageningen University and Research

2. Maastricht University

Evolutionary plant biologists have for a long time only used a limited number of markers to infer the phylogeny of plant families or genera. With sequencing now becoming increasingly cheap, the usage of whole genome data is becoming more commonplace. The data used for inferring phylogenies has often been derived from the chloroplast genome as it was long assumed that the evolution of the chloroplast was a good indicator of the evolution of the entire plant species. This study gives an example of why using only a single plant genome for phylogenetics might obscure important evolutionary patterns. The evolutionary history of the plant family Annonaceae has, over the years, been quite well established aside from a few nodes in the phylogeny which are difficult to resolve. One of these unresolved nodes involves the genus *Oxandra* from the tribe Malmeeae. In previous phylogenetic analyses, monophyly of the genus was not demonstrated whilst (floral) morphologically it is a homogeneous genus. This study aimed at resolving the phylogeny of *Oxandra* using genomic scale chloroplast data as well as nuclear ribosomal DNA. We generated high-throughput sequence data for 33 species of the Malmeeae clade, including 20 species of *Oxandra*. From the sequence data we obtained a data set of 61,000 bp of chloroplast sequences, and 5,800 bp of nuclear rDNA sequences.Based on chloroplast DNA, the genus *Oxandra* is polyphyletic. However, the genus was inferred to be monophyletic using nuclear ribosomal DNA. These incongruences between the different phylogenies affect nodes deep in the phylogeny, placing all *Oxandra* species in one clade or placing the species in two different clades with genera such as *Klarobelia* and *Ephedranthus* separating them. The incongruent nodes all receive high posterior probabilities (> 0.98). The mechanisms causing this strongly incongruent pattern is yet unknown and the species phylogeny of *Oxandra* remains unresolved as it can be both a monophyletic or polyphyletic genus depending on what genome you are looking at. The results of this study show that it might be wise for phylogenetic studies to sample multiple genomes that are available within the plant as these might shed a different light on the organismal evolution.

Is *Angelica sylvestris* (Apiaceae), a supergeneralist plant, locally adapted to its pollinators?

Marcin Zych[1], *Katarzyna Roguz*[1], *Małgorzata Stpiczyńska*[1], *Massimo Nepi*[2], *Robert R. Junker*[3]
1. Botanic Garden, Faculty of Biology, University of Warsaw
2. Department of Life Sciences, University of Siena
3. Department of Ecology and Evolution, University of Salzburg

In terms of the pollination system umbellifers (plants of the Carrot family, Apiaceae) are regarded generalists, since their (usually dichogamous) flowers are visited by a wide range of insects representing several taxonomic orders. However, recent analyses of insect effectiveness revealed that the plants may be effectively pollinated by a narrow assemblage of flower visitors. In our study we focused on *Angelica sylvestris* L., a common European species pollinated by a taxonomically diverse insect assemblage. In three populations, located along approx. 500 km long transect, over three years we analysed floral visitors, assessed insect effectiveness, studied nectar and scent composition and performed transplantation experiment. We showed that our study populations differ in nectar and scent profiles and despite similar taxonomic composition of insect visitor assemblages, they are effectively pollinated by different pollinator guilds. Although this suggests local adaptations to the most effective pollinators, our transplantation experiment showed that reproductive success is not related to the origin of experiment plants and insect do not exhibit preferences towards local genotypes. Our paper discusses possible evolutionary pathways leading to the observed diversity of local variants of the *A. sylvestris* pollination system. The study was financially supported by the National Science Centre, Poland grant 2011/01/B/NZ8/03146 and by Faculty of Biology, University of Warsaw DSM grant 112630.

The taxonomic treatment of the *Dryopteris varia* complex in Japan

Kiyotaka Hori[1], *Atsushi Ebihara*[3], *Noriaki Murakami*[2]
1. Makino Botanical Garden
2. Makino Herbarium, Tokyo Metropolitan University
3. National Museum of Nature and Science

The *Dryopteris varia* complex (subg. *Erythrovariae*, sect. *Variae* Fraser-Jenk.) is an apogamous fern complex. Most species of the complex are triploid apogamous, show morphological and genetic variation, and have taxonomic problems especially in their species classification. Recent molecular researches suggested that the complex experienced reticulate evolution through hybridization between diploid sexual and triploid apogamous species, and that is the reason why each apogamous species are so variable. In this study, we summarized the taxonomic treatment of 11 species within the *D. varia* complex on the basis of their genome constitutions revealed by the molecular analyses.

XII Latin American Botanical Congress, Quito, Ecuador October, 2018

Alina Freire-Fierro
IKIAM Universidad Regional Amazónica, and Asociación Latinoamericana de Botánica ALB. Vía Tena-Atacapi, Ecuador

Latin American Botanical meetings have been organized since 1938, and in 2018 we will be celebrating 80 years of these congresses. Next year will be also the 20th anniversary of the publication of the first Angiosperm classification based on molecular data published by the Angiosperm Phylogeny Group. In order to reflect these two important events, we have chosen as a theme for the congress the reality and virtual development in Latin American botany, and the logo for the congress represents an Asteraceae species endemic to the Andes, Chuquiraga jussieui J.F.Gmel. The congress, to be held in Quito, Ecuador, during October 21-28,2018, is being organized by the Latin American Botanical Society (ALB), the Ecuadorian Botanical Society (ABE), and IKIAM Universidad Regional Amazónica. For this event, we expect to host 1500-2000 participants, and the guest speakers are: Tod Stuessy (USA), Jorge Crisci (Argentina), Danna Leaman (Canada), Fausto Sarmiento (Ecuador/USA), Lucia Lohmann and Mónica Carlsen (Brasil/Venezuela), Ernesto Medina (Venezuela), Mark Chase (UK), Katya Romoleroux (Ecuador), Neill (Ecuador-USA), and Pamela Soltis and Douglas Soltis (USA). The ALB was founded in 1986 and nowadays includes more than 300 members. The board is formed by Ecuadorian and Latin American botanists and has, as one the main objectives, the organization of Latin American botanical congresses and the ABE was recently formed to allow legal transactions incurred during the congress in Ecuador. IKIAM is a young emblematic research university created by the Ecuadorian government. It is located in the eastern Andean slopes towards the Amazon, and it is the responsible for managing the +93.000 Ha Colonso-Chalupas Biological Reserve.
In addition to ALB, ABE and IKIAM, for the XII CLB, there are many national and international collaborating institutions, among them the IAPT, BSA, SENESCYT, *etc.*

Phylogenetic analysis of the genus *Convolvulus* L. (Convolvulaceae) using chloroplast DNA sequences from *trn*L-*trn*F region

Perveen Anjum, *Kousar Shazia*
University of Karachi

The family Convolvulaceae consists of species rich genera from which *Convolvulus* is next to *Ipomoea*. *Convolvulus* is a large and diverse genus, It is a cosmopolitan genus but the Mediterranean and East Asia are the major points of diversity of *Convolvulus*.
Chloroplast non-coding regions are now frequently use in Phylogenetic studies. A consensus tree based on chloroplast DNA sequences from the *trn*L-*trn*F region was examined by evaluating phylogenetic relationships in 12 species of *Convolvulus*. Result indicated that Phylogenies based on *trn*L-*trn*F sequences incongruent with traditionalmorphological classification in which, the

genus *Convolvulus* is divided into different sections based on spine and growth forms. The present study revealed that all species are delimited into three distinct lineages. In the first lineage, *C. kotscyanus*, and *C. arvensis* showed sister association while *C. leiocalycinus*, *C. acanthocladus* and *C. psedocantabricus* were grouped together. Within the second lineage, *C. virgatus* and, *C. aitchisonii* were closely related while *C. spinosus*, *C. scindicus* and *C. prostratus* occupied position on second branch. The third branch made the largest cluster of *C. lineatus*, *C. rhyniospermus*, *C. cephalopodus*, *C. fruticosus* and *C. glomeratus, C. pyrrhotrichus* located distantly in the third lineage.

P1414

Jekyll existing in two major allelic variants is a lineage-specific gene for the closely related Triticeae and Bromeae tribes

Volodymyr Radchuk[1], *Rajiv Sharma*[1,2], *Elena Potokina*[1,3], *Ruslana Radchuk*[1], *Eberhard Munz*[1], *Martin Mascher*[1], *Benjamin Kilian*[1,4], *Ljudmilla Borisjuk*[1]
1. Leibniz-Institute of Plant Genetics and Crop Plant Research (IPK)
2. Division of Plant Sciences, School of Life Sciences, James Hutton Institute, University of Dundee
3. Vavilov Institute of Plant Industry (VIR)
4. The Crop Trust

Due to economic value and intriguing genetic and agricultural histories of Triticeae species, search for lineage-specific, domestication and agronomically-relevant genes for the tribe are of high importance. Earlier we have discovered the *Jekyll* gene which is expressed in nucellar projection of the developing barley (*Hordeum vulgare*) grains and in tapetum of developing anthers, whereupon *Jekyll* protein is localized on the pollen surface. The *Jekyll* plays pivotal role in terminal cell differentiation of nucellar grain tissues and influences nutrient delivery to the endosperm during grain feeling. In the tapetum, *Jekyll* is important for pollen maturation and anther dehiscence. Repression of *Jekyll* resulted in a significant loss of fertility and thus proves the role of this gene in sexual reproduction. We found also two additional sequences, from which *Jek3* was established as an allelic variant of *Jekyll* (further *Jek1*) despite of low identity at nucleotide and amino acid levels. The *Jek1* and *Jek3* proteins share identical signal peptides, conserved cysteine positions in the variable middle regions and several direct repeats at C terminals. The *Jek1/Jek3* sequences are located in the same locus on chromosome 3H and inherited by monogenic Mendelian fashion. *Jek3* has similar expression patterns to *Jek1* and can also complement the *Jek1* function in *Jek1*-defficient plants. Analyzing characteristic genetic background in sequenced genome of barley, we suppose that huge allelic dimorphism betweenJek1 and *Jek3* is originated by retrotransposition. Analysis of *Jek1/Jek3* molecular diversity in 494 accessions of barley core collection showed that both allelic variants were almost equally distributed among cultivated and wild barleys. All cultivated barleys with *Jek1* allele belong to single haplotype indicating genetic bottleneck during domestication. Cultivated barleys with *Jek3* allele distributed among three haplotypes.

Phylogenetically related groups of species contain lineage-specific genes, which exhibit no sequences similarity to any genes outside of lineage. We found *Jekyll*-like sequences in all analyzed species of closely related Bromeae andTriticeae tribes (constituting Triticodae lineage) but not in other Poaceae lineages. Comparative grain analysis using Nuclei Magnetic Resonance Imaging demonstrates that *Jekyll* appearance is linked with the formation of nucellar cavity and modified aleurone cells in Triticodae. We postulate that emergence of *Jekyll* during molecular evolution of Poaceaewas a driver for separation of the Triticodae lineage and herewith the *Jekyll* is a lineage-specific gene. The acquisition of new *Jekyll* gene in course of Triticodae separation also leads to rapid innovation in grain phenotype, namely in a formation of a maternal/filial conduit for assimilate transfer towards endosperm consisting of the nucellar projection and modified aleurone cells. Aleurone cells faced this cavity are delayed in differentiation and retain their assimilate transfer function over whole grain development. In contrast to typical aleurone layer (like Brachypodium), modified aleurone layer in Bromus and species of Triticeae does not acquire abilities for accumulation of lipids and storage proteins. Therefore, *Jekyll* has become an essential genetic component controlling endosperm development and storage accumulation.

Genetic identification of *Amomum villosum* from different planting areas based on internal transcribed spacer of ribosomal DNA

Chang Su[1], *Xiaoying Guan*[1], *Yaoxuan Xie*[1], *Siyue Liu*[2], *Xiaoxiao Song*[1], *Shuhong Wang*[1]
1. Shenzhen Institute for Drug Control
2. Saint Edward's School

Yang Chun Sha is the dried ripe-fruit from *Amomum villosum*. It is one of the four most famous herbs in Southern China, and has been used on clinic for more than 1,300 years. According to the ancient herbal records, *Amomum villosum* was discovered from the city of YangChun in Guangdong province, however about 40 years ago, *Amomum villosum* were introduced and artificial planted to Guangxi and Yunnan province to increase the yield, and are extended to surrounding Southeast Asian countries (Laos and Myanmar) recent years. But traditionally *Amomum villosum* from Guangdong is considered as the best in medicinal quality and has much higher market values than the herbal products from other planting areas. In this study we investigate the genetic diversity of *Amomum villosum* from different planting areas by analyzing the nucleotide sequences of internal transcribed spacer (ITS) of ribosomal genes. Phylogenetic trees were constructed using several clustering methods, including unweighted pair-group method with arithmetic average (UPGMA), neighbor-joining (NJ) and maximum evolution (ME). The present work also provides the original planting investigation on two planting area in China and morphological identification on its herbal products from other two Southeast Asian countries (Laos and Myanmar). The results of the phylogenetic trees constructed using UPGMA, NJ and ME method shows the same grouping pattern, all 21 testing samples from different countries form separate clades respectively, but samples from different areas in China are closely related and nested in the tree. Herbal products of *Amomum villosum* from China and Laos show no difference in morphological features, but products from Myanmar present significant differences in the part of peel and the arrangement of the seed mass. Therefore, the ITS region could be adopted as a molecular marker for differentiating the herbal products of *Amomum villosum* from different planting areas.

Reproductive adaptations of *Lycium ruthenicum* and *L. qingshuiheense* in sandstorm environment, at Kasghar, China

Aysajan Abdusalam
Key Laboratory of Ecology and Biological Resources in Yar kand Oasis, College of Life and Geography Sciences, Kashgar University

Temporal variation in flowering phenology and pollination in sandstorm environment may completely switch mating pattern and show some adaptation in flowering plants. We investigated this prediction by exploring the reproductive adaptations of conducted in a natural population of homostyly plant *Lycium ruthenicum* and approach herkogamy plant *L. qingshuiheense* in sandstorm environment, at Kashgar China. We investigated the variations of floral traits, pollinator activity, self-incompatibility and mating patterns in both species along a sandstorm and sunshine spring environment on the south Xinjiang. There were significant differences in flowering phenology, floral traits, nectar volume, self-incompatibility and mating patterns in both sexual morph speceis. Flowering phenology of *L. qingshuiheense* was shorter than *L. ruthenicum*, and flowering time of *L. qingshuiheense* was finished before summer. Sandstorm harsh environment can be negatively effect female reproductive success of self-incompatible approach herkogamy plant *L. qingshuiheense*. Pollen limitation increased in *L.qingshuiheense*, but harsh environment have no effect on self-compatible homostyly *L. ruthenicum* female reproduction and pollen limitation. Our results suggested that pollinator activity and floral traits in *L. qingshuiheense* plants is relatively more important to seed set and pollen limitation than that of *L. ruthenicum*, and self-compatible homostyly of *L. ruthenicum* is highly adaptable than self-incompatibility of approach herkogamy of *L. qingshuiheense* in long term sandstorm climate.

Plant-pollination interactions in generalized food-deceptive genus *Dactylorhiza*

Ada Wróblewska[1], Izabela Tałałaj[1], Andrzej Bajguz[1], Lech Szczepaniak[2], Beata Ostrowiecka[1], Emilia Brzosko[1], Edyta Jermakowicz[1], Paweł Mirski[1], Agata Kostro-Ambroziak[1]
1. University of Białystok, Faculty of Biology and Chemistry, Institute of Biology, Poland
2. University of Białystok, Faculty of Biology and Chemistry, Institute of Chemistry, Poland

In the animal and plant kingdoms, deception is the most effective and widespread strategy for survival. Although, there are differences between animals and plants in deception strategy, the fitness was always important in estimation with being a deceiver. *Dactylorhiza* genus belongs to generalized food-deceptive orchids. This genus complex is a good study object of food-deception strategy because evolution by recurrent hybridization and polyploidization particularly have resulted in a wide spectrum of taxa with different flower signals, and in consequences of specific-pollinator associations as well reproductive fitness. Here, we analyzed and compared the interaction between pollinating insects and floral display (different floral morphs and floral scent) of four *Dactylorhiza* taxa including two coloured morphs *D. incarnata* ssp. *incarnate* and *D. incarnata* ssp. *ochroleuca* as well as *D. fuchsii* (diploid plants) and *D. majalis* – allotetraploid taxa, which have evolved repeatedly by hybridization between two broadly defined parental lineages: *D. incarnata* and the *D. fuchsii*. We questioned what are differences between these four *Dactylorhiza* taxa taking into account their floral display (different floral morphs and especially floral scent) and the pollinating species/their behavior with respect to food-deceptive strategy.

Calcium improves the leaf physiology of salt treated *Limonium stocksii*: A floriculture crop

Muhammad Zaheer Ahmed, Muhammad Yousuf Adnan, Tabassum Hussain, Salman Gulzar, Muhammad Ajmal Khan
Institute of Sustainable Halophyte Utilization, University of Karachi

Calcium acts as a signaling molecule to improve resistance during unfavorable environment. *Limonium stockii* seedlings were grown in 0, 300 and 600 mM NaCl and in 0 and 600 mM NaCl with additional Ca^{++} in the nutrient solution for 15 days. The effects of these treatments were studied on plant growth, leaf water relations, MDA content, Na^+ secretion rate, ion flux and photosynthesis. Plant biomass reduced by 50% and MDA content increased 50% when treated with 600 mM NaCl for 15 days. Decline in leaf WC, RWC and increased in sap osmolality began from 3rd day after 600 mM NaCl treatment. Leaf Na^+ and Na^+/K^+ ration were higher 7th days after salinity treatment while Na^+ secretion rate increased with the increase in NaCl concentration and duration of treatment. Decrease in the rates of photosynthesis was coupled with lower stomatal conductance and intercellular CO_2, however, WUE improved under salinity. Efficiency of PSII, ETR, Pq and NPQ were reduced but photosystem was intact with higher Y (NO) under salinity. The Ca^{++} application improved 25% plant FW at high salinity (600 mM NaCl) and lowers the membrane damage. In addition, Ca^{++} enhanced leaf WC and reduces tissue OP. The Na^+ accumulation in leaf reduced while the secretion increased in the presence of additional Ca^{++}. However, CO_2 assimilation and light harvesting complex remained unaffected by Ca^{++} application. The result obtained from our experiment indicate that the decrease WC, down regulation of photosynthesis and respiration, higher leaf Na^+ and energy intensive defense prevent *L. stocksii* development at 600 mM NaCl. Application of Ca^{++} enhanced salinity resistance by improving water balance, salt-secretion and membrane integrity.

Phytoremediation ability of *Calotropis procera* in reducing air

pollution in Jeddah city-Kingdom of Saudi Arabia

Alkhazzan Mulook Mohammed
King Abdul-Aziz University

This study was conducted in Northeastern part of Jeddah city. *Calotropis procera* plant was used as bioindicator and phytoremediator of contamination with heavy metals arising from the cement factory located in this area. Three study sites were chosen, the first site (control) where *C. procera* plants growing 4.88 km far away from the polluted area (the cement factory) and the other sites at the cement factory has also been divided into two sites the first one include *C. procera* plants growing around the factory (location 2), the second site include *C. procera* plants growing 150 meters far away from the factory (location 1). Samples of plants and soils were collected during summer and winter seasons (2013-2014) for laboratory works. Amount of some heavy elements (Aluminum, Chromium, Boron, Barium, Copper, Manganese, Iron, Lead and Zinc), were estimated, in plants and soil. Results revealed that, *C. procera* has the ability to have reasonable amount of heavy elements at normal ranges. Worth mentioning is that soil heavy elements were less than in plants, indicating the phytoremediation ability of this plant in cleaning the soil, meaning that, this plant absorbs the pollutants from the atmosphere. It is noticeable that heavy elements accumulated more during winter season in plants and during summer season in soil. Therefore, *C. procera* can be used as protective belts near polluted areas in Jeddah.

Importance and conservation status of forest tree species in Turkey

Volkan Altay[1], *Munir Ozturk*[2]
1. Biology Department, Faculty of Science & Arts, Mustafa Kemal University, Antakya-Turkey
2. Centre for Environmetal Studies and Botany Department, Ege University, Izmir, Turkey

Nearly 90 percent of the forests in Turkey are natural in origin and contain over 450 species of trees and shrubs. These are spread over an area of around 21.2 million ha. A major part of these forests are located in the Euro-Siberian and the Mediterranean phytogeographical regions. The dominant broad-leaved species are *Quercus* spp. (22.7%), *Fagus orientalis* 82 (3.3%), *Alnus* spp. (0.2%), and *Castanea sativa* (0.1%). Others include mixed broad leaved forests (18.5%), maquis (8.4%), coniferous species (60%), *Pinus* spp. (30%), *Juniperus* spp. (4.6%), *Abies* spp. (0.9%), *Picea orientalis* (0.7%), *Cedrus libani* (0.5%) and mixed coniferous forests (5.5%). The broad leaved trees contribute to 32 percent and coniferous species 68 percent of the timber resources. *Quercus* species occupy 6.4 million ha, *Pinus brutia* 5.4 million ha, *Pinus nigra* 4.2 million ha, *Fagus* 1.7 million ha, *Pinus sylvestris* 1.2 million ha, *Abies* 0.6 million ha, *Juniperus* 0.5 million ha, *Cedrus* 0.4 million ha and *Picea* 0.3 million ha of forest area. The biodiversity resource utilization by local people from these forest species has been elucidated in terms of tree use such as medicinal, food, handcrafts, firewood, dye, fodder and other uses. A total of 130 naturally distributed tree species are utilised economically. The most common economic uses are: medicinal (99 species), followed by food (87 species), handcrafts (65 species), firewood (60 species), dye (38 species), fodder (30 species) and other uses (56 species). Terrestrial biodiversity has decreased mainly because of the loss and/or deterioration of forest ecosystems. There is a great need for developing a system to utilize forest resources while conserving biodiversity. This study aims to elucidate the socio-economic background causing forest decrease, its effects on biodiversity, and ecological services that might be lost. We also evaluate the forest use options both from ecological and socio-economical aspects to develop a sustainable utilization system.

P0743

Clusia - one genus, many pollination mechanisms

José Elvino Nascimento Jr.[1], *Ana Cláudia A. Silva-Santos*[1], *Volker Bittrich*[2], *Maria C. E. Amaral*[1,3]
1. Programa de Pós graduação em Biologia Vegetal, Institute of Biology, University of Campinas - UNICAMP, Campinas, SP
2. Rua Dr. Mario de Nucci 500, Campinas, SP
3. Departamento de Biologia Vegetal, Institute of Biology, University of Campinas - UNICAMP, Campinas, SP

One of the remarkable features in *Clusia* (Clusiaceae) is the great variation in floral morphology, especially in staminate flowers. There are flowers with four and others with hundreds of stamens, an enormous variety of androecial morphology, with stamens free or fused in various ways, and normal anthers or athecate multilocellate ones. *Clusia* has some unusual features in relation to reproduction, such as dioecy, present in almost all species, and the secretion of resin by stamens and staminodes, a feature widely dispersed throughout the phylogeny of *Clusia*, but lacking in several species. The pollination biology of most *Clusia* species studied involves floral resin, and showed some very unusual mechanisms. Species that secrete floral resin are pollinated by bees that use the resin for nest construction. Only three species not offering floral resin were already studied: *Clusia pusilla* and *Clusia criuva*, pollinated by bees and beetles, respectively, in deceit systems; and *Clusia sellowiana*, pollinated by cockroaches in a system for which the possibility of attraction by floral scent similar to sexual pheromones of cockroaches was suggested. In order to verify if cockroaches and beetles could carry out the pollination through other mechanisms, we studied the pollination of *Clusia burle-marxii*, *Clusia obdeltifolia*, and *Clusia sellowiana*. The first two are pollinated by small beetles of families Chrysomelidae and Curculionidae. Unlike *Clusia criuva*, the flowers are not pollinated by deceit. Beetles feed mainly on pollen of staminate flowers, also using these as place of aggregation and copulation. For oviposition, female beetles fly to pistillate flowers and lay eggs at the ovary base. During this process, pollen grains are deposited on stigmas. After hatching, the larvae penetrate the ovary, where they remain for some time feeding on the developing seeds. Before the pupal stage, larvae perforate the wall of the immature fruit and drop to the soil, where they conclude their development. Although the larvae are able to pierce the outer fruit wall, they do not pierce septa dividing locules, thus feeding on young seeds of only one locule, leaving the other locules intact. Pollination of *Clusia sellowiana* is performed by cockroaches, practically the only flower visitors. Cockroaches are attracted to the flowers by acetoin, a volatile compound released also by decaying leaves, which are the main food of cockroaches in natural environments. It was previously suggested that cockroaches would be lured to the flowers through sexual attraction, since acetoin is part of the pheromone composition of some cockroach species. However, almost half of the visitors are nymphs, which are not sensitive to sexual signaling. In other words, cockroaches are attracted to food, not sex. In addition, acetoin possibly repels pollen thieves. Our studies show even more unusual pollination mechanisms in *Clusia* and that the same groups of pollinators may be involved in different mechanisms of pollination.

Prediction of the *Acacia decurrens* Willd. invasion using habitat suitability index (HSI) modelling in The Mount Merapi National Park

Susilo Ari Wibowo
Gunung Merapi National Park

Acacia decurrens . is a foreign species in The Mount Merapi National Park (TNGM). In its development after the eruption of Mount Merapi in 2010, the plant is actually growing rapidly in the open areas caused by the eruption. In this area, *Acacia decurrens* . be a threat to the recovery of mountain flora. This study aims to identify factors that affect the distribution and how wide of the *Acacia decurrens* . invasion. The approach in this study using HSI spatial modeling with binary logistic regression analysis. This analysis predicted the presence or absence of characteristics of the response variable based on the prediction of predictor variables. Then the model equation is transformed into a spatial form with ArcGIS 10.1 software. This model was validated in order to obtain a model that is totally appropriate. Based on this model, habitat suitability classes can be classified based on environmental factors that influence and wide of the *Acacia decurrens* . invasion in TNGM region can be known. Results of this study concluded that *Acacia decurrens* . tend to be invasive and is influenced by: the distance of the settlement as a function of the community activities that tend to hinder the process of natural succession in the invasion area, the distance from the seedbank as a function of source of seed for the *Acacia decurrens* . invasion, and the Normalized Difference Vegetation Index (NDVI) as a function of vegetation density of the area of the *Acacia decurrens* . invasion in TNGM region. While the invasion has evolved from the original planting (years 1968-1993) covering an area of 1,080.66 ha into 1,676.25 ha and for 47 years, has invaded outside the planting plots areas, covering an area of 783.79 ha or 72.53% of the total planted area.

The role of inbreeding depression in selecting for the link between selfing and dispersability: The case of *Hypochaeris salzmanniana*

Montserrat Arista
University of Seville

The evolutionary link between breeding system and dispersability has been proposed due to both traits affect genetic variability, gene flow and colonizing capacity. In plants, the few empirical data up to date show contrasting results, sometime associating selfing and non-dispersal and others selfing and dispersal. Consistently, theoretical models that take into account range position also result in opposite associations making necessary to test that link in model species. We test the association between selfing and dispersability in the heterocarpic *Hypochaeris salzmanniana*. We used both an experimental approach and surveys during two years in five natural populations. These populations differ in breeding system and occurr in a gradient of pollinator availability. Traits affecting dispersability, and the heritability of dispersability were also studied. Dispersability had a high narrow-sense heritability, as h2 for mid-parent regression was 0.56. Non-beaked fruits were thinner and slighter and showed higher dropping velocity and lower dispersal distance than beaked fruits. Dispersability and selfing ability were linked at all the scales studied. Experimentally, self-incompatible plants showed lower dispersability than self-compatible plants, and dispersability in self-compatible plants after outcrossing was lower than after selfing. This link was also supported in nature because populations with high proportion of self-compatible plants showed higher dispersability than self-incompatible populations. The link between selfing and dispersal seems to be a consequence of inbreeding depression that causes both, lower production of the costly non-beaked fruits and more lighter dispersible fruits. The higher dispersal of selfing fruits would be selected as a way of avoiding inbreeding depression and sib-competition. The high dispersability of selfers improves colonizing capacity in *H. salzmanniana*, as self-compatibility confers reproductive assurance in pollen limiting conditions.

Global survey of the dryland forest

Fabio Attorre[1], *Danilo Mollicone*[2], *Chiara Patriarca*[2], *Mario Messina*[1]
1. Sapienza University of Rome
2. Food and Agriculture Organization of the United Nations

The extent of forest in the world's drylands is a major source of uncertainty in estimates of global forest area, and hence in estimates of global carbon stocks and fluxes too. A convenient proxy estimate for forest area in drylands has long been the 734 million hectares (Mha) of tropical open canopy forest in 1980; this accounted for about a fifth of global forest area, though not all of it was in the drylands, not all drylands are in the tropics and some dry forest has a closed canopy. Few estimates have been made subsequently, since drylands forest is rarely surveyed, even though its overuse contributes to climate change and desertification. Recent global maps based on medium resolution (30 metre) satellite images provided new estimates, but such images are too coarse to accurately assess open canopy forest. Here, we fill this gap by reporting the first global estimate of forest area in drylands based on visual interpretation of very high resolution (≤ 1 metre) satellite images, supported by time series of vegetation indices from high temporal resolution satellite imagery. Using Collect Earth software, the Google cloud computing system and Microsoft Bing Maps, we found that 1,327 Mha of land in the drylands had ≥ 10% tree canopy cover in 2010, of which 1,079 Mha constituted forest as defined by the UN Food and Agriculture Organization. Surprisingly, the majority of all dryland forest was closed canopy, while only one third was open canopy. These findings raise the estimate of tree canopy cover in one recent Landsat map by 427 Mha (47%), equivalent to forest area in Amazonia; suggest that recent estimates of world forest area might be underestimated by at least 9%; and could help resolve current uncertainty around terrestrial carbon sink estimates.

Effect of salt stress on Rubisco enzyme and chlorophyll content of some cowpea [*Vigna unguiculata* (L) Walp] cultivars grown under irrigation in Hadejia-Nigeria

Mohammed Isa Auyo
Federal University, Dutse-Nigeria

The current climatic changes experienced globally is undoubtedly increasing salt content of our soils threatening plants growth and making them to thrive poorly and making agricultural practices challenging, costly and difficult. It is in this regard that, a research work was conducted in the field under irrigation in the Phase II Irrigation Scheme of the Hadejia-Jamaare River Basin Development Authority in Auyo and Ayama communities in Jigawa State, Nigeria, irrigating plants with surface water and ground water, to determine the effect of varying concentrations of NaCl, $CaCl_2$ and $CaCO_3$ with ECe values of 2.0 dSm^{-1}, 3.0 d Sm^{-1} 4.0 d Sm^{-1} and 5.0 dSm^{-1} in addition to 0.0 dSm^{-1} which served as control. These were evaluated on Rubisco Enzyme Concentration and Leaf Chlorophyll content of IT97K-452-2, IT04K-332-1, IT98K-503-1, and *Dan Wuri* varieties of Cowpea (*Vigna unguiculata)* Linn, (Walp). Result from the experiment revealed that both Rubisco Enzyme Concentration and Leaf Chlorophyll were inhibited by the salts, particularly at higher concentrations of 4.0 dSm^{-1} and 5.0 dSm^{-1}. $CaCO_3$ and $CaCl_2$ proved to be the salts that greatly suppressed these parameters. Local varieties of cowpea were observed to thrive more poorly in saline soils than improved cultivars. Rubisco Enzyme Concentration and Leaf Chlorophyll content were significantly ($P \leq n0.05$) inhibited as the concentration of the salt increased from 3.0dSm^{-1} to 4.0dSm^{-1}, with 5.0dSm^{-1} showing the greatest inhibition. Variety, IT97K-452-2 appeared most tolerant and *Dan wuri* were most susceptible. Concentration of 4.0 dSm^{-1} and 5.0 dSm^{-1} were most inhibitory, killing some of the plants involved. The salt concentration tolerated by the varieties was generally in the range of 0.0 to 2.0 dSm^{-1}. The research reveals that cowpeas varied in their response to salinity and salt stress inhibited important photosynthetic characters thus inhibited photosynthesis and therefore crop yield, as such it is wiser cowpea is better grown in non saline soil and other varieties to be used in large scale production ought to be screened for salinity tolerance prior to their cultivation.

Community of arbuscular mycorrhizal fungi in different ecosystem on the east of Qinghai-Tibetan Plateau

Ali Bahadur, ***Zhongcai Jin****, Yongjun Liu, Huyuan Feng*
School of Life Sciences, Lanzhou university

The community of arbuscular mycorrhizal fungi (AMF) is designated for the first time in different ecosystems on the east of Qinghai-Tibetan Plateau. Arbuscular mycorrhizal fungi have mutualistic linked with the roots of over 80% of all the plant species, as they regulate nutrient and carbon cycles, and influence ecosystem multifunctionality and soil structure. We explored the diversity and structure of AMF communities in forest, shrubs, alpine meadow, and farmland. Soil and roots from different ecosystems were sampled for the analysis of soil characters and AM fungal parameter. In farmland significantly lowest glomalin-related soil protein (GRSP) and AM fungal hyphal length density was found, while highest was indicated in shrub and forest. As predicted, soil moisture content was dominant factor revealing the difference of AM fungal spore density and hyphae length in each ecosystem. Soil phosphorus, carbon and pH were significantly correlated with AMF colonization, representing that these abiotic variables could be responsible for community composition differences among ecosystem. Water-stable soil aggregate, hyphae length and spore density were positively associated with glomalin, while the negative correlation between spore density. On the other hand, soil pH showed the opposite effect on the variables. AM fungal spore density and hyphae length increased with soil pH, while GRSP decreased. Our data reveal a sharp differentiation of AMF communities between forested areas, shrubs, alpine meadow and periodically disturbed farmland. Our results highlighted and emphasized the divergence in AM fungal diversity with different ecosystems.

Identification of an environmental-dependent mutant

Xue Bai[1,2]*, Shengyang Wu*[1]*, Chunming Liu*[1]
1. Key Laboratory of Plant Molecular Physiology, Institute of Botany, Chinese Academy of Sciences
2. University of Chinese Academy of Sciences

Unlike animals, plants cannot move to avoid environmental damage. Environmental stress can be divided into biotic and abiotic stress. It is estimated that abiotic stress, like drought, heat, cold and nutrient deficiency, is responsible for 50% decrease in crop yield worldwide. Deciphering the mechanism that how plant sense and respond to environmental stress would greatly benefit for crop yield improvement. We used rice as a model crop plant, and planted an EMS-mutagenized rice population in Hainan and Beijing to screen mutants which exhibit different phenotype in both places. Fortunately, we identified a mutant that shows similar phenotype with wild type when planted in Beijing, however, shows severely dwarf and sterile phenotype in Hainan. It would be interesting to characterize what kind of environmental signal contributes to the phenotype difference.

3. Museum of Natural and Environmental History, Shizuoka
4. Natural History Museum and Institute, Chiba
5. Iriomote Station, Tropical Biosphere Research Center, University of the Ryukyus

The symbiotic relationship between leguminous plants and root nodule bacteria is a well-known example of mutualism. Host plants provide photosynthetic products and safe habitats to their bacterial symbionts, and the symbionts return products of nitrogen fixation to the host plants. With the proliferation of bacteria in nodules, legumes can get enough nitrogen products and can grow on the soil with the low level of nitrogen. Symbiotic relationships with rhizobia significantly enhance the fitness of legumes in this way; However, legumes do not develop symbiotic relationships with every rhizobium due to host-symbiont specificity. When legumes are dispersed into a novel habitat where no suitable symbionts exist, colonization may not be successful because of lack of the symbiotic relationships. The presence of rhizobial bacteria in soils are influenced by local environments in a small scale, although the spatial distribution of rhizobia community has not been well understood. In this study, to understand the spatial response of rhizobial communities in sandy beach environments in which gradient change of environmental factors is expected, we conducted metagenome analysis using soil samples collected along line transects from tideline to inland. Using soil samples collected at two locations in Iriomote Island, Japan, environmental DNA were studied by amplifying *glnII* (glutamine synthetase II protein) gene using the primers specifically designed to target *Rhizobium*, *Ensifer*, *Mesorhizobium*, and *Bradyrhizobium*. *GlnII* gene amplicons were sequenced by an Illumina Miseq platform and metagenomic data were processed and analyzed to recognize OTUs. To extract solely rhizobial OTUs from the metagenome data, BLAST searches were performed using the center sequence of OTU cluster as a query. Using the 2,609 rhizobial OTUs detected from the metagenome data, diversity analyses suggested that alpha diversities of the rhizobial communities are correlated with the distance from tidelines. Also, beta diversity analysis among rhizobial communities showed that there are significant differences between seaward and landward communities. These results suggest that the rhizobial communities in sandy beach environments are spatially influenced by environment gradient in a small scale.

