Although controlling the diseases observed in farms is very difficult, there appears to be great benefits for grow-out producers to provide a disease-free environment since the presence of pathologies had very large negative effects on survival of both species.

Introduction

Structural variants (SVs) are a major component of genetic variation additional to single nucleotide polymorphisms (SNPs). SVs include duplications, deletions and inversions, ranging in size from hundreds to millions of bp, and are known to impact gene expression dosage and function, contributing to commercially relevant phenotypic variation in livestock (e.g. Hou *et al*, 2012; Xu *et al*, 2014; Xu *et al*, 2019). However, there remains a major gap in our understanding and exploitation of SVs within the genomes of farmed aquatic species. Atlantic salmon (*Salmo salar*) is a commercially important salmonid contributing extensively towards global economic and food security. A reference genome (Lien *et al*, 2016), combined with sharply declining sequencing costs, will enable genome-wide studies of SVs at high resolution in this species, which may add significantly to current selective breeding programs

Methods

We have developed computational pipelines to detect SVs in Atlantic salmon genomes, and validated them both bioinformatically and experimentally. The basis of our approach involves SV detection usisng short-read paired-end sequencing data (10-20x coverage) aligned to the current reference genome assembly/annotation. The LUMPY framework, which incorporates multiple SV detection signals (Layer *et al*, 2014), is used for SV calling, with subsequent genotyping done using svtyper (Chiang *et al*, 2015). Our pipeline includes bioinformatic filtering steps to reduce false positive calls inherent to SV detection when using short-read data with complex genomes and imperfect reference assemblies. Critically, we use a tool called SV-plaudit (Belyeu *et al*. 2018) that allows efficient manual visual curation of SVs, enabling retention of only high-quality bioinformatic calls. We have also developed an amplicon-based long-read sequencing approach using the Oxford Nanopore MinION platform to validate SVs experimentally. Finally, we employ established tools to annotate the genomic location of SVs and their predicted impact on functional features including protein-coding genes.

Results

Our first in-depth SV analysis used n=9 resequenced Atlantic salmon individuals from distinct aquaculture strains, which led to ~32,000 highly-significant SV calls following initial filtering. Notably, only ~20% of these SV calls were retained as high confidence variants after SV-plaudit filtering, highlighting the inherent high false positive rate of SV detection using resequencing data, which is likely the case for many species. Among ~7,000 high confidence SVs 90% are deletions, 6% are duplications, and 4% are inversions. Around half the high-confidence SVs overlap with genes, and ~5% are predicted to strongly modify gene function or dosage. Notably, we identified a large number of immune genes affected by SV with predicted large effect. MinION sequencing of PCR-amplified genomic regions containing high confidence SV calls revealed that the true-positive call rate of our pipeline is ~95% (true genotyping call rate ~90%) for deletion variants, with lab validation work ongoing for duplications and inversions. We are currently using the same pipeline for SV detection in a broader set of resequenced Atlantic salmon, representing hundreds of individuals from diverse wild and farmed populations. We are using this dataset to document the SV landscape of Atlantic salmon as a species, including the impact an ancestral whole genome duplication event (Macqueen and Johnston, 2014; Lien *et al*, 2016) had on the probability of SV retention.

(Continued on next page)

Future work and perspectives

In a new project funded by the Biotechnology and Biological Sciences Research Council, we are focussing on exploitation of SV data in Atlantic salmon breeding. We will genotype high-confidence SVs across a pedigreed commercial population with natural variation in resistance a problematic disease in modern salmon aquaculture. The overall goal will be to assess the extent of heritability in resistance explained by SVs, ii) use association analysis to identify SV regions/genes underlying resistance, iii) establish the effect of incorporating SVs into genomic prediction for resistance, versus the predictive ability of SNP genotypes alone and iv) identify the impact of SVs on gene expression variation associated with resistance.