Inventorization of lianas in north-eastern India with notes on their climbing modes and reproductive attributes

Debjyoti Bhattacharyya*, Lalawmkima Darlong, Malemnganbee Longjam Chanu*
Assam University, Silchar

Lianas, the woody vines, are one of the most curious growth forms with diverse morphology and twinning patterns. They are abundantly distributed in the tropics of the globe and are one of the key components of tropical forests. North-eastern region of India, which falls under Indo-Burma biodiversity hotspot, shows great diversity in liana flora both in terms of species composition and richness. A study on inventorization of lianas in northeastern India (particularly Assam, Manipur and Tripura) based upon morpho-taxonomic investigation is going on since 2013. Their twining patterns and reproductive attributes have also been taken into consideration. The study reveals the occurrence of 95 species of lianas under 58 genera and 32 families from the region. Fabaceae is found to be the largest family with 11 genera and 23 species. Some other dominant families found are Apocynaceae (eight species), Vitaceae (six species) and Combretaceae (five species), *etc*. Genus *Combretum* is the largest with five species. Gymnospermous liana is represented only by the genus *Gnetum* (Gnetaceae) with two species viz. *G. montanum* and *G. oblongum*. The taxa enumerated show four distinct types of climbing modes, viz. stem twinner, tendril climber, hook climber and thorn climber among which stem twining is the chief climbing pattern (85%). Study of reproductive attributes reveals the presence of 27% taxa with inconspicuous (< 1 cm) flowers and 73% with conspicuous (> 1 cm) flowers. Two flowering peaks have been observed with a major peak in March-April and a minor peak in October while fruit ripening and dispersal of seeds take place mainly before the monsoon. The fact of major peak of flowering during March–April can be correlated with entomophilous nature of pollination in most of the species which is driven by enhanced insect activity in warm and dry months. For seed dispersal, four major types of diaspores are recorded viz. Barochore, Sarcochore, Pogonochore and Pterochore among which Barochory is the most recurrent attribute (45%). It has been observed that the species richness and abundance of lianas in the region is diminishing gradually, mostly due to anthropogenic activities. Habitat destruction by eradication of supporting host tree species, practice of jhum cultivation, rubber and areca nut plantation, and tea and pineapple cultivation, extension of villages and agricultural fields due to human population explosion are some of the alarming threats for lianas growing in the region. Many IUCN red-listed taxa viz. *Gnetum montanum*, *G. oblongum*, *Derris cuneifolia* and *Spatholobus parviflorus* occurring in the region are facing serious threats of extermination in near future. Genus *Tetrastigma* (Vitaceae) is proposed to be considered as threatened as three species of this genus viz. *T. lanceolarium*, *T. obovatum* and *T. serrulatum* could not be traced in the field in recent times. *Beaumontia grandiflora* (Apocynaceae), *Parabarium micranthum* (Apocynaceae) *Pueraria bella* (Fabaceae) and *Uncaria sessilifructus* (Rubiaceae) are also rare in the region. So, conservation of lianas in the region is a matter of concern and a proper policy needs to be framed immediately.

Finding the best match: Comparing preferences of *Nicotiana attenuata* and its pollinators

Julia Bing*, Danny Kessler, Ian Thomas Baldwin*
Max Planck Institute for Chemical Ecology

The self-compatible wild tobacco plant *Nicotiana attenuata* grows in genetically diverse populations and is visited by a variety of pollinators, such as hummingbirds, hawkmoths and bees. These floral visitors show differences in their behavior and flower handling. They also vary in their response to floral traits, such as scent or nectar, which the plant uses to allure potential floral visitors. Pollinators choose based on their adaptations to different floral traits. But not only pollinators make a choice, tobacco does as well. If pollen of different paternal genotypes has been transferred to the stigma of *N. attenuata*, the plant is able to select its mates from this diverse pool of pollen. For this, two questions have to be considered: 1) what floral traits are important for the different pollinators? 2) which pollinators match the plant's preferences? To answer this, we conduct natural and semi-natural experiments with transgenic lines and native accessions that show differences in floral traits. Since ethylene plays an important role in enabling the mate selection process we used transformed plants with silenced ethylene production (ACO) in comparison to empty vector control plants (EV). Pairs of EV and ACO plants were planted in a population of different native accessions that vary in floral traits important for pollinator attraction. Seeds produced after pollinator visitation will be used for genotyping. The comparison of the seed set from both transformed lines will shed light on which pollen was brought by the pollinators (ACO plant) and what pollen was selected by the plant to set seeds (EV plant). That allows us to uncouple the events of pre-pollination sexual selection (pollinator choice) and post-pollination sexual selection (mate choice of plant) to get an idea if there are pollinators that transfer exactly the pollen genotypes to the flowers that also the plant would choose based on its mate selection pattern. This will give us further insight into the ecological coadaptation between different genotypes and there best pollinators.

Lichen as a biomonitor of nitrogen and sulfur depositions in petrochemical, agricultural and forested areas in Thailand

Chaiwat Boonpeng[1], *Wetchasart Polyiam*[1], *Chutima Sriviboon*[2], *Tunsinee Jhampasri*[2], *Kansri Boonpragob*[1]
1. Lichen Research Unit, Department of Biology, Faculty of Science, Ramkhamhaeng University
2. Department of Chemistry, Faculty of Science, Ramkhamhaeng University

Nitrogen oxides (NO_x) and sulfur oxides (SO_x) are mainly originated by fossil fuel combustion. These compounds are toxic to human health and ecosystems, thus amounts of them are necessary to measure in order to evaluate human and environmental impacts. These gases can be monitored by air monitoring equipment, but only a few stations could be achieved due to financial constraint especially in developing countries such as Thailand. Alternatively, lichens are widely used as biomonitors of atmospheric deposition, moreover; this technique is cost effective. Therefore, the main goal of this research was to use lichen as a biomonitor of atmospheric deposition of nitrogen (N) and sulfur (S) in petrochemical, agricultural and forested areas in Thailand. Intact thalli of the epiphytic foliose lichen *Parmotrema tinctorum* (Despr. ex Nyl.) Hale were collected from a relatively unpolluted area, and then transplanted at one forested site in the Khao Yai National Park, at two agricultural sites near Wang Chan District, Rayong Province, and at eight petrochemical industrial sites in Map Ta Phut, Rayong Province. The transplantation was lasted for 8 month (October 2013 to June 2014) and the lichen samples were periodically collected for analyzing amounts of N (as NO_3^-) and S (as SO_4^{2-}) using Ion Chromatography (IC). The result showed that mean concentrations of both N and S in the lichens in the petrochemical industrial area (304 mg/kg for N and 664 mg/kg for S) were evidently higher than those from the agricultural (193 mg/kg for N and 437 mg/kg for S) and the forested areas (159 mg/kg for N and 381 mg/kg for S). N content showed strongly positive correlation with S content ($r = 0.82$, $p < 0.01$), and both compounds trend to decrease with increasing distance from the main industrial area. This study reinforced the utilization of lichen as a biomonitor of atmospheric N and S depositions, which is appropriate for developing countries where air quality monitoring instruments are insufficient.

Comparison of herbivory intensity and impacts on populations of *Trichocentrum undulatum* in southern Florida and neighboring Cuba

Haydee Borrero[1,2], *Hong Liu*[1,2, 3]
1. Florida International University
2. International Center for Tropical Botany
3. Fairchild Tropical Botanic Garden

With a rapidly changing climate it is important to study the role of plant-animal interactions and species' persistence within their distributional margins. The mule-ear orchid *Trichocentrum undulatum* is endemic to the Caribbean region. Southern Florida is the species distribution northern limit, with only one surviving population, in the Everglades National Park (ENP). A rare (possibly endemic) herbivorous fly, *Melanagromyza miamensis*, which is able to halt the development of the orchid's inflorescence, has incurred an alarmingly high rate of attacks in recent years. Flower development was halted by the herbivore in 94% of the new flower stalks with only 3% producing any fruit in the 2013 flowering season at a site in ENP and no fruit being produced in either 2014 or 2015. As a consequence, the population has largely not been able to reproduce for several years. The future of this species may be at risk due to its inability, or significantly reduced capacity, to produce either flowers or fruits. In this study, we wish to compare the nature and intensity of interactions between the herbivorous insect and the rare orchid in both southern Florida (the species' marginal distribution range) and Cuba (the core range). On a recent exploratory trip to the field in Cuba, populations were visited to determine the presence of this particular herbivore. Indeed, all populations showed similar signs of inflorescence stalk herbivory by the fly. We are not aware of any report prior to ours on the inflorescence herbivory of the *T. undulatum* in Cuba. Further evaluating and comparing the impacts of the insect on populations throughout the island and those in southern Florida would shed light on this complex plant-animal interaction.

Species composition, stand strusture and environmental interpretation in the forest community dominated by *Pinus kwangtungensis*, a Chinese endemic

Linying Cai, *Xinyuan Zhang, Ding Ma, Lu Zhang*
South China Agricultural University

Pinus kwangtungensis is the pines with five needles located in the montane areas. Global warming and long-term disturbance threaten its existence, and *Pinus kwangtungensis* is listed as vulnerable in the Species Red List in China. To analyse whether and how major environmental factors influence the species composition and stand structure in the subtropical forest community dominated by *Pinus kwangtungensis*, a total of seventy-two 100 m^2 plots were laid out in the southern slope of the Nanling Mountains, South China (1,100–1,900 m a.s.l.). We found that 227 species in 138 genera and 76 families of vascular plants were recorded in the plots. Both family and genus present a highly significant relationship with the species richness ($P < 0.001$). Contrary to previous studies, abundant saplings of *Pinus kwangtungensis* were found in the forest community and the analysis based on diameter class of the endangered species showed a normal pyramidal shape, indicating that the species was not a regressive species at the population and community level. Canonical Correspondence Analysis and Cluster Analysis were used to analyze and portray the relations of *Pinus kwangtungensis* to other species in the forest community and the relations of species patterns to their habitat. Spatial distribution of *Pinus kwangtungensis* in the forest community showed a significant pattern along an altitudinal gradient ($P < 0.001$). The endangerment status of *Pinus kwangtungensis* can be ascribed to large-scale events such as habitat fragmentation, natural and human disturbance, which has important implications for species conservation at the landscape or regional level.

The shape is more important than we ever thought: Plant to plant interactions in a high mountain community

*Marcelino De La Cruz, **Julia Chacón-Labella**, David S. Pescador, Adrian Escudero*

Universidad Rey Juan Carlos

Working with fully mapped communities provides the ecologist the opportunity to estimate precisely who interacts with who, how frequently and which of those interactions are important for the assembly of the community. Most analyses of fully mapped communities have employed point pattern analysis techniques, as these extract the maximum information available in the dataset. However, when dealing with high mountain communities, an important part of the spatial structure of the community is lost by approximating plant individuals as points when most chamaephyte and hemicryptophyte individuals have non-symetric, irregular sizes that are best represented by planar shapes. Based on this, we have developed a new method to test for the existence of interactions between individuals. Shapes of the individuals are mapped in the field and intersections (i.e., interactions) between them are quantified and tested against the expectations of a null model of spatial configuration of shapes (e.g., random rotation). We applied our new method to study community assembly in a two-phase pasture-like alpine Mediterranean community in central Spain analysing pair-wise interactions between the 11 most abundant species and compared the results to those obtained by a traditional point pattern analysis (ppa). We found that our new method increased the number of significant interactions from 21% (ppa) to 55% and changed the sign of around half the interactions detected with ppa. Most significant interactions were negative. Therefore, our method provides a new efficient tool to study community assembly in alpine communities.

What is driving species' independence in a species-rich shrubland? Evidences for a stochastic geometry of biodiversity

__Julia Chacón-Labella__, Marcelino De La Cruz, Adrian Escudero

Universidad Rey Juan Carlos

Most ecological theories seeking to explain coexistence in megadiverse communities share a set of three rules describing a stochastic geometry of biodiversity: (1) individuals show intraspecific clustering; (2) species abundances vary following a log-normal distribution; (3) the spatial arrangement between species is independent. The first two rules have received strong empirical support, however the third one remains highly unexplored. To fill this gap, we evaluated the independent species arrangement rule in a species-rich shrubland, and its potential drivers: the levels of species richness and intraspecific clustering experienced by a given species at different scales and the relative abundance of such species in the community. Here we show that interspecific associations were rare and that independence was positively related to species richness and intraspecific clustering, and negatively related to relative species abundances. Our results concur with the independent species arrangement rule and provide empirical support to a stochastic geometry of biodiversity. In a context of species-rich plant communities, the likelihood of two species to encounter become really small. However, what our study reveals as a novelty in this context, is that both, intraspecific clustering (as the result of dispersal limitations) and the relative species abundances are playing a fundamental role determining the probability of two species to encounter and interact, especially at very fine spatial scales.

Individual species affect plant traits structure in their surroundings: Evidence of functional mechanisms of assembly

__Julia Chacón-Labella__, Marcelino De La Cruz, David S. Pescador, Adrian Escudero

Universidad Rey Juan Carlos

Evaluating community assembly through the use of functional traits is a promising tool for testing predictions arising from Niche and Coexistence theories. Although interactions among neighbouring species and their inter-specific differences are known drivers of coexistence with a strong spatial signal, assessing the role of individual species on the functional structure of the community at different spatial scales remains a challenge. Here, we ask whether individual species exert a measurable effect on the spatial organization of different functional traits in local assemblages. We first propose and compute two functions that describe different aspects of functional trait organization around individual species at multiple scales: individual weighted mean area relationship and individual functional diversity area relationship. Secondly, we develop a conceptual model on the relationship and simultaneous variation of these two metrics, providing five alternative scenarios in response to the ability of some target species to modify its neighbour environment and the possible assembly mechanisms involved. Our results show that some species influence the spatial structure of specific functional traits, but their effects were always restricted to the finest spatial scales. In the basis of our conceptual model, the observed patterns point to two main mechanisms driving the functional structure of the community at the fine scale, "biotic" filtering meditated by individual species and resource partitioning driven by indirect facilitation rather than by competitive mechanisms.

Strong effects of slope aspects on arbuscular mycorrhizal fungal communities: Evidence from differences in composition on Qilianshan Mountains, Northwest China

Yuxing Chai, *Huyuan Feng*
School of Life Sciences, Lanzhou University

Arbuscular mycorrhizal (AM) fungi are root-associated microorganisms which play an important function in the terrestrial ecosystem. The diversity of AM fungi can be affected by series of biotic and abiotic factors. As an important topographical factor, slope can change the biodiversity and community structure via changing the illumination, temperature and soil physical and chemical properties. But for underground microbes, especially for arbuscular mycorrhizal (AM) fungi, its distribution characteristics along slope is rarely reported. The Tibetan Plateau is considered to be particularly vulnerable to climate changes. Meanwhile there are many natural many similar ridges and valleys in which the vegetation types are significant different. To reveal the distribution of AM fungi along the different slopes aspect, an investigation about the diversity of AM fungi was conducted on the Qilianshan Mountains. Significant difference of vegetation types existed in the different slopes, and the North-facing slope contained the higher species richness. The vegetation in South-facing slope mainly consisted of some grasses and compositae, such as *Stipa capillata*, *Heteropappus altaicus,* while the vegetation in North-facing slope was dominated by weeds, such as *Polygonum viviparum*, *Anaphalis lactea.* Inconsistent to the plant distribution pattern, the North-facing slope showed lower root length colonization (% RLC) and AM fungal extraradical hyphal length density. A total of 32 AM fungal phylotypes were described in our study using 18S rRNA clone library, which belonged to 7 genus: *Glomus*, *Rhigophagus*, *Funneliformis*, *Septoglomus*, *Claroideoglomus*, *Diversispora*, *Gigaspora* . There were 22 phylotypes found in North-facing slope and 23 phylotypes found in South-facing slope. Furthermore, significant difference of the AM fungal community composition also existed between different slope, and soil pH, moisture, organic C, total N and available N were significantly correlated with the AM fungal community. Besides, the variance decomposition results show that 29.82% of the variation of community structure of AM fungi was explained, and revealed that plant properties (12.42%) explained the largest variance in AM fungal composition. And the similarity of plant properties and composition, which is usually determined by climatic and soil conditions, was positively correlated with the similarity of the AM fungal composition. Our data provide important insights that host plants and mutualistic fungi may respond to slope aspect change idiosyncratically, potentially altering carbon and nutrient cycles in relation to the plant–fungus associations.

Natural colonization of plant species in sites deranged by opencast mining in Raniganj colliery, Burdwan District, West Bengal

Priyanka Chatterjee, *Ambarish Mukherjee*
The University of Burdwan

The present work reveals the floristic assemblage and the physico-chemical characters of the over-burdens (OB) resulting from dumping of residues (spoil) from the opencast mining of coal at Raniganj Colliery of Burdwan district, West Bengal. Values of pH of the spoils collected from six sites ranged from 6.6 (Nidha) to 8.63 (Bhuianpara). The organic carbon content of the spoils ranged from > 0.5% (site Nathman colliary; SiteIIA &IIB) to 0.5% (Site Nidha, Bhuianpara and Mahabir chanak). Negligible amount of nitrate–nitrogen could be found in the spoil of Sahebkothi which was very low in case of Nathman Colliary (Site IIA). Interestingly the nitrate-nitrogen content was found to be very high in Nathman colliery (Site IIB) and high in case of others (Nidha, Bhuianpara and Mahabir chanak). Spoils were with low contents of ammoniacal nitrogen in all cases in general and that of Sahebkothi in particular. The phosphate content of spoils of Sahabkothi was negligible and those of Nidha and Bhuimpara were low. Medium levels of phosphate were found in the spoil samples collected from Mahabir chanak and the second site of Nathman colliary (SiteIIB).

The first site of Nathman colliary (Site IIA) was exceptional in having high content of phosphate in their spoil samples. From the study sites as many as 37 species of angiosperms belonging to 15 families were detected. Interestingly all the individual plants were highly reduced in size under extreme xeric conditions. So far the dominant families are concerned Poaceae with six species and followed by Acanthaceae with four species. The most prevalent species is *Croton bonplandianum* which is present in 4 out of 5 sites studied (80%) which is followed by *Tephrosia purpurea* with prevalence value of 60%.

Overexpression of a *Chorispora bungeana CBF* gene in *Arabidopsis thaliana* enhances freezing tolerance and affects growth

Jian Chen, *Lixiang Ma, Zhiguang Zhao, Huyuan Feng*
School of Life sciences, Lanzhou University

Freezing stress is a major environmental factor that limits plants growth and development. CBFs play important roles in plant freezing tolerance. In this work, we analyzed the functions of CbCBFx1 from a subnival alpine plant, Chorispora bungeana. The results showed that the CbCBFx1 was localized to the nucleus and expressed in roots, leaves. Further analysis showed that the expression of CbCBFx1 was influenced by the circadian clock and cold stress. CbCBFx1 overexpression in Arabidopsis resulted in freezing tolerance increasing, cold-regulated (COR) genes expression, vegetative growth inhibition and flowering delay. Furthermore, our results showed that overexpression of CbCBFx1 in *Arabidopsis* leads to multiple biochemical changes associated with cold acclimation. These results suggest that CbCBFx1 might play a role in cold acclimation and freezing tolerance of *C. bungeana* in subnival alpine environment.

Rising variability as a leading indicator of a stochastically driven abrupt transition in a dryland ecosystem

Ning Chen[1], *Ciriyam Jayaprakash*[2], *Kailiang Yu*[3], *Vishwesha Guttal*[4]
1. Lanzhou University
2. The Ohio State University
3. University of Virginia
4. Indian Institute of Science

Complex systems can undergo abrupt state transitions near critical points. Theory and controlled experimental studies suggest that the approach to critical points can be anticipated by critical slowing down (CSD), i.e., a characteristic slowdown in the dynamics. Validity of this indicator in field ecosystems, where stochasticity is important in driving transitions, remains unclear. We analyzed long-term data of a dryland ecosystem and showed that it underwent an abrupt transition from a nearly bare to a moderate grass-cover state. Prior to the transition, the system showed no (or weak) signatures of CSD, but exhibited expected increasing trends in variability of the grass-cover, quantified by variance and skewness. We argue that these surprising results are consistent with the theoretical expectation that abrupt transitions occurring away from critical points due to increasing driver stochasticity; Indeed, a driver of vegetation - annual rainfall - showed rising variance prior to the transition. Our study suggests that rising variability can potentially serve as a leading indicator of stochastically driven transitions in real world ecosystems.

How do ontogeny, temperature and precipitation impact on biomass allocation for desert ephemeral plants and shrubs in Northwestern China?

Renfei Chen
Lanzhou University

Biomass allocation plays a key role in precisely predicting global carbon sink. In this paper, we observed the biomass allocation pattern for vegetation in Northwestern China (including ephemeral plants and shrubs in deserts) as well as global forests respectively. Furthermore, we explored the variation of Root Shoot Ratio (R/S) along with total biomass and climate. In addition to this, we also studied the consistency between optimal theory and allometric approach. Lastly, we discussed the effect of ontogeny and climate on the scaling exponent between above- and belowground biomass for different plant types. Our results show that (1) the scaling relationships between above- and belowground are allometric for ephemeral plants and shrubs in desert of Northwestern China. (2) For both ephemeral plants and shrubs, there is no consistency observed between two biomass partitioning theories. (3) Moreover, unimodal curve occurs which indicates that scaling exponent varies in logistic rule along with plant ontogeny. According to climate factors analysis, plant taxon plays an important role in biomass allocation.

Studies on *Platycarya* (Juglandaceae) highlight the boundary between floristic sub-kingdoms in the East Asia flora and adaptive genetic variation

Shichao Chen[1], *Douglas E. Soltis*[2], *Pamelas Soltis*[2], *Li Zhang*[1]
1. Tongji University
2. University of Florida, Florida Museum of Natural History

The flora of Eastern Asia is distinctively rich compared with other floristic regions in the northern hemisphere. However, knowledge of its evolution is limited. The genus *Platycarya* (Juglandaceae) is endemic to Eastern Asia. It was once widespread and provides an excellent opportunity to investigate the role of Pleistocene climatic change on the distribution of Eastern Asian biodiversity. We employed AFLP and cpDNA and nuclear sequence data, and sampled plants over the present distribution, to reconstruct phylogenetic relationships among haplotype and their geographical distribution patterns - we sought to highlight its origin, speciation, migratory route and demographic history. The geographic pattern of cpDNA suggests a long-term fragmentation and multiple refugia survival during the Quaternary climatic oscillations; no recent expansions were suggested. Previous study revealed two divergent lineages in a line with the boundary between the Sino-Japanese Floristic Region and Sino-Himalayan Region. In Platycarya, we discuss the possible formation of two Eastern Asiatic Floristic Sub-Kingdoms. The new RAD-seq technique produced high-resolution genomic data sets and available environmental databases promise to increase our knowledge of adaptive genomic variation of Platycaryaon the landscape.

Ammonia emissions from agriculture over China

Youfan Chen[1], *Lin Zhang*[1], *Yuanhong Zhao*[1], *Binxiang Huang*[2]
1. Peking University
2. China Agriculture University

This study presents an improved bottom-up estimate of ammonia emissions from fertilizer use in China at a horizontal resolution of 0.5° × 0.5° and monthly variability. We collect the data of crop planting area, fertilizer application time and rate for 18 main crops to estimate the fertilizer application amount in China. Ammonia emission factors from fertilizer use are estimated by soil properties such as soil pH, cation exchange capacity (CEC), and agricultural activity information such as crop type, fertilizer type, application mode, *etc*. We further consider ambient temperature and wind speed to account for the meteorological influences on ammonia emission factors. The derived ammonia emission from fertilizer use in China is about 4.75 Tg NH_3 for the year 2008. Henan province and Jiangsu province are the two largest emitting areas (621 Gg NH_3 and 469 Gg NH_3). The ammonia emissions from fertilizer use have distinct seasonal variability; the largest emission is in June with nearly 816 Gg NH_3 emitted, and the minimum is in January (90 Gg NH_3). We also estimate the ammonia emission from livestock is 5.31 Tg using method adjusted from Huang *et al.,* (2012). Combining with other ammonia source (e.g. human waste and transport) estimates from the REAS v2.1 emission inventory, we obtain a total ammonia emission inventory in Asia for the year 2008. The total ammonia emissions in Asia are 30.5 Tg NH_3 in 2008. China emits 12.6 Tg NH_3, accounting for 41.3% to the total Asia ammonia emissions. The most important ammonia sources are fertilizer use and livestock waste, which contribute respectively 46.9% and 29.1% in Asia, and 37.8% and 42.1% in China. With this improved Asian ammonia emission inventory, we use the GEOS-Chem chemical transport model to simulate the ammonium wet deposition fluxes over Asia, and compare with measurements from EANET. The model simulated ammonia wet deposition fluxes show a good agreement with measurements (r = 0.62-0.91). What's more, the temporal and spatial distribution of our ammonia estimate is consistent with ammonia column from satellite (IASI).

P0768
Mechanism of plant invasion in relation to performance, chemical defense and herbivore resistance: A case study of *Senecio vulgaris* L. (Asteracea) in China

Dandan Cheng[1,2], *Jiwen Ge*[1], *Viet -Thang Nguyen*[1], *Noel Ndihokubwayo*[1]
1. School of Environmental Studies, China University of Geosciences (Wuhan)
2. State Key Laboratory of Biogeology and Environmental Geology, China University of Geosciences (Wuhan)

The research of biological invasion is valuable in relation to the theoretical and practical aspects. The reason for success of invasion is one of the hotspots of the researches about biological invasion. As an extension of the Evolutionary of Increase Competition Ability (EICA) Hypothesis, the Shift Defense Hypothesis (SDH) argues that the success of plant invasion can be explained by the evolution of chemical defense in the invasive populations. The chemical defense of plants can be divided into two kinds: quantitative defense and qualitative defense. In invasive ranges alien plants are released from specialist herbivores, increase the qualitative defense and reduce the quantitative defense. Thus, they allocated more resource to growth and reproduction, which leads to the more fitness and successful invasion of the plants. *Senceio vulgaris* L. (Asteraceae) is an invasive species wildly distributed in China. Few previous studies have been conducted to investigate the invasive history, mechanism and risk management of this species in China. We conducted experiments with *S. vulgaris* seeds collected from the native and invasive populations, in order to figure out whether the invasive populations of *S. vulgaris* in China have evolved the shift defense and improved the fitness. Comparison of plants grown in green houses and common gardens in native and invasive ranges showed that the invasive *S. vulgaris* plants outperformed than their conspecific plants in relation to the growth and reproduction traits. Moreover, the relative dry matter content, considering as quantitative defense, was no different in these two kinds of plants. We determined pyrrolizidine alkaloids (PAs) from shoot and root of *S. vulgaris* plants originated from native and invasive populations using Liquid Chromatography–Tandem Mass Spectrometry (LC-MS/MS). There was a slight trend indicating lower PA diversity and lower total PA concentration in invasive *S. vulgaris* populations than native populations. A non-choice feeding bioassay was conducted in a laboratory using generalist herbivore (White jade land snail, *Achatina fulica*) fed with leaves from native and invasive *S. vulgaris* plants. The result indicated that native and invasive *S. vulgaris* plants are resistant to *A. fulica*, and there were no significant differences between native and invasive *S. vulgaris* plants in relation to the resistance against *A. fulica*. We confirmed the outperformance of *S. vulgaris* plants originated from invasive populations compared to those originated from native populations. But we did not regard that this was attribution to the chemical defense shift, because the PAs, the main qualitative defense compounds, in the invasive plants were not more than those in the native plants. Another important result is that the invasive *S. vulgaris* were not more resistant again a general snail than the native ones. As a summary, we regarded that the invasive *S. vulgairs* might retain increased completive ability, as expected by EICA. However, not as predicted by SDH, this is not necessarily caused by enemy release or defense shift.

Habitat environment and population characteristics of *Megaleranthis saniculifolia* Ohwi

Seung Ho Choi, *Jin Su Seo, Kyeong Bae Nam, Bon Yeol Koo, Hye Jin Kwon, Yong Chan Cho, In Sik Kim*
Korea National Arboretum

Megaleranthis saniculifolia is a perennial herb belong to family Ranunculaceae. It is a monotypic species and only found in Korea (rare and endangered species; EN class). Although interest on conservation and restoration of biodiversity is increased, researches for understanding species and habitat characteristics are relatively insufficient. Through examining population characteristics, we can understand rationally the environment, vegetation change and bio-interaction processes of a species in a particular area. Thus, this study was conducted to evaluate habitat environment and population characteristics of *M. saniculifolia* in natural habitat such as Mt. Dosolsan and Mt. Jumbongsan in Gangwon-do and Mt. Sobaeksan in Chungcheongbuk-do. The distribution pattern of *M. saniculifolia* was mostly formed a group of discontinuous populations in the shaded sites along the valley. The average irradiance in study areas was 40 ± 15.8% (Mt. Dosolsan), 29 ± 7.4% (Mt. Sobaeksan) and 25 ± 14.1% (Mt. Jumbongsan). The variation in specific lear area (SLA) of mature individuals was significantly different among populations; Mt. Sobaeksan (n = 12, 350 ± 63.1 $cm^{-2}\ g^{-1}$), Mt. Dosolsan (n = 10, 290.7 ± 57.0 $cm^{-2}\ g^{-1}$), and Mt. Jumbongsan (n = 7, 277.7 ± 35.2 $cm^{-2}\ g^{-1}$). Relatively high SLA in Mt. Sobaeksan is indicative of low leaf nutrient efficiency and water stress tolerance of individuals in the area. Leaf area and SLA were negatively correlated each other. SLA was positively correlated with altitude in all three areas. The average biomass was not significantly different among populations; Mt. Sobaeksan (0.6 ± 0.5 g), Mt. Jumbongsan (0.5 ± 0.8 g). Mt. Dosolsan (0.4 ± 0.1 g). The biomass ratio (above/underground) was 3.0 ± 1.9 in Mt. Jumbongsan, 2.4 ± 0.9 in Mt. Dosolsan and 0.5 ± 0.0 in Mt. Sobaeksan ($p > 0.05$). ll populations of *M. saniculifolia* showed a stable population structure of the inverted J type, which number of individuals gradually decreasing with increasing the diameter of the stem. Overall result indicated that small individuals of the species are constantly settling down.

Responses of seed size variation on the germination of a coastal tree species: *Calophyllum inophyllum*

Jin Chang Yang[1], ***Fung Yun Chong***[2], *Ying Fah Lee*[2], *Roland Kueh*[3]

1. Research Institute of Tropical Forestry, Chinese Academy Of Forestry
2. Sabah Forestry Department
3. Universiti Putra Malaysia

As part of the China-Malaysia bilateral research collaboration, a study on seed characteristics of the coastal tree species, *Calophyllum inophyllum* was conducted in Sabah, Malaysia. This study was aimed to trace the response of seed characteristic toward seed germination. *C. inophyllum* is a coastal tree that helps in stabilizing the soil erosion, and sometime being used in medicinal and biodiesel oil purposes. The *C. inophyllum* seeds were collected from 6 trees for each study site (N = 24) along the coastal areas representing Eastern (1 plot) and Western parts of Sabah (3 plots), Malaysia. The seed size variations, namely seed length, seed diameter and seed weight were measured and further germination test was conducted at the nursery of the Research Institute of Tropical Forestry, Chinese Academy of Forestry. Our findings showed that the seed germination was significantly related to seed weight, while there were no relationship to the seed length and width. With respect to germination, optimum seed weight, 3.5-4.0 g gave seedlings higher germination compared to lighter seeds or heavier seeds. These seed traits variation can help in improving to the knowledge of their ecology, especially in regards to conservation and establishment of excellent germplasm resources.

Germination characteristics of two desert species and its ecological significance in the low temperature condition

Guangming Chu

Shihezi university

Germination behaviour played an important role for seedlings regeneration and the sustainable development of population in arid and semiarid areas. The objectives of the study were to explore the low temperature germination characteristics of Haloxylon ammodendron and Anabasis aphylla and its ecological significance in Junggar basin of China. Germination was studied in the illumination incubators with six temperature gradients of 20/15 ℃, 15/10 ℃, 10/5℃, 5/2 ℃, 2 ℃ and 2/-3 ℃ for 16 days. Final germination percentages of two species among temperatures were not obviously different and all were greater than 90%. Meanwhile, germination percentages of two species surpassed 50% in the eighth day under low temperature condition. In conclusion, final germination percentages of *H. ammodendron* and *A. aphylla* between low temperature and high temperature were not obviously different and only reduced germination speed. Germination behavior of two desert species in the low temperature habitat may take advantage of favorable edaphic conditions in the snowmelt period, and promote seedling growth and lignification before experiencing desiccation of early spring. Moreover, *H. ammodendron* and *A. aphylla* had different germination strategies in the low temperature habitat.

Fruit production adjustment in a dynamic coastal environment: Insights from *Corema album*, a dioecious shrub

Ana Martins[1], ***Joana Costa***[1], *Helena Freitas*[1], *Sofia Costa*[2,3]

1. Centre for Functional Ecology, University of Coimbra
2. Mountain Research Center, Polytechnic Institute of Bragança
3. Centre of Molecular and Environmental Biology, University of Minho

Flowering plants usually produce large floral displays, but only a small fraction of flowers develop into mature fruits. Available empirical evidence suggests that resource availability is fundamental in regulating fruit maturation and consequently, female reproductive success. We used *Corema album*, a dioecious, wind-pollinated, coastal shrub, to investigated Lloyd's serial adjustment hypothesis (that is, plants adjust the maternal investment in reproduction at three sequential stages: flower development, ovary production, and fruit and seed maturation, depending on resource availability). Because male and female functions are separated in different individuals, *C. album* allows a comprehensive analysis of patterns of flower and fruit production from the maternal viewpoint. To test the serial adjustment hypothesis, we examined flower and fruit production in two habitat types: coastal semi-fixed dunes, and woodland further inland, from three selected sites inhabited by *C. album* along the Portuguese West coast in a north to south cline: Tocha (T), São Pedro de Moel (S) and Vila Nova de Santo André (A). In sites T and S, five males and five females were randomly marked for sampling in each of three plots established in each habitat type. In site A, sampling took place only in the semi-fixed dune. In addition, flower and fruit related variables were measured in ten inflorescences/infructescences per marked individual. Overall, the site had a stronger impact on flower and fruit production variables than habitat type. Nevertheless, fruit weight and diameter, and seed set showed no variation between habitat types or among sites. We detected a strong positive correlation between fruit weight and diameter (r = 0.95), and fruits originating from larger infructescences were also larger (r = 0.34) and heavier (r = 0.33). Fruit set was also larger for larger infructescences (r = 0.66). Female plants displaying more flowers per inflorescence also produced more (r = 0.45) and larger fruits (r = 0.27), but had a lower fruit set (r = -0.29) and the seeds were lighter (r = -0.46). *Corema album* inhabits in a dynamic environment, and several factors conditioning resource availability (e.g., solar irradiance, water availability, salinity) differ considerably between flower development and fruit maturation times. Differences in flower production among sites suggest intra-specific genetic variation and/or environmental heterogeneity. Collectively, our results provide evidence supporting Lloyd's serial adjustment hypothesis in *C. album*. Females produced a large number of flowers per inflorescence, thus maximizing the probability of successful mating. Subsequent maturation of a reduced number of fruits supports sequential maternal adjustment according to limiting factors, such as resource availability. This conclusion is further supported by the fact that plants that yielded more fruits per infructescence were also able to produce larger and heavier fruits. In conclusion, the adjustment of fruit development under dynamic environmental conditions is likely to play an important role in the overall reproductive success of *C. album*.

Antioxidant capacity in sedges on the Qinghai-Tibetan Plateau is adequate for yaks

Guangxin Cui[1,2], *Fuping Tian*[1], *Yuan Lu*[1], *Yu Hu*[1]
1. Lanzhou Institute of Husbandry and Pharmaceutical Sciences of Chinese Academy of Agriculture Science
2. International Centre for Tibetan Plateau Ecosystem Management, Lanzhou University

Traditionally, yaks (*Poephagus grunniens*) raised on the Qinghai-Tibetan Plateau, an area characterized by strong UV radiation, hypoxia and severe cold, are often subjected to poor nutrition and used as pack animals. The extremely harsh environment on the Qinghai-Tibetan Plateau is associated with high oxidative stress to the animals and with an increase in altitude there is an increase in oxidative stress. Keeping a proper balance between oxidants and antioxidants is crucial for biological systems to maintain a healthy status. As antioxidant production in animal cells is limited, consumed feed is the basis for the elimination of ROS. Under traditional husbandry, yaks graze only natural pasture and receive little or no feed supplement. In fact, yaks lose close to 25% of their bodyweight during the cold season because of insufficient feed intake. Study shows that protein, fat, total phenols, tannins contents and trolox-equivalent antioxidant capacity (TEAC) within plant species tended to increase with increasing elevation. Sedges are the main forage consumed by yaks, accounting to 64.1% of dietary dry matter intake in summer, although three (*Kobresia humilis, Kobresia capillifolia* and *Kobresia royleana*) of four sedges available to yaks on the Qinghai-Tibetan Plateau were classified as containing a medium level of TEAC and one (*Kobresia tibetica*) as low. Yaks are well adapted to the harsh conditions both anatomically and physiologically. Thus it is conceivable that the antioxidant capacity in the high altitude sedges was adequate for yaks .

Combined effects of water and nitrogen addition on nitrogen recovery in *Haloxylon ammodendron* based ecosystems in the Gurbantunggut Desert

Xiaoqing Cui[1], *Ping Yue*[2], *Xuejun Liu*[1]
1. China Agricultural University
2. Xinjiang Institute of Ecology and Geography, Chinese Academy of Sciences
3. China Agricultural University

Desert ecosystems are prone to respond to global climate change and reactive nitrogen deposition in biological and biogeochemical respect. The effect of increase precipitation and nitrogen deposition in deserts largely depend on its fate in the plant- soil ecosystems. However, there had limit researches about the fates of nitrogen deposition in desert ecosystems, and quantifying plant and soil retention response to water and nitrogen increase. Here we reported the results using ^{15}N labeling experiment from the *Haloxylon ammodendron* based Gurbantunggut Desert in northwest China. We chose $^{15}NH_4NO_3$ as ^{15}N tracer and added water and nitrogen twelve times every year evenly distributed in three month of growing seasons in the year 2015 and 2016. The herbs exhibited a lager sink of nitrogen retention than *Haloxylon ammodendron* forests, and the nitrogen retention had different response to water and nitrogen addition in 2015 and 2016 relative to precipitation. The different parts of Haloxylon ammodendron forests had distinct recovery with the branches largest retention. Soil as the majority sink of nitrogen retention, most of nitrogen accumulated in the topsoil layer and the topsoil and subsoil had different response to water and nitrogen addition in different years. The whole ecosystem recovery ranged from 40% to 60%. The whole ecosystem retention significantly increased with precipitation increase and adding nitrogen deposition decreased the whole ecosystem recovery inverse. All this indicated that in future climate change the desert ecosystem recovery will increase.

Within-inflorescence resource reallocation patterns following differential pollination in *Sagittaria trifolia*

Can Dai, *Lu Miao*

Hubei University

Resource allocation to reproduction through time and space have long attracted ecologists and yielded many ecological principles. Despite its popularity and importance, resource reallocation, the possibility of resource movement among flowers during fruit production, has been rarely examined and largely taken for granted. In this study, we aimed to empirically explore resource redistribution patterns among flowers within inflorescences in response to differential pollination intensity. Using a common herb *Sagittaria trifolia*, we conducted supplemental and controlled pollination for single, partial, or all the flowers in simple and complex inflorescences. The fruit set, seed production, and average seed weight between flowers of different manipulations or different treatment levels were compared within each inflorescence type, in order to reveal the possibility of resource reallocation and the limiting factors for reproduction on a fine scale. Pollen supplementation on a single flower significantly promoted fruit set; however, the same manipulation on an inflorescence did not result in any increase in reproduction. Comparing the fruit set following supplemental pollination at flower and inflorescence levels, single flowers had a higher percentage fruit set than the inflorescences. In complex inflorescences, there was no difference between supplemental and controlled pollination for flowers on main branches, neither for lateral branches. The results pointed out that single flower manipulation would exaggerate pollen limitation and lead to biased understanding on individual's reproductive status. There was evidence of resource reallocation among flowers in simple inflorescence following differential pollination. However, resource was unlikely to move between main and lateral branches in complex inflorescences, suggesting a flowering branch as an integrated physiological unit (IPU) in *S. trifolia*.

16S rDNA fingerprinting of rhizosplane soil bacterial communities associated with *Elephantopus scaber* L., a reputed medicinal plant

***Moumita Das**, Abhijit Bandyopadhyay, Ambarish Mukherjee*

The University of Burdwan

A growing body of research on plant–microbe interactions in soil has been contributing to the development of new microbial perspectives of community-ecology. Soil-dwelling microorganisms are diverse and their interactions with plants vary with respect to specificity, environmental heterogeneity, and fitness impact. Plant-associated microorganisms fulfill important functions for plant growth and health. Direct plant growth promotion by microbes is based on improved nutrient acquisition and hormonal stimulation. Diverse mechanisms are involved in the suppression of plant pathogens, which is often indirectly connected with plant growth. The species is rich in different types of secondary metabolites many of which are bioactive, thus reflecting efficacy in adaptive and defensive strategies. The present study focuses on association of bacteria in rhizoplane with *Elephantopus scaber* L., a plant traditionally popular in treatment of cancer, diabetes, rheumatism, fever, scabies and many other ailments. The plant usually prefers sandy-loam to lateritic soil with alkaline pH ranging from 7.97 to 8.47, concentrations of organic carbon ranging from 0.64 to 1.89% ; phosphorus ranging from 0.92 to 6.1 mg/L; nitrogen from 31 to 50 mg/L and potassium from 105 to 245 mg/L. Molecular identification of the bacteria was done by 16S-rDNA sequencing which enabled to record three bacterial entities in data point 1 i.e. Golapbag campus of Burdwan University and 4 in data point 2 i.e. Shibpur forest beat of Durgapur forest range. Capability of producing extracellular enzymes like catalase and citrate were checked. For better visualization of the isolates fluorencence microscopy and scanning electron microscopy were done. It was *Psychrobacillus psychrodurans* which showed psychrophilic nature. Sensitivity to antibiotics viz. Ampicilin, Streptomycin and Chloramphenicol was cheeked against all the isolates. Interestingly only one isolate, *Psychrobacillus psychrodurans*, was found to be resistant to all the three type of antibiotics used. Gram properties of the isolates were also visualized. The need for intensive exploration of beneficial plant–microbe interactions was realized since such a study offers promising environment friendly strategies for conventional and organic cultivation of plants worldwide.

Fungal symbionts of the conifer-infesting bark beetle *Ips typographus* in China

*Rl Chang[1], Ta Duong[1], Sj Taerum[1], Mj Wingfield[1], Xd Zhou[2], **Zw De Beer**[1]*

1. Forestry and Agricultural Biotechnology Institute (FABI), University of Pretoria

2. FuturaGene Biotechnology

Ips typographus (Coleoptera, Scolytinae) infests several species of conifer trees, including *Pinus* (pine), *Larix* (larch), and *Abies* (fir), but it is primarily known for the considerable damage it can cause to *Picea* (spruce) forests. This happens especially when populations of the beetle build up where trees were damaged or stressed by external factors like wind or drought. Although some studies have shown that populations of *I. typographus* in Europe, Japan and China are genetically distinct, the populations are biologically similar, including a strong association with ophiostomatoid fungi, some of which might assist the beetle in overcoming host responses of the tree. To date, only two *Leptographium* spp. have been reported from *I. typographus* in China, while more than 40 and 10 ophiostomatoid species are known associates of the beetle in Europe and Japan respectively. In this study, we collected and identified the ophiostomatoid fungal associates of *I. typographus* in northeastern China, and determined whether the fungal assemblages reflect the different geographical populations of the beetle. Field surveys in Jilin and Heilongjiang provinces yielded a total of 1,046 isolates from 145 beetles and 178 galleries. Isolates were grouped based on morphology and representatives of the groups were identified using DNA sequences of the ribosomal LSU, ITS, β-tubulin and elongation factor 1-α gene regions. A total of 24 species of ophiostomatoid fungi were identified, including 12 previously described species and 12 novel species. The dominant species were *Ophiostoma bicolor*, *Leptographium taigense* and *Grosmannia piceiperda* representing 40%, 28% and 18% of the isolates respectively. Making comparisons between the species from China, Europe and Japan is complicated by the fact that some of the European and all the Japanese identifications were based on morphology only and DNA sequences are lacking for these fungi. However, assuming that previous identifications are correct, only five species (*Endoconidiophora polonica, G. cucullata, G. penicillata, O. ainoae* and *O. bicolor*) are shared between Europe, Japan and China which matched with the population structure of the beetle. Only one fungal species is shared between China and Japan (*O. japonicum*), five species (*G. olivacea, Graphium fimbriisporum, L. taigense, O. brunneolus* and *O. floccosum*) are shared between Europe and China, and two species (*Ceratocystiopsis minuta,* and *O. piceae*) are shared between Europe and Japan. The results from our work showed that the symbionts of the bark beetle could only reflect the population structures to some degree, and the use of fungal symbiont assemblages to infer population structures and invasion history of its vectors need to be carefully interpreted. In addition, our results highlight the risks of moving infested logs or timber of the tree species involved between different countries and geographical regions, as new fungal species that might pose a risk to tree health can inadvertently be introduced together with the beetles. As has been the case with other conifer-infesting bark beetles, climate change will have an impact on the spread of *Ips typographus*, but to fully comprehend this impact, more research on this beetle and its fungal symbionts is needed.

P0778

Re-evaluating the genus *Grosmannia* (Ophiostomatales, Ascomycota), with special emphasis on conifer-infecting species from China

*M Yin[2], Mj Wingfield[1], Xd Zhou[1], **Zw De Beer**[1]*

1. Forestry and Agricultural Biotechnology Institute (FABI), University of Pretoria, Pretoria

2. College of Forestry and Landscape Architecture, South China Agricultural University, Guangzhou, Guangdong Province

The fungal genus *Grosmannia* (Ophiostomatales, Ascomycota) includes numerous ecologically and economically important species that stain and degrade wood. The genus is typified by *G. penicillata*, and includes an additional 19 species, most of which are associates of conifer-infesting bark beetles. Many of these species were previously treated in the genus *Leptographium,* but the two genera were recently separated based on a comprehensive multigene phylogenetic study of the Ophiostomatales. During a survey of ophiostomatoid fungi associated with bark beetles and sapstained wood in the spruce forests of western China, we obtained 45 isolates from three bark beetle species (*Ips shangrila, I. nitidus* and *Polygraphus poligraphus*) infesting *Picea purpurea* and *P. crassifolia*. The aim of this study was to identify these isolates based on multigene (ITS, βT, TEF1-α, and Calmodulin) phylogenetic analyses and morphological comparisons with other species in the genus. At the same time it provided the opportunity to revise the taxonomy and produce a robust phylogeny including all species in the genus for which cultures were available. The results revealed four novel *Grosmannia* species from spruce in China that are in the process of being described. Some isolates from pine in the USA that had previously been identified as *L. abietinum*, also represented a distinct taxon that is being described. An interesting outcome of the study was that conifer isolates were separated into three well-supported lineages that respectively included six European and Asian species from spruce, one Norwegian species from spruce, and five North American species from spruce, fir and larch. A fourth lineage included three species from hardwoods in East Asia and Africa. From our results it is clear that the diversity of ophiostomatoid fungi occurring in Chinese forests need to be explored further, as some of these fungi and their beetle vectors might pose threats to forests when introduced into new environments as a result of human activity or movement due to a changing climate.

P0779

Pollen limitation and reproductive effort: The role of the quantity and quality factors on fitness consequences and reproductive costs

***Rafael F. Del Castillo,** Sonia Trujillo-Argueta*

Instituto Politécnico Nacional

Understanding the factors limiting reproduction and their consequences is fundamental for answering essential questions in biology such the evolution of sex, breeding systems, and life history. Pollination often limits the female reproductive function. However, pollen limitation has often been estimated only in terms of seed numbers; thus, its fitness consequences remain elusive. Life history theory posits that organisms can succeed in a given environment through the combination of resources allocated to survival, growth, and reproduction that optimizes fitness. By competing for the same resources, fitness components are constrained by trade-offs. Consequently, resource allocation affects not only the processes to which plant resources are allocated but also the processes to which resources are not allocated. This requires assessing not only the increases in seed quantity and quality gained by supplemental pollination but also their costs. Such costs instead can be diverted to other fitness components. If pollination levels are suboptimal, provisional commitment to seed production can be revoked. Decreases in fruit or seed set may increase fitness at least in two ways: by improving offspring quality or by saving resources that can be diverted to other vital functions. We test these ideas in a sexually polymorphic population of *Opuntia robusta* (Cactaceae) two of which sex morphs have contrasting sensitivities to pollen limitation. Females are entirely dependent upon external pollination; while hermaphrodites, by virtue of their autonomous selfing, depend partially on external pollination. We estimate the quality and quantity of pollen limitation by applying to randomly selected females and hermaphrodites in the field two kinds of pollen treatment to different flowers: pollen from males' plant and pollen from hermaphrodites' and estimated their consequences, not only in terms of fitness but also in terms of reproductive costs, by comparing supplemental pollination with natural pollination. We found that the quality and quantity component of pollen limitation affect significantly both plant fitness and reproductive effort. Fitness estimated in terms of fruit set, seed set, seed germination and seedling survival increases with supplemental pollination. Further, male's pollen tends to boost fitness more than hermaphrodite's pollen particularly in females. We conclude that in females, fitness can be enhanced above the levels expected for plants with lower dependence on external pollination, such as hermaphrodites. Full pollination can make that female seed quantity and quality exceed substantially those of hermaphrodites, but also increased significantly reproductive cost. Under conditions of pollen limitation, however, females may invest less in reproduction than hermaphrodites. Such savings may contribute to explain why females tend to exceed hermaphrodites in clonality under conditions of pollen limitation. Our results suggest that understanding the consequences of pollen limitation requires considering not only their reproductive effects of their quantity and quality components on plant reproduction but also their costs. We hypothesize that individuals more susceptible to pollen limitation might be more plastic in their responses before environmental uncertainty.

Zonation patterns of pteridophytes along the northeastern slope of a secondary forest in Mt. Makiling, Philippines

Marjorie Delos Angeles, *Inocencio Buot Jr.*
University of the Philippines Los Banos

Pteridophyte zonation patterns as well species composition along the northeastern slope of Mt. Makiling during the wet season were determined. The plot technique method was employed along the altitudinal gradient of Mt. Makiling resulting to 9 sampling sites during the months of December 2010 and January 2011. A total of 31 fern species were identified belonging to 19 genera and 14 families during the wet season. There were three zones identified during the wet season using a dendogram by average clustering: (i) Zone 1: *Bolbitis* – Ferns sp.1 (150-250 m.a.s.l.); (ii) Zone 2: *Lygodium – Christella - Sphaerostephanos* (350-650 m.a.s.l.); (iii) Zone 3: *Sphaerostephanos – Selaginella* (750-1050 m.a.s.l.). Moisture content, pH, and substrate contributed to a higher diversity of ferns during wet season. There is an increasing trend in diversity along the altitudinal gradient.

Soil organic carbon storage and pattern in Northwest China

Longwei Dong, *Jianming Deng*
Lanzhou university

The desert ecosystem accounts for the 20% of territorial area in China, at the same time soil organic carbon plays a very important role in the terrestrial ecosystem . In this paper, we choose the desert ecosystem located in the northwest China arid areas as the research object. From the investigation in the field, we find that in the depth of one meter the soil organic carbon storage is 7.02 Pg, the average soil organic carbon density is 5.64 Kg C m^{-2}. Among them, the average soil organic carbon density in the desert steppe (6.22 Kg C m^{-2}) is remarkable higher ($P < 0.01$) than that in the desert shrub (3.00 Kg C m^{-2}). The main factors which influence the average soil organic carbon density from zero to twenty centimeters are different for different vegetational types. NDVI and the content of clay respectively explain the variation of soil organic carbon density by 39% and 24% in the desert steppe ecosystems, meanwhile, the content of sand explains that by 31% in the desert shrub ecosystems .

The conservation and management of Tertiary relict plants will eventually depend on knowledge of their geographic distribution and the environmental changes that threaten them. This study, using species distribution modeling (involving a new approach that allows for uncertainty), predicts the distribution of climatically suitable areas prevailing during the mid-Holocene, the Last Glacial Maximum (LGM), and at present, and estimates the potential formation of new habitats in 2070 of the endangered and rare Tertiary relict tree *Davidia involucrata* Baill. The results regarding the mid-Holocene and the LGM demonstrate that south-central and southwestern China have been long-term stable refugia, and that the current distribution is limited to the prehistoric refugia. Given future distribution under six possible climate scenarios, only some parts of the current range of *D. involucrata* in the mid-high mountains of south-central and southwestern China would be maintained, while some shift west into higher mountains would occur. Our results show that the predicted suitable area offering high probability (0.5–1) accounts for an average of only 29.2% among the models predicted for the future (2070), making *D. involucrata* highly vulnerable. We assess and propose priority protected areas in light of climate change. The information provided will also be relevant in planning conservation of other paleoendemic species having ecological traits and distribution ranges comparable to those of *D. involucrata*.

Convergence of carbon and nitrogen isotopes in terrestrial bryophytes across global nitrogen deposition and climate gradients

Yuping Dong, *Xueyan Liu, Wei Song, Xinchao Sun, Congqiang Liu*
Institute of Surface-Earth System Science, Tianjin University

Bryophytes, a widespread and functionally important vegetation in almost all terrestrial ecosystems, have been recognized to be one of the most sensitive biomes to reactive nitrogen (N) deposition. It has been reported that increased N deposition can influence photosynthesis, N utilization, species composition and productivity in bryophytes. However, the knowledge on C and N biogeochemistry in terrestrial bryophytes has not been well-established, which prevented a mechanical understanding of N-deposition effects on terrestrial bryophytes. Natural C and N isotopes are unique tools to provide *in situ* evidences on the responses of C and N dynamics in terrestrial bryophytes to N deposition. This work complied worldwide data of C and N concentrations, and stable isotope compositions (i.e., $\delta^{13}C$ and $\delta^{15}N$ values) of terrestrial bryophytes, as well relevant data of environmental and climatic factors. We examined correlations among bryophyte C and N concentrations, $\delta^{13}C$ and $\delta^{15}N$ signatures, mean annual temperature (MAT), mean annual precipitation (MAP), and N deposition levels. No significant correlation was found between bryophyte $\delta^{13}C$ and MAT or MAP. N deposition enhanced bryophyte N uptake, which explained more variations of bryophyte C concentrations and $\delta^{13}C$ values than species differences. The negative relationship between $\delta^{15}N$ values and N concentrations in bryophytes indicates that bryophytes assimilated more ^{15}N-depleted N sources that dominated in high N deposition. Moreover, we proposed a level- and N form-dependent mechanisms for N-deposition effects on bryophyte C and N fixation, which should be considered in future species- and ecosystem-specific studies. In summary, this study furthered the interpretation of C and N geochemical records in terrestrial bryophytes, which is useful for evaluating influences of anthropogenic N deposition on C and N cycles in bryophytes and moss-dominated ecosystems.

Community nitrogen indicator: An new tool to indicate ecosystem nitrogen availability

Enzai Du
Beijing Normal University

Nitrogen (N) deposition has been increasing globally and has arisen concerns of its impacts on terrestrial ecosystems. Ecological indicators play an important role in ecosystem monitoring, assessment and management in the context of an anthropogenic transformation of the global N cycle. By integrating species composition and leaf N stoichiometry, a new community N indicator was defined and tested in the understory plots of an N enrichment (as NH_4NO_3) experiment in an old-growth boreal forest in Northeast China. Three-year N additions showed no significant effect on the understory species richness, but an obvious shift in species composition occurred. The response of leaf N content to N additions was generally positive but varied by species. Overall, the community N indicator increased significantly with higher N addition level and soil available N content, being in the shape of a non-linear saturation response curve. The results suggest that the community N indicator could be an effective tool to indicate changes in ecosystem N availability. Critical values of the community N indicator for specific vegetation type could potentially provide useful information for nature conservation managers and policy makers.

Facilitation or competition? The effects of the shrub species *Tamarix chinensis* on herbaceous communities are dependent on the successional stage in a coastal wetland of North China

Ning Du[1,2], *Pan Wu*[1,2], *Franziska Eller*[3], *Dayou Zhou*[1,2], *Jian Liu*[4], *Wenhao Gan*[1,2], *Ruirui Yang*[4], *Min Dai*[1,2], *Yandong Chen*[1,2], *Renqing Wang*[1,2,4], *Weihua Guo*[1,2]
1. Institute of Ecology and Biodiversity, Shandong University
2. Shandong Provincial Engineering and Technology Research Center for Vegetation Ecology, Shandong University
3. Department of Bioscience, Aarhus University
4. Institute of Environmental Research, Shandong

The responses of herbaceous species to shrubs are crucial for community succession, but are not fully understood. Three sites experiencing degraded, early positive and late positive successional stages in Laizhou Bay coastal wetland of North China were selected to investigate herbaceous responses to the dominant shrub *Tamarix chinensis* at both community and species level. Plots both inside and outside the shrub canopy were surveyed. The effects of *T. chinensis* on plant diversity and growth of herbaceous community were negative in the degraded succession but facilitative in the positive succession. Solar irradiance was the only significant environmental factor for species' proximity to the shrub in the degraded succession, while both aboveground (solar irradiance) and belowground environmental factors (soil conductivity, water content, nitrogen concentration) played an important role in the positive succession. The performances of dominant herbaceous species in interaction with *T. chinensis* were both species-specific and traits-specific. Solar irradiance and soil conductivity, both significantly affected by the shrub, were the key factors for plant growth and leaf nutrient concentration at the species level. Thus, *T. chinensis* played an important role in the succession processes of the coastal wetland, but mainly in the positive succession stage and less in the degraded succession.

Investigation on siderophore production by the arbuscular mycorrhizal fungi, *Glomus* species

Sunanda Dutta, *Medhatithi Sen, Sikha Dutta, Jayanta Chakraborty*

The University of Burdwan

Siderophores, the low molecular weight (<10 KD) iron chelating compounds are produced by Arbuscular mycorrhizal fungi (AM) (Boer-de *et al.,* 2003; Aliasgharzad *et al.,* 2009). These compounds are ferric specific ligands and are produced by microorganisms as agents for iron scavengeing in order to combat low iron stress. Siderophores solubilize the insoluble iron present in the soil and transfer it into the microbial cell. The ferric specific free ligands of siderophores produce intricated complex compound with ferric iron (Fe^{3+}) to form ferrated siderophores which is then transported to microbial cell *via* specific transport receptors located in the plasma membrane. Dhanya and Potty (2007) reported that inside the cell, siderophores turn into free form, from Fe^{3+} to repeat and the cycle. Depending upon the functional group iron siderophores are classified into three types *viz.,* hydroxamat type, catecholate type and carboxylate type (Jalal and Dick, 1990; Dutta *et al.,* 2006). Siderophore production by microbial agents has long been identified as an important antagonistic characteristic of several biocontrol agents including arbuscular nycorrhizal fungi which are efficient antagonists against many soil borne phytopathogens (Neilands, 1984; Leong, 1986; Bossier *et al.,* 1988; Barash, 1990; Boer-de *et al.,* 2003). In consequence, the ability of siderophores production by many VAM fungi, may certainly be one of the important reasons for reduction in infection and disease severity of many economically important plants. Present study emphasizes on the production of siderophores by the VAM fungi, *Glomus mossae* and *G. intraradices.* It also transact with the exploration of the threshold value of the ambient concentration of ferric Fe (Fe^{3+}) at which siderophore production by the test fungi is maximum. The effect of pH on siderophore production by *G. mossae* and *G. intraradices* was also investigated.

Pre-mycorrhizal seedlings: An alternative for the cultivation of *Jatropha curcas* L. in salinized soils

Dilliani Felipe Barros Oliveira, Jose Vieira Silva, ***Lauricio Endres***
Universidade Federal de Alagoas

The cultivation of *Jatropha curcas* to produce biodiesel is a possibility to use saline areas; however biomass production is limited in these soils. Arbuscular mycorrhizal fungi (AMF) are a promising alternative for bioremediation in salinized soils. However, salinity also affects the AMF and, in this case, not always the symbiosis is established. Therefore, this study aimed to verify whether seedlings previously inoculated with AMF in non-salinized soil, subsequently transplanted to salinized soil, are more tolerant to salt stress. The experiment was carried out in a greenhouse, using a randomized blocks design in a 4 x 2 factorial scheme. The first factor consisted of soil salinized with electrical conductivity of 2, 5, 8 and 10 dS/m, and the second one was the presence or absence of AMF, with eight repetitions. Salt had a deleterious effect on the AMF non-inoculated plants, which had a reduction in the growth and photosynthetic activity, and an increase in stress indicators such as lipid peroxidation, proline accumulation, and high antioxidant enzyme activity. On the other hand, pre-mycorrhizal plants were less affected by the presence of salt in the soil. The AMF pre-inoculated seedlings had no reduction in photosynthesis and growth in saline soil. No increase in lipid peroxidation and antioxidant enzyme activity was observed in the AMF pre-inoculated seedlings, even under a high salt stress. The results suggest the existence of a mechanism that mitigates salt stress effects in pre-mycorrhizal seedlings. Therefore, previously mycorrhizal *J. curcas* seedlings may be an alternative to the cultivation of this species in salinized soils.

Vegetation changes and perturbation events by anthropic activity based on core peat bogs in Escalerani (Bolivia)

Katerine Escobar-Torrez[1]*, Teresa Ortuño*[2]*, Marie-Pierre Ledru*[2]
1. Herbario Naciona de Bolivia
2. Museo Nacional de Historia Natural
3. Institut de recherche pour le développement

We realized a palynological study from 1 m depth sediment core. The study area is in the Paramo yungueño, nearest a *Polylepis* forest remnant, in the eastside of the Cordillera Real, Escalerani. Results show us relationship Poaceae/Asteraceae pollen before 7,505 cal. yr BP, we have had a wetter period than the actual, followed by a gradual change. The study of Sandoval (2011) find that *Polylepis* pollen do not allow long distance than 100m, then we can conclude that the presence of *Polylepis* pollen around 5,600 cal. yr BP, could give us insights about a major extension of the *Polylepis* forest near the peat bog. Additionally, there is another charcoal peak 3,655 cal. yr BP that is coincident with a Poaceae, probably Festuca-type, these results could show us the beginning of the camelid harvest in a near place. Furthermore we find charcoal peaks from 450 cal. yr BP, with an increase in their frequency until the present; These results are also supported with a reduction of pollen taxa concentration, and are coincident with the beginning of the Columbian colonization. At the top of the core we see high values of *Plantago* pollen, actually is the major taxa represented in the peat bog. Actually we are doing studies of $^{13}C/^{15}N$ and XRF to have a better understand of Climate Change in this particular area, and its responses to major climate drivers in the continent.

P0789

Assessment of contribution of allelospoly and allelopathy to interference of *Medicago sativa* with *Raphanus sativus*

Salama El-Darier[1]*,* ***Esraa Fawzy***[2]*, Eman El-Kenany*[3]
1. Botany and Microbiology Department, Faculty of Science, Alexandria University, Alexandria, Egypt
2. Botany and Microbiology Department, Faculty of Science, Alexandria University, Alexandria, Egypt
3. Botany and Microbiology Department, Faculty of Science, Alexa

A simple mathematical model was applied to quantify the relative contribution of allelopathy to interference against *Raphanus sativus* by *Medicago sativa*. The interference by *M. sativa* was assessed and the relative contributions of allelopathy and allelospoly to overall interference were modeled. Competitive interference by *M. sativa* was eliminated and there were high R^2 values (0.937, 0.939) in dry weight of shoot and root of *R. sativus* respectively.

The contributions of competition and allelopathy to the interference by *M. sativa* were averaged as 13.5% and 86.5% at 6R, 23.74% and 75.37% at 12R and 3.9% and 96% at 18R in shoot dry weight, while 85% and 14.9% at 6R, 98.59% and 1.4% at 12R and 44.27% and 55.72% at 18R in root dry weight respectively. The agglomerative cluster analysis of the four samples (12R, 12R + E, 12R + 12M and 12R + 12M + E) showed two major clusters. This study suggested the complex effect of both components of interference (allelopathy and allelospoly) on the composition of vegetative proteins, and confirms the modeling results

Bryophytes in field culture as excellent model organisms for ecological experiments

Belén Estébanez[1]*, Nagore G. Medina*[2]*, Belén Albertos*[3]*, Mónica Tamayo*[1]*, María Leo*[4]*, Cristina Branquinho*[5]*, Sara Lobo-Dias*[5]*, Victoria González-Cascón*[6]*, M. Cruz Díaz Antúnez-Barradas*[7]*, Pedro Aragón*[6]*, Joaquín Hortal*[6]
1. Universidad Autónoma de Madrid
2. University of South Bohemia
3. Universitat de València, Spain
4. Real Jardín Botánico, RJB-CSIC
5. Faculty of Sciences, University of Lisbon
6. Museo Nacional de Ciencias Naturales, MNCN-CSIC
7. Universidad de Sevilla

Research on bryophyte ecology has grown steadily during the last years. Indeed, their dimensions and relatively easy culture in field and lab conditions can make them particularly useful to evaluate diverse ecological hypotheses. Also, they can be considered as sentinels of ecosystem health. Bryophytes are small, allowing multiple experimental replicates in limited spaces. Many species are also quick and easy to grow, and gardening techniques are developing rapidly, so results from common garden and/or reciprocal transplant experiments can be obtained in short periods of time. Besides, they can be easily subjected to simple growth measurements (for instance, total biomass production), or effective proxies of it coming from spectral reflectance characteristics (including NDVI). We present an example of how to combine field and growth chamber experiments to determine the optimal environmental conditions, growth periods and rate of growth for some common moss species. We set up experiments in three localities along an altitudinal gradient in Central Spain, plus additional ones near the coast at Portugal and Eastern Spain. We evaluated the effects of two factors (sun vs. shadow conditions, and entire shoots vs. ground moss material) on six species, with ten replicates per experiment, totalling at least 280 culture plots per locality (including control plots). In Eastern Spain, two additional factors (substrate and propagule density) are evaluated on three species with ten replicates per factor (total 381 plots including controls). Such experimental setup needed a total space of less than 10 m^2 per locality (mostly for the shaded area). Preliminary results will be used to develop a similar experimental setup in growth chambers at several key temperatures, representing the whole range of variation in the conditions between field localities. Besides the difficulties of adjusting bryophyte culture protocols developed in temperate climates to Mediterranean environments, preliminary results are indeed promising. We detected differences in growth in less than one month, as well as some previously unexpected results, such as some species thriving outside their natural area, or the importance of shading even for heliophilous species. We remark the advantages of these organisms for large-scale culture experiments, and their potential usefulness for tackling many research questions, such as community-level experiments on coexistence, dispersal, recruitment, effects of community structure on ecosystem functioning or *ex situ* conservation.

P0791
The effect of soil copper on moss patches of *Ptychostomum capillare*, a resistant moss species

Nuria J. Elvira[1]*, Nagore G. Medina*[2]*, María Leo*[3]*, Victoria Cala*[1]*,* ***Belén Estébanez***[1]
1. Universidad Autónoma de Madrid
2. University of South Bohemia
3. Real Jardín Botánico, RJB-CSIC

The mining industry produces diverse and profound disturbances in the environment, and is one of the main sources of heavy metal pollution in the soil, with long-lasting toxic effects. Among these heavy metals, copper considerably affects the growth, development and interspecific relationships of plants. Bryophytes have shown contrasted sensitivity to copper pollution, and could play an interesting role in biomonitoring or in bioremediation. This work aims at studying the effect of copper mining on *Ptychostomum capillare (= Bryum capillare)*, a moss species known to be resistant to several pollutants. In order to assess the effect of this metal on reproductive and developmental parameters, and on other coexisting moss, lichen and algal species, we established nine plots (1 x 1 m) along a copper pollution gradient in the mine tailings of an obsolete mine in Lozoyuela (Madrid, Central Spain). In each plot, we recorded the abundance and size of all *P. capillare* patches, its growth parameters, the observed damage in vegetative and reproductive structures of this moss, the presence of other vegetal organisms in the plots, and the incidence of epiphytic algal communities. We observed a significant effect of soil copper concentration on several factors, especially shoot density, size of the rhizoidal gemmae, tissue yellowing percentage, and presence and covering of coexisting organisms. We also noticed some additional damages in *P. capillare*, such as the persistence of protonematal stages and elongated caulidia in the plots with the highest copper concentrations. The positive relationship between copper concentration and shoot density might be due to the successfull competitive interactions of this resistant moss. Finally, we remark the interaction of other environmental factors, such as humidity and organic matter in the soil, with the effect of copper.

Impact of climate variability on dispersal and distribution of airborne pollen and fungal spores in Nsukka (South-east Nigeria); implication on public health

Dimphna Ezikanyi*, Catherine Nnamani*
Ebonyi State University, Abakaliki, Nigeria

Airborne pollen and fungal spores are major triggers of allergies and their abundance and seasonality depend on plant response to climatic variable and change. Studies on seasonal prevalence of airborne pollen and fungal spores in Nsukka (South-east Nigeria) and their relationship to climatic variables were carried out from June 2015-May 2016. The aim of the study was to determine the seasonal variations of airborne pollen and fungal spores and ascertain the impact of weather variables on their spatial distribution. Airborne samples were collected using a Tauber-like pollen sampler modified to a height of 5 ft above the ground, aerosamples were collected monthly and acetolysed. Dominant pollen recorded were those of Poaceae, *Elaeis guineensis* Jacq., *Aspilia africana* (Pers.) C. D. Adams, *Olax subscorpioides* Oliv., *Alchornea cordiforlia* (Schum. & Thonn.) Mull.-Arg, *Pentaclethra macrophylla* Benth. *and Casuarina equisetifolia* Forst & Forst. Total pollen count correlated positively with temperature and wind, though not significant and negatively with rainfall, relative humidity and wind. Fungal Spores dispersed by *Fusarium*, *Nigrospora, Puccinia, Spadicoides, Alternaria and Helminthosporium* were more abundant. A positive correlation occurred between total spores count and monthly rainfall. Rainy season (May–August) had lower records of pollen whereas the principal pollination period was during the dry season (September–November). The allergenic and pathogenic fungal spores were more abundant in rainy season (June–August) and late rainy season (September–November). The study revealed a strong influence of climatic variables on abundance and spatial distribution of pollen and fungal spores.

Genome-wide association mapping of growth response to flooding stress in sunflower (*Helianthus annuus* L.)

Lexuan Gao, *Joon-Seon Lee, Loren Rieseberg*
University of British Columbia

Sunflower, as a globally important oil crop, whose growth and production are limited by flooding stress. However, the understanding of how growth is affected by flooding stress is lacking. In this study, a large scale phenotyping experiment was performed to evaluate the variation in growth responses to flooding stress in a diverse collection of cultivated sunflower accessions. Flooding responses in multiple traits, such as shoot biomass reduction, chlorosis and hypocotyl hypertrophy were collected as an estimate for flooding resistance. The genetic architecture underlying the growth responses upon exposure to flooding stress was investigated by performing a genome-wide association (GWA) mapping on the different growth related phenotypes. No locus with major effect was found to be associated with differential growth responses to flooding stress, while many promising peaks of association with small phenotypic effects were identified. Many candidate genes underlying the associations were suggested. Further functional analyses of allelic variation in candidate genes will provide insights into the genetic basis of variation in flooding resistance in sunflower.

Chinese management status of exotic invasive plants and quarantine

Zhenshuan Zhao, *Jun Wang, Lie Qian, Guiming Zhang*
Shenzhen Entry-exit Inspection and Quarantine Bureau

With trade globalization, exotic plant invasion has become a worldwide problem, not only bringing serious harm to the ecosystem and environment, but also threatening human survival and development. Compared with invasive animals and other species, invasive plants have more species, ecological adaptability and stronger ability to reproduce and spread. China has so far confirmed 291 species (including varieties) of invasive plants, with common means of spreading through improper human introduction, being carried via various forms of transportation, international trade of goods and natural transmission. According to statistics, the inspection and quarantine department yearly intercept over one thousand kinds of exotic weeds, hosted mainly in products such as imported grain, wool, and crop seeds, and prevent their introduction and spread through their destruction and regular supervision of domestic storage places and processing plants, effectively alleviating the pressure of propagule invasion. At present, there are many problems in the research and prevention of alien invasive plants, such as bull management, imperfect laws and regulations, management lag, lack of in-depth study, lack of early warning, low public awareness and so on. In this regard, the entry-exit inspection and quarantine departments cooperate with related departments, strengthen the research and prevention of invasive plants, through strengthening the evaluation of imported seeds, perfecting the risk early warning system, exotic weed monitoring, strengthening the on-site inspection and quarantine identification technology research, and improving the processing and control. Comprehensive measures such as these have made staggered results in the prevention of exotic plant invasion. Further measures to prevent exotic plant invasion requires perfecting the system of the rule of law, enhancing the promotion of national security, and to launch the power of the whole society to participate.