In summary, it is important to understand the SV landscape of farmed aquatic species, and to establish the extent of commercial trait variation explained by SVs as putative causative mutations. As sequencing technology improves and becomes cheaper, we predict it will become routinely possible to incorporate accurate SV data into breeding programmes in many aquaculture species.

LINKING FRESH WATER QUALITY AND FISH WELFARE WITH SEA WATER FEEDING PERFORMANCE IN CHILEAN SALMON FARMING: A MODELLING TOOL BASED ON SMOLT PHYSIOLOGICAL STATUS

X. Gutiérrez[1], FA. Briceño[1] (*), R. León[2] and P. Feest[1]

Introduction

Salmon farming productivity strongly relies on smolt adaptability success on seawater (SW) environment after transference from the freshwater (FW) phase, especially during the first weeks after the arrival. According to current understanding, sub-optimal water quality (WQ) and physiological status at the end of FW stage are able to alter key smolt physiological traits (e.g. osmoregulation), which can be determinant for the further fish performance (growth and survival) (Brauner et al., 2000; Kroglund & Finstad, 2003; Damsgård et al., 2006; Emparanza, 2009; VKM, 2012; Filvestad et al., 2015). Even though there are advances on smolt welfare in land-based farming (VKM, 2012; Noble et al., 2018), there is a lack of quantitative tools to assess the link between fish welfare and physiological traits with subsequent SW smolt performance (e.g. feeding rate and growth). Also, recirculating aquaculture system (RAS) smolt production has increased over the years at a global scale (Emparanza, 2009; VKM, 2012). However, there are many uncertainties on smolt quality from RAS facilities which are known to be different from flow-through facilities (Gutierrez et al., 2018). Hence, we aim to understand the relationship between smolt physiological status and production systems for developing innovative predictive tools which can enhance salmon farming.

Materials and methods

The current study analyzed data from an ongoing smolt (*Salmo salar*) physiological monitoring program undertaken by NIVA Chile from both RAS and flow-through (FT) fish farms between 2015-2018 in Southern Chile. A total of 23 consecutive fish batches were examined days before the smolts are transferred to the sea. Our methodological approach is based on the integration of key WQ parameters at tank scale, as well as physiological blood parameters and metals concentration in target organs. These parameters were sampled at tank scale, with three tanks for each smolt batch. This information from FW farms was integrated with feeding and survival performance of transferred smolt during the initial of marine on-growing phase.

We categorized four types of components for the modelling: (1) FW farm-based information related to fish biomass and density, among others (FW-F); (2) water quality information from tank (WQ); (3) both blood parameters and heavy metal quantification were referred as fish welfare (W) and; (4) SW feeding and survival performance (SW-P). The four components (FW-F, WQ, W and SW-P) were analyzed by multivariate techniques such as Principal Component Analysis (PCA) and Path Modelling (PM). The first modelling stage consisted in an explorative analysis for identifying major variability from variables by using PCA. Afterward, we selected main variables by applying a relationship modelling by PM with the following criteria: unidimentionaly, loadings and communality, and cross-loadings. Variables selection was an iterative process based on mentioned criteria by including only those variables that better represent each component.

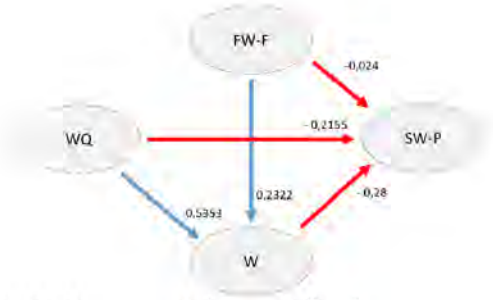

Figure 1: Path model which shows associations and directions among components. Arrow color indicates the sign of coefficients (blue=positive) which relate each component. All coefficients were significant ($p<0.05$), with the exception FW-F > SW-P.