P0795

The weed seeds quarantine and analysis of imported agriculture product in Shenzhen port

Dongmei Chen, *Caiyu Xiang, Xingyuan Ling, Ruifang Gao, Ying Wang, Guiming Zhang, Lin Kang*
Shenzhen entry-exit inspection and quarantine bureau

Each year Shenzhen imported from abroad a large number of agricultural products. According to the statistics during 2014-2016, a total of 8,228 batches of food and oil products, which were 16.4158 million tons and $6.66 billion US dollars, were imported. The mainly involving food types are soybean, wheat, corn, canola, sorghum, oats, barley, rice, *etc.* and the mainly producing areas are the United States, Argentina, Brazil, Canada, Australia, Thailand, Vietnam and other countries. According to the national quarantine law on the entry and exit animal and plant, pest quarantine on above large number of imported agricultural products were carried out, and the weed quarantine results were statisticed and analyzed. Totally, 34 kinds of quarantine weed seeds that were prohibited from importing, such as *Sorghum halepense* (L.) Pers., *Ambrosia artemisiifolia* L., *Lactuca serriola* L, *Euphorbia dentata* Michx. and *Crotalaria spectabilis* Roth *etc.*, 49 kinds of poisonous weed seeds such as *Datura stramonium* L., *Phytolacca americana* L., *Crotalaria mucronata* Desv., *Agrostemma githago* L., *Euphorbia heterophylla* L., and 396 kinds of other harmful weed seeds that were first intercepted or new listed weed seeds such as *Leucospora multifida* (Michx.) Nutt., *Kochia californica* S. Watson, *Pilea microphylla* (L.) Liebm., were intercepted. These quarantine weed seeds, poisonous and harmful weed seeds and other ones that have no risk assessment, and were not distributed or not widely distributed in our country are extremely dangerous. Once invasion and colonization, they will seriously affect the city's ecological environment, production of agriculture, forestry and animal husbandry, and people's life safety. According to the data in the nearly three years, in 2014, 14,197 times of 334 species weeds, including 993 times of 24 species quarantine weeds and 32 species poisonous weeds, were intercepted; in 2015, 28,942 times of 367 species weeds, including 2,275 times of 31 species quarantine weeds and 43 species poisonous seeds, were seized; in 2016, 24,433 times of s 422 species weeds, including 1,504 times of 32 kinds of quarantine weeds and 36 kinds of toxic seeds, were captured. Data also showed that among all weed seeds intercepted, according to the species of agricultural products, 175 kinds of weeds seeds were intercepted from imported rapeseed, 262 from wheat, 280 from soybean, 78 from corn, 75 from sorghum, 130 from barley, 50 from oats and 77 from rice; according to the importing country, 390 species of weeds were intercepted from the products imported from the United States, 209 from Canada, 115 from Argentina, 148 from Brazil, 157 from Australia, 71 from Thailand and 45 from Vietnam, indicating the situation of pest invasion was very serious. To stop the distribution and spread of foreign poisonous and harmful weeds in our country, measurements like strengthening the quarantine treatment technology research, standardizing operating procedures, strengthening the management of source, enforcing stringent examination and approval of the imported agricultural products, stating detailed inspection and quarantine requirements, carrying out further pest risk analysis of the exporters' agricultural products, and formulating corresponding management measures, should be carried out. Except for to handle the outbreak in time and do a good supervision on the epidemic situations, regular outbreak investigation and control work within the respective jurisdictions should be carry out, so that the spread of the epidemics were prevent and the safety of the city's ecological environment and production of agriculture, forestry and animal husbandry are protected.

P0796

Late holocene hydroclimatic variability in the Darjeeling Himalaya, India and corresponding vegetation response

Ruby Ghosh[1], *Oindrila Biswas*[2], *Dipak Kumar Paruya*[2], *Shailesh Agrawal*[1], *Anupam Sharma*[1], *C. M. Nautiyal*[1], *Subir Bera*[2]
1. Birbal Sahni Institute of Palaeosciences
2. University of Calcutta

Hydroclimatic variability in the Darjeeling Himalaya over the past ~2400 years has been explored using a range of palaeoclimatological tools combining pollen, phytoliths, non-pollen palynomorphs (NPPs), stable carbon isotope (δ^{13}C), TOC and grain size data from a lacustrine deposit. It is evident that this climatic variability also induced changes in the regional vegetation succession. The region was wet harbouring a dense broad-leaved evergreen forest between ca. BC 364 and AD 131 while, a comparatively drier condition prevailing between ca. AD 131 and 624 might be the reason behind the thinning in the forest cover. A recovery wet phase was observed after ca. AD 624. Signature of an intensified monsoon was noticed during ca. AD 1,367 that persisted till ca. AD 1,800. For the two late Holocene transient rapid climatic phenomena, i.e. Medieval Warm Period (MWP) and Little Ice Age (LIA), which are broadly regarded as wet and dry phases respectively present data further shows departures from general trends. Considerable variations exist globally for these warm (moist) and cool (dry) periods with respect to their timing, duration, and hydroclimatic dynamics. Our results identified a humid climatic phase at the beginning of the last millennium, a pre-MWP less humid phase, while MWP was similar to present day with a minor change in rainfall pattern and a wet LIA in the Darjeeling Himalaya. Reviewing the records from other proxy data, plausible reasons of these departures are addressed which indicate centennial scale variations in frequencies of "active dominated" and "break-dominated" periods are the key forcing mechanisms behind the differential behavior of the ISM (Indian summer monsoon) over the Himalayas and the peninsular India.

Host plant alters soil bacterial community through arbuscular mycorrhizal fungi in subtropical forest soils during litter decomposition

Heng Gui[1,2], *Peter Mortimer*[1], *Jianchu Xu*[1], *Kevin Hyde*[2]
1. Kunming Institute of Botany, Chinese Academy of Sciences
2. Mae Fah Luang University

Interrestrial ecosystems, most of plants cooccur with arbuscular mycorrhizal fungi (AMF) and AMF play a crucial role on linking host plant and belowground soil bacterial community. However, the interaction between these AMF and soil bacterial community and their effects on litter decomposition remains largely unexplored. In order to help overcome this knowledge gap we investigated the effect of arbuscular mycorrhizal fungi (AMF) on soil bacterial communities found in a subtropical rainforest, in southwestern China. Our experimental set up included a dual microcosm unit and two treatments: with (AM) and without (NM) AMF. Illumina sequencing was used to assess any changes in the soil bacterial communities. We found that most of the obtained operational taxonomic units (OTUs) from both treatments belonged to the phylum of Proteobacteria, Acidobacteria and Actinobacteria. The community composition of bacteria at phylum and class levels was slightly influenced by both time and AMF. However, time and AMF significantly influenced the structure and dynamics of the bacterial communities at the genus and OTU levels. Opposite to the bacterial community composition, we found overall soil bacterial OTU richness and diversity are relatively stable and were not significantly influenced by either time or AMF inoculation. OTU richness at phylum and class levels also showed consistent results with overall bacterial OTU richness. Our study provides new insight into the influence of AMF on soil bacterial communities at a fine scale resolution.

Estimating vegetation biomass using very high resolution satellite image in a karst watershed of Guizhou province, southwestern China

Yinming Guo
State Key Laboratory of Environmental Geochemistry, Institute of Geochemistry, Chinese Academy of Sciences

Vegetation biomass in karst terrain has been rarely measured because the steep and harsh mountainous limestone landscape limited our ability to sample woody plants. Satellite observation, especially in high spatial resolution, is therefore an important surrogate to estimate biomass of karst forest and shrubland. In this study we build an Artificial Neural Network (ANN) model using very high resolution (VHR) satellite imagery and field biomass measurements to estimate the aboveground biomass (AGB) in the Houzhai River Watershed, a typical plateau karst basin in central Guizhou province, southwestern China. A Back Propagation ANN (BP ANN) model was developed. Seven vegetation indexes including the Atmospherically Resistant Vegetation Index (ARVI), Enhanced Vegetation Index (EVI), Normalized Difference Vegetation Index (NDVI), Difference Vegetation Index (DVI), Green Normalized Difference Vegetation Index (GNDVI), Ratio Vegetation Index (RVI), Soil-Adjusted Vegetation Index (SAVI), two spectral bands of Pléiades-1A, and one geomorphological parameter were selected as inputs while the AGB as output. Vegetation biomass at 78 plots estimated by allometric functions was used as training data (58 plots, 75%) and validation data (20 plots, 25%). Data-model comparison showed that the ANN model performed well with the absolute RMSE of 8.22 t/ha, which is 6.51% of the average AGB. In addition, seven land cover types, with a total accuracy of 95.33% and the Kappa coefficient of 0.93, were classified based on the Pléiades-1A satellite image. On the base of the newly developed ANN model, a AGB map in the Houzhai River watershed was produced. The estimated AGB of the main forest type in the watershed, the secondary evergreen and deciduous mixed forest, was 147.85 t/ha in average. The large distributed shrubland, tussock and farmland had averaged AGB of 41.24,9.08 and 12.44 t/ha, respectively. This finding indicated that the spatial distribution pattern of AGB estimated by the new ANN model in the karst basin is consistent with the field investigation. This model can be further used to estimate vegetation biomass in the regional scale of karst lanscapes distributed in the surface of the Yun-Gui Plateau.

Transcriptomes provide new insights into community assembly in a subtropical forest

Baocai Han[1], *María Natalia Umaña*[2], *Xiangcheng Mi*[1], *Xiaojuan Liu*[1], *Lei Chen*[1], *Yunquan Wang*[1], *Yu Liang*[1], *Wei Wei*[1], *Keping Ma*[1]
1. Institute of Botany, The Chinese Academy of Sciences
2. Department of Biology, University of Maryland

Differences in seedling survival of tree species have a lasting imprint on community structure. Therefore, identifying the underlying mechanisms of these differences is a critical research objective regarding how organismal functions interact with the local environment that influences survival rates. In tree communities, differences in light use strategies are frequently invoked to explain differences in seedling demographic performance. For example, shade tolerant species grow slowly and have higher survival rates, whereas light demanding species grow quickly and have lower survival rates. Thus, functional traits related to photosynthesis/light should be strong predictors of seedling species survival. Here we provide the community-wide inventory of transcriptomes in a subtropical tree community. This information is utilized to determine the degree to which species share homologous genes related to gene ontologies for light harvesting and use. These species similarities are used in neighborhood models of seedling survival and we ask whether survival increases or decreases in the presence of transcriptomically similar or dissimilar species. We also compared the effects of phylogeny, functional traits and transcriptomes related to light and examined the effects of conspecific neighbor density, heterospecific neighbor desity on the seedling survival of 85 seedling species in a subtropical of China. Our results show that the gene ontologies related to the light quantity (GO:0010196) and light quality (GO:0010201) significantly affect the seedling survival. However, there is not significant effect for phylogeny. For functional traits, only the length to width ratio (LWR) has significant effect on seedling survival both for all species and for shade tolerant species. We found that the coefficient of the correlation between LWR and GO:0010201 is high (mantel $r = 0.185$, $p = 0.021$). Our results indicate that light is a limit factor for seedling survival in the subtropical forest and the new approach could detect the light use strategies not only in the light quality but also in the light quantity. However, the phylogeny could not detect the light use strategies. For functional traits, only LWR could detect the light use strategies. The high correlation between the LWR and GO:0010201 reconfirms the reliability of the transcriptomic approach. Synthesis: The present work takes a novel approach by sequencing the transcriptomes of naturally co-occurring tree species in a subtropical forest in China. The study demonstrates that exploring the functional genomic similarity of non-model species in natural community would greatly increase the breadth and depth in quantifications of functional similarity among coexisting species.

Plant community patterns in the hot-dry valleys of Southwestern China

Cindy Q. Tang, ***Peng-Bin Han***, *Diao-Shun Huang*, *Li-Qin Shen*, *Yi-Fei Dong*
Institute of Ecology and Geobotany, Yunnan University, Kunming 650091, China

The hot-dry valleys are steep gorges created by major rivers in the subtropical area of SW China, particularly the deeply incised valleys along the Nu River (Nujiang, upper reaches of the Salween, below 1,200 m asl), the Lancang (Lancangjiang, upper reach of the Mekong, below 1,000 m), the Jinsha (Jinshajiang, the upper section of the Yangtze, below 800–1,200 m), the Yuan (Yuanjiang, the upper stretch of the Red River, below 1,000–1,400 m), and the Nanpan (Nanpanjiang, below 1,000 m) in Yunnan, also in the down-stream stretch of the Jinsha river, as well as its tributaries including the Yalong (Yalongjiang), Anning (Anninghe), Dadu (Daduhe), Min (Minjiang), Baishui (Baishuihe) rivers of western Sichuan. Some hot-dry valleys are also found in the Southeast (Wushan, Fengjie, Xuyong, Gulan and Pingshan in Chongqing Municipality) along the Yangtze and Chishui rivers of the Sichuan Basin. In Guizhou, hot-dry valleys are confined to the southwestern part of the province, as in the Nanpanjiang and Beipanjiang valleys. A foehn effect caused by the rain shadow on the leeward slopes of the mountains accounts for their hot-dry climate. Many genera of plant communities in the hot-dry valleys have affinities with the xeric flora of tropical Asia and tropical Africa, including Woodfordia, Calotropis, and Adinandra, which are disjunctly distributed in areas of tropical Asia (including India, Malaysia and southern Yunnan) and tropical Africa. Ecologically the major vegetation in the hot-dry valleys is comparable to that of savannas of India and Africa. However, these valleys are densely inhabited by humans because their high temperatures favor good crops, as well as grasses for cattle grazing. Human activities have greatly modified the vegetation and changed these into what we now call semi-savannas (semi-natural savannas) or secondary savannas. These semi-savannas typically include the sparse woody grassland and the thorny succulent shrubland. Besides the semi-savanna, some scrublands are also found. In this study, plant communities are differentiated and vegetation-environment relationships are analyzed. For each community, we identify indicator species. Ecological preferences of each community are examined.

Impacts of long-term nitrogen addition on biodiversity and nutrient ecological stoichiometry in a temperate steppe

Tianxiang Hao[1], *Ling Song*[2], *Xuejun Liu*[1]
1. China Agricultural University
2. Institute of Mountain Hazards and Environment, CAS

Atmospheric nitrogen (N) deposition has been verified to decrease biodiversity and alter nutrient cycle in terrestrial ecosystems. Nitrogen deposition, as an important N input to natural ecosystems, has significantly increased across China over last three decades. As aggravated phenomenon was concerned, N deposition was supposed to increase or decline via non-controlled or controlled anthropogenic emissions of reactive N, just as China (increase), European Union (decrease) and the United States (stabilization) experienced. However, the response of species richness and nutrient ecological stoichiometry to long-term N enrichment in Chinese grassland is still lacking. To answer this crucial question, we did an 11-year grassland N addition experiment with N rates varying from 0 (N0), 30 (N30), 60 (N60), 120 (N120), 240 (N240), and 480 (N480) kg N ha^{-1} yr^{-1} in Inner Mongolia, China. In this study, we ceased N addition in N480 treatment since the fifth year (2009) of the experiment to observe the potential restoration from an extremely N-enriched condition. The species richness of grasses (dominant species) did not suffer from all N addition treatments, while the species richness of forbs (rare species) showed significant reduction in species richness at N30 and N60 (part years) or N120 and higher N treatments (almost all years).This indicates that forbs are more sensitive to N enrichment compared grasses in this grassland region. In N480, significant decrease in plant species richness since the first year of the experiment but a step by step restoration of biodiversity was observed when we ceased N addition in this treatment since the fifth year (2009), suggesting the ecological restoration from an extremely N-enriched condition. Meanwhile, 9 elements (carbon / N / phosphorus / potassium / calcium / magnesium / iron / sodium / aluminum) in shoots after 9 years (2013) fertilization presented three different N-induced variations. As increasing N addition, the concentrations of C and N significantly increased and saturated at N addition rates of 30 and 60 kg N ha^{-1} yr^{-1}, respectively; for Ca, Na, Fe and Al, the concentrations almost decreased in stages; the concentrations of P, Mg and K were always stable. It is noticed that, after 5 years cessation of N addition, N480 was still in line with the above rules of elements' concentration. Furthermore, plant species richness increased partly after ceasing N addition in N480 for last three years, but it seems unlikely to recover to the original status for dominant species and plant nutrients (except N) in N0. Our findings suggest that the critical threshold for N-induced species loss in this temperate steppe is between 30 and 120 kg N ha^{-1} yr^{-1}. Even the N addition rate as low as 30 kg N ha^{-1} yr^{-1} can significantly alter shoot nutrient concentrations. As reduced N inputs, the grassland would recover much of the plant species that had been lost, but the changes in plant nutrients would be hardly back to the original level. This work highlights the ecosystem recovery that exist in assessing the impacts of N deposition on biodiversity and nutrient ecological stoichiometry.

Population genetic analysis of invasive Kudzu (*Pueraria montana* var. lobata) throughout Asia and the United States with emphasis on varietal delimitations

Matthew S. Haynsen[1,2], *Mohammad Vatanparast*[2], *Lu-Xian Liu*[3,4], *Cheng-Xin Fu*[4], *Keith A. Crandall*[1,5], *Ashley N. Egan*[2]
1. The George Washington University, Department of Biological Sciences
2. Smithsonian Institution National Museum of Natural History, Department of Botany
3. Henan University, College of Life Sciences
4. Zhejiang University, College of Life Sciences
5. The George Washington University, Computational Biology Institute

Pueraria montana var. lobata (Kudzu), one of the most invasive plant species in the United States, is native to southeastern Asia. The twining vine was initially introduced into the United States from Japan during the Centennial Exposition in 1876 with subsequent mass introductions throughout the southeastern United States through the 1930s to 1950s. The native geographic origins of these introductions remain unknown, which poses a concern due to the wide native range of *P. montana*, a species containing three recognized varieties that share overlapping ranges and delimiting morphological characteristics. It is possible that the invasiveness of Kudzu found in the United States can be ascribed to not only admixture from geographically and genetically distinct populations of *P. montana* var. lobata, but hybridization among two or more varieties of *P. montana*. Only through the use of high resolution molecular markers on populations of *P. montana* across both its native and introduced ranges will it be possible to identify the geographic and varietal sources of genetic diversity within introduced populations of invasive Kudzu. In this study we used Genotyping-by-Sequencing, a next generation sequencing methodology, to assess the genetic variation of over 700 individuals of *P. montana* from China, Japan, Thailand, and the United States. Through the collection of hundreds of SNPs per individual we assessed both the among and within nation genetic diversity, native and introduced range structuring of genotypes, and models of introduction pathways. We also combined morphological measurements with genotypic assignments to determine the native range varietal boundaries and to assess areas of varietal hybridization within the native and introduced ranges.

Genetic analysis of inherited reduced susceptibility of *Fraxinus excelsior* L. seedlings in Austria to ash dieback

Berthold Heinze[1], *Alexandra Wohlmuth*[1], *Franz Essl*[2]

1. Austrian Federal Research Centre for Forests, Department of Forest Genetics

2. University Vienna, Division of Conservation, Vegetation and Landscape Ecology

Hymenoscyphus fraxineus causes massive dieback of common ash (*Fraxinus excelsior*). Previous studies have revealed differences in susceptibility among individuals, suggesting a genetic basis for reduced susceptibility to the pathogen. The aim of the study was to identify any correlation between damage intensity of mature trees and their offspring in natural ash stands. Crown and shoot damage of naturally infected trees and saplings were assessed in two isolated stands in Austria, and parentage analysis was carried out with molecular markers. No significant correlation could be verified using Spearman's rank correlation analysis, suggesting a lack of evidence for genetically inherited resistance at the sites. We thus support the results of other studies, i.e. that resistant individuals occur only at low frequency within European ash populations. While most of the previous studies were conducted in progeny trails or seed orchards and suggested a fairly strong genetic component, results from our investigation support a more complex mechanism of susceptibility differences under natural, heterogeneous conditions. Further analyses are needed to obtain a better understanding of gene-environment interactions and individual infection pressure of ash dieback in natural environments. Identification and propagating of non-susceptible ash trees is an important challenge to halt large-scale dieback of *Fraxinus excelsior*.

Removing the sun and shade confounding factor from fossil leaf palaeoenvironment interpretations.

Kathryn Hill, *Robert Hill, Alice Jones, Fiona Mcqueen*

The University of Adelaide

Leaf anatomy has been used as a palaeoclimate predictor for decades. Anatomical features such as stomatal and epidermal cell measurements change in response to climate and environment changes to modify maximum potential physiology such as gas exchange and hydraulic conductivity. We can optimise the use of anatomical features to more accurately predict past climate changes by aiming to remove the confounding factor of light availability. The aim of the project is to determine how leaf anatomy changes both between sun and shade, and along an environmental cline. Thus we can determine what leaf anatomy measurements constitute a sun or shade (or part-shade) leaf and thus determine what light environment a leaf grew in. Having removed light availability as a factor driving leaf anatomy change we can determine palaeoclimate by comparing (for example) living shade leaf anatomy from varying environment types with fossil shade leaves to determine to what paleoclimate the fossil shade leaves were exposed.

The warmest habitat where plants linger on? - Climate change vulnerability assessment of vascular plants in Taiwan

Huan-Yu Lin[1,2], *Wei-Chun Chao*[3], *Chang-Fu Hsieh*[1], *Tze-Ying Chen*[4], ***Jer-Ming Hu***[1]

1. Institute of Ecology and Evolutionary Biology, National Taiwan University

2. Taiwan Forestry Research Institute

3. Department of Forestry and Nature Resources, National Chiayi University

4. Department of Forestry and Nature Resources, National Ilan University

Taiwan is a continental island on the Tropic of Cancer with an area of 35,980 km^2. More than 73% of the land is hills and mountains, with the highest central ridge close to 4,000 m, while 60% of the land is covered by forest. Because of the diverse topography and warm-humid climate, this island supports over 4,200 vascular species, of which 1,052 (22.9%) are endemic to Taiwan. The annual mean temperature in Taiwan showed an increase by 1.4°C from 1911 to 2009, which is twice higher than the global warming rate of 0.07°C per decade. It is thus urgent to investigate habitats that are vulnerable to global warming and make conservation strategies in advance. In 2015, we complied a geo-referenced database with 1.4 million records of the flora of Taiwan for analyzing areas that are sensitive to climate change. Projected temperature tolerance range were estimated for each species based on their geo-reference information. Based on the upper distribution limit of each species' optimal temperature range, we found 19 areas showed more upper-limited individuals aggregated, and could be highly sensitive to global warming. We also found that 7 of 19 sensitive areas are isolated mountain tops represented by fragmented cool-temperate vegetation. Some of these areas suffered climatic change or extreme natural disasters (e.g. weakening of northeast monsoon, landslides, typhoons and droughts) during the past 30 years, and induced an evident recession of scarce populations, such as *Fagus hayatae, Lithocarpus formosanus* and *Rhododendron simsii*. For the sake of making adequate conservation strategies, we established an evaluation scheme that integrates vegetation characteristics and environmental factors to assess conservation priority among sensitive habitats. Lower cost and feasible conservation strategies, including in-situ conservation, building corridors and assisting migration, are suggested for populations that are not endangered critically. Furthermore, immediate ex-situ conservation is essential for rare species suffering critical recession.

Sexual system of *Daphne arisanensis* Hayata (Thymelaeaceae)

Wei-Jie Huang, ***Jer-Ming Hu***
Institute of Ecology and Evolutionary Biology, National Taiwan University

Angiosperms exhibit great diversity of sexual systems, combining different degrees of male and female function at flower, inflorescence, and individual level. As the majority of extant species are hermaphrodite, the evolution of unisexuality has drawn attention since Darwin's age. Here we documented the rarely known sex expression patterns for the flowers of *Daphne arisanensis* Hayata (Thymelaeaceae), an endemic shrub in Taiwan. Both morphologically bisexual and male-sterile flowers were found on different individuals among *D. arisanensis* populations, hence the species might be gynodioecious. However, we demonstrated clearly that it is not the case after our thorough investigation of the spatial and temporal expression of sexuality. The gynoecia of morphologically bisexual flowers displayed receptivity to pollens from either itself or other plants, but they hardly set fruits among all pollination treatments. We also found some male-sterile flowers had the ability to set fruit even without fertilization, i.e. apomictic. In addition, there is no individual altered the flowering type during the three-year observation. These findings suggest that the sexual system of *D. arisanensis* is a cryptic and leaky dioecy, and the evolution toward dioecism probably underwent gynodioecy pathway.

The genome of *Pugionium* and climatic adaptation

Quanjun Hu, *Tao Ma, Kun Wang, Huan Hu, Xinyi Guo, Yazhen Ma, Jianquan Liu*
Sichuan University

Understanding the mechanisms of speciation is a fundamental problem in evolutionary biology. To identify genome-wide patterns underlying ecological speciation, we assembled a high-quality reference genome of *Pugionium dolabratum*, an endangered psammophyte. We conducted genome-wide population surveys of natural populations to investigate the evolutionary processes and the genetic basis underlying speciation. Our findings highlight the prevalent role of geographic isolation and climate change in speciation. We identified several genes related to stress tolerance, leaf morphology and root growth. Our work highlights the value of genome-wide population surveys of natural populations in non-model species to understand the genetic basis for evolutionary change.

P0808
The relationships between above- and belowground biodiversity and ecosystem multifunctionality, and its drivers in the drylands of China

Jianming Deng, Qiajun Du, ***Weigang Hu***
Lanzhou University

Biodiversity is the foundation for the maintenance of ecosystems, which are valued for their ability to provide multiple functions and services simultaneously (ecosystem multifunctionality; EMF). However, we have limited knowledge of the links between biodiversity and multifunctionality as well as drivers of these relationships in large-scale natural ecosystems. This gap in our understanding is particularly true for drylands, areas covering 41% of Earth's land surface and supporting over 38% of the global human population, which are among the most sensitive ecosystems to climate change. Here, we present a regional-scale field study conducted along natural aridity gradients across 157 dryland sites from northwestern China. We surveyed plant community by measuring 30 m × 30 m plots, characterized bacterial, archaeal and fungal communities in the soil surface (top 20 cm) by using Illumina Miseq profiling of ribosomal genes and internal transcribed spacer (ITS) markers, gathered a range of key abiotic factors (i.e. climate, elevation, and soil texture), and assessed 14 ecosystem function indicators (aboveground biomass, plant carbon, plant nitrogen, plant phosphorus, soil organic carbon, soil nitrogen, soil phosphorus, nitrate, ammonium, soil available phosphorus, β-glucosidase, urease, phosphatase, and soil microbial biomass) related to soil biogeochemical cycles, soil fertility, biological productivity, and the build-up of nutrient pools. In this study, we aim to elucidate the relationships between above- and belowground biodiversity and multifunctionality, and to illustrate the interactions among abiotic factors and biotic attributes (i.e. above- and belowground biodiversity) in driving multifunctionality. We also evaluate how increases in aridity, as defined by the aridity index, affect biotic attributes and multifunctionality, and further emphasize the role of biological feedbacks on the responses of ecosystem multifunctionality to increasing aridity. This knowledge is essential to predict responses of dryland ecosystems to ongoing global change, and guide conservation and sustainable management efforts in drylands of China.

Studies on tracheary element of several native cycad species in Australia and two American plants

Yu-Yuan Huang[1]*, Harvey Ottley*[2,3]*, Yolande Yep*[4,5]*, Sharon Wilson*[2]*, David Griffiths*[2]*, Nikeeta O'Sullivan*[4,5]*, Jane Hempel*[2]
1. College of Life Sciences, Zhongkai University of Agriculture and Engineering, Guangzhou, Guangdong 510225, China
2. George Brown Darwin Botanic Gardens, Darwin, NT 0820, Australia
3. Palm and Cycad Society of the Northern Territory, Darwin, N T 0820, Australia
4. School of Environment, Charles Darwin University, Darwin, NT 0909, Australia
5. Research Institute for Environment & Livelihoods, Charles Darwin University, Darwin, NT 0909, Australia

Cycas angulata, Cycas amstrongii and *Cycas conferta* which are native species of Australia were collected in Darwin city of tropical region, *Zamia erosa,* and angiosperm *Guaiacum officinale* which are introduced collected in the Darwin Botanic Gardens, and were carried out electron microscope observed research to tracheary element and parenchyma tissue cells of leaflet and rachis. The results showed that there were more vessel elements in their xylems. The length of vessel element of Cycadaceae with Zamiaceae were not obvious difference, the length of vessel element of angiosperm *Guiacum officionale* was shorter, showed its more evolutional characteristic. These vessel were annular vessel, spiral vessels, scalariform vessels, reticular vessels, pitted vessels and scalariform-pitted vessels. In the transverse section, the vessel elements of Cycadaceae and Zamiaceae were circular, polygonous, more similar to vessel characteristics of petiole and stem of some angiosperms; however, the number of circular vessel of *Guiacum officionale* were more, about occupied 35%, others were polygonous. The diameter of vessel were that annular vessel, spiral vessel were least, scalariform vessel was medium, reticular vessel and pitted vessel were biggest, the characteristic was same as angiosperm. In *Cycas conferta etc.* plants often seen several large perforations in the end walls, some species were several big scalariform or pitted perforations formed multiple perforation plates, in many vessel element lateral walls, there were some perforations formed a horizontal transport avenue of aqueous solution. The scale of diameter of *Cycas* vessel element were similar to that of *Zamia*, and was bigger than that of *Guiacum officionale*, although *Cycas* plants are more primitive than *Zamia* plant, and *Guiacum officionale* is more evolutionary, but the scale of vessel diameter of *Cycas* plants is similar to *Zamia*, even larger than *Guiacum officionale*, these showed that cycads have more evolutionary and more developed characteristics in aqueous solution transport system. In the respect of observed parenchyma tissue, any parenchyma tissue cells were without perforation, all cell walls were smoothed and like a membrane. Aimed at only one or two people pointed the query about Jeffery's method, some scholars have made comparative researches, their research used as follow methods: (1) The fresh materials were cut sections 1–2 mm thick by hand (the query person provided and thought right method), were examined with SEM. (2)The materials were treated by Jeffrey's Fluid and observed with SEM and so on. The results showed that the pit membrane, the remnants in the perforation and the structural characteristics of perforations were no different. These results justified that Jeffrey's method is reliable and reasonable. Our research result showed that only vessel element can formed perforation, and in other all parenchyma tissue cells can not formed perforation are also proved that the perforations of vessel element are natural inherited character. The research is important significant and theory reference to understand cycads evolutionary aqueous solution transport system, and understand the ecological adaptation mechanism which why present cycads of 3 families in world major distributed in tropical or subtropical regions, even many drought and barren areas.

The comparative studies on plant diversity and their ability of absorbing and reducing to PM2.5 of Xiaonanshan with Dananshan Mountain areas

Yun-He Lu[1], *Ruo-Yu Wei*[2], *Hai-Yang Wen*[2], *Zhen Ye*[2], *Xin-Fan Yu*[3], *Fan Wang*[2], ***Yu-Yuan Huang***[2], *Kang-Sai Zhao*[3], *Hong Liang*[3], *Long He*[3], *Zhi-Ming Yang*[2], *Ya-He Li*[1]

1. Environmental Monitoring Station of Nanshan District, Shenzhen, China
2. College of Life Sciences, Zhongkai University of Agriculture and Technology, Guangzhou, China
3. Shenzhen Environmental Monitoring Center, Shenzhen, China

The plant community structure and plant diversity of Dananshan and Xiaonanshan Mountain areas were carried out measured studies, meanwhile measured PM2.5 concentration indices of outside and inside of forests of 17 communities, comparative analysed the ability of absorbing and reducing of forests with different structures, and explored the argument problem on which kind community is biodiversity higher? Is natural forest, artificial forest or is more artificial disturbed forest higher? The results showed that: there were 195 species in 12 communities of natural forests in Xiaonanshan, in these species, ferns, gymnosperms, and angiosperms were 14, 2 and 179, respectively. Because Dananshan Mountain areas almost all areas were the artificial forests, and several document species in tree layer, so chose 6 communities made research. There are total 137 species, and ferns, gymnosperms, and angiosperms were 16, 2, 119, respectively. The number of species of Xiaonanshan was obvious higher than that of Dananshan. The values of Simpson indices, Shannon–Wiener indices and Odum, Menhinnick richness indices and Pielou evenness indices of Xiaonanshan were also higher than that of Dananshan artificial forests. In respect of community structure, the forests of several species of *Eucalyptus* and *Acacia auriculaeformis* in Dananshan, the tree layer had only 5-6 species, and the individual number of document species occupied most proportion, other species were mainly shrubs and herbs. However, in the communities of Xiaonanshan, the tree layer usually was richness with 15-22 species. And the height of shrub layer was higher and more species, the herb species were also more than that of Dananshan. In the community distribution, the plant diversity of lower altitude places were lower than middle altitude places in Xiaonanshan, maybe the reason was more artificial disturbed, and more pollutants emission. In higher altitude of near 265 m, the plant diversity were also below, probably where were approach top of the mountain, wind was stronger. The situation of Dananshan was similar to Xiaonanshan, but the difference was relative little because of artificial forest. In aspect of absorbing and reducing air pollutant of PM2.5, in the 17 plant communities of Dananshan and Xiaonanshan, the concentration of forest inside were lower 6-7 ppm than that of outside of forests, but the effects of Xiaonanshan communities were stronger than Dananshan. In the southern slope of Xiaonanshan, it is toward the see, in the foot of hill, there was a big heat and power plant, it 24 hours per day continuous emitted pollutant of PM2.5. This caused the concentration of PM2.5 of forest outside usually was 65-69 ppm, but 8 communities of Xiaonanshan could still reduced 6-8 ppm concentration of PM2.5. Only several low altitude communities were a little difference of PM2.5 concentration where were near the heat and power plant, because the high concentration and continuously emitted pollutants. So that these plants the absorbing speed equation or slower than that of pollutants entry forest inside, showed that complex structure and high plant diversity of community have better effects to absorbed and reduced PM 2.5 pollutants.

Conservation genetics/genomics of *Oxera* species (Lamiaceae) diversified in New Caledonia — The speciation process and implications for appropriate conservation

Yuji Isagi[1], *Yoshihisa Suyama*[2], *Kentaro Uchiyama*[3], *Gildas Gâteblé*[4], *Ayu Narita*[1], *Kohei Kamasaka*[1], *Ryohei Nishijima*[1]
1. Kyoto University
2. Tohoku University
3. Forestry and Forest Products Research Institute
4. Institut Agronomique Neo-Caledonien

New Caledonia is a global biodiversity hotspot, where the flora is characterized by high levels of endemism and diversity. The flora includes ca. 3,400 vascular plants, and 77% of them are considered endemics, which makes New Caledonia as the third highest ranked island for endemism, after Hawaii (82%) and New Zealand (82%). Further, the flora contains very unique taxa such as the most basal angiosperm (*Amborella trichopoda*) and parasitic gymnosperm (*Parasitaxus ustus*). Unfortunately, however, many of these endemic plants are threatened with extinction by various factors as mining, fires, logging, urbanization, and introductions of exotic species. Being a small area size (18,575 km^2), New Caledonia is inhabited by many genera of diversity which are composed of over 20 species. Typical examples of these are *Phyllanthus* (Phyllanthaceae, 113 species), *Psychotria* (Rubiaceae, 85 species), *Syzygium* (Myrtaceae, 70 species), *Pycnandra* (endemic genus, Sapotaceae, 57 species), *Eugenia* (Myrtaceae, 54 species), and *Tapeinosperma* (Primulaceae, 53 species). These taxa are suitable for ecological genetic/genomic research of adaptive speciation, and *Oxera* (Lamiaceae) comprising ca. 32 species in New Caledonia (including several undescribed species) is one of the potential genera for the research. The *Oxera* species in New Caledonia are all endemic, showing rich diversity in size (ten centimeters to several meters), plant form (trees, shrubs, forbs, vines), and flower (color, shape, position). Occurrence frequency of each species is also diverse throughout the country, ranging from micro-endemic to omnipresent. To understand the diversification processes in the genus *Oxera*, we selected several species with different traits to perform extensive genetic/genomic analysis by RAD-seq, RNA-seq, and MIG-seq. Consequently, a significant genetic differentiation was found between subpopulations of a species with wide distribution range (*O. baladica*) along with a speciation process of its sister taxon (undescribed species). We searched for loci with the dN/dS ratio of more than zero among the species with distinct traits, and have identified several candidate genes involved in the speciation. As for species with limited distribution ranges such as *O. rugosa* and *O. pancheri*, we inferred optimum ESU (Evolutionarily Significant Unit) and MU (Managing Unit) by analyzing their demography and genetic differentiation among remnant populations.

Real-time analysis of the variation of volatile components in *Polygonum hydropiper* by GP-MSE/GC-MSafter the induction of *Plutella xylostella*

Shicui Jiang, *Ziyu Guo, Donghao Li*
Key Laboratory of Natural Resources of Changbai Mountain & Functional Molecules (Yanbian University), Ministry of Education

The volatile components of plants are essential chemical signals of the transmission of information between plants and insects, which also act as thedirect expression of repellent response from plants. Among the volatile compounds in plants, the composition and concentration of terpenes exert significant influence on the repellent effect. The volatile compounds of *Polygonum hydropiper* were analyzed by using the GP-MSE/GC-MS technique. A total of 50 compounds were qualitatively identified, among which were 9 species of terpene compounds. Due to the different amount of volatile compounds being released at different times, this study aimed to analyse the variation of constituents and concentration of volatile compoundsin *Polygonum hydropiper* under normal conditions from 0 to 48 hours after the induction of *Plutella xylostella*. By examining the gene expression profile based on time differences, the candidate genes of terpene weredetermined and were subsequently verified by employing the real-time PCR quantification approach. A novelgene expression pattern of the variation of constituentsin *Polygonum hydropiper* was developed. This study will provide the basic data to research further on the repellent effect of *Polygonum hydropiper* and for the future development of biopesticides.

Paleoenvironmental evolution since 45ka BP based on sedimentary pollen records of 12I712 core in the Northeastern Indian Ocean

Weiming Jiang[1], *Chuanxiu Luo*[2]
1. School of Geographical Sciences of Guangzhou University
2. CAS Key Laboratory of Marginal Sea Geology, South China Sea Institute of Oceanology, Chinese Academy of Sciences

Based on sporo-pollen assemblage characteristics and AMS 14C dating results of 12I712 core in the Indian Ocean, the authors determined four pollen assemblages from A to D from bottom to top by using Tilia software. The following results can be found in the analysis of the 4 zones: 1. The pollen and spore composition of the surface sediments were complex. We identified 50 different pollen and spore taxa. The spores included *Microlepia, Cyathea, Pteris,* Polypodiaceae, *Cibotiumbarometz, Hicriopteris, etc.* Herbaceous pollen were from Chenopodiaceae, *Artemisia,* Compositae, Ericaceae, Poaceae, Polygonaceae, Cyperaceae, Caryophyllaceae, *etc.* The tree pollen included *Pinus,* Palmae, *Picea,* Tiliaceae, *Alnus,* Betula, Juglans, Quercus, Myrtaceae, *etc.* 2. Pollen diagram in core 12I712: A zone, about 45~42 ka BP: fern (45.32%), tree pollen (32.61%), herb (only 22.08%), pollen concentration (632 grains/g). B zone, about 42~36 ka BP: fern (49.37), herb (26.14%), tree pollen (only2 4.48%), pollen concentration (964 grains/g). C zone, 36~26 ka BP: fern (53.75%), herb (28.10%), tree pollen (only 18.15%), pollen concentration was very low (73 grains/g). D zone, 26~5 ka BP: fern (50%), herb (31.58%), tree pollen (only 18.42%), with a lowest pollen concentration (22 grains/g). 3. Comparing the percentage of spores: In the A zone and B zone, the *Castanopsis* and Evergreen *Quercus* have a high pollen percentage, and there is a large amount of pollen of the Chenopodiaceae and Poaceae. On the contrary, In the C zone and D zone, the

Castanopsis and *Evergreen* Quercus have a low pollen percentage, and the pollen percentage of *Alnus* and *Betula* is gradually increasing. At the same time, the number of pollen of the Chenopodiaceae and Poaceae in this zone was gradually decreasing. About 18ka BP, the pollen number of Chenopodiaceae, Caryophyllaceae, Euphorbiaceae, Alnus and Pinus reached the maximum. In summary, we can find the conclusions as follow:
1). About 45~36 ka BP, there is a large amount of pollen of *Castanopsis* and Evergreen *Quercus*. Combined with high pollen concentration, it can reflect warm and humid climate of the resource areas. 2). About 36~5 ka BP, The percentage of pollen of *Castanopsis* and Evergreen *Quercus* was gradually decreasing, but the percentages of pollen of *Betula* and *Alnus* (belong to the temperate zone) increased, which reflects the climate at that time was turning cold. Herbaceous pollen percentage (such as Chenopodiaceae, Poaceae) increased, it is reflecting the climate gradually becoming cold and dry, the vegetation becoming scarce and drought. About 18 ka BP, the pollen number of Chenopodiaceae, Caryophyllaceae, Euphorbiaceae, *Alnus* and *Pinus* reached the maximum, which reflects the climate was coldest and dryest. And this moment coincides with the Last Glacial Maximum.

Relationships between aboveground biomass and plant cover at two spatial scales and their determinants in northern Tibetan grasslands

Yanbin Jiang
College of Resources and Environment, Huazhong Agricultural University

Questions: (1) How does aboveground biomass (AGB) of alpine grassland relate to plant cover at different spatial scales? (2) Does response of AGB–cover relationship to biotic and abiotic factors depend on scales? Location: Northern Tibet, China. Methods: Community survey (species, cover, height, and abundance) was conducted within 1 m × 1 m plots in 70 sites. Linear regression, Pearson correlation analyses, and hierarchical partitioning were employed to identify contributions of community features (total cover of community, cover of cushion species, height, and species richness) and environmental factors (mean annual precipitation, mean annual temperature, soil bulk density, and carbon and nitrogen contents) to AGB. Results: AGB exponentially increased along a precipitation gradient and was positively and linearly correlated with community cover for all grasslands without alpine meadow. AGB was also linearly correlated to species cover at both regional and landscape scales. Community attributes and environmental factors to AGB significantly depended on spatial scales. Total community coverage was decisive factor for most alpine grassland AGB except for alpine meadow. Cushion plants and species richness significantly affected AGB–cover relationship at both spatial scales. Mean annual precipitation (MAP), soil bulk density and soil nitrogen content influenced the regional AGB variation. Conclusion: Present study indicated generally positive and linear relationships between AGB and cover are at both regional and landscape scales. Spatial scale may affect ranges of cover and modify contribution of cover to AGB. AGB–cover relationships are influenced by many other variables. Species composition, especially presence and cover of cushion plants, and species richness were important community variables that controlled landscape AGB pattern. By contrast, at regional scale, AGB was significantly affected by MAP, soil bulk density, and soil nitrogen content. Therefore, in deriving AGB patterns at different spatial scales, community composition and related environmental factors should be considered to obtain acceptable accuracy.

P0816

Biogeographical evolution of *Toxicodendron* (Anacardiaceae) mixed with pantropic to temperate disjunctions in the Northern Hemisphere

Ying Jiang[1], *Ying Meng*[1], *Jun Wen*[2], *Ze-Long Nie*[1]
1. Jishou University
2. National Museum of Natural History, MRC 166, Smithsonian Institution

Biogeographic diversification of flowering plants in the Northern Hemisphere is extremely complicate due to the dynamic exchanges between tropic to temperate regions. It is necessary to includes close relatives from the pantropic to fully elucidate the evolution of the temperate disjunctions in the Northern Hemisphere. *Toxicodendron* contains approximately 24 species disjunct distributed between eastern Asia and North America, extending to both southeastern Asia and the neotropics, which is an excellent model for investigating the complexity of biogeographical evolution in the Northern Hemisphere. Phylogeny of the genus have been studied, but with limits of tropical samplings. The aim of this study is to reconstruct the phylogenetic relationships in the genus using two nuclear ribosomal DNA (ITS, ETS) and two chloroplast (*ndhF*, *trnL-F*) sequences to examine the evolutionary history of biogeography in *Toxicodendron* in the phylogenetic context of its closely related tropical taxa. Twenty-two species of *Toxicodendron* are sampled, covering the whole taxonomic and biogeographic distributions, especially including samples from tropical SE Asia. Divergence times of disjunct lineages are estimated with relaxed Bayesian dating with fossil constraints. Phylogenetic analysis strongly support *Toxicodendron* as a monophyletic group. *Toxicodendron borneense* (sect. *Simplicifolia*) and *T. nodosum* (section *Toxicodendron*) from SE Asia form a clade sister to *T. trichocarpum* from central China. *Toxicodendron lamprocarpum* from New Guinea is sister to sect. *Griffithii*. Two temperate disjunct lineages were well supported with disjunction in the late Miocene, one from section *Toxicodendron* and the other between the eastern North American *T. vernix* and the eastern Asian *T. vernicifluum*. The two temperate disjunctions likely favored the migration route by way of the Bering land bridge. The pantropical disjunction between section *Griffithii* (warm temperate to tropical Asia) and *T. striatum* (from the neotropic) was also supported and their divergence time was estimated to be 24.73 (10.19–30.58) Ma. This pantropical disjunct between the Old and New World could be exchanged by North Atlantic land bridge corresponding to global warm in the late Oligocene. However, it may have also resulted in range expansion of tropical forest belt via long distance dispersal. Two disjunct lineages are found between tropical Pacific and the mainland Asia (*T. lamprocarpum* - section *Griffithii, T. borneense* and *T. nodosum* - *T. trichocarpum*), consistent with the southward retreat of many tropical taxa into the equator due to global temperatures declined markedly after Eocene.

Leaf functional traits reveal that fern's living strategies have diversified in response to angiosperm-dominated forests since Upper Cretaceous

Dongmei Jin[1], *Harald Schneider*[2,3], *Xile Zhou*[1], *Guohua Zhao*[1,4], *Ying Wang*[1,5], *Yuehong Yan*[1]

1. Shanghai Chenshan Plant Science Research Center, Chinese Academy of Sciences/ Shanghai Chenshan Botanical Garden
2. College of Ecology and Evolution, Sun Yat-Sen University
3. Department of Life Sciences, Natural History Museum
4. Key Laboratory of Plant Biology, Harbin Normal University
5. College of Life and Environmental Sciences, Shanghai Normal University

Ferns (monilophytes), the sister group of seed plants, first appear 360 million years (My) ago in the Late Devonian Period. With estimated 11,929 extant species globally, they are the second most diverse group of vascular plants. About 80% of extant fern species, mostly Polypods, have derived in recent 100 My after angiosperm-dominated forests became prominent in terrestrial ecosystems. These findings suggest that ferns have diversified in response to the new environments shaped by angiosperms. However, few evidence from the change of living strategies in ferns have been reported. Leaf functional traits, which shaped by both evolutionary and environmental drivers, can reflect plant living strategies. Analyzing leaf functional traits of abundant fern species against a phylogenetic background may reveal the changes of living strategy in ferns and may detect major changes of the environment during evolution. Thus, we may find evidence about whether and how angiosperms have driven the evolution of ferns since Upper Cretaceous. We sampled sporophytes of 240 fern species covering main linages in fern phylogeny during growing seasons from five natural reserves in China. Five leaf functional traits which are closely related to photosynthesis were measured, namely, leaf mass per area (LMA), chlorophyll content (SPAD), nitrogen content (Narea), nitrogen concentration (Nmass), and leaf area (Area). Leaf traits of ferns were compared to documented traits of seed plants; differentiation of leaf traits among five major groups in fern phylogeny were analyzed using multiple comparisons; and ancestral state of fern leaf traits since 350 My ago were estimated using Phylocom. Our results showed that, in general ferns have lower LMA and Narea but higher Nmass than seed plants, suggesting a preferred shade tolerant strategy in ferns. Within ferns, Early monilophytes, Early polypods, and their ancient nodes were moderate in the leaf traits suggesting a moderate shade tolerance strategy in general, except that Hymenphyllaceae species form an extremely shade tolerant clade. Derived ferns of Eupolypds II were low in SPAD, LMA, and high in Nmass and Area, suggesting an increased shade tolerance. The mainly epiphytic Polypodiaceae clade and part of Dryopteridaceae clade showed increases in SPAD, Narea and LMA, and reduces in Nmass and Area, suggesting an adaption to light-exposed and dryer environment. The expanded variation of fern leaf traits coincided with the divergence of derived ferns since Upper Cretaceous. Our results support that fern's living strategies have diversified in response to the rise of angiosperm-dominated forests, most species belong to Eupolypds II have adapted to the shady, humid forest floor, while most Polypodiaceae species and part of Dryopteridaceae species have adapted to the xeric, light-exposed forest canopy.

Environment effects on trait distributions in forests of a fragmented landscape

Yi Jin[1], *Jingjing Yu*[1], *Shilu Zheng*[1], *Zuhua Wang*[1], *Guang Hu*[2], *Jinfeng Yuan*[1], *Jinliang Liu*[1], *Mingjian Yu*[1]

1. Zhejiang University
2. Zhejiang Sci-Tech University

Understanding environment effects on trait distributions of forest communities is meaningful to inferring the underlying assembly processes. Here we investigate how the trait distributions of local assemblages of the secondary Masson pine (*Pinus massoniana*) forests are affected by environment in a fragmented landscape (i.e. the Thousand Island Lake) of Eastern China. We established forest dynamics plots (FDPs) in the Masson pine forests on 29 land-bridge islands that largely differ in size, shape and isolation. We conducted the first survey of all woody stems with diameter at breast height (1.3m; DBH) ≥ 1 cm in these FDPs during 2008–2009, and recorded a total of > 180,000 stems belonging to 77 species. We measured ten functional traits (e.g. leaf chloroplast concentration, leaf stomata density, specific leaf area, *etc.*) for these 77 species, and built species trait dendrograms for the traits together and each trait separately. We then calculated trait distributions (i.e. community mean trait value, $-1 \times SES.D_{pw}$ and $-1 \times SES.D_{nn}$) of local scale forest assemblages. By adopting a linear mixed effects modeling framework, we predicted trait distributions using environmental factors (e.g. island area, distance to mainland, distance to forest edge, elevation, slope, soil phosphorous availability, *etc.*). We found the environmental factors largely determined trait distributions in most cases. The results suggest that environment, possibly through regulating habitat filtering, to control the assembly of Masson pine forest communities in the study fragmented landscape.

Abiotic factors responses of invasive *Solidago canadensis* populations in China: Plasticity versus local adaptation

Li Junmin
Taizhou University

Plasticity and local adaptation are both important to help plants adapt to environmental heterogeneity. *Solidago canadensis*, which is invasive in China, has spread widely. We sampled 15 populations of *S. canadensis* in China and conducted common greenhouse experiments to test the plasticity of *S. canadensis* populations in response to abiotic factors treatment, including temperature, water, shade and salt. Among the four traits with significant variation in plasticity among populations in response to temperature, plasticity of leaf length-to-width ratio was significantly positively correlated with latitude and temperature seasonality of the populations. In addition, root/shoot ratio and water-use efficiency showed significant variation in plasticity among populations in response to water availability, and plasticities of these two traits were significantly negatively correlated with longitude and positively correlated with precipitation seasonality. The observed geographic clines in plasticity suggest that phenotypic plasticity of *S. canadensis* may have evolved rapidly in regions with different climatic conditions. Compared to control, shadetreatment significantly reduced growth and content of defense metabolites in *S. canadensis*. Three-way analysis of variance revealed geographical origin to significantly affect the basal diameter of *S. canadensis,* while genotype significantly affected plant height, intercelluar CO_2 concentration (C_i), transpiration rate (T_r), and proline content. Most of the phenotypic variations can be found among individuals within populations. Phenotypic selection analysis revealed that fitness was significantly positively related to plant height, basal diameter, C_i, total flavonoid content, as well as the plasticity of plant height, leaf length, leaf width, g_s, C_i, total flavonoid content, and malondialdehyde content under the control condition. Salt treatment significantly decreased the growth of *S. canadensis*, including the rates of increase in the number of leaves and plant height; the root, shoot, and total biomass; and the root/shoot ratio. Furthermore, salt stress significantly reduced the net photosynthetic rate, g_s, T_r and relative chlorophyll content but significantly increased peroxidase activity and the proline content of *S. canadensis*. Two-way ANOVA showed that salt treatment had a significant effect on the physiological traits of *S. canadensis*. Most of the variation in plasticity existed within populations, not among populations. *S. canadensis* populations from soil with moderate/severe salt levels grew similarly to *S. canadensis* populations from soils with low salt levels. No significant correlation between salt tolerance indices and soil salinity levels was observed. The plasticity of proline content, C_i and the chlorophyll content had significant correlations with the salt tolerance index. Rather than local adaption, these results suggest that individual plasticity played a more prominent role in the shade and salt response of the invasive *S. canadensis*. In summary, both plasticity and local adaptation to abiotic factors may contribute to the spread of this invasive species in novel invaded regions.

Interactive effects of disturbances on grassland soil and vegetation

Katlego Mashiane[1], *Natalie Haussmann*[1], *Peter C. Le Roux*[2]
1. Department of Geography, Geoinformatics and Meteorology, University of Pretoria, South Africa
2. Department of Plant and Soil Sciences, University of Pretoria, South Africa

Disturbances by alien plant species pose a significant threat to indigenous plant biodiversity and host ecosystems. Similarly, large herbivores can act as disturbance agents, in that their actions can trample plants, and modify resource availability and physical soil properties. The purpose of this study was to gain a greater insight into the effects of these two potential disturbance agents and their interactive effects on soil and vegetation characteristics in a conserved grassland (Rietvlei Nature Reserve, Pretoria, South Africa). Soil and vegetation data were collected from 22 sites, and comprised four treatments: 1) trampled, and invaded by the alien plant species *Campuloclinium macrocephalum*, 2) trampled and uninvaded, 3) untrampled and invaded and 4) untrampled and uninvaded. The two disturbance agents did not interactively affect soil organic matter and soil organic carbon. However, trampled sites had significantly higher soil compaction values than untrampled sites, with this difference being larger at invaded sites. Species richness and diversity were largely unaffected by trampling and invasion, while vegetation cover was lower under trampling and/or *C. macrocephalum* invasion. Of the biotic characteristics analyzed, only species composition showed a significant (albeit weak) response to the interaction between trampling and invasion, with results suggesting that trampling reduces the difference in composition between invaded and uninvaded sites. Thus, while the effects of trampling and alien plant invasion were interactive for some variables, for most soil and vegetation characteristics the impacts of these two disturbances were independent of each other.

Does the flowering period differ between trees and herbs? A test based on phylogenetic relationship

Ai Kawakubo, *Tetsukazu Yahara*
Kyushu University

There have been many comparative studies about the relationship between growth form and flowering phenology of plants. However, no consensus has been obtained in previous studies. This lack of consensus may be partly due to the lack of statistical tests based on phylogenetic relationship in previous studies. In this study, we tested difference of the flowering period between tree and herbaceous species using independent contrasts calculated from a phylogenetic tree. We observed flowering phenology of 144 plant species growing in the Biodiversity Reserve of Kyushu University from April to July in 2015 and from March to July in 2016. We recorded the presence or absence of flowering for each species along an observation route every three to seven days. The flowering period of *Salix triandra* was the shortest among the 56 tree species, being only 9 days. In contrast, the flowering period of *Rubus hirsutus*, 105 days, was the longest among the tree species. The flowering period of *Cardiocrinum cordatum* was the shortest among the 88 herbaceous species, being 8 days. In contrast, the flowering periods of *Trifolium repens*, 138 days, were the longest among the herbaceous species. To test difference of the flowering period between trees and herbs, we constructed a phylogenetic tree for 144 species based on DNA sequences (*rbcL* and *matK*) and reconstructed ancestral states of growth form and flowering period in each internode of the phylogenetic tree. Then, each speciation event was classified into three categories; ‘tree-tree’, ‘tree-herb’, and ‘herb-herb’, and the average of the contrast of flowering period (difference of flowering period evolved in each speciation event) was compared among three categories. Speciation events where ancestral states are ambiguous are excluded from the analysis. As a result, the average of tree-tree contrast was significantly smaller than that of herb-herb contrast, and there was no significant difference between tree-tree and tree-herb, or tree-herb and herb-herb contrast. The result suggested that flowering period changes tend to be larger in herb-herb speciation events than in tree-tree speciation events, resulted in relatively longer flowering periods in herbaceous species than in trees. This difference of flowering periods between trees and herbs may be associated with the difference of pollinator species. Understory-flowering herbs are usually pollinated by endothermic species such as bumblebees, and a longer flowering period may be advantageous because of their high flower constancy. In contrast, canopy-flowering trees are mostly pollinated by ectothermic insects such as syrphid flies and small bees, and mass flowering with shorter flowering periods may be advantageous to attract those opportunistic pollinators.

MPRR1 is a quick response E3 ligase that immediately eliminates emergent misfolded proteins bypassing chaperone-mediated triage decisions

Jong Hum Kim[1], *Seok Keun Cho*[1], *Oh Tae Rin*[1], *Ryu Moon Young*[1], *Yang Seong Wook*[1,2], *Kim Woo Taek*[1]

1. Department of Systems Biology, College of Life Science and Biotechnology, Yonsei University

2. Section of Plant Biochemistry, Department of Plant and Environmental Sciences, Faculty of Sciences, University of Copenhagen

Proteotoxic stress induced by misfolded proteins is one of the most important causes of cell disorder throughout whole eukaryotic organisms. UPS (Ubiquitin-Proteasome System) is well-known defense mechanism via degradation of misfolded or disordered protein in eukaryotic cells. Besides animal systems, plant also use UPS for maintaining and regulating crucial cellular processes such as signal transduction, cell death, and nutrient regulation. Here, we show that MPRR1 (Misfolded Protein Responsive RING protein 1) is a regulator of 26S proteasome activity under proteotoxic stress. We investigated transcript expression profiled under proteotoxic stress and generated transgenic plants, which over-expressed arabidopsis E3 ligases responsive to proteotoxic stress. Among the transgenic plants, MPRR1 over-expressor showed enhanced growth and reduced Ub-positive aggregates compared to wild-type plant. Knock-down transgenic plant of MPRR1 and Stable over-expressor of MPRR1^{C153S} RING domain mutant protein showed impaired growth under proteotoxic stress. Because we found that proteasome inhibitor MG-132 decreases tolerance of over-expression transgenic plant of MPRR1 under proteotoxic stress, we hypothesized that enhanced fitness of the transgenic plant is originated from enhanced proteasome activity. The activity of 26S proteasome was up-regulated compared to wild-type plant and the amount of 26S proteasome was maintained when it of wild-type was decreased. In addition, artificial substrate clearing activity was enhanced in the over-expressing plant compared to wild-type plant. Because MPRR1 interacted with 19S subunits physically, regulation of 26S proteasome activity might be direct. We also found that MPRR1 protein is stabilized under proteotoxic stress post-translationally and the regulation of the protein stability was dependent to its RING E3 ligase activity. Collectively, a cytosolic RING E3 ligase, MPRR1 improves plant fitness and an aberrant protein clearance under proteotoxic stress condition through stabilization of 26S proteasome activity by physical interaction and ubiquitination.

P0823

A geographic cline in pollen color may be driven by abiotic selection

Matthew Koski, *Laura Galloway*

Department of Biology, University of Virginia

Floral pigmentation functions in both attracting pollinators and ameliorating abiotic stress experienced by pollen and ovules. The study of floral color diversity is often restricted to petal pigmentation though many floral reproductive parts can display marked variability in color. Here, we explore the degree of pollen and petal pigmentation diversity across the range of the North American herbaceous plant, *Campanula americana*, and address whether geographic patterns may be explained by abiotic factors. Pollen color ranges from white to deep purple, and there is a strong geographic cline whereby eastern populations have light pollen while western populations have darker pollen. After accounting for latitudinal variation in temperature, UV and precipitation, both temperature and UV are higher in the western portion of the range. Thus, both temperature and UV are associated with pollen color diversity. Experiments show that dark purple pollen tends to germinate better in higher temperature and UV conditions, but that light and dark pollen perform similarly under lower temperature and UV conditions. Dark pollen may therefore be adaptive under high heat and UV conditions, but the fitness benefits of light pollen remain unclear. Our results contribute some of the first data on geographic clines in pollen color and the adaptive nature of pollen pigmentation with respect to abiotic stress. Further studies of neutral genetic diversity will elucidate whether selection drives the observed geographic cline in pollen color.

A phylogeographical transect study of Central European steppe grassland species from the Hungarian Pannonicum towards the westernmost limit

Kristina Plenk[1], *Katharina Bardy*[1], *Maria Höhn*[2], *Mike Thiv*[3], ***Matthias Kropf***[1]

1. University of Natural Resources and Life Sciences, Institute for Integrative Nature Conservation Research

2. Szent István University, Department of Botany and Botanical Garden of Soroksár

3. Stuttgart State Museum of Natural History

In our study, genetic and performance data were used to analyse genetic structuring and diversity, performance parameters, and biogeographical history of different “steppe grassland plants” in an east-west transect representing their distribution range periphery. This transect explicitly covers the absolute distributional limit of most investigated taxa, which typically show a more widespread continuous occurrence in the eastern region (Pannonian Basin, Hungary), compared to populations at the margin of this continuous Pannonian occurrence (Eastern Austria) and the (north) westernmost exclaves in western Germany (especially in Rhineland-Palatinate). Referring to theories like the “Abundant

Centre" hypothesis and the "Central-Marginal-Model" we assume more isolated and individual-poor populations at the (north) westernmost absolute distribution limit and therefore, reduced fitness, increased among population differentiation as weIl as decreased within population diversity. All study species presented here, namely *Adonis vernalis* (Ranunculaceae), *Carex supina* (Cyperaceae), *Inula germanica* (Asteraceae), *Linum flavum* (Linaceae), *Oxytropis pilosa* (Fabaceae), and *Poa badensis* (Poaceae), are rare and endangered in Central Europe. To analyse patterns of genetic diversity and structuring, Amplified Fragment Length Polymorphisms (AFLPs) and chloroplast (cp) DNA sequence data were generated usually for four representative populations per study region and species. Plant fitness was investigated based on the same populations using different field performance parameters like fruit set and mass, as well as germination rates under standardized conditions. Results from the fitness analyses indicate marked differences among study species and regions, but do not clearly support the idea of declining performance towards the absolute distribution range limit. Depending on the species surveyed, other factors like life history traits (notably, clonal growth) and/or variation in population size seem to have greater impact on plant performance. Genetic data (AFLPs & cpDNA), currently available for *C. supina*, *L. flavum*, *O. pilosa*, *P. badensis*, and *A. vernalis* (only AFLPs) partially show expected patterns: particularly, AFLP data group samples predominantly according to their geographical origin (i.e. representing the three study regions), interpreted as vicariance. However, with respect to the extent of population differentiation and genetic diversity patterns, again no study species follows all of the hypotheses as assumed, even though several species fulfil single expectations. In summary, we have therefore to note that phylogeographical patterns observed in Central European steppe grassland plants are mostly species-specific.

Plant-microbial interactions: Depth-dependent effects of roots on microbial activities in arable soil

Amit Kumar, *Muhammad Shahbaz, Yakov Kuzyakov, Johanna Pausch*

Georg-August University of Göttingen

In rooted soils, microbially mediated soil organic matter (SOM) decomposition is of special interest as roots are characterized by inputs of high quality of substrates for microbial uptake. A direct expression of soil microorganisms to available nutrients and metabolic requirements are extracellular enzyme activities (EEA). Production of extracellular enzymes by microorganisms is an important mechanism to obtain energy and nutrients from soil via SOM decomposition; however, various biotic and abiotic factors regulate microbial activities. Furthermore, energy sources (root-derived organics) decrease with soil depth and consequently microbial activities are hampered. In addition, application of inorganic N-fertilization also affects microbial activities and consequently affects SOM decomposition. Therefore, we hypothesized that planting increases EEA via microbial activation and N-fertilization reduces EEA because microorganisms are less dependent on nutrient acquisition through SOM decomposition. A field experiment was established on an arable soil in Gottingen, Germany. Maize was grown in plots (5 x 5 m^2) with- or without N-fertilization and the plots were separated with 2 m wide buffer strip to avoid neighboring effects. Control plots (without maize) with- and without N-fertilization were also established. Plants biomass (root and shoot biomass) and microbial biomass C and N, and potential activity of C-, N-, and P-acquiring enzymes were measured with fluorogenically-labeled substrates at 4 soil depths and two sampling times (72 and 130 days after maize planting). We found that roots enhanced microbial biomass C and N and potential activities of C-, N-, and P-acquiring enzymes, especially in the rooting zone at 5-15 and 15-25 cm soil depth. Moreover, N-fertilization had minor effects on microbial biomass C, and C-, and P-acquiring enzyme activities; however, it increased shoot biomass and decreased microbial biomass N and N-acquiring enzyme activities. Higher microbial activity in rhizosphere provides evidence of root-mediated microbial activation resulting in increased SOM decomposition and consequently release of nutrients into the soil. It is noteworthy finding that in short-term, the root-mediated microbial activation and not N-fertilization will accelerate nutrient cycling in arable soil.

Testing the scaling effects and mechanisms of N-induced biodiversity loss: Evidence from a decade-long grassland experiment

Zhichun Lan[1,2], *G. Darrel Jennerette*[3], *Shuxia Zhan*[2], *Wenhuai Li*[2], *Shuxia Zheng*[2], *Yongfei Bai*[2]

1. Institute of Watershed Ecology, Nanchang University

2. State Key Laboratory of Vegetation and Environmental Change, Institute of Botany, the Chinese Academy of Sciences

3. Department of Botany and Plant Sciences, University of California, Riverside

Although extensive studies demonstrate that nitrogen (N) enrichment frequently reduces plant diversity within small quadrats (0.5–4 m^2), only a few studies have evaluated N effects on biodiversity across different spatial scales. We conducted the first experimental test of the scale dependence of N effects on species richness from a 10-year N treatment (1.75-28 g N m^{-2} yr^{-1}) in a typical steppe. We used species area relationship (SAR) to analyze the scale dependence of species loss with power model $S = cA^z$ (S is species number, A is area, c is intercept, and z is slope). We found that: (1) absolute species loss decreased at sampling area > 8 m^2; (2) proportional species loss (compared to control) decreased and critical threshold (N_{crit}) for biodiversity losses increased with sampling areas; (3) these scale dependences were quantified as increasing slope (z-value) of SAR with N addition. Through SAR decomposition, we found that this overall positive effect was in response to positive effects of changes to the species abundance distribution over negative effects of overall species richness losses. As N enrichment typically occurs at scales much larger than individual plots, understanding how N enrichment affects the scaling patterns of biodiversity is necessary for biodiversity conservation and ecosystem management in response to anthropogenic N deposition.

The potato (*Solanum tuberosum*) rhizosphere and novel methods for controlling potato cyst nematodes (*Globodera pallida* and *G. rostochiensis*)

***Eoin Lettice**, Rachel Hearne, Peter Jones*
University College Cork, Ireland

Potato cyst nematodes (PCN; *Globodera pallida* and *G. rostochiensis*) are known to be significant pests of potato crops in agriculture and are a threat to global food security. The pests are involved in a tritrophic interaction with potato (*Solanum tuberosum*) and the soil microbiome. Central to this interaction is the release of allelochemicals ('hatching factors') from the plant roots which trigger a break in dormancy in the plant pathogenic nematodes. A series of experiments were conducted in order to elucidate the role played by each element, including the host plant, in this tritrophic interaction. Soil samples from potato ridge and bulk areas of a commercial potato field were collected and the impact of the potato rhizosphere effect was assessed using community-level physiological profiling. Soil bacterial activity and diversity were shown to be greater in potato ridge soil compared to bulk soil, indicating a direct effect of potato root leachates on the soil microbiome. The use of soil bacteria, isolated from the rhizosphere of a non-host plant (sugar beet; *Beta vulgaris* ssp. *vulgaris*) as a biological control agent for PCN was examined. Two of three isolates assessed were found to be competent colonisers of the sugar beet rhizosphere and were able to significantly increase the hatch of *G. pallida* in the absence of the host plant. The use of such a trap-crop system to induce the hatch of PCN in the absence of the host plant is proposed as a potential control option for the pest. In addition to further elucidating the tritrophic interaction between PCN, potato and soil microorganisms, the interaction between the sibling species of PCN was also examined. PCN-susceptible potato cultivars were inoculated with single- and mixed- species populations of PCN. This experiment demonstrated that the maturity class of the potato cultivar has a significant influence on PCN multiplication with *G. rostochiensis*, for example, performing better on late maincrop cultivars Kerr's Pink and Golden Wonder. Overall, *G. pallida* was found to outcompete *G. rostochiensis* in mixed-species populations. This work has demonstrated the increasing problems posed by PCN and *G. pallida* in particular. It also confirms that the host plant is crucial to our understanding of the pest lifecycle. By understanding the potato rhizosphere we can better understand and control this important plant pest.

Environmental heterogeneity and mechanism of stoichiometry properties of vegetative organs in dominant shrub communities across the Loess Plateau

Danfeng Li
Institute of Botany, Chinese Academy of Sciences

Exploring variation patterns of C, N, P contents and their ratios of plant vegetative organs along environmental gradient can provide insight on the resource allocation strategy of plants. In order to search the environmental heterogeneity and mechanism of stoichiometry properties of plant vegetative organs (including root, stem and leaf), we investigated the influences of different soil nutrients conditions on the element allocation among plant vegetative organs in the dominant shrub communities along a hydro-thermic gradient across Loess Plateau. The species compositions and structures of 123 small quadrats (5 m × 5 m) of dominant shrub communities in 41 sites were investigated by standard community sampling method along the declined hydro-thermic conditions from southern Gansu Province to northern Ningxia Hui Autonomous Region and western Gansu. The data about height, coverage and number of the dominant shrub were recorded. At least 369 biological samples of plant vegetative organs (root, stem and leave) of dominant shrubs were collected and their fresh and dry mass were measured, respectively. About 123 soil samples were taken by earth boring auger and ring knife. C, N and P contents of all biological and soil samples were measured after lapping and sieving. Important findings: 1) Organic matter content (mean concentration of leaf C ((424.11 ± 42.21) mg·g^{-1})) in Gansu and Ningxia Hui Autonomous Region was relatively low, and nitrogen (mean concentration of leaf N ((23.00 ± 8.09) mg·g^{-1})) was higher while phosphorous (mean concentration of leaf P ((1.18 ± 0.50) mg·g^{-1})) was relatively deficient. 2) Along the increasing growing season temperature and declining annual precipitation from southern Gansu to northern Ningxia Hui Autonomous Region and western Gansu, soil nutrients content decreased, and the storage of C, N and P in root, stem and leaf decreased. The shift trends of C:N agreed with the N storage's shift trends in root and stem while N:P in all organs were contrary to the P storage's shift trends. Meanwhile, the allocation patterns of C, N and P among vegetative organs among the three regions dominated by shrub communities were much different. 3) In the region with high soil nutrients, the nutrient storage in vegetable organs were similar among different species in the same dominant shrub regions, but in the regions with low soil nutrients, the nutrient storage in vegetable organs displayed high variations. The variations of nutrient storage of vegetable organs for the same shrub communities from different regions were not significant.

Water depth affects reproductive allocation and allometry in the submerged macrophyte *Vallisneria natans*

***Lei Li**[1,2], Jiakuan Chen[2], Zhiping Song[2]*
1. Center for Watershed Ecology, Institute of Life Science, Nanchang University
2. Institute of Biodiversity Science, Fudan University

The relationship between size and reproductive output is a fundamental aspect of a plant's reproductive strategy: the conversion of growth into fitness. Differences among populations in the reproductive allometry have been attributed to environmental conditions. However, the causes of variation in reproductive allocation are still debated (i.e. due to fixed patterns of development, or plasticity in the developmental trajectory of vegetative and reproductive allocation). Using a mesocosm experiment, we investigated variation in reproductive allocation of a semelparous submerged macrophyte, *Vallisneria natans*, growing at three levels (shallow, intermediate and deep) of water depth, to test the hypothesis that

allometric trajectories of reproductive allocation are highly plastic in *V. natans*. Plants were measured after 26 weeks of growth. The allometric relationships between reproductive (R) and vegetative (V) biomass among treatments were compared. In deep water treatment, total plant biomass decreased, average height increased and individuals started flowering in smaller size when compared to the two shallower water treatments. Deep water affected the biomass and number of fruits produced per plant leading to less sexual reproduction. Plants in deep water (the more stressful treatment) had relatively high allocation to reproduction, though they were quite small. The log R vs. log V slope in deep water treatment was much lower than those in more favourable treatments, and shallow water plants exhibited a very different log R-log V relationship than intermediate water plants. A possible explanation is that the environmental limits on size in deep water should favour a relatively large reproductive allocation at smaller sizes and a smaller investment in reproduction per additional unit of biomass accumulated. Our results demonstrated that water depth affects the observed pattern of reproductive allometry among experimental *V. natans* populations, and this has important implications for the fitness of macrophytes under environmental changes due to anthropogenic disturbance (e.g. dam constructions) and climate change (changes in precipitation pattern). Environmental stress in deep water tends to favor reproduction at relatively small sizes, associated with lower slopes of the log R-log V relationship, supporting that reproductive allometry can be interpreted as an adaptive strategy of plant growth and allocation, rather than as the product of fixed developmental constrains.

The effectiveness of *Wedelia trilobata* of man-made slopes in Hong Kong

Lu Li[1], *Sai Leung Ng*[2]
1. Baoan Urban Management Bureau, Shenzhen
2. Department of Geography and Resource Management, The Chinese University of Hong Kong

With a dense population, Hong Kong often suffers from geological hazards of landslide in the rainy season. Slopes are widely concerned by the public and government. Safety and aesthetics are two major considerations when man-made slopes constructed. The objective of this study is the assessment on *Wedelia trilobata* performance of man-made slopes with the hard surface. In this study, three surveys were conducted in 2007, 2008 and 2009 on man-made slopes with the hard surface applied with fifteen products of slope bioengineering techniques. Substrates of different products were sampled and analyzed. Results of this study indicated that successful greenery on man-made slopes with the hard surface can be achieved by monotonous use of fast-growing landscaping taxa, such as *Wedelia trilobata*, which is an exotic species with a wide range of environmental tolerance. This species inhibited the development of other species although it provided lush vegetation coverage. The main benefit of using fast growing landscaping taxa stems was from their ability of forming large colonies over the slope in a very short time period. However, the drawback of landscaping taxa was the out-competition or even elimination of other plant species. Therefore, selection of landscaping plants for greening would have significant effects on the vegetation development. Once the slope was dominated by fast growing landscaping taxa, processes and patterns of natural succession can be highly disturbed and altered. In the study, biodiversity could not be improved by increasing vegetation cover. Simple species composition of our man-made slopes calls for room for improvement in this area. Therefore, slope engineers or landscape managers, who used to emphasize the establishment of green cover, can be reminded that the consideration of urban biodiversity should be incorporated into the management of urban slopes. Slope engineers or landscape managers are encouraged to put more efforts into stimulating and accelerating natural succession.