(Continued on next page)

Results

Explorative analysis by PCA showed that most variability for each component depended on one to four variables. For the FW-F component, main variables selected were flow/load ratio, fish biomass, number of fish and tank density. In term of WQ, carbon dioxide (CO_2) was the main variable selected. Welfare blood traits such as bicarbonate (HCO_3) and partial CO_2 pressure (pCO_2) were selected. SW-P variables such as feeding intake at 2, 3 and 4 weeks after smolt transfer.

A first inner relationship by PM demonstrated that FW-F and WQ (predictors) have a causal and positive effect on W (response variable). In this case, both predictors were significant ($p<0.05$). A second inner model, using W and WQ as predictors to SW-P (response variable) showed a causal negative effect ($p<0.05$). The F-FW and SW-P relationship was no significant, demonstrating the lack of effect on tank traits on feeding and survival performance on SW phase. The following diagram shows direction and type of effect (negative/positive) among components (Figure 1).

Discussion and conclusion

Our modelling approach demonstrated that both WQ and tank traits can cause a positive impact on Atlantic salmon smolt welfare in terms of physiological blood traits such as acid-based parameters (HCO_3, pH and pCO_2). Importantly, we confirm that high levels of water CO_2 can alter acid-base equilibrium, increasing the risk of hypercapnia, as previously reported (Brauner et al., 2000; Fivelstad et al., 2015). This impaired smolt physiological condition was correlated with a poor feeding performance between 2 to 4 weeks after transfer to the sea farms. This revels the high importance of CO_2 for the physiological status of the smolt and its further initial feeding performance on sea water.

Outcomes from this study can serve as a guideline for decision making process to identify the risk of these variables over fish welfare and performance. The producer, for example, is able to prioritize and improve aspects of water quality conditions, which in turn, result in better fish physiological condition and further feeding performance.

POTENTIAL OF GENOMIC SELECTION FOR THE IMPROVEMENT OF PACIFIC OYSTER RESISTANCE TO *Ostreid herpesvirus* (OSHV-1)

Introduction

In genomic selection (GS), genome-wide SNP markers are used to generate genomic estimated breeding values (gEBVs) for selection candidates. The accuracy of the predictions obtained from GS for both livestock and aquaculture species has been shown to be higher than accuracy using traditional pedigree-based approaches. GS is particularly useful for the selection of polygenic traits and the benefits have been described for several aquaculture species (Zenger et al. 2019). The application of GS in shellfish also looks promising and has the potential to help in dealing with one of the main issues currently affecting Pacific oyster production worldwide, which is the so called "summer mortality syndrome". This causes periodic mass mortality in farms worldwide and has mainly been attributed to a specific variant of the *Ostreid herpesvirus* (OsHV-1-µvar) (Segarra et al. 2010). In the current study, we evaluated the potential of genomic selection for host resistance OsHV in Pacific oysters, and compared it to pedigree-based approaches.

Materials and methods

31 oyster families were produced in 2015 at the Cawthron Institute's hatchery in Nelson, New Zealand, as part of an ongoing selective breeding program (Camara and Symonds, 2014). Disease challenge was performed based on the preparation of a standardized, cryopreserved stock of the OsHV-1 virus and an immersion-based virus exposure treatment for oysters for seven days. Mortalities were recorded twice a day. DNA was extracted from survivors and mortalities, and 768 samples were genotyped using the medium density SNP array for oysters (Gutierrez, et al. 2017). GWAS was performed for the survival trait using a GBLUP approach in BLUPF90 software. Heritability and gEBV calculations to obtain genomic prediction accuracies were performed using the ASReml 4 software (Gilmour et al. 2015). Various different marker densities were tested to determine the number of SNPs needed to obtain high prediction accuracies. The first approach involved a progressive increase of the minor allele frequency (MAF) threshold, resulting in a progressive decrease in SNP numbers. The second involved choosing random subsets of SNPs for inclusion on low density panels.