Consequences of drought for recovery from defoliation in *Robinia pseudoacacia* and *Sophora japonica*

Ming-Yan Li[1,2], *Wei-Hua Guo*[1,2], *Xiao Guo*[3], *Ning Du*[1,2]
1. Institute of Ecology and Biodiversity, College of Life Sciences, Shandong University
2. Shandong Provincial Engineering and Technology Research Center for Vegetation Ecology, Shandong University
3. College of Landscape Architecture and Forestry, Qingdao Agricultural University

Climate change may result in the increase of both pest insect damage and the frequency of drought. Therefore, there is a need to better understand the combined effects of defoliation and drought on tree growth, and physiological processes to predict the effect on forest ecosystem productivity in response to climate change. Artificial defoliation was often used to simulate the pest insect damage. In this study, we conducted a manipulative experiment in a greenhouse, where 1-year-old seedlings of both *R. pseudoacacia* and *S. japonica* were exposed to three soil moisture conditions (75%, 55%, 25% of saturated soil moisture content) and three defoliation regimes, i.e. control, removed upper canopy leaves (approximately 48% of total leaf area) and all leaves (100% defoliation). We found that after 14 days of treatment, photosynthetic capacity of *R. pseudoacacia* was higher than that of *S. japonica* regardless of water treatments. Photosynthetic capacity of the two species was significantly increased under defoliation treatments, which indicated that plants have already started to compensate growth by increasing photosynthetic capacity, especially in *S. japonica*. After a period of growth, photosynthetic capacity and chlorophyll content of the two species under defoliated treatment had no significant difference between all treatments. However, the parameter of growth, biomass accumulation and non-structural carbohydrate were lower under 100% defoliation treatment regardless of water condition, which means seedlings of both species are difficult to recover under any water regime. In addition, most of measured parameters were inhibited by drought. Meanwhile, our results showed additive effects of defoliation and water stress on most of parameters, which suggests drought inhibited the recovery capacity after defoliation. We also observed that biomass accumulation of *S. japonica* had no significant difference among defoliation treatments, while biomass accumulation of *R. pseudoacacia* under 100% defoliation treatments was significantly lower than the control treatments. Meanwhile, gas exchange of *S.*

japonica was higher than that of *R. pseudoacacia* after 14 days of treatment. According to our results, we concluded that recovery capability of *S. japonica* is stronger than that of *R. pseudoacacia*. By studying recovery capability, *S. japonica* may have a better ability to adapt to future global change than *R. pseudoacacia*. Thus, *S. japonica* suits for vegetation restoration and reconstruction in this warm temperate zone.

Responses to successional water deficit and recovery in four warm-temperate tree species

Qiang Li, *Ning Wang, Shuna Liu*
Shandong University

To detect the responses to successional drought stress and recovery, studies of physiological attributes and growth of the seedlings of four warm-temperate trees (*Robinia pseudoacacia* L., *Amorpha fruticosa* L., *Vitex negundo* L. var. *heterophylla* (Franch.) Rehder, *Quercus acutissima* Carruth.) were conducted in a greenhouse. In the study, 3-month-old seedlings were subjected to a progressive drought and a following rewatering treatment at two different drought stages. Stomatal conductance (g_s) was measured daily to show plant water status, and seedlings of well-irrigated (control), mild drought stress (MD, with g_s 50% declined), severe drought stress (SD, with g_s declined to the lowest point), rewatering after MD (RMD) and SD (RSD) were sampled. Soil water content, stem water potential, xylem hydraulic conductivity, leaf photosynthetic rate and osmoprotectant contents were measured. The treatment significantly influenced many aspects of seedlings performance, but water-stressed seedlings repossessed most physiological functioning after the recovery period. *Q. acutissima* and *V. negundo* var. *heterophylla* seedlings exhibited a greater degree of isohydry with drought, since they controlled stomata timely from the onset of dehydration. However, *R. pseudoacacia* and *A. fruticosa* behaved near-anisohydric, because they kept stomata open longer during drought. Our results support mounting evidence that xylem hydraulic conductivity interacts with leaf gas exchange and stem water potential, which might be the final recovery in the hydraulics-photosynthetic attributes continuums. We also demonstrate trade-offs and coordination among attributes influencing plant water use, photosynthesis and compounds regulation.

The role of arbuscular mycorrhizal fungi in plant nitrogen uptake of temperate grassland

Yawen Li[1], *Yongfei Bai*[1], *Ping Wang*[2], *Baoming Ji*[2]
1. Institute of Botany, the Chinese Academy of Sciences
2. Beijing Forestry University

Arbuscular Mycorrhizal Fungi (AMF) are ubiquitous microbes in the ecosystem, which can form symbiont with 80% terrestrial plant species. The significant function of AMF is to help plants get water and mineral elements from soil. Traditional researches are more focused on phosphorus uptake, and we know less about nitrogen uptake. Especially in grassland ecosystem, Nitrogen (N) is a key factor for its productivity and stability. Thus, we use a split-compartment cultivation system and ^{15}N-labeling technique to test the uptake of different forms of N (NH_4^+, NO_3^-, GLY) in different N levels by AMF. *Leymus chinensis*, *Cleistogenes squarrosa,* and *Stipa grandis*, which are constructive species of temperate typical grassland, are inoculated with indigenous field soil. The results show that ^{15}N uptake capability vary from plant species to N levels. *Cleistogenes squarrosa* are more rely on AMF, especially with high N content in the soil. No significant effects are observed on dry weight of *Leymus chinensis* and *Stipa grandis* with AMF inoculation. And the ^{15}N uptake capability enhances with the increasing N content in soil among all these species. However, the ^{15}N uptake capability of AMF is not influenced by N forms. The efficiency of AMF to transfer nitrogen is from 0.2%~27%.

Early positive effects of tree species richness on soil carbon sequestration in a large-scale forest biodiversity experiment

Yin Li
State Key Laboratory of Vegetation and Environmental Change, Institute of Botany, the Chinese Academy of Sciences

Tree species richness has been reported to have positive effects on above-ground biomass and productivity, but little is known about the effects on soil organic carbon accumulation. To close this gap, we made use of a large biodiversity ecosystem functioning experiment in subtropical China and tested for tree species richness and environmental effects on soil organic carbon accumulation. In 2008 and 2015, soil samples were taken by depth increments to the depth of 30 cm from 57 plots ranging in tree richness from one to eight species. Redundancy analysis, linear mixed-effect models and structural equation models were used to test for correlation of plant-related and topographic variables with soil organic carbon accumulation, to assess the relative importance of these predictors and to compare direct and indirect effects of plant-related and topographic variables on the soil organic carbon accumulation. Soil organic carbon stocks decreased by 253.7 g C m^{-2} in the top 0-5 cm, but increased by 309.3 g C m^{-2} in the 10-30 cm depth, resulting in an increase of 6.2 g C m^{-2} from 2008 to 2015 over the whole depth profile. Soil organic carbon accumulation significantly increased with tree species richness, slope and leaf litter carbon content. While tree species richness and slope had direct effects on the change of soil organic carbon stocks, there were only weak or absent indirect effects of the other variables tested. Our results indicate that tree species richness has direct positive effects on soil organic carbon stocks, which however, are only weakly mediated via leaf litter biomass, fine root biomass and leaf litter carbon content. Future studies should make more effects on the impact of leaf litter turnover rates, leaf litter quality and soil microbial community structure on soil organic carbon accumulation.

Canopy trees of dominant species shape fine-scale spatial heterogeneity of soil nutrients in Xishuangbanan tropical rainforest

Zhipeng Li[1,2], *Shangwen Xia*[1], *Luxiang Lin*[1], *Douglas Schaefer*[1], *Xiaodong Yang**[1]

1. Key Laboratory of Tropical Forest Ecology, Xishuangbanna Tropical Botanical Garden, Chinese Academy of Sciences, Mengla 666303, China
2. Department of Agricultural Soil Science, Georg-August University of Göttingen, Busgenweg 2, Göttingen 37077, Germany

The highly spatial heterogeneous of soil properties plays an important role in species coexistence and biodiversity maintenance via leading niche partition in tropical rainforest. Although plants effects (PEs) have been shown to be one of the most important mechanisms influencing soil heterogeneity, the relative importance and characteristic scales of them on fine scale soil heterogeneity (in 1 ha area) still remain unclear. In this study, we combined mapping trees information and high resolution soil nutrients data (scale is 5 meters), using multivariate statistical analysis and wavelet analysis tool to analysis relationship between trees biomass, topography and soil nutrients at multiple scales. Among five selected tree species, only PARACH had strong and positive correlation with all measured macronutrients. The magnitude of its effects on soil properties were P > NO$_3$-N > Total N > K which may reflect the degree of demand in tree growth. Wavelet analysis showed that topography and plants significant driven soil heterogeneity at multiple scales. Topography influenced soil pH at whole scale, inorganic N at small scale and P at large scale. Effects of PARACH influenced soil NO$_3$-N at whole scale and P at large scale. The effects of PARACH were independent of topography. Our result indicates that canopy trees of dominant species play a crucial role in soil heterogeneity generation in tropical rainforest, and more efforts needed to be devoted to understanding the relation between traits of dominant tree species and ecological consequences which they probably cause.

Hunan Chang-Zhu-Tan City Cluster National Research Station of Forest Ecosystem

Juyang Liao[1,2], *Youjun He*[1,2]
1. Hunan Forest Botanical Garden
2. Hunan Chang-Zhu-Tan City Cluster National Research Station of Forest Ecosystem

To be approved by the panel of CFERN, "Hunan Chang-Zhu-Tan City Cluster National Research Station of Forest Ecosystem" is the first urban agglomeration forest ecosystem observation research station in China. The main station is located in Hunan Forest Botanical Garden (N 28°06′40″, E 113°01′30″), the slave station is located in Zhaoshan Scenic Spot. The station is located in downstream of Xiangjiang river. It has a humid subtropical monsoon climate. The main soil types: red soil, yellow soil and yellow brown soil, the main vegetations: *Pinus massoniana* forest, Chinese fir, bamboo and *Camellia* forest. It has the typical characteristics of subtropical evergreen broad-leaved forest. The station aims to analyze and study the interaction between forest ecosystem and human activities, economic and social development, then provide scientific and accurate data for ecological environment improvement and forest ecosystem self-recovery of Chang-Zhu-Tan City Cluster, and offer the scientific decision-making basis for ecological environment construction, economic sustainable development; To provide data collection, processing, sharing services for the national ecological environmental science research and the majority of users.

The investigation of potential interactions between chosen grass plants in savanna ecosystem in the Nylsvley Nature Reserve, Limpopo Province, South Africa

Maanda Hadzhi Ligavha-Mbelengwa
University of Venda

Potential interactions between grass plants was investigated in the Nylsvley Nature Reserve. Nearest neighbour analysis technique was used to study the interactions between grass individuals and it was possible to prove that within and between species interactions, particularly competition was occurring between grasses investigated. Two phases were employed in the removal experiments where the first phase entailed pre-removal bombing wherein the xylem water potentials of all the individual species still neighboured were determined. A month later post-removal pressure bombings were conducted wherein three nearest-neighbour grass individuals of the same species were removed to isolate the fourth similar individual species. On the other hand three similar species different from the one isolated were also removed to isolate the individual species different from those three similar individual species. Removal of plants from both monospecific and mixed stands resulted in less negative soil water potentials as was observed by an improvement in xylem water potentials on cleared stands. Removal experiments also led to changes in plant growth, production and reproduction. Plant individuals in cleared stands showed out-of-season leaf flowering tillers production. It was concluded that there was an increase in soil moisture content and prolongation in the period of soil moisture availability for non-neighboured plant individuals. Root of some plant species of each of the two species on both cleared and uncleared stands were excavated. Some root extensions into new soil volumes were observed; and such might be proof enough that water and space are some of the resources necessary for the wellbeing of plants.

Ephemeral root modules widely exist in 12 perennial herb, shrub and tree species

Bo Liu[1,2], *Fanjiang Zeng*[2], *Arndt Stefan K.*[3]
1. Linyi University
2. Xinjiang Institute of Ecology and Geography, Chinese Academy of Sciences
3. University of Melbourne

The terminal branch orders of plant roots have been proposed as a short-lived 'ephemeral' modules specialized for resource absorption. The occurrence of ephemeral root modules has so far only been reported for a temperate tree species and it is unclear if the concept widely exists in other woody (shrub, tree) and herb species. Fine roots of 12 angiosperm perennial herb, shrub and tree species were monitored using branch-order classification, sequential sampling and improved rhizotron in a warm temperate China Taklimakan desert, and their median life spans, anatomical traits, nitrogen concentrations and respirations were also compared through two years' experiments. Two different classes of root modules existed in all monitored plant functional types. The first two (perennial herbs, shrubs) or three (trees) root orders were of ephemeral nature and had a primary structure, consisted mainly of cortex cells, had no secondary growth, high nitrogen concentrations and respiration rates and very short life spans of one to four months. The last two branch orders (third and fourth orders in herbs, shrubs; fourth and fifth orders in trees) in all plant functional types were of a perennial nature, with roots of greater diameters, no cortex, distinct secondary growth and cork cells, and these roots had lower nitrogen concentrations and respiration rates but much longer life spans. Ephemeral and perennial branch orders probably form two different functional modules: a primary ephemeral module that has mainly absorptive functions and a secondary perennial module that has mainly transport, storage and structural functions. The distinct short-lived distal cohorts of roots seem to be widely distributed and maybe even a general feature amongst many plant functional types. Ephemeral root modules method will simplify root differentiating and sampling, and enriched method of root system classification compared to coarse–fine root dichotomies and branch orders.

Warming-determined spatial and temporal patterns of forest dieback in Inner Asia

Hongyan Liu

Peking University

Temperate and boreal forests border Inner Asia, the world's largest dryland, and form a long and diversified forest-steppe ecotone. Forest dynamics in this circum-gobi ecotone strongly contribute to regional climate feedback, carbon pool, as well as environmental conditions in the northern hemisphere. Geographical heterogeneity was stressed in studies on vegetation response to climate change at site scale albeit water deficit was documented to be commonly constraining tree growth. Here we report a MAP-associated forest growth pattern with dieback of all forest types near the xeric treeline, reduction in forest-growth within the forest-steppe ecotone and increase in forest-growth in continuously distributed forests. Tree-growth as indicated by ring-width and basal area index (BAI) is significantly associated with Palmer drought severity index, proxy of soil moisture, in this region. We also identified a threshold of drought duration of 15 dry months during the growing season of the prior three year for forest dieback, regardless of contribution from winter water storage. The border between water surplus and water deficit for tree-growth has shifted and area of water deficit has been enlarged, which is clearly caused by raised temperature, during the last 50 years. To monitor forest dynamics in this region, transect across the ecotone is proposed.

Landscape tree species selection and climatic adaptability evaluation using distribution mapping in Shanghai, China

Ming Liu, *Deshun Zhang*

Tongji University

Landscape trees play a fundamental role in urban green spaces such as the living environment improvement, landscape beautification, microclimate regulation, disaster prevention and other benefits and services. However, urban landscape trees are demanded stronger resilience and resistance in the severe environmental stresses higher than their natural habitats. Furthermore, ongoing climate change will bring new challenges in urban landscape trees selection and landscape design. Shanghai is located in east China, the west coast of the Pacific. And Shanghai City belongs to China's high-density urbanized metropolis, affected by climate change in addition to the urban climate impacts, where exacerbated by the difficulty of planning urban landscape trees. In the recent 30 years, the temperature increasing, precipitation rising, sunshine diminishing and wind fluctuations hazards are new four major characteristics of Shanghai climate change: (1) Urban heat island (UHI) effect is more significant, and the trend of UHI has spread to the eastern region. (2) The urban rain island (URI) effect has enhanced with the average annual precipitation rising. (3) The air pollution and haze are more and more serious due to the increased days of cloudiness and rainy. (4) The southeast wind is still the driven wind possibly lead to hotter summer and warmer winter. However, there are virtually little native plants and endemic vegetation as in the alluvial plain of the Yangtze River Delta in history. The vast majority of plants are imported from domestic provinces or around the world. At present, the main plants include trees, shrubs, vines and bamboos, having 738 species belong to 215 genera and 78 families. After climatic adaptability assessment by using climate envelopes models, the result shows that 85.12% of the tree species can well adapt to the future climate change in Shanghai. Yet, about 72 tree species may not be in a good state under climate change. These species are mostly limit to some climatic factors for the normal metabolic function, some species are probably due to extreme cold temperature in the winter, some trees required a more appropriate habitat for the growth in the cold would not grow well in warmer and humid climates in Shanghai. Finally, these selected landscape tree species shape the landscape of green land in Shanghai, building a rich diversity of ecological communities, maintain the stability and sustainability of urban ecosystem.

Random species loss underestimates dilution effects of host diversity on foliar fungal diseases under fertilization

Xiang Liu, *Shurong Zhou*

Ministry of Education Key Laboratory for Biodiversity Science and Ecological Engineering, School of Life Sciences, Fudan University

With increasing attention being paid to the consequences of global biodiversity losses, several recent studies have demonstrated that realistic species losses can have larger impacts than random species losses on community productivity and resilience. However, little is known about the effects of the order in which species are lost on biodiversity-disease relationships. Using a novel removal experiment manipulating plot-level plant diversity, and multi-year nitrogen addition and artificial warming experiments, in natural assemblages of alpine meadow vegetation on the Qinghai-Tibetan

Plateau, we explicitly compared the effect sizes of random versus realistic species losses under fertilization and/or warming on plant foliar fungal diseases. We found that realistic species losses under fertilization had greater effects than random losses on fungal diseases, and that species identity outweighed nested structure itself in driving the diversity-disease relationship. The plant species most prone to foliar fungal diseases were also the least vulnerable to extinction under fertilization, demonstrating the importance of protecting low competence species to impede the spread of infectious disease. In contrast, there was no difference between random and realistic species loss scenarios on the diversity-disease relationship under experimental warming (or the combination of warming and fertilization), an important reminder that the functional consequences of species losses may vary under different drivers.

A comparative research on ecological adaptability between alien and native woody plants in warm temperate region

Xiao Liu, *Qiang Li, Ning Wang, Ning Du*
Ecology and Biodiversity Institute

Under the background of global change, warm temperate region is becoming drier and drier. In order to compare the ecological adaptability between alien and native woody plants in warm temperate region, via researching water utilization strategy in different time and season, a field experiment was designed in Fanggan Village, where there is an ecological experimental base of Shandong University. In this experiment, *Quercus acutissima* Carruth., *Vitex negundo* L. var. *heterophylla* (Franch.) Rehd., *Robinia pseudoacacia* L., *Rhus Typhina*, were chosen as the research objects. This research shows that when the climate becomes drier, different kind of plants has different strategy in ecological adaptability. As arbors, *Quercus acutissima* Carruth. grows slower than *Robinia pseudoacacia* L., but the former is abler to resist the drier envoriment, so in *Robinia pseudoacacia* L.- *Quercus acutissima* Carruth. mingled forest, with the help of the global change, *Quercus acutissima* Carruth. may occupy more advantage, and at the end, it may be the only dominant species in the forest. In terms of shrubs, the ability of drought resisting in V*itex negundo* L. var. *heterophylla* (Franch.) Rehd. and *Rhus Typhina* shares on a fifty-fifty basis. But compared with V*itex negundo* L. var. *heterophylla* (Franch.) Rehd., the ability of metabolism in *Rhus Typhina* is higher when the weather is a little dry. On the contrary, when it is a little moist, *Vitex negundo* L. var. *heterophylla* (Franch.) Rehd. is better. In the future, V*itex negundo* L. var. *heterophylla* (Franch.) Rehd. - *Rhus Typhina* mixed shrub may be faced with niche separation, *Rhus Typhina* may move to the dry place while the other may stay in the wet ground.

Size fractions of air dust and associated metals removed by plant leaves in water soluble and liposoluble states at roadside of Beijing urban area

Yanju Liu, *Zheng Yang, Minghao Zhu*
Beijing Milu Ecological Research Center

Phytoremediation is a cost-effective and environmentally friendly method to improve air quality. Previous study observed that plant leaves of *Ulmus pumila* (S2), *Prunus cerasifera* f. *atropurpurea* (S3), *Jasminum nudiflorum* (S5), *Euonymus japonicas* (S6), *Populus tomentosa* (S11), *Salix babylonica* (S12), *Parthenocissus tricuspidata* (S13), *Ailanthus altissima* (S20), *Robinia pseudoacacia* (S21), *Koelreuteria paniculata* (S24), *Weigela florida* cv. Red Prince (S25), *Magnolia denudate* (S26), *Ligustrum vicaryi* (S29), *Malus micromalu* (S30), *Syringa oblate* (S32) could efficiently remove air dust. However, it is unknown what size fractions of dust were accumulated. In this study, the above 15 plant species leaves were collected at the roadside of Beijing urban area and their size fractions of water soluble and liposoluble dust (WLD = WD + LD) and associated metals Cd, Cr, Cu, Fe, Mn, Pb, Zn were analysed. In total, plant leaves could remove 321-2,757 (mean 1,159) mg m^{-2} WLD with the highest values for S6 and S30. Higher proportions of leaf dust were observed as water soluble, and the highest WD value occurred in S6, with a range of 193-1,971 (mean 817) mg m^{-2}. Varied size fractions of WD were found from different plant leaves, showing higher ratios of WD >100 μm in S2, S26, S11, S12, S24, S20 (57.8%, 55.6%, 47.6%, 47.2%, 42.9%, 32.9%); WD at 10-100 μm in S30, S13, S25, S29, S6, S32 (67.0%, 53.6%, 49.1%, 46.1%, 38.4%, 36.1%); and WD at 2-10 μm in S3, S5, S21 (41.3%, 39.1%, 39.1%) respectively. Low ratios of WD at 0.2-2 μm were observed in all species leaves. Liposoluble dust (LD) ranged from 51 to 965 (mean 342) mg m^{-2} with the highest value also for S6. Generally, LD occurred mostly in the size fraction over 10 μm. Values of dust associated metals and their size distributions were also different for individual plant species and metals. WLD Cd was in the range of 321-2,757 (mean 1,159) μg m^{-2} with higher values and larger size fractions occurred in S6, S30 and S2. Similar WLD ranges were found for Cr as 438-4,348 (mean 1,725.6) μg m^{-2} and Pb as 104-4,974 (mean 890.0) μg m^{-2}, but the highest WLD values were observed for Cr in S12, S6, S29 and for Pb in S24. The highest WLD Cu occurred in S29 with a range of 103-2,717 (mean 795.7) μg m^{-2}. Both highest WLD values of Fe and Mn were observed in S6 with larger particle size fractions, apart from the differed value ranges (Fe: 7,300-117,086, mean 41,587.1 and Mn: 49-2,030, mean 727.7) μg m^{-2}. WLD Zn ranged as 294-3,411 (mean 1,340.7) μg m^{-2}, with higher values for S5, S6 and S29, whilst higher fractions of 10-100 μm WD Zn for all three species and 3-10 μm LD Zn for S6 and S29 were observed.

Evaluation of airborne dust and heavy metal pollution at seven sites in Beijing by analyzing five common tree species leaves

Zheng Yang, *Yanju Liu, Minghao Zhu*
Beijing Milu Ecological Research Centre

Fast urbanization has been damaging the environment and bringing heavy pollution to the atmosphere, soil and water. Phytoremediation has been used to reduce pollution, and to evaluate overall environmental quality. Chinese capital city Beijing, located at the core area of Beijing-Tianjin-Hebei, is suffering from increasing traffic pressure, air pollution and water safety risks. To meet current ecological need of city construction, further trials are required to explore the roles of plants in urban pollution control and evaluation. This study aims to assess airborne dust and heavy metal pollution status by analyzing plant species leaves. Five common plant species leaves were sampled from seven sites (traffic roads and parks), including *Ailanthus altissima*, *Sophora japonica*, *Populus beijingensis*, *Ulmus pumila* and *Prunus cerasifera* f. *atropurpurea* in September 30, 2015 (no rain for 18 days prior to collection). Three sample duplicates were collected for each species. Dust accumulation per leaf area was measured for all species at all sites. Both unwashed and washed leaves were analyzed for metal concentrations of Cd, Ni, Cr, Pb, Cu, Zn, Mn by Atomic absorption spectrometry. The average concentration of each metal in leaves was calculated for every species to identify the best monitoring plant species for certain metals. Metal Accumulation Index (MAI) was used to evaluate multi-metal pollution status at each site. In result, *A. altissima* accumulated the highest amount of dust (39.4 g/m^2), and *S. japonica* the lowest (5.22 g/m^2). Average leaf dust accumulation of all species for individual site follows the order from high to low as (g/m^2): Wangjing Park (27.9) > Chaoyang Park (26.5) > Yuting Bridge (25.2) > Yuegezhuang Bridge (22.6) > Niantan reservoir (21.8) > Milu Park (21.2) > Jingcheng Highway (19.3). Also, dust accumulation per leaf area was significantly related to the mean PM$_{10}$ value in 30 days just before sampling date. Different species leaves have different element accumulation preference. *A. altissima* accumulated the highest Cd (unwashed/3.71 mg/g and washed/3.67 mg/g) and Cu (unwashed/28.8 mg/g and washed/27 mg/g), whilst *P. beijingensis* accumulated higher amounts of Pb (unwashed/10.9 mg/g and washed/6.39 mg/g), Zn (unwashed/75.3 mg/g and washed/72.1 mg/g) and Mn (unwashed/72.2mg/g and washed/70.6mg/g). The highest accumulations were observed for Ni in *U. pumila* (unwashed/7.31 mg/g and washed/6.03 mg/g) and for Cr in *S. japonica* (unwashed/9.06 mg/g and washed/7.86 mg/g). Higher geometric mean MAI of unwashed leaves of all plant species occurred at sites Jingchen Highway (4.89) and Yuting Bridge (4.32), reflecting heavy metal pollution in atmospheric dust, which is mainly affected by traffic activities, whereas higher geometric means of MAI in washed leaves, observed at sites Niantan Reservoir (7.22), Chaoyang Park (4.19) and Yuting Bridge (4.10), reflected heavy metal pollution status on a general basis due to probably water sources nearby.

From greenhouse to the wildlife: Invasion patterns of *Kalanchoe × houghtonii* using ecological niche modeling

*Pilar Cachón[1,2], Sonia Herrando-Moraira[1], Neus Nualart[1], **Sergi Massó**[1,3], Daniel Vitales[1], Jordi López-Pujol[1]*
1. Botanic Institute of Barcelona (IBB-CSIC- ICUB)
2. Facultat de Biologia, Universitat de Barcelona
3. BioC-GReB, Laboratori de Botànica, Facultat de Farmàcia, Universitat de Barcelona

Alien species are currently considered one of the main direct threats to global biodiversity in our planet. Some alien plant species can become invasive and damage ecosystems, leading to negative effects on the local and global economy and society. Here, we have studied *Kalanchoe* × *houghtonii* D. B. Ward (Crassulaceae), a hybrid species artificially created by the horticulturist A. D. Houghton with gardening purposes in the 1930s. It was a result of the crossing between *K. daigremontiana* Raym.-Hamet & H. Perrier and *K. delagoensis* Eckl. & Zeyh., two endemic species from Madagascar. Soon, the hybrid taxon showed large colonizing capacity, escaping outside the cultivation spots and rapidly expanding its distribution area. Now, *K.* × *houghtonii* is currently found in all continents except Antarctica. Therefore, considering the well-known background of the species, as well as its strong invading abilities, this plant represents an attractive model to investigate the expansion of alien species. The aims of the present study are evaluating the potential worldwide habitat of *K.* × *houghtonii* at different time frames, from present to future, employing various scenarios of climate change. To reach these goals, we first carried out documentary research, involving the finding of localities where the species is present, through online databases (such as GBIF), citizen science web portals, as well as many published academic papers. With the obtained occurrences, and using the maximum entropy algorithm implemented in MaxEnt, we modeled the potential habitat of the species to the present, which was later projected to the future under different scenarios. Results derived from this study would allow us to better understand the invading behavior of species with high potential invasion such as *K.* × *houghtonii*, and, at the same time, inferring possible range contractions or expansions of the species across its whole distribution area in the context of climate change.

Past, present, and future of the invasion of *Senecio pterophorus*

*Cristina Rubió, Sonia Herrando-Moraira, Neus Nualart, Roser Vilatersana, **Jordi López-Pujol***
Botanic Institute of Barcelona (IBB-CSIC- ICUB)

Senecio pterophorus DC. is a perennial shrub of the family Compositae native to eastern South Africa (Eastern Cape and KwaZulu-Natal provinces) that inhabits forest margins, grasslands, and fynbos. One hundred years ago, *S. pterophorus* expanded into Western Cape in South Africa and was introduced cross-continentally in Australia as well. A more recent expansion occurred 25–30 years ago in Europe, concretely in Liguria (NW Italy) and Catalonia (NE Spain). In the introduced ranges, it mainly appears in disturbed areas such as railroads or roadsides, although it can also occur in natural areas. During the late 19th and the early 20th centuries, *S. pterophorus* was recorded in Belgium and the United Kingdom, respectively, although it is now considered extinct in both countries. We used ecological niche models [geographic (G) space] and niche comparisons analyses [both in geographic and environmental (E) spaces] aimed to: (1) determine whether the species has changed its niche during the invasion process, (2) ascertain why the species has not succeeded neither in Belgium nor in United Kingdom, and (3) assess possible expansions and/or contractions of the species under different climate change scenarios by comparing habitat suitability between present and future models. In the G-space we used the maximum entropy algorithm (implemented in MaxEnt) to create niche distribution models, which are projected and evaluated in the native area vs. the invaded ones, and vice versa. Possible differences in niches of native and invaded areas were also tested by comparing background divergence with the observed niche divergence in the Principal Components Analysis (PCA)-reduced axes. The results of this study would contribute to understand in which conditions *S. pterophorus* is behaving as an invasive plant.

Montjuïc Mountain (Barcelona, Spain): A "natural" laboratory for plant invasions?

Paula Farelo[1], *Josep Maria Montserrat*[2], *Samuel Pyke*[2], ***Jordi López-Pujol***[3], *Neus Ibáñez*[3]
1. Unitat de Botànica, Facultat de Biociències, Universitat Autònoma de Barcelona
2. Jardí Botànic de Barcelona, Consorci del Museu de Ciències Naturals de Barcelona
3. Botanic Institute of Barcelona (IBB-CSIC-ICUB)

Invasive alien species are currently considered the second most important direct driver of global biodiversity loss. Urbanization is a major factor promoting biological invasions worldwide, because (i) cities contain heterogeneous, highly disturbed habitats that provide ecological niches for alien species (where native species cannot be able to adapt to the new conditions), and (ii) cities often act as gateways to alien invasions through airports, harbors, highways, and train stations, whereas gardens, urban parks and other tracts of suitable habitat (streetscapes, vacant lots, front and backyards, courtyards, balconies, terraces, rooftops, fences, hedges, walls, and so on) can become propagule sources for spreading to natural areas. We have chosen one of the main European cities, Barcelona, as a case study to illustrate how such a city can become a major pathway for the introduction and establishment of plant invasions. Specifically, we have selected Montjuïc, an urban mountain (the top is at 183 m) of ca. 3.6 km^2 (the core area) that is located in the sea front, just behind the commercial port (albeit there is an expressway and a railway between the mountain and the docks). Whereas the northern and western outskirts are occupied by residential areas, most of the mountain is occupied by public gardens and urban parks (including the Barcelona Botanical Garden), cultural (museums, art galleries, and music and theater halls) and sport facilities (the mountain was home of a large part of the 1992 Olympic venues). There are also many historical assets, such as a military fortress (dating from 18th century), Roman and Iberian quarries, and even remains from the Paleolithic period, which illustrate the deep transformation of the mountain. Together with the fact that the mountain is visited yearly by nearly 20 million people, all these factors make Montjuïc a candidate to be a "natural" laboratory for plant invasions. We present herein the first results of a project aimed to obtain a comprehensive catalogue of the mountain's alien flora. The study area was divided into Operational Geographic Units (OGUs), which were UTM (Universal Transverse Mercator) squares of 0.25 km^2, and extensive fieldwork was carried out (combined with database/literature search) to identify all alien plant species thriving in the mountain, both as casual and naturalized (that is, fully established). Areas with evident management, such as botanic gardens, have been avoided for obvious reasons. Vouchers for some species have been deposited in the BC Herbarium, with special focus on floristic novelties and the potentially most harmful species. At the completion of the catalogue, the following information will be available for all the identified alien species: (i) distribution within Montjuïc Mountain (by OGUs); (ii) habit (annual, biennial or perennial); (iii) life form (herb, shrub, or tree); (iv) habitat type in Montjuïc; (v) native range; and (vi) whether they are listed as alien in any of the reference catalogues at regional or state levels.

Characterisation of the sporophytic self-incompatibility (*S*) locus in *Senecio squalidus* (Asteraceae)

Ying-Qi Lou[1], *Batstone Tom*[2], *Navado Bruno*[1], *Quillet Marie-Christine*[3], *Hendriks Theo*[3], *Filatov Dmitry*[1], *Hiscock Simon J*[1]
1. Department of Plant Sciences, University of Oxford
2. School of Biological Sciences, University of Bristol
3. Unité Evolution, Ecologie, Paléontologie, UMR 8198, CNR

Around 80% of all plants in the wild take outbreeding as the normal mode of reproduction, which allows genetic diversity to protect against pressures from the environment. In flowering plants, outcrossing is frequently imposed by self-incompatibility. Self-incompatibility (SI) is defined as the inability of a fertile hermaphrodite seed plant to produce zygotes after self-pollination. It is a pollen discrimination system, usually controlled by a single *S*-locus with multiple *S*-haplotypes (*S*-alleles) which carry genetically tightly linked male (pollen-expressed) and female (pistil-expressed) determinant genes. SI is classified as either gametophytic SI (SSI) or sporophytic SI (SSI). Research on the molecular mechanisms of SI systems in the Brassicaceae, Papaveraceae and Solanaceae have shown that a collection of divergent molecular mechanisms control SI in different families. Thus to better understand the molecular diversity of SI and the evolution of SI in angiosperms, it is vital to characterize more SI systems in diverse families. The Asteraceae is the second largest angiosperm family containing 1,620 genera, approximately 23,600 species, many of which are economically important such as sunflowers, lettuce, chicory and Artemisia. One UK species, *Senecio Squalidus* (Oxford Ragwort) has undergone a unique invasive history to become a successful colonizer of the British Isles since its introduction from Sicily, Italyin the late 17th century. It was confirmed to have strong sporophytic SI with a low *S* allele number. It also exhibits common features of SSI systems such as dominance interactions and pseudo-self-compatibility. *S. squalidus* is an ideal model to study the SI system as a member of the Asteraceae. Here we conduct bioinformatics analysis of the genome sequence of *S. squalidus* to screen for specific male and female *S*-determinants linked to the *S*-locus on the basis of recently mapped *S*-locus region. And with the help of preliminary comparative transcriptome data analysis of *S. squalidus* and other SI plants, we characterize the tissue-specificity of expression of candidate genes and testfor polymorphism in the alleles of putative *S* genes. Overall, the purpose of the project is to elucidate the molecular genetic basis underlying the SI mating system of the Asteraceae.

Effects of silicate application on photosynthesis and transpiration in winter wheat under elevated UV-B radiation

Yunsheng Lou

Nanjing University of Information Science and Technology

A field experiment was conducted to investigate the effects of silicate application onphotosynthesis and transpiration in winter wheat under elevated UV-B radiation. The experiment had two UV-B radiation levels, i.e. ambient UV-B (A, ambient) and elevated UV-B radiation (E, elevated by 20%); and two silicate application levels, i.e. a control (Si0, 0 kg SiO_2/hm^2) and added silicate (Si1, 200 kg SiO_2/hm^2). The results indicated that, compared to ambient UV-B radiation, elevated UV-B radiation decreased the net photosynthesis rate (Pn), stomatal conductivity (Gs), intercellular CO_2 concentration (Ci) and transpiration rate (Tr) at different stages by 9.21%-18.94%, 7.56%-23.66%, 1.24%-12.81% and 13.88%-27.85%, respectively, increased stomatallimitation (Ls) and water use efficiency (WUE) by 5.07%-19.67% and 2.35%-27.86%, respectively, in the no silicate treatment (Si0). Under elevated UV-B radiation, silicate application significantly increased Pn, Ls and WUE at different stages by 5.23%-12.23%, 4.61%-45.32% and 18.15%-61.33%, respectively, decreased Gs, Ci and Tr by 6.35%-10.94%, 5.41%-11.01% and 6.75%-30.51%, respectively. In conclusion, elevated UV-B radiation significantly decreased the net photosynthesis rate (Pn) and transpiration rate (Tr), increased water use efficiency (WUE) in winter wheat leaves, however, silicate application could alleviate the depressive effects of elevated UV-B radiation on net photosynthesis rate and further decrease transpiration rate and water use efficiency.

Investigate how plants response to local climate change at an organic tea farm in Nantou, Taiwan

Pei-Luen Lu, *Yi-Shuo Liang*

Department of Life Science, National Taitung University

According to mounting pressure on the available water resources is occurring as the global temperature increases, there is a risk of a truth in the intensity and duration of extreme weather, causing flooding and droughts in the future. Transpiration of vegetation is the most difficult estimate in the global water cycle and is an important process in water cycle of ecosystem for forests and agriculture. Sap flow is one of the proper indicators to understand transpiration in plants. Tea tree is one of the best candidates to investigate this question, including their response to the being frequently extreme weather in Taiwan. Tea is one of the most important cultural and economic drinks in the world. Taiwan has native tea tree species and commercially grows a lot of tea trees in various mountains and hills for domesticated consuming and export. Tea trees' growing habitat and environment is similar to cloud forests. Thus, tea trees play an important but unclear role in transpiration. For improving the sustainable water usage and understanding the response to local climate change, we conducted this research at an organic tea farm in central Taiwan, with a heat balance method. The evolution of the daily and severe weather sap flow was observed and recorded in the dynamics for twelve months based on the plant *Camellia sinensis* L. varieties Jin Xuan (TTES#12). The results were calculated by Penman-Monteith equation. Ecosystem of organic tea farm for local climate change and recommendation made for further work on using the technique and tea agriculture were addressed.

Distribution and transportation of modern pollen in the northeastern Indian Ocean and their paleoenvionmental application

Chuanxiu Luo

South China Sea Institute of Oceanology, Chinese Academy of Sciences

In order to analyze the terrestrial area, thirty-three seabed surface sediment samples from the northeastern Indian Ocean were selected and thirty-one airborne pollen samples were collected from the study area for pollen analysis. Then pollen analysis in two cores from north east Indian Ocean were conducted and compared with fossil pollen results from South China Sea. Firstly it was found that spores comprised the highest percentage in the surface sediment samples in the northeastern Indian Ocean, while the overall percentage of herb pollen was higher than that of tree pollen. Utilizing the 90 °E Indian Ridge as a dividing line, more *Microlepia* spores and herbaceous pollen were present on the west or northwest of the line, possibly originating in Sri Lanka and India. More Polypodiaceae spores and tree pollen (*Pinus* excluded) were present on the east or southeast of the boundary; therefore, it is inferred that Polypodiaceae pollen and tree pollen may originate from Sumatra Island. Based on PCA analysis, it was found that two main factors affect pollen percentage: ocean currents from southeast to northwest and the distance from landmasses around the study area. In the northeastern Indian Ocean, airborne pollen types and concentrations showed a close relationship with wind direction and distance from the sampling point to the continent. Combined with pollen analysis from surface sediment pollen samples, inferences that Fagaceae (including *Castanopsis)* pollen and Chenopodiaceae pollen in surface sediment were transported mainly via ocean currents instead of early summer or spring wind. Based on fossil pollen analysis in two cores from north east Indian Ocean, we found that warm pool can be taken as an climate humidity index both in South China Sea and Indian Ocean based on the fossil pollen of the cores. *Pinus* pollen can be taken as an index of sea level change, its percentage increase in the high sea level period only in the cores near continent shelf, its percentage decrease in the cores in the north east Indian Ocean because they are almost in the deep sea and the pollen transporting distance did not change.

Autonomous selfing provides potential reproductive assurance in *Conandron ramondioides* (Gesneriaceae)

Hong-Wen Ma[1], *Kai-Hsiu Chen*[2], *Kuan-Ting Hish*[1], *Chun-Neng Wang*[2]

1. Institute of Ecology and Evolution and Evolutionary Biology,

National Taiwan University
2. Department of Life Science, National Taiwan University

Conandron ramondioides is a perennial herb survived in patches of high humidity habitat in dense shade forests where pollinators are scare. Observations of high proportion (ca. 78%) of fruit set in the field and caged flowers imply that autonomous selfing is possible for *C. ramondioides*. To understand the mechanism of autonomous selfing in *C. ramondioides*, we conducted pollination experiments to answer the following two questions: (1) Whether autonomous selfing is its major reproductive strategy? (2) When during anthesis does autonomous selfing occur? (3) If so, does selfing evolve due to less prone to inbreeding depression? (4) Whether selfing provides reproductive assurance for *C. ramondioides* survival? In pollination experiments, the seed set resulted from emasculation (allow insect pollination) is 523.5 and direct bagging (prevent insect but selfing) is 541.9, which suggests that *C. ramondioides* had well-developed capacity for autonomous selfing. The timing of autonomous selfing can continuously occur during anthesis because seed sets continuously increased from bagged flowers emasculated at different time intervals, which indicates the mode of autonomous selfing is competing selfing. The calculated inbreed depression is low (δ = 0.29) based on proportional of seed germination rate differences between outcrossing and selfing. The proportion of autonomous selfing seed set among intact flower seed set is an indication of reproductive assurance (RA). We found autonomous selfing in *C. ramondioides* provided middle level of reproductive assurance (RA = 0.22). According to our pollination experiment, we suggest that *C. ramondioides* evolved an efficient strategy of mixed breeding system. The well-developed capacity for competing autonomous selfing, low inbreeding depression and high effect of insect-pollination allowed *C. ramondioides* to survive in isolate and patchily natural habitats. This is the first study to reveal autonomous selfing mechanism and its implication of mating system in Taiwan.

The physiological function of chloride and its possible molecular basis in the xerophyte *Pugionium cornutum* in response to salt and osmotic stresses

Yannong Cui, Xiaoting Li, Chenghang Yang, Huan Guo, Suomin Wang, ***Qing Ma***
Lanzhou University

Pugionium cornutum, as one kind of succulent xerophyte species that is widely distributed throughout the desert regions of Northwestern China, can well cope with salt stress, moreover, has an excellent adaptability to arid environments. Our previous investigations showed that *P. cornutum* could accumulate high Cl^- in shoots, which contributes to enhancing the osmotic adjustment capacity under salt treatments. To further reveal the physiological function of Cl^- in *P. cornutum* under salt and osmotic stresses, 4-week-old seedlings were treated with 50 mM NaCl together with the inhibitors of Cl^- channels (20 μM DIDS and Nif); seedlings were also subjected to sorbitol-induced osmotic stress (-0.3 MPa) in the presence or absence of additional 20 mM NaCl. The result indicated that under 50 mM NaCl treatment, the addition of 20 μM DIDS and Nif significantly decreased the net Cl^- uptake rate, Cl^- concentration in shoots and the contribution of Cl^- to leaf omostic potential in *P. cornutum*, and as a result, inhibited plant growth. Compared with control, the net Cl^- uptake rate, Cl^- concentration in shoots and its contribution to leaf omostic potential were significantly increased under -0.3 MPa osmotic stress. The addition of 20 mM NaCl significantly increased the shoot water content and net photosynthesis rate under -0.3 MPa osmotic stress, and the further addition of 20 μM DIDS significantly reduced Cl^- concentration in shoots and the contribution of Cl^- to leaf osmotic potential, and consequently, counteracted the mitigative effect of 20 mM NaCl on the osmotic stress-induced growth inhibition of *P. cornutum.* These findings suggested that *P. cornutum* could accumulate high concentrations of Cl^- in shoots and use the Cl^- as an osmoregulator to cope with salt and osmotic stress. We further investigated the possible molecular basis of Cl^- transport by performing transcriptome sequencing after *P. cornutum* were treated by 50 mM NaCl for 6 and 24 h. The results showed that in roots, chloride channel genes *PcCLC-a* and *PcCLC-g* were significantly induced by 9.4- and 1.1-fold at 6 h, respectively, and the transcripts of *PcCLC-g* and *PcCLC-f* were significantly increased by 9.3- and 3.1-fold at 24 h, respectively; while in shoots, 50 mM NaCl triggered a 8-, 7.7- and 2.4-fold increase in the transcripts of *PcCLC-f*, *PcCLC-b* and *PcCLC-g* at 6 h, respectively, and increased the expression levels of *PcCLC-f*, *PcCLC-g* and a cation-chloride co-transporter gene (*PcCCC1*) by 1.7-, 1.2- and 7.2-fold at 24 h, respectively. These genes may probably play crucial roles in Cl^- transport in *P. cornutum.*

Responses of forest understorey plants and soil microbial community to multiple global environmental changes - The key role of light availability

Shiyu Ma*, Pieter De Frenne, Kris Verheyen*
Ghent University

Multiple global environmental changes are affecting ecosystems around the world. In forests, stratified canopy structures result in shading, which can buffer the effects of both nitrogen deposition and global warming on understorey communities. However, the effects of multiple environmental changes, and the role of light, on co-occurring ecosystem compartments above- and below-ground are barely studied together. To better understand the co-occurring response and the link of plant and soil microbial communities to multiple global environmental changes, we manipulated light with fluorescent tubes, nitrogen fertilization and temperature (with experimental warming) in a full factorial design in an ancient temperate forest from 2011 to 2015. Our results show that light has a strong effect on plant community diversity but nitrogen addition and warming had no such effect. Illuminated plots experienced a substantial decrease of soil microbial biomass. However, the microbial structure (defined as the ratio of fungi to bacteria) remained unchanged based on phospholipid fatty acids (PLFA) analyses. High throughput sequencing illustrated that the bacterial community diversity responded significantly to the treatments of light and warming but did not respond to nitrogen addition, although a large amount of unique operate taxonomy units (OTUs) were observed. The effect of light on the bacterial community diversity depended on nitrogen addition and warming. Co-inertia analyses demonstrated that plant and microbial communities were co-structured and light explained most of the deviance in the co-structures. Our results provide robust evidence of light as a driver for changing plant and microbial communities' composition, and advocate for more multi-factor experiments that scrutinize the direct and indirect effect of light in changing the plant – soil continuum in the context of global change.

Long-term nitrogen deposition negatively affects physiological traits of light-preferring species in the understory layer of a tropical reforested forest

Qinggong Mao[1], *Xiankai Lu*[1], *Cong Wang*[2], *Kaijun Zhou*[2], *Jiangming Mo*[1]
1. Chinese Academy of Science
2. University of Chinese Academy of Science

Reforested forests are becoming the dominant forest cover type in the tropics where N deposition has been elevated. However, less is known about long-term effects of N deposition on diverse understory plants in tropical forests. To test the following hypothesis: long-term N additions negatively affect the understory plant by decreasing the light penetration from canopy in reforested forests. Physiological responses (photosynthetic capacity, physiological stress and foliar N storage) of seven understory species to a decade gradient N additions were examined in a typical reforested forest in south China. Experimental N additions were conducted at the following levels from July 2003 to July 2013: no addition (Control); 50 kg N ha^{-1} yr^{-1} (N 50); 100 kg N ha^{-1} yr^{-1} (N 100). Results showed that six of seven understory species did not physiologically respond to N addition, whereas the most light-preferring species (*Alchornea trewioides*) responded significantly to N addition by showing decreased maximum photosynthesis (Pmax). Furthermore, the decreased Pmax of *Alchornea trewioides* was significantly correlated to the increased canopy closure with N addition ($P = 0.05$). Our findings suggest that the understory species are less limited by N availability in tropical reforested forests under high ambient N deposition, and long-term N deposition could suppress understory light-preferring species by decreasing the light penetration from canopy.

The role of sandstone refugia in the distribution and diversification of andromonoecious and functionally dioecious *Solanum* in the Australian Monsoon Tropics

Christopher T. Martine[1], *Jason T. Cantley*[1], *Emma S. Frawley*[1], *Daniel Hayes*[1], *L. Mae Lacey*[1], *Peter Jobson*[2], *Ingrid E. Jordon-Thaden*[3]
1. Bucknell University
2. Northern Territory Herbarium, Alice Springs
3. University of Calfornia, Berkeley

The Australian Monsoon Tropics (AMT) is one of the least disturbed tropical biomes on the planet. Surprisingly little is known about the evolution of its flora or how past geologic and climatic events may have shaped it, particularly during the dynamic climate fluctuations of the Quaternary that ushered in numerous periods of hyper-aridity. We present the initial results of a project to investigate the biogeographic origins and patterns of historical distribution for two lineages of narrowly endemic AMT *Solanum* clades, one functionally dioecious and one andromonoecious, across both spatial and temporal scales. These lineages occur, in part, along the escarpment edges of three major sandstones, which support a sporadically distributed microclimate maintained by shaded gorges and some orographic precipitation. We hypothesize that: a) the same natural breaks occur within the geographic ranges of these lineages (and potentially other unrelated angiosperm lineages), and that b) these breaks reflect barriers formed during unfavorable glacial periods of hyper-aridity when escarpment microclimates acted as habitat refugia. To uncover current AMT biogeographic patterns of angiosperms, we collected populations of taxa and constructed molecular phylogenies for each lineage to understand phylogenetic relationships and time of lineage divergence obtained from molecular clock techniques. Descriptive statistics and demographic modeling allow for the inference of historical bottlenecks, effective breeding sizes through time, reticulate evolution, and periods of range expansion. Phylogenetic and demographic data are then correlated with niche models of each taxon's present day distribution via robust geospatial data, which in turn are combined with Global Circulation Models to illuminate historical areas of suitable habitat during the Last Glacial Maximum (LGM) when the AMT was last postulated to have undergone a period of hyper-aridity. Upon this biogeographic background we then overlay reproductive biology studies examining rates of *ex situ* hybridization within and between clades, comparative measures of genetic diversity between obligately outcrossing species (dioecious) and potential selfers (andromonoecious), and efforts to identify and describe novel taxa.

What is the extend of calotropis procera along road verges in the mutale local municipality within the Vhembe Biosphere Reserve, Limpopo, South Africa

Sipho Mbambala, *Peter Tshisikhawe*
University of Venda

Biological invasions are considered the second major cause of the world biodiversity loss and, even more worrying, is the irreversibility of the impacts caused by invasion, which worsens within the time, as the exotic species disseminate. Aggressive invasion of road verges by alien invasive plant species such as calotropis procera may have negative impacts on road verges biodiversity. Road verges have long been seen as being of potential biological value and are believed to make a major contribution to the conservation of indigenous flora in various parts of the world. Road verges are considered to be important in the conservation and management of landscapes used for agricultural purposes. Sites will be selected, transects of 10 m by 10 m will be constructed running parallel to the road, will be examining the plant cover, species richness, frequency and abundance on road constructions compared with places without road construction impact. For the fenced sites, transects will be located at 1 m from the road edge, 2 m from the fence defining the road verge on the road side of the fence. Signs of disturbance including evidence of erosion, grading and vehicle tracks will be recorded.

Effect of the light habitat on the structure, diversity and dynamics of the tropical dry forests of the Magdalena river high valley, Colombia, South America

Omar Melo[1], *Nathaly Rodriguez*[2]
1. Tolima University
2. Universidad Austral de Chile

Tropical dry forests are complex and fragile ecosystems with high anthropogenic intervention and restricted reproductive cycles. They are rich in unique structural, physiological and phenological diversity. This research was carried out in the upper Magdalena river high valley, in four fragments of tropical dry forest with different successional states. The flat coordinates of the zone are: 4° 59’53.48” N and 74° 55’38.87” E. The study area has an average annual temperature of 27°C, an average annual precipitation of 1,750 mm and a relative humidity of 71%. The height above the sea level oscillates between the 475 to 580 m of altitude. In each fragment four permanent plots of 1.0 hectare were established. And the richness, relative abundance and species rarity were evaluated, as well as the forest dynamics that included mortality, recruitment and diametric growth for a period of 10 years. To evaluate the light habitat that indicates the amount of energy used by the forest cover to perform functional processes of assimilation and productivity, the direct measurement of leaf area index (LAI) was used with a LI-2200TC leaf analyzer. The different levels of light absorbed by the canopy of the evaluated forests were expressed in relative values of the photosynthetically active radiation (PAR), which was measured as the non-absorbed radiation on the forest floor surface expressed as the density of photosynthetic photon flux ($\mu mol.m^{-2}.s^{-1}$), between 400 and 700 nm of the light spectrum, for which the LI-191SA - Line Quantum Sensor and LI-190SA - Quantum Sensor sensors were used and a collector Of LI 1400 data (LI-COR Inc., Lincoln, NE, USA). Likewise, the coefficient of extinction of the light (K) was derived, by means of the application of the Beer & Lambert Law. The results showed that there is a direct relationship between the availability of the light resource and the dynamics of the tropical dry forest, the higher growth rates of the tropical dry forest are associated to habitats with high availability of PAR that is absorbed by a canopy with high LAI, a high growth that generates an increase in the mortality rate. The liberated spaces are occupied by new individuals who are waiting for the opportunity for growth. For more advanced successional state such as the mature forest, the canopy that characterizes the forest structure has a lower LAI, which allows greater availability of resources in the understory allowing a greater diversity of habitats that are occupied by several species types, hence the greater heterogeneity and structural complexity this generates a smaller growth and greater stability between the mortality and the recruitment, which owes their dynamics to factors endogenous to the biotic community.

Impact of nitrogen fertilizer on foliar endophytic fungal communities in an alpine meadow ecosystem

Yiming Meng, *Qi Zhang, Yongjun Liu, Huyuan Feng*
Ministry of Education Key Laboratory of Cell Activities and Stress Adaptations, School of Life Sciences, Lanzhou University

Endophytic fungi are present in all plants in natural ecosystems, yet our understanding of their community dynamics and processes is very limited. Here we examined the foliar endophytic fungal communities associated with three grass species along a four-year nitrogen fertilizer gradient in an alpine meadow ecosystem. Ascomycota and Basidiomycota were the dominant phyla, and the proportion of Ascomycota and Basidiomycota fungi significantly shifted with high fertilizer inputs, indicating that nitrogen changed the role of endophytic fungi in plant. Besides, water-soluble carbohydrates, and carbon/nitrogen ratio of leaves also affected fugal community assemblage. Our research first revealed endophytic fungal community structure and offered clues of their nitrogen acquisition strategies across this cold terrain, indicating that variations in diversity and community composition of endophytic fungi measured here may feedback and influence nitrogen cycling and dynamics in this alpine meadow ecosystem.

Study on ecological effects of indoor vertical greening plants

Hui-Zhi Mo, *Xu-Rong Luo, Jing Zhang, Liang Zhao, Jian-Xin Xu*
Shenzhen Techand Ecology & Environment co., Ltd., Shenzhen 518026, China

To investigate the ability of vertical greening plants on improving indoor environment (air quality and micro-climate), the efficiency of carbon sequestration, oxygen release, cooling, humidification and dust-retention of 6 indoor vertical greening plant species have been quantitative measured and comprehensive evaluated. The results suggested that all the vertical greening plants showed significantly improvements on indoor environment quality, with various effects by different plants. *E. aureaum* ‘Virens’ was the best plant species of carbon sequestration and oxygen release per unit of plant green area, which absorbed 5.48 g CO_2 and released 3.98 g O_2 every daytime. While *P. mandaianun* ‘Royal Queen’, released 581.34 g water vapor and absorbed 1415.85 KJ heat every daytime per unit of green area, as well as reducing temperature of 0.12 ℃ , was the best plant with cooling and humidification capabilities. *A. andraeanum* has the best capability of daily dust-retention per unit of green area, which retained 0.01 g dust daily and 3.64 g annually. The ranking of comprehensive ecological effect of the 6 vertical greening plants per unit of green area was *A.* ‘Sliver Queen’ > *E. aureaum* ‘Virens’ > *P. mandaianun* ‘Royal Queen’ > *A. andraeanum* > *P. tetraphylla* > *S. podophyllum* ‘While Butterfly’. This study implies building vertical greening system should consider the integrated ecological effect instead of purely landscape effect. Enhancing indoor light intensity and planting density are two effective approaches to improve the ecological effects of indoor vertical greening.

Isolation, screening, and characterization of bacteria associated with rhizosphere soil of *Holoptelea integrifolia* Roxb. : A tropical medicinal plant

Sumita Mondal[1], *Moumita Das*[2], *Swastika Banerjee*[2], *Abhijit Bandyopadhyay*[2]
1. Vivekananda Mahavidyalaya
2. The University of Burdwan

The interaction of plants with microbes is of great importance for growth and productivity of plants in agriculture and natural ecosystem. Rhizosphere means the soil region nearest to plant root system. Exploiting microbial synergism is one of the popular methods of soil dynamics and associated changes in nutrient environment of rhizosphere. Microbial activity of rhizospheric region affects pH, oxygen, carbondioxide concentration as well as nitrogen to the benefit of the plant. The present study focuses on association of bacteria in rhizosphere with *Holoptelea integrifolia.* It is a road side tree species belongs to the family Ulmaceae. From ancient time, various part of this tree had been reported to use because of its ethno-medicinal properties such as anticancer, antidiabetic, antiemetic, antioxidant, hepatoprotective, wound healing and many others aliments. The present study reveals the presence of four bacterial entities in the rhizospheric soil at Golapbag Campus of Burdwan University. Various enzyme production capability like Lipase, citrate, amylase of 4 bacterial strain has been checked. Thermal death points of 4 isolates are also determined. Sensitivity to antibiotics like Ampicillin, Streptomycin, chloramphenicol are also checked against all isolated bacteria. Gram properties of the isolates are also visualized. Fluorescence microscopy for each bacterium is done for better visualization. The plant usually prefers sandy-loam to laterite soil. The data obtained for pH, organic carbon, nitrogen, phosphorus and potassium are: 8.46, 1.405 (mg/l), 49 (mg/l), 1.2 (mg/l), 150 (mg/l) respectively. Molecular identification of the bacteria was done by 16s-rDNA sequencing. Plants microbe interaction provides a rational basis for developing sustainable strategies for disease resistance in next generation crops.

4. Conservatoire et Jardin Botaniques de la Ville de Geneve (Switzerland)
5. University of Innsbruck, Institute of Botany (Austria)
6. Conservatoire Botanique National Alpin, Gap (France)

Alps are one of the 24 centres of plant diversity in Europe, with almost 4,500 taxa of vascular plants, representing 148 families. Yet the ecosystems supported by these mountains are under threat, mostly due to changes of land use and climate warming. Consequently, many plant species require urgent conservation action. To this end, a new project has been developed by RBG Kew (UK), with funding from the David and Claudia Harding Foundation, to conserve European alpine flora and to raise awareness of its increasing vulnerability. The Alpine Seed Conservation and Research Network (http://www.alpineseedconservation.eu/) currently brings together six plant science institutions from five countries housed at leading universities and botanic gardens. The aim of the project is to set up a network of seed conservation and research in the European Alps and improve the conservation status of endangered plant species and communities in their habitats in the European Alps. Over three field seasons seeds of 500 vascular plant species will be collected from subalpine, alpine and nival altitudinal belts and adjacent plant communities, giving priority to endemic and threatened species. The project got underway in 2016 with a highly successful collecting season. In addition to the conservation actions, one MSc and three PhD research projects will investigate the evolutionary patterns and processes of alpine species resulting from global warming, identify niche adaptation and gather new data on the conservation status of endemic species in the target areas. Additionally, public outreach, involving stakeholders and schools across the alpine region, is being developed.

6. World Agroforestry Centre, East & Southern Africa Region, Woodlands, Lusaka, Zambia

The conversion of tropical forests to monoculture rubber plantations throughout Southeast Asia threatens to have widespread negative impacts on ecosystem services. Despite this, little is known about the effect of this land use conversion on soil microbial communities. This study addresses the questions: (1) How do soil microbial communities respond to conversion from natural forests to rubber plantations, and how do responses change as rubber plantations mature? (2) Assuming that changes do occur, what are the main environmental factors which drive changes in soil microbial communities after conversion of forests to rubber plantations? Using phospholipid fatty acid analysis of soil samples taken from natural forests, young and old rubber plantations, we found that total microbial biomass significantly decreased following conversion from forests to rubber plantations. This was true for young and old rubber plantations tested in both dry and wet seasons. We also found that the composition of microbial communities differed among natural forests, young rubber plantations and old rubber plantations. These differences were influenced by soil pH, total phosphorus, soil texture, soil moisture and soil temperature. Our results also show that seasonal variation is an important driver of changes in soil microbial community composition in forests and plantations. The loss of soil microbial biomass and the changes in soil microbial community composition in rubber plantations observed in this study highlights the potential negative consequences for soil health of converting forests to rubber plantations.

Local reproductive neighborhood, flowering synchrony, and female reproductive success of the dioecious neotropical tree *Virola surinamensis* (Rol. ex Rottb.) Warb. (Myristicaceae) in a human-modified landscape

Juan Isaac Moreira Hernandez[1,2,3], *Pablo Riba Hernandez*[1,2], *Jorge Lobo Segura*[2]
1. Proyecto Carey, Peninsula de Osa
2. Universidad de Costa Rica
3. University of Missouri-St. Louis

Understanding plant reproductive patterns in disturbed environments is crucial to evaluate population level responses to disturbance and to determine current and future reproductive potential to persist in human-modified landscapes. For dioecious species, in which sex expression occurs in separate individuals, seed production by females could decrease if post-disturbance conditions result in diminished local availability of male plants as sources of pollen in space and time. We evaluated local reproductive neighborhood structure (to 100 m), flowering synchrony between sexes at the local and population level, and seed production of 18 *Virola surinamensis* (Myristicaceae) female trees during two years in a human-modified landscape in southern Costa Rica. Focal female neighborhoods included an average of one male tree and two other female trees. Local sex ratio in neighborhoods was skewed towards females, showing that female *V. surinamensis* trees occur in clumps at the disturbed sites studied with few or no males in close proximity. Average distance to nearest male was 87.10 ± 86.89 m (range: 8-302 m), while mean diameter at breast height of closest male neighbor was 70.9 ± 20.5 cm, and it did not differ from that of the focal female (76.1 ± 16.0 cm). In both years, the population of male trees started flowering earlier and a higher proportion maintained > 50% coverage by inflorescences with open flowers for a more extended period compared to the female population. Males' flowering peak always occurred between late December and early January. Females exhibited a shorter, more synchronous flowering period on the first year with a flowering peak that occurred about two weeks later than that of males, while on the second year they flowered for a longer time but at a lower intensity, and their flowering peak coincided with the males. Total fruit production by the 18 focal females was influenced by the total number of flowers produced per year, and by flowering synchrony with local males during the second year only. The ratio of matured versus initiated fruits was also correlated with female tree crown size suggesting a role of resource availability on female reproduction. Taking together, our results show that female investment in flower production is generally sufficient to secure high fruit production in *V. surinamensis* at our study landscape, but also that local reproductive neighborhood effects on female reproduction in disturbed landscapes can manifest via reduced flowering synchrony between sexes in some years.

P0866

Reproductive biology and pollinator sharing in two unrelated (from different families), but morphologically similar flowers; *Thunbergia atriplicifolia* and *Sebaea grandis*

S.M. Msweli, *S.D. Johnson*
School of Life Sciences, University of KwaZulu-Natal

Co-existing, morphological similar flowers that flower simultaneously, may interact with the same pool of pollinators, therefore sharing pollinating species and individuals. Pollinator sharing may be detrimental (i.e. competition), beneficial (i.e. facilitation or mimicry) or have no effect on the interacting species. This study was conducted to determine the reproductive biology of *Sebaea grandis (S. grandis)* and *Thunbergia atriplicifolia (T. atriplicifolia)* and document pollinator sharing between the two species. Investigated aspects of reproductive biology are: flowering phenology, nectar rewards, floral colour, scent analyses and breeding system. The study was conducted at Vernon Crookes Nature Reserve. Weekly survey of flowers indicated that both plants flower simultaneously but *S. grandis* is at low density. They provide similar amount of nectar but *S. grandis's* has a high sucrose concentration. Both flowers have similar spectral reflectance and the colour hexagon showed that they are indistinguishable to a bee pollinator. Colour similarity in the two species was found to be coincidental and not adaptive. The scent profile of the two species is similar, rendering them undistinguishable by scent. Hand-pollinations established that *T. atriplicifolia* is self-compatible and self-autogamous but self-pollen results to reduced seed set. From literature, *S. grandis* has a heteromorphic self-incompatibility system (Wolfe 2009). Both species are pollinated by solitary bees from the Apideae and Hactilidae family. Pollinator observations and stigma analysis show that the two species share pollinators but those pollinators are generalist in the community. The striking similarity between floral signals and evidence for pollinator sharing suggests a potential positive interaction between the two species. More research is required to understand the consequences (if there are any) of pollinator sharing between the two species.

A strong phylogenetic signal in Mongolian seed weight data

Amartuvshin Narantsetseg, *Karl Hülber*
1. Institute of General and Experimental Biology
2. Department of Botany and Biodiversity Research, University of Vienna, Austria

The evolution of seeds is one of the most important and successful innovations in the history of plants. Seeds enable vascular plants to migrate, to survive long periods of hostile environmental conditions and to establish even under unfavourable environmental conditions. The high functionality is reflected by a huge variation in seed weight spanning 9 to 10 orders of magnitude representing differences in phylogenetic history, reproduction strategy and habitat conditions. However, our knowledge on the drivers of the evolution of the observed variation is still limited. Several studies found correlations between mean seed weight or seed weight variation and climatic factors like temperature, precipitation and aridity, but even the direction of climate effects remain a matter of debate. Based on a huge collection of seed weight data (241 species from 118 sample sites collected from 1978 to 2007) covering the major vegetation zones of Mongolia, we aimed at quantifying the relative effects of climatic conditions and the phylogenetic history. We evaluated the correspondences between seed weight and growth form or dispersal type and detected a strong phylogenetic signal in seed weight data, but only weak effects of climatic parameters. Furthermore, we found seed weight to be related to growth form, trees seeds are heavier, and dispersal type, seed weight of anemochorous plants Iower than that of hydrochorous or zoochorous species. Our results suggest seed weight to be a highly phylogenetically conserved functional trait.

Invasive plant *Cassia atala* root traits and its competition with neighbor species

Ming Ni, *Suqin Fang, Yu Liu*

SYSU-Alberta Joint Lab for Biodiversity Conservation, Sun Yat-sen University

Biological invasion causes huge impacts on ecosystem and human society. Knowing what kind of species are more invasive can help us establish effective prevention program. But traditional trait comparative studies usually have different conclusions. To solve this inconsistence, we should consider the invasion process and traits' roles in invasion, especially the competition with native species. Limited by technique, seldom research studied invaders' root traits and root competition. In this study, three plant species including invasive herb *Cassia atala*, naturalized plant *Corchorus capsularis* and native plant *Desmodium reticulatum* were selected and grown together in the transparent plant growth system to *in situ* compare their competition ability dynamically. Our results showed that *C. atala'* s roots grew much faster than *C. capsularis* and *D. reticulatum* in all three weeks. *C. atala* had significantly larger total root length, root volume, root surface area than *C. capsular* and *D. reticulatum* while there were no significant differences between the latter two species on these three traits. *C. atala* demonstrated an apparent root competition advantage compared with two other species. Competing with *C. capsularis* or *D. reticulatum* didn't cause *C. atala* significant biomass decrease. While *C. atala* had huge impacts on *C. capsularis* and *D. reticulatum*. Especially competing with two *C. atala* individuals made *C. capsularis* and *D. reticulatum* about 77% and 81% total biomass decrease respectively. Rapid root growth and large root system may help invaders outcompete natives. We should extend this research by combining with other techniques, like minirhizotrons and X-ray computed tomography, to investigate invasive plants' root in future. Our finding also indicates that we should also consider root traits of potential invasive plants to prevent biological invasion.

Low flower-size variation in bilaterally symmetrical flowers

Aoi Nikkeshi[1], *Daiki Kurimoto*[2], *Atushi Ushimaru*[2]

1. Faculty of Life and Environmental Science, University of Tsukuba, Japan

2. Graduate school of Human Development, Kobe University, Japan

The evolutionary shift from radial to bilateral symmetry in flowers is generally associated with the evolution of low flower-size variation. This supports the hypothesis that the lower size variation in bilateral flowers could be attributed to low pollinator diversity. To test the three hypotheses, we examined the relative importance of pollinator diversity, composition, and bilateral symmetry itself as the selective forces on low flower-size variation. We examined pollinator diversity and composition and flower-size variation for 36 species in a semi-natural ecosystem with high bee richness and frequent lepidopteran visitation. Bilateral flowers were more frequently visited by larger bees compared to radial flowers, but functional group diversity of pollinators did not differ between symmetry types. Although bilateral flowers had significantly lower flower-size variation than radial flowers, flower-size variation did not vary with pollinator diversity and composition but was instead related to bilateral symmetry. Our results suggest that the lower size variation in bilateral flowers might have evolved under selection favoring the control of pollinator behavior on flowers to enhance the accurate placement of pollen on the body of the pollinator, independent of pollinator type. Because of the limited research on this issue, future work should be conducted in various types of plant-pollinator communities worldwide to further clarify the issue.

Effect of crude oil on coastal plants

Yanisa Olaranont[1,2,3], *Paweena Traiperm*[2], *Alyssa Stewart*[2]

1. Master of Science Program in Plant Science, Faculty of Graduate Studies, Mahidol University, Bangkok

2. Department of Plant Science, Faculty of Science, Mahidol University, Bangkok

3. Department of Pharmaceutical Botany, Faculty of Pharmacy, Mahidol University,

Nowadays, industries are an important part of human society and can help drive a country's economy. However, they can be harmful to the environment and living organisms. Oil pollution is one hazardous effect of industry development, and oil spills occur in many countries around the world, including Thailand. However, few studies have examined the detrimental effects of oil on plants. Therefore, the objectives of this study were (1) to determine the impacts of crude oil on the anatomy and growth of two coastal plant species, and (2) to investigate their potential as an indicator of oil pollution. Two common coastal plants, *Ipomoea pes-caprae* (L.) R. Br. (Convolvulaceae) and *Ischaemum muticum* L. (Poaceae), were treated with four concentrations of crude oil (1%, 2%, 3% and 4% volume/weight). Physiological parameters such as greenness content and chlorophyll fluorescence were measured for four months. Leaves of the two species were also collected in order to study micromorphology using epidermal peeling and transverse sectioning. Moreover, plant tissue was stained with Oil red O to detect crude oil. The effect of crude oil on plant physiology and micromorphology over time will be presented. This research addresses an understudied topic and is important to understanding how plants respond to oil pollution.

Recent genetic differentiation of *Phaedranassa dubia* and *P. brevifolia* in Ecuador

Nora Oleas[1], *Javier Francisco-Ortega*[2], *Alan Meerow*[3]
1. Universidad Tecnológica Indoamérica
2. Florida International University
3. United States Department Of Agriculture

Phaedranassa is a genus of Amaryllidaceae restricted to Costa Rica, Colombia and Ecuador. Seven out of the eight species described in Ecuador are endangered or vulnerable to extinction. *Phaedranassa dubia* is the only species found in Ecuador and Colombia. Both *P. dubia* and *P. brevifolia* are located at northern Ecuador. We genotyped 11 microsatellite loci in 12 populations for both species. We used a Bayesian approach to identify genetic groups. We estimate population history with an Approximate Bayesian computation analysis (ABC). Also we estimate species distribution models based on bioclimatic variables and species geographic coordinates. Bayesian structure clustering analysis suggests that *Phaedranassa* populations at northern Ecuador correspond to different genetic groups. The assignment of individuals of these two species together shows a higher degree of admixture between the geographically closer populations of the two. ABC estimates suggest a recent differentiation between species. Vegetatively, the most evident difference between this species and *P. dubia* is the length of the leaves. *Phaedranassa brevifolia* is the species with the smallest leaves (ca. 12 cm long) while *P. dubia* leaves length are ca. 20 cm long. *Phaedranassa dubia* has larger flowers with a slightly inflated perianth base and darker red color (Fig 1). Moreover, the Species Distribution Models (SDM) for these two species do not overlap, indicative of niche differentiation. The results show that these two species seem to be an example of peripatric speciation and may be a result of a recent divergence. The topographic complexity of the Andes, which creates local microhabitats that might explain the patterns of *Phaedranassa* species differentiation.