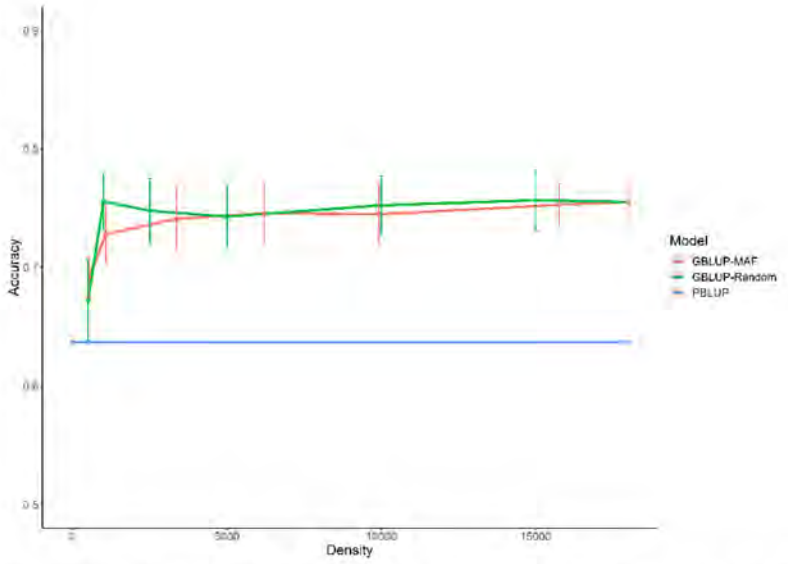

Figure 1. Genomic prediction results showing mean accuracies (±s.d) obtained from both pedigree A-matrix (PBLUP) and genomic matrix G-matrix (GBLUP).

(Continued on next page)

Results

No major QTL associated with OsHV-1 resistance were identified, although regions explaining moderate percentages of the genetic variance were located on LG1, LG7, LG8 and LG10. Heritability ranged from 0.25±0.05 to 0.37±0.05 (mean±s.e) based on pedigree and genomic information, respectively. Genomic prediction results showed that both SNP reduction approaches had little impact on prediction accuracy until marker densities dropped below ~1,000 SNPs, below which the accuracy tended to drop. With the MAF approach, the genomic prediction accuracies obtained using the lower density SNP panels ranged from 0.755 to 0.693 (MAF>0.475, 530 SNPs), while using the random subsets, accuracies ranged from 0.758 to 0.678 (500 SNPs), as shown in Figure 1.

Discussion

These results suggest that OsHV-1 resistance in this Pacific oyster population is polygenic. Under this scenario, the application of GS can still improve selection by taking into account the effect of all SNPs instead of only those linked to a particular QTL. Our results show that the accuracies obtained from GS are higher than pedigree-based values, even at low SNP densities. This demonstrates the potential for GS in Pacific oyster breeding programs and importantly, demonstrates that a low number of SNPs might suffice to obtain accurate gEBVs, thus potentially making the implementation of GS more cost effective.

Introduction

Fish welfare is a growing area of research that has gained increasing public awareness over the last decade (Ashley 2007; Noble et al. 2012). A practical approach on how to measure welfare in farmed species is using Operational Welfare Indicators (OWIs) (Treasurer et al. 2018). Lumpfish (*Cyclopterus lumpus* L.) are widely used as biological alternatives to the use of medicines for sea lice control in the salmon farming industry (Powell et al., 2018a) but their survival is often challenged by poor husbandry practices and disease outbreaks (Brooker et al. 2018), both important causes of concern from a welfare perspective. Also, as a novel species, it is important to identify when their welfare is being compromised to maintain health and delousing efficienc . We have developed and validated a rapid Welfare Index based on visual scores of fin damage, external lesions, eye condition and suction disc deformities that can be easily implemented under farm conditions at both pre- and post-deployment stages.