Determination of heavy metal and mineral elements in flowers of some medicinal plants widely used in Turkey

Ibrahim Ilker Ozyigit[1], *Cengiz Colak*[1], *Sedat Karadeniz*[1], *Goksel Demir*[2], *Ibrahim Ertugrul Yalcin*[3]
1. Department of Biology, Faculty of Science and Arts, Marmara University, Istanbul, Turkey
2. Department of City and Regional Planning, Faculty of Architecture, Kirklareli University, Kirklareli, Turkey
3. Department of Molecular Biology and Genetics, Faculty of Engineering and Naturel Sciences, Bahcesehir University, Istanbul, Turkey

In this study, flowers of some widely used medicinal plants were obtained from the herbalists of three different districts (Kadıköy, Bakırköy and Güngören) of Istanbul-Turkey, and their mineral element and heavy metal amounts were analyzed by using ICP-OES apparatus. Among these plants; strawflower, chamomile, common marshmallow, pomegranate, jasmine, high mallow, elderberry, basswood, pot marigold, common hops, sage, yarrow, klamath weed, European centaury and lavender were analyzed. The quantities of copper (Cu), boron (B), zinc (Zn), iron (Fe), cadmium (Cd), mercury (Pb), magnesium (Mg), manganese (Mn), nickel (Ni), potassium (K) and sodium (Na) were determined. Copper in the flower samples were measured as the highest rate in common marshmallow with 9.833 mg/kg and the lowest rate in pomegranate with 0.500 mg/kg. The rates of other plants are as follows; Boron, the highest rate in sage with 16.339 mg/kg, the lowest rate in Klamath weed with 1.697 mg/kg zinc, the highest rate in sage with 35.279 mg/kg, the lowest rate in lavender with 1.504 mg/kg, iron, the highest rate in sage with 276.056 mg/kg, the lowest rate in pomegranate with 31.216 mg/kg, calcium the highest rate in basswood with 6,265.794 mg/kg, the lowest rate in jasmine with 1,858.219 mg/kg, magnesium, the highest rate in elderberry with 1,653.869 mg/kg, the lowest rate in strawflower with 636.962 mg/kg, manganese, the highest rate in lavender with 34.744 mg/kg, the lowest rate in jasmine with 3.709 mg/kg, nickel, the highest rate in lavender herb with 2.245 mg/kg, the lowest rate in Klamath weed with 0.216 mg/kg, potassium, the highest rate in chamomile with 8,167.861 mg/kg, the lowest rate in elderberry with 2,328.003 mg/kg, sodium, the highest rate in pot marigold with 1,648.676 mg/kg, the lowest rate in basswood with 25.743 mg/kg is measured. When we compare the maximum and minimum rates of elements, heavy metal densities of analyzed samples were not at toxic level. As a result of this study we reach the fact that plants which are sold as medicinal purpose in selected districts have no risk for human health.

Effect of nano-bentonite in compound fertilizer on rice growth

Fuyun Pei, *Tianye Wang, He Ren, Qin Peng, Xiaoyan Feng, Luming Tan*
Shenzhen Techand Ecology & Enviroment CO., Ltd.

Silicon is one of the beneficial element for rice growth, and natural bentonite is a convenient resource of silicon. The research investigates the effect of bentonite with different particle size in conpound fertilizer an rice growth. The compound fertilizer was prepared by tower granulation process. Bentonite was appended according to different weight ratios as 1%, 3% and 5%. Root application of different compound fertilizer was evaluated for their effects on promoting growth and the quality of rice via pot experiment. The dry weight of plant was increased with addition of bentonite with different partilce size. A comparison of several treatments showed that addition of both bentonite and nano bentonite increased the dry biomass, fresh weight, and root system. With the 3 g/100 g addition of bentonite and nano bentonite in the compound fertilizer, dry biomass increased by 9.49% and 34.40%, respectively. Compared to the control, the total nitrogen, phosphorus and potassium contents were increased by 6.13% and 21.47%, respectively, and the root dry weight increased by 16.10% and 61.25%, respectively. The statistical results revealed that nano bentonite possess high activity and bentonite improved the slow-release of fertilizer because of its lamellar structure.

Evaluating biodiversity losses and exotic species invasion in the Sierra de Cordoba ecosystems

Ana María Planchuelo
Centro de Relevamiento y Evaluación de Recursos Agrícolas y Naturales

The province of Cordoba (Argentina) has a continental location with a landscape which includes flat land, hill and mountain regions with a land cover varying from grassland, xerophytic forest, wetlands, high mountainous ecosystems and agricultural areas. In the last decades many natural areas have been degraded by deforestation, urbanization, invasion of exotic plants, overgrazing and rural fires. These biotic and abiotic processes caused changes in the landscape, accelerated biodiversity losses and created dispersion barriers for many valuable species. The study area is located in the Paravachasca valley (31.70° to -32.62° S and 64.40° to -65.10° W), in the eastern side of the Sierras Chicas. Field observations were carried in five geo-referenced sampling sites of 10.5 ha. Vegetation cover was classified as natural forest, shrub land and prairies. Three land uses were identified: natural undisturbed areas, cultivated land, and disturbed areas by rural fires and/or anthropogenic activity. The analysis of vegetation cover changes were carried out using the program Land Change Modeler and selected LANDSAT images (2009-2016), after the area was affected in 2009 by extensive rural fires, which affected significantly the native vegetation. Type and abundance of species were recorded and they were classified using a priority conservation index. Results indicates that rural fires, as well as, agricultural activities caused, in short time, a massive ecological impact; while overgrazing caused in a slow process changes in the flora composition and urban development created disjunctive patches of natural vegetation. All the disturbances, changed the flora biodiversity and many native species were replaced by weeds and patches of invasive trees such as: *Ligustrum lucidum* W.T. Aiton (Oleaceae) an evergreen tree native to the Southern China known as privet or locally "ligustro". Although it has some ethnomedical uses it is difficult to eradicate; *Melia azedarach* L. (Meliaceae) native to Indomalaya and Australasia, known by several common names including Chinaberry tree, Persian or Indian lilac, and locally as "paraiso". Although it is used as timber and other economic uses it is an invasive species.; *Gleditsia triacanthos* L. (Fabaceae) native to central North America known by the names of honey or thorny locust and locally as "acacia negra" (black acacia). Although it is cultivated as ornamental tree and produce quality wood it is well known that has become a significant invasive in many regions of the world; *Pyracantha* spp. (Rosaceae) natives to the Southwestern Europe and Southeastern Asia are evergreen thorny shrubs known with the common names of pyracantha, firethorn and crataegus in Argentina. Although it is a valuable ornamental plant for gardens and green fences, its rapid dispersal makes this species very invasive along water streams. Several approaches are considered to eradicate or to find no negative environmental impacts of the invasive species.

Juncus fontanesii J. Gay ex Laharpe (Juncaceae) as a new host plant for *Livia junci* (Schrank, 1789) (Hemiptera: Psyllidae)

Paweł Jarzembowski[1], *Anna Faltyn*[2], ***Jarosław Proćków***[2]
1. Institute of Environmental Biology, University of Wrocław
2. Institute of Biology, Wrocław University of Environmental and Life Sciences

In the herbarium material from Portugal we found the specimens of *Juncus fontanesii* with characteristically transformed shoots, so-called "witches' brooms". Inside their structures we observed a few larvae of *Livia junci* (Hemiptera: Psyllidae). Similar changes were found in the specimens collected in Iraq, however due to the feeding of insects, the plants had been deformed to the extent, that we were unable to certainly confirm if they belong to *J. fontanesii*, especially that the taxon is highly variable morphologically. In southern Europe, it grows mainly in Mediterranean humid grasslands of tall grasses and rushes, and alongside streams and in temporarily inundated sites, and it also occurs in northern Africa and western Asia. "Witches' brooms" is a disease or deformity in a plant, where the natural structure of the plant is changed, i.e., a dense mass of shoots grows, usually from a single point, with the resulting structure resembling a broom. The direct causes of the enormous changes of the plant have not been known so far, although they have been related to the presence of parasite Livia junci. To date, the Hemiptera insect has been already found on different rushes mainly belonging to the Ozophyllum section (and also others). To date, Livia junci has not been mentioned from *J. fontanesii*. Therefore, this is the first report of the feeding of this parasite on this host plant species. Additionally, this taxon formed galls in response to the feeding, similar to other representatives of the genus *Juncus*. *Livia junci* is the only representative of the genus *Livia* that feeds on Juncus species in the Western Palearctic area. Thus the mass occurrence of this insect can cause a decrease in the yields of different rush species. Namely, in such situations the plants cannot flourish, so it is impossible to produce fruit and seeds to be spread. Taking into account the character of these changes as well as the manner of feeding of the insect (pricking tissues near vascular bundles), we claim that *L. junci* is only a vector, while the factor responsible for producing galls is phytoplasma.

First report of jointleaf rush (*Juncus articulatus*) as a new host plant for *'Candidatus* Phytoplasma asteris' associated with "witches'-brooms"

Paweł Jarzembowski[1], *Hanna Berniak*[2], *Anna Faltyn*[3], *Anna Jakubska-Busse*[1], ***Jarosław Proćków***[3]
1. Institute of Environmental Biology, University of Wrocław
2. Research Institute of Horticulture, Skierniewice
3. Institute of Biology, Wrocław University of Environmental and Life Sciences

Juncus articulatus L. (Juncaceae) is a species of rush occurring in Eurasia, Canada and the United States of America. In 2013 symptoms of "witches'-brooms", similar to those associated with phytoplasma infection in other plants, were observed on jointleaf rush plants in Lower Silesia, with some pests feeding on them. "Witches' brooms" is a disease or deformity in a plant, where the natural structure of the plant is changed, i.e., a dense mass of shoots grows, usually from a single point, with the resulting structure resembling a broom. The direct causes of the enormous changes of the inflorescence have not been known to date, although they were related to the presence of the insect. *Livia junci* (Liviinae, Hemiptera), is a small plant-feeding sap-sucking insect that affects monocotyledonous plants. To confirm the presence of phytoplasma in fifteen examined plants, total DNA was extracted from 100 mg of inflorescence and leaf samples collected on July 2013, in Bogatynia, Poland, from six symptomatic and six asymptomatic plants. Additionally, three leaf samples from asymptomatic rush plants, collected from a location where the disease was not observed (Wrocław, Poland), as well as water blank samples were included as negative controls. Moreover, thirty-two insects were collected from symptomatic plants. DNA from *L. junci* specimens (the imago and the last larva stage) was extracted. Extracted nucleic acids were used as templates for PCR employing: a) phytoplasma universal rRNA primer pairs P1/P7 followed by R16F2n/R16R2 (1), b) primers rp1-rp2 followed by rp3-rp4 allowing amplification of fragments of ribosomal protein rpl22 and rps3 genes (2), and c) primers AYsecYF1/AYsecYR1 (3) for amplification of the secY gene. The phytoplasma was detected in insects and plant samples. No amplification products were detected in negative control samples from Wrocław or in water blanks. The fact that we detected the pathogen in some asymptomatic plants indicated that a low titre may have been prior to the development of disease symptoms. Amplicons representing three genetic loci were sequenced. To avoid sequencing errors, all DNA samples were sequenced twice in both directions. The obtained sequences were nearly identical, and representative sequences isolated from two plants and one insect, were deposited in GenBank. BLAST analysis of the sequenced 16S rDNA fragments revealed that tested strains shared more than 99% sequence identity to the sequences of phytoplasmas from the aster yellows group. The same analysis performed for ribosomal proteins and secY genes confirmed the highest identity (99%) of analyzed sequences with those of '*Candidatus* Phytoplasma asteris'. Thus the mass occurrence of this insect can cause a decrease in the yields of different rush species which are usually common components of the meadow communities of various parts of Europe. Namely, in such situations the plants cannot flourish, so it is impossible to produce fruit and seeds to be spread.

P0878
Current and future potential distribution of *Selinum alatum* – Plausibly another invasive Apiaceae in Europe

Kamil Konowalik[1], *Małgorzata Proćków*[2], ***Jarosław Proćków***[1]
1. Institute of Biology, Wrocław University of Environmental and Life Sciences
2. Museum of Natural History, University of Wrocław

Selinum alatum (M. Bieb.) Poir. is native to the Caucasus and the Armenian Highlands. Recently a few established populations of this plant have been found in the north-eastern part of the Carpathians. Currently the species is spreading particularly in Poland where it outcompets native plants in several areas. In this study a potential climatic niche of the plant is described with the goal to also highlight future spreading of the species. Our results demonstrate that the extent of the favourable habitat of this plant is broader than currently known. This suggests that *S. alatum* may become a potential new component in some semi-natural or disturbed ecosystems associated with mountainous areas, especially in Central and Southern Europe. Future (2070) models mostly rendered similar suitability maps, but showed slight differences over particular areas and a contraction of suitable habitats, mainly in the northern part of the non-native range.

The late holocene mangrove dynamics in the upper Gulf of Thailand

Paramita Punwong[1], *Katherine Selby*[2], *Rob Marchant*[2]
1. Faculty of Environment and Resource Studies, Mahidol University
2. Environment Department, University of York

The mangrove dynamics in Samut Songkhram along the upper Gulf of Thailand was reconstructed using pollen analysis from a 460-cm sediment core. The results show that initial colonization of the area was made by true mangroves dominated by *Rhizophora* sp. and back mangroves characterised by *Suaeda* sp. This indicates that this area has been influenced by sea water since at least AD 1,200 until AD 1,250. After that, *Rhizophora* sp. gradually declined and were replaced by grass, indicating lower in sea level allowing mangroves to retreat seaward until AD 1,800. An increase in cereal pollen is also present suggesting possible human activities occurring around this area from AD 1,250 to the present day. Mangroves dominated by *Avicennia* sp. re-colonised at the top of the core suggesting a shift of mangroves landward probably due to a sea level rise until the present day.

Bryophyte preferences in bryophagous insects – What matters?

Petr Pyszko, *Katerina Kuravova, Zuzana Skoupa, Michaela Drgova, Petr Kocarek, Vitezslav Plasek, Pavel Drozd*
University of Ostrava

Which features predetermine moss to be consumed by insects?

Despite bryophytes represent favorable habitat for great diversity of arthropods, their dietary utilization is marginal, seemingly due to toxicity and poor nutrition quality. We focused on three largest consistent bryophagous taxa with chewing mouthparts: Tetrigidae (Orthoptera), Scopariinae (Lepidoptera) and Byrrhidae (Coleoptera). All groups have been neglected by ecologist for a long time, and almost nothing have been known about their host specificity and preferences. Unlike vascular plants, bryophytes are determinable according to phylloid fragments also in gut content. Insect specimens were collected by individual sampling or sweeping in Central Europe, Borneo and China and some samples were reared in growing chambers. The gut content was disected or gained from frass, and analyzed to identify and quantify mosses. Host preferences were also tested by measuring survival and fitness on different host species. Whereas mosses comprise only about 15% of diet in Tetrigidae, Byrrhidae and some Scopariinae are strictly bryophagous, despite mosses are defecated seemingly undigested. Majority of bryophagous taxa are surprisingly highly polyphagous, consuming plenty of mosses with preferences for particular species. Shared traits of preferred bryophytes are discussed, but physical properties as cell wall thickness or structure of moss cushions seem to be essential.

What determines Theaceae diversity in China: Ecological or evolutionary processes?

Mide Rao[1,2], *Manuel Steinbauer*[3], *Xiangcheng Mi*[2], *Xiaoguo Xiang*[2], *Keping Ma*[2], *Jingtun Zhang*[1], *Jens-Christian Svenning*[3]
1. Beijing Normal University
2. IBCAS
3. Aarhus University

The geographic variation of species richness is one of the most obvious patterns on earth. Ecological and evolutionary factors have been thought to be major drivers. However, the relative important of ecological and evolutionary factors remains to be determined, and the role of two hypotheses (time-for-speciation and evolutionary rate) that integrate evolutionary and ecological factors are still far from universal. In this study, we used the data both on species richness and phylogeny of tea family, and environmental variables (the mean temperature of the coldest month, mean annual precipitation and soil pH) to reveal the processes underling species richness patterns of Theaceae *s.s.* across China. We found: (1) Both ecological and evolutionary factors have effects on species richness patterns of Theaceae *s.s.* (2) The former has effects at both family and tribe level. However, evolutionary effect takes place at family level. Species richness and phylogenetic relatedness show the responses to minimum temperature and pH which is based on time for diversification hypothesis, while precipitation reflects the prediction of evolutionary rate hypothesis. (3) At tribe level, annual precipitation and soil pH are related to species richness but not to phylogenetic relatedness. On the contrary, minimum temperature has effect on phylogenetic relatedness rather than species richness. These results suggest that the species richness patterns of Theaceae *s.s.* appear to be predominantly the result of both ecological and evolutionary drivers. Moreover, different environmental factors relate to different mechanisms in species richness pattern, and different taxon levels also reflect different underling processes.

Worldwide hemisphere-dependent lean in Cook pines

Jason Johns[1], *Jenn Yost*[1], *Dean Nicolle*[3], *Boris Igic*[2], ***Matt Ritter***[1]
1. Department of Biology, California Polytechnic State University, San Luis Obispo, USA
2. Department of Biological Sciences, University of Illinois at Chicago, Chicago, USA
3. Currency Creek Arboretum, Currency Creek, Australia

A tree's form is determined by a complex interaction of genetics and environmental stimuli. Under most conditions, trees grow vertically in response to the opposing influences of light and gravity. In challenging environments, where competition for light or mechanical stress is intense, trees may grow in a non-vertical fashion. Although these growth responses have been studied for over 100 years, there is still much to learn about the mechanisms driving them. Here we describe a novel leaning growth habit in *Araucaria columnaris* (Cook pine), a conifer endemic to New Caledonia and cultivated throughout the world. We document for the first time a remarkable pattern of directional hemisphere-dependent leaning. Specifically, in a large sample of individuals from around the world, we show that Cook pines display a consistent lean, commonly several meters away from the base of the trunk. This incline away from the vertical axis is highly non-random—trees in the northern hemisphere lean south, and those in the southern hemisphere lean north. Additionally, the magnitude of the lean is more pronounced at higher latitudes. The Cook pine's unique growth pattern may be the first-documented species-wide disruption of the balanced interactions between gravitropism, phototropism, and other environmental factors that influence tree architecture.

Growth, mortality and wood density of liana communities in fragmented forests

Mareike Roeder
Xishuangbanna Tropical Botanical Garden

High abundance of liana stems is an indicator for forest disturbance, as they often occur on forest edges, secondary forest succession or gaps. Forest fragmentation was found to increase liana abundance due to edge effect. However not all liana species benefit from disturbance and it is rarely studied how diversity and traits of liana communities change with disturbance. For example can climber types of lianas change with forest succession, as tendril climbers tend to depend on trees of small diameter for climbing, whereas stem twiners were associated with larger trunks for support. Large lianas are indicators for old growth forest, due to their slow diameter increment. For a more accurate picture of forest communities, it is crucial to go beyond stem counts for lianas. We include growth, mortality, wood density, liana size, and climber type to examine how liana communities change with disturbance and in different habitats. We wanted to know, if fragmented (disturbed) forests tend to have liana communities of more pioneer like growth forms, e.g. more lianas species with lower wood density, increased growth, high mortality rates, more tendril climbers, small but many stems; or if different habitat types rule the liana communities. We conducted a repeated survey (2014 & 2016) of lianas (> 0.5 cm diameter) in 47 forest fragments around a township in SW China and gathered wood density data for 67% of species and 90% of all stems. The fragments were distributed in several forest types that are characterized by different bedrock (limestone yes or no), elevation and topography. We tested how growth, mortality and average wood density, number of small stems (< 2 cm) and climber type changes with fragmentation and habitat. Predictors for the models were fragmentation (edge distance OR forest area in a 500 m circle around the plot), canopy cover and habitat (elevation, topography and limestone). In general, the natural habitat explained most variation in liana communities: valleys had high growth and mortality rates of lianas and high abundance of small liana stems. Forest on limestone hosted more tendril climbers and less small stemmed lianas. Fragmentation explained less variation: growth and mortality increased with fragmentation, average wood density decreased. Generally the explanatory power of the models for growth, mortality and wood density was low (Pseudo-$R^2 < 0.35$). Nonetheless, the trends found in our study of lianas confirm patterns found in other fragmentation studies on different growth forms such as trees, e.g. a higher turnover with increased fragmentation.

Efficacies of Northern Shakti fertilizer on the yield and quality of mango

Durlave Roy

Northern Agro Services Ltd

A field trial was conducted to evaluate the efficacies of Northern Shakti fertilizer on yield and quality of mango in acidic soil of Bangladesh. Three treatments -T0 untreated control, T2 = Recommended dose (Cowdung 26-30 kg + Urea 1000 g + TSP 500 g + MOP 350 g + Gypsum 350 g + Zinc Sulphate 15 g), T1= Northern Shakti fertilizer 1.5 kg + Urea 200 g + Northern organic fertilizer 3.5 kg). Results revealed that the treatment T1 significantly increased the mango per plant. It was 45.8% higher yield over control. It is concluded that Northern fertilizer with recommended urea is superior sustainable production of mangoes.

Lineage divergence of a temperate forest species in Eastern Asia, *Smilax sieboldii* (Smilacaceae): Vicariance vs. adaptive divergence

Yalu Ru[1,2], *Ruijing Cheng*[1,3], *Hanyang Lin*[1,2], *Yunpeng Zhao*[1,2], *Pan Li*[1,2], *Chengxin Fu*[1,2]

1. The Key Laboratory of Conservation Biology for Endangered Wildlife of the Ministry of Education, College of Life Sciences, Zhejiang University

2. Laboratory of Systematic & Evolutionary Botany and Biodiversity, Institute of Ecology and Conservation Center for Gene Resources of Endangered Wildlife, Zhejiang University

3. College of Agriculture & Biotechnology, Zhejiang University

Elucidating how various evolutionary factors interact to affect speciation is an ssential theme in evolutionary biology. Insights of incipient speciation can be gained from studying lineage divergence. Eastern Asia harbors world richest temperate flora. The mechanisms generating such rich species and genetic diversity have been fascinating evolutionary biologists for decades while considerable gaps remain in particular whether adaptive divergence also plays a role and its importance relative to vicariance. *Smilax sieboldii* is a typical woody climbing plant inhabiting temperate forests in eastern Asia with a disjunct distribution in mainland China and Taiwan, Japanese Archipelago and Korean Peninsula, providing us an ideal study system to test the relative role of vicariance and adaptive divergence. We employed three data sets including plastid genomes of 12 haplotypes previously suggested by two cpDNA fragments, EST-SSRs for 400 individuals from 38 populations, and RADseq tags for 45 representative individuals (one accession per population). Multiple data sets will be analyzed to confirm geographic lineages, to reconstruct their phylogenetic relationships and demographic histories, e.g., divergence times, dynamics of population sizes and gene flow. We will test competing hypotheses explaining the lineage divergence in relation to historical climate oscillation, sea level fluctuation, emergence and submergence of East China Sea Landbridge, and range shifts. Finally, canonical correlation and redundancy analysis will be utilized to compare the relative contribution of environment and geography to genetic divergence of the focal species. Our findings will imply the evolutionary process of *S. sieboldii* and indicate the relative role of geographical isolation and differential selection which shaped the diversity and phylogeographic structure of temperate forests plants in eastern Asian.

Floristics and distribution of spiny bamboo (*Bambusa spinosa* Roxb., Hort. Beng. [1814]; Poaceae: Bambusoidea) stands in Cebu Island, Philippines

Val Salares

University of San Carlos

The woody bamboos of the subfamily Bambusoideae play a critical role in the ecology of their forest habitats and have long been of economic importance to humans. This study followed an observational/descriptive research design using naturalistic observational methods of field measurements and utilized random sampling method along the boundaries of fragmented forest remnants of Cebu Island. Quadrat sampling method was employed with an area of 20 m by 20 m and a total of thirty (30) quadrats were randomly surveyed per area with a total of four municipalities. A survey of different areas in Cebu Island was done from August 2014 to March 2015 to observe the occurrence of natural bamboo stands in the island and the municipalities of Balamban, Tuburan, Barili, and Moalboal with only *Bambusa spinosa* Roxb., Hort. Beng. [1814] stands included. In all four areas, *B. spinosa* Roxb., Hort. Beng. [1814] is one of those with the highest Importance Value which means that is contributes much to the productivity and biomass of the area. For the similarity index, Tuburan is the most dissimilar to all the sampling areas. Species richness (D_{mg}) and diversity (H’) were relatively low. Low values were also obtained for Simpson's Diversity Index (D) but since this focuses on dominant species, diversity increases as the value nears zero. Floral association values show tendencies towards indigenous species although the values are low. The Floristic Quality Index show values between 3 to 5, which shows a trend towards disturbed environments and association with flora that are either invasive or higher tolerance to disturbance. All the natural bamboo stands exhibited heights ranging from 17 to 20 m and DBH ranging from 5 to 8 cm. The number of culms was very varied from 10 to almost 60. Basal area were usually more than 10% of the 20 × 20 m quadrat. Biomass ranged from 150 to 250 kilograms where Moalboal had the highest values. MODIS products showed that bamboos stands have low LAI as the bulk of their bodies are the culms but with variable FPAR, GPP and Net Photosynthesis. Many bamboos prefer soil with good water holding ability (high SMI) and water permeability for optimum rhizome growth but cannot tolerate water logging (low NDWI and MNDWI). High NRI values denote presence of nitrogen in high levels. Multiple correlations were analyzed and of all the physiognomic characters, biomass had the most correlations with the other factors especially with species richness and diversity. Principal Component Analysis was utilized as a dimension reduction procedure. The community, physiognomic and physico-chemical parameters were reduced to six principal components namely (1) reflectance-based (soil physico-chemical) parameters, (2) productivity, (3) temperature regime, (4) species richness and diversity, (5) floristic quality, and (6) water availability. These parameters contribute most to the distribution of natural bamboo stands.

Phytochemical analysis of a novel medicinal plant *Clerodendrum indicum* L. under in-vitro condition

Avishek Sarkar*, Anindita Mulkerjee, Abhijit Bandyopadhyay, Sikha Dutta*
The University of Burdwan

Plants have great potential use especially as traditional medicine and pharmacological drugs. A bulk of the world population still depends on traditional medicines. Medicinal plants have provided the modern medicines with numerous plant derived therapeutic bioactive compounds. Natural products play pivotal role in the discovery of new drug resources for the cure and prevention of diseases. In India large number of plant species had been screened for their pharmacological properties but still a vast range of endangered species remain unexplored. *Clerodendrum indicum* L. – a little explored ethnomedicinal plant belonging to the family verbenaceae in India and China contain a number of therapeutic chemicals. The alkaloids, steroids and phenolics present in this plant were reported to possess significant antimicrobial property (Venkata *et. al.*, 2010; Ravindranath *et. al.*, 2003; Rahaman *et. al.,* 2000). In present communication an attempt has been made to assay the phytochemicals present in the calli of *Clerodendrum indicum* L. produced under in vitro condition. Phytochemical assay of the calli was done both under controlled condition as well as under pathogenic stress exerted by *Curvularia lunata* (Wakker) Bodiejn. To identify the novel phytochemicals GC-MS and NMR studies were performed. A number of compounds were identified from both the control and treatmen sets and the treatment sets showed some more novel compounds in contrast to the control set, like, benzene1, 4dichloro compound which has been recommended as halogenated benzene and used as insecticide and pesticide. 3- (1-Ethoxy-ethoxy)—4,4, 4trifluro butyric acid which is suggested to be flurobutyrate benzene used to reduce triglyceride and cholesterol level in blood. Ethaneperoxic acid, 1-cyano-1-[2-(2-phenyl-1,3-dioxolan-2-yl) ethyl] pentyl ester which was reported to be a potent antimicrobial agent (Janakiramann *et.al.,* 2012). The $_1$H NMR analysis of the methanolic extract of *C. indicum* exhibited presence of aromatic group of compounds which might be responsible for the bioactive properties of the plant extract. A phenolic compound Cleroindicin (A, B, C, D, E, F) was identified by NMR studies.

Effect of strong phenotypic selection on *Pinus sylvestris* genomic variation

Outi Savolainen[1]*, Jaakko Tyrmi*[1]*, Rami-Petteri Apuli*[1]*, Sonja Kujala*[1]*, Tanja Pyhäjärvi*[1]*, Katri Kärkkäinen*[2]
1. University of Oulu, Dept Ecology and Genetics
2. Natural Resource Center Finland

Scots pine has a very large range spanning diverse environmental conditions. Climatic variation subjects conifers to strong selection for climatic adaptation in different life stages. Extensive provenance trials and other experiments demonstrate adaptation to local climatic conditions, as seen in patterns of phenotypic variation correlated with climatic conditions. These data also allow quantification of selection. We examine patterns of sequence variation in exome capture data along two north-south transects, to search for patterns consistent with local adaptation. On the other hand, after self-fertilization, there is high mortality at especially early life stages due to the high numbers of lethal equivalents. The effects of selection due deleterious recessives on genomic patterns of variation have also been predicted. Genetic data from exome capture in Scots pine can be contrasted against some of these predictions.

Evaluation of heavy metal accumulation capacity and mineral nutrient status of aquatic plant *Vallisneria nana* in artificially contaminated media

Ugur Sen[1]*, Ibrahim Ilker Ozyigit*[1]*, Mehmet Emin Uras*[1]*, Ibrahim Ertugrul Yalcin*[2]*, Elif Yilmaz*[1]
1. Marmara University/Faculty of Science and Arts, Department of Biology, Istanbul, Turkey
2. Bahcesehir University, Faculty of Engineering and Natural Sciences, Department of Molecular Biology and Genetics, Istanbul, Turkey

Heavy metal pollution recently increased because of anthropogenic effects due to rising usage of heavy metals in different area of industry. The major heavy metal sources are mining, metal industry, fuel combustion, and production of some goods like paints, battery. This type of pollution is a serious problem due to toxic effects of heavy metals to every members of every ecosystems.

Heavy metals are very persistent and remains in ecosystem for a long time. Aquatic organisms are also suffered from heavy metal accumulation caused by disposal of industrial waste water into their ecosystem. This study was investigated the heavy metal accumulation and mineral nutrient element conditions of *Vallisneria nana* plats that were treated with several concentrations (100, 200 and 400 μM) of Cd, Cu, Ni and Pb elements as artificially contaminated solutions including 0.2% Hoagland solution). Some heavy metals and mineral nutrient elements (Ca, Cd, Cu, Fe, K, Mg, Mn, Na, Ni, Pb and Zn) were determined by using ICP-OES. According to results, levels of Ca, Cd, Cu, Ni and Pb increased in plant root and stem/leaf while mineral elements decreased such as Fe, K, Mg, Mn, Na and Zn. Measured lowest and highest (dw-mg/kg) element values, respectively include 11,860.091 ± 230.062 (stem/leaf; 100 μM)-16,031.537 ± 329.276 (root; 400 μM) for Ca; 9.519 ± 0.120 (stem/leaf; 100 μM)-42.669 ± 0.676 (root; 400 μM) for Cd; 83.292 ± 1.618 (stem/stem; 100 μM)-151.786 ± 2.536 (root; 400 μM) for Cu; 425.668 ± 8.268 (stem/leaf; 400 μM)-736.138 ± 14.299 (root; 100 μM) for Fe; 15,080.103 ± 407.911 (stem/leaf; 400 μM)-21,732.795 ± 420.366 (root; 100 μM) for K; 2,060.485 ± 39.990 (stem/leaf; 100 μM)-3,189.129 ± 61.888 (root;100 μM) for Mg; 125.712 ± 2.440 (stem/leaf; 400 μM)-268.455 ± 5.215 (root; 100 μM) for Mn; 669.329 ± 13.001 (stem/leaf; 400 μM)-928.905 ± 18.043 (root; 100 μM) for Na; 27.225 ± 0.529 (stem/leaf; 100 μM)-60.013 ± 1.166 (root; 400 μM) for Ni; 55.135 ± 1.071 (stem/leaf; 100 μM)-98.141 ± 1.906 (root; 400 μM) for Pb; 181.387 ± 3.523 (stem/leaf; 400 μM)-263.734 ± 5.123 (stem/leaf; 100 μM) for Zn. *V. nana* could accumulate Cd as 646.9 times than control in stem/leaf and 710.5 times than control in root. Therefore it can be suggested that *V. nana* can be called as a good accumulator for Cd.

Assessing and predicting biodiversity response to impacts of climate change: A case study Western Soutpansberg Mountain Range; Vhembe Biosphere Reserve Limpopo, South Africa

David Sengani[1], *Natasha Potgieter*[1], *Peter Tshisikhawe*[1], *Benis Egoh*[2]

1. University of Venda; School of Mathematical and Natural Sciences; Department of Botany

2. Council for scientific and Industrial Research (CSIR) Biodiversity and Ecosystem Services Group

Assessing and predicting biodiversity responses to climate change and its impacts on human well-being are high priority targets for this study. The climate is changing, yet to which degree and in what pattern remains uncertain in many areas (Rasche, 2014). Temperature is a key driver of organism function and ecosystem processes (Forsman *et al.,* 2016). Previous studies projected global warming as an effect to world's biodiversity. Accurately predicting climate change effects at the ecosystem level is complex and anxious with difficulty (Clark *et al.,* 2017). However, such knowledge is critical to understanding future biodiversity and the impact on ecosystem services. Understanding the controls of geographic distribution of species is a central issue in ecology (Overgaard *et al.,* 2010). Little is known regarding the driving factors of the species distribution including its limiting factors. Notably, the world's biodiversity is foreseen to be critically threatened not only by land-use changes and contingent habitat loss but also by climate change (Overgaard *et al.,* 2010). Why Vhembe Biosphere Reserve (VBR)? Vhembe Biosphere Reserve is one of the largest reserves in South Africa rich in biological diversity, and is recognized as a centre of endemism with at least 57 endemic plant species. VBR is subjected to a wide range of environmental stress including changes in climate. Climate change is widely recognized as a significant threat to biodiversity and ecosystem services. The main objective of this study is to provide answers on how biodiversity response to temperature shifts due to climate change effects. To identify the factors that lie behind the sensitivity or resilience of a range of species. Understanding species' responses to environmental change underpins our abilities to make predictions on future biodiversity under any range of scenarios (Clark *et al.,* 2017). These assessments and predictions are essential inputs to defining and optimizing adaptation and mitigation strategies for climate change. The findings from this study will thus be useful for policy and decision making processes relevant to biodiversity conservation in a changing climate and sustaining ecosystem services to support for human well-being.

Soil salinity remains to be a major threat to the global food security, and the progress in crop breeding for salinity stress tolerance may be achieved only by pyramiding key traits mediating plant adaptive responses to high amounts of dissolved salts in the rhizosphere. This task may be facilitated by studying natural variation in salinity tolerance among plant species and, specifically, exploring mechanisms of salinity tolerance in halophytes. The aim of this work was to establish the causal link between mesophyll ion transport activity and plant salt tolerance in a range of evolutionary contrasting halophyte and glycophyte species. Plants were grown under saline conditions in glasshouse, followed by assessing their growth and photosynthetic performance. In a parallel set of experiments, net K^+ and H^+ transport across leaf mesophyll and their modulation by light were studied in control and salt-treated mesophyll segments using vibrating non-invasive ion selective microelectrode (the MIFE) technique. The reported results show that mesophyll cells in glycophyte species loses 2 to 6 fold more K^+ compared with their halophyte counterparts. This decline was reflected in a reduced maximum photochemical efficiency of photosystem II, chlorophyll content and growth observed in glasshouse experiments. In addition to reduced K^+ efflux, the more tolerant species also exhibited reduced H^+ efflux, which is interpreted as an energy-saving strategy allowing more resources to be redirected towards plant growth. It is concluded that the ability of mesophyll to retain K^+ without a need to activate plasma membrane H$^+$-ATPase is an essential component of salinity tolerance in halophytes and halophytic crop plants.

Increased precipitation and nitrogen alter shrub architecture in a desert shrubland: Implications for primary production

Weiwei She, *Yuqing Zhang, Shugao Qin, Bin Wu, Yuxuan Bai*

Shrublands are one of the major types of ecosystems in the desert regions of northern China, which is expected to be substantially more sensitive to global environmental changes, such as widespread nitrogen enrichment and precipitation changes, than other ecosystem types. However, the interactive effects of nitrogen and precipitation on them remain poorly understood. We conducted a fully factorial field experiment simulating three levels of precipitation (ambient, + 20%, + 40%) and with two levels of nitrogen deposition (ambient, 60 kg N ha^{-1} yr^{-1}) in a desert shrubland in the Mu Us Desert of northern China. We used plant architectural traits (plant cover, volume, twig size and number) as proxies to predict aboveground net primary productivity (ANPP) of the dominant shrub (*Artemisia ordosica* Krasch), and assessed the responses of plant productivity and architectural traits to water and nitrogen addition. We found significant differences in twig size and number of *A. ordosica* under water and nitrogen treatments but not in shrub cover/volume, which suggest that twig size and number of the shrub species were more sensitive to environmental changes. The productivity of the overall community was sensitive to increased precipitation and nitrogen, and shrubs played a more important role than herbaceous plants in driving productivity in this ecosystem. Precipitation- and nitrogen-induced increases in vegetation production were positively associated with increases in twig size and number of the dominant shrub. Water addition enhanced the twig length of *A. ordosica*, while nitrogen addition resulted in increased twig density (the number of twigs per square meter). Water and nitrogen interacted to affect twig length, but not twig number and shrub ANPP. The trade-off, defined as negative covariance between twig size and number, was likely the mechanism underlying the responses of twig length and shrub ANPP to water and nitrogen interactions. Our results highlight the sensitivity of twig size and number as indicators to estimate shrub production and the mechanism underpinning desert shrub ANPP response to global environmental changes.