Material and Methods

Juvenile lumpfish (n=95) of two different stages of development (pre-deployment, mean weight=37.78g±4.74; post-deployment, mean weight=53.54g±3.08) were measured, weighed and photographed to obtain information on (1) external condition, (2) fin damage (Hoyle et al. 2007), (3) eye condition, (4) eye darkening (Champneys et al. 2018; Freitas et al. 2014; Volpato et al. 2003) and (5) suction disc deformity, to develop a Scoring Index. Plasma cortisol and relative weight (Wr), obtained from the logged length-weight relationship, were used to validate the Index. Percentage of exact agreement and Cohen's weighted kappa coefficients were used to assess inte -rater and intra-rater reliability of the measured scores.

Results

Principal Component Analysis (PCA) indicated that the first component accounted for 39% of variation and was mostly associated with suction disc deformity (-0.56), eye darkening (0.47) and external condition (0.46). The second component explained 21% of variation and was mostly affected by eye condition (-0.79) and fin damage (-0.45), being also positively related to plasma cortisol levels (R^2=0.4, $p<0.01$). Welfare indicators were affected by age (Fig. 2), suggesting that welfare indicators should be tailor-made depending on life stage (pre- or post-deployment). The repeatability of welfare metrics was generally high, with quadratic weighted kappa values ranging from 0.74 to 1.00, for measurements between different observers (inter-rater) and the same observer and different sampling points (intra-rater).

Discussion and conclusions

Lumpfish (*Cyclopterus lumpus* L.) are increasingly being used as cleaner fish for sea lice control in salmon cages but knowledge on their welfare is poor. The development of reliable and easy-to-use Operational Welfare Indicators (OWI) for this species has been flagged as a priority by industry and will help with quality assurance. The OWIs we present here were based on the visual assessment of external condition, fin damage, eye condition, eye darkening and suction disc deformities. These proved to be repeatable and easy to implement in both hatcheries and sea farms and can serve as indicators of lumpfish welfare that depend on life stage. Fin damage and eye condition were the most important determinants of lumpfish welfare at post-deployment stage (sea cages), while suction disc deformities were more important at the hatchery stage. This could be explained because lumpfish producers select their fish for quality before deployment. Also, it was observed that fin damage and eye condition can deteriorate with time at sea cages as it is a more exposed and uncontrolled environment than in tanks on land, so the probability of suffering external physical lesions is quite higher. Eye condition, which included eye damage, cataracts and exophthalmia, is particularly important in sea cages as it can affect delousing efficienc , known to be highly dependent on having unimpaired vision (Jonassen et al. 2017). Our Welfare Score, which has been simplified into a Welfare Scoring Index based on the first results, is being tested currently in different hatcheries and sea farms to assess its practicality.

IMPACT OF CLIMATE CHANGE ON CARP YIELDS IN HUNGARIAN POND AQUACULTURE

Gergő Gyalog*, Béla Csukás, László Berzi-Nagy, Mónika Varga

NAIK Research Institute for Fisheries and Aquaculture (HAKI), 5540 Szarvas, Anna-liget 8., Hungary
E-mail: gyalog.gergo@naik.hu

INTRODUCTION

Pond culture is the dominating sub-sector in Hungarian aquaculture with an output of 14893t from 26065ha of fish ponds in 2017. Low-input farming technologies are dominant, characterized by reliance on natural pond food sources and high dependence on environmental conditions making the farming technology sensitive to climate change. In this paper, we describe a model that simulates the impact of climate change on carp yields.

MATERIALS AND METHODS

The model used for simulating yields is a food web based fish pond model implemented in Direct Computer Mapping (DCM) Programmable Structures. The model describes and simulates: i) physical processes (e.g. air-water temperature exchange, evaporation, air-water oxygen transmission); ii) nutrient flows among the elements of pond food web; and iii) managerial interventions (stocking, feeding, manuring, water management). Both climatic and managerial stressors were introduced into the model in order to simulate the impact of different climate regimes and several pond farming technologies on carp yields. NORESM 4.5 and 8.5 climate scenarios were used for forecasting the impact of climate change on production. Two geographical locations were considered representing the two main production regions. The model was validated by industrial production data.

RESULTS

Figures 1 present the forecasted gross common carp yield as function of technological settings in the Southern Great Plain simulation locations. Simulated results show that there is a monotonic increase of yields over time. Yields in 2046-55 will be 3-8% higher than in the reference period taking into account the most typical technological options. There is minor difference between climate scenarios. In the mid run (2026-35), climate change impacts are higher under RCP8.5 than under RCP4.5. In the long run (2046-55), there is no any significant di ference between RCP scenarios.

However, there is large difference in climate change impacts between different management scenarios:

- Higher feeding rates are associated with bigger growth in yields (A -> D subgraphs). This is because warming temperature positively influences the anabolic activity of carp and its capability to take up food. Thus, more intensive feeding is required to meet increased nutrient demand and to exploit growth potential.
- Increment in yields is higher for strategies with lower stocking densities. Enhanced plankton productivity can be fully exploited with more extensive technologies, when predation pressure on zooplankton fauna is lower.

CONCLUSION

Simulation results show that global warming may generally increase carp yields. However, different farming technologies will unequally benefit from climate change: farming technologies, applying low stocking densities and intensive feeding will be impacted more beneficially than the other technological options

Two laboratory experiments were conducted to determine (1) the influence of a cheap and widely available agriculture by-products (soybean, rice bran and cotton seed meal on survival , growth and fecundity of *Artemia sp.* beside fresh algae as control diet for 25 days. (2) Effect of dried adult *Artemia* as sole food, mixed with formulated diet (50:50) and formulated diet as control on growth performance and feed utilization of the freshwater prawn, *Macrobrachium rosenbergii* . *Artemia* were fed a concentration of 60 mg per day up to 10 days and 80 mg per day up to 25 days was found to be the best regime for culturing *Artemia* in all cases. Growth, fecundity and naupliar production differed significantly ($P<0.05$) for *Artemia* fed on soybean than other test diets.

The proximate and minerals composition of *Artemia* fed on optimum concentration (80 mg/day) of different diets were determined.

M. rosenbergii fed on mixed diet (dried adult *Artemia* and formulated diet) showed the best significant ($P<0.05$) growth performance, survival and feed utilization. It can be suggested that dried *Artemia* can be mixed with artificial diets for larvae of the freshwater prawn *M. rosenbergii.*

MOLTING CAN BE A MAJOR CAUSE OF MORTALITY IN INTENSIVE SYSTEMS (RAS) FOR SHRIMP (*L. vannamei*) CULTURE

E. Hadas*, A. Elkayam, D. Hazut

Maof Hanegev Ltd., 11 Amal St., I.Z. Afeq, Rosh-Ha'ayin, 4809239, Israel
eran@aquamaof.com

1. Introduction

Culture of shrimps in controlled systems, such as RAS, seems by many to be a sustainable alternative to the traditional, outdoor culture systems of shrimps; the controlled systems can be bio secured, not depending in environmental conditions and can have low environmental impact.

Culture of shrimp in RAS requires intensification of the shrimps. Substantial loss of shrimps along the culture period is one of the major bottle necks in developing this technology.

In a bio-secured facility, when the stocked animals are Specific Pathogen Free (SPF), no outbreak of acute shrimp diseases are expected. Yet, previous observations carried out in the experimental RAS facility of Maof Hanegev Ltd., revealed that in high densities (>1000 shrimps/m^3) there is a significant loss of shrimps during culture time; the cause of mortality of these animals is unknown as the dead shrimps do not show any clinical signs and their mortality cannot be related to any known environmental factor.

The data that has been collected until now in Maof Hanegev support the assumption that this apparent asymptomatic mortality might be focused to negative processes occurring during molting time of the cultured shrimps.

The aim of the present research was to make histological and microbiome analyses in shrimps that were collected (dead/alive) from intensive RAS and to estimate the primary cause of mortality in these culture conditions. This research is an important step for developing the required technology to reduce mortality of shrimps cultured in high densities and by that contributing to optimization of shrimp culture in RAS.

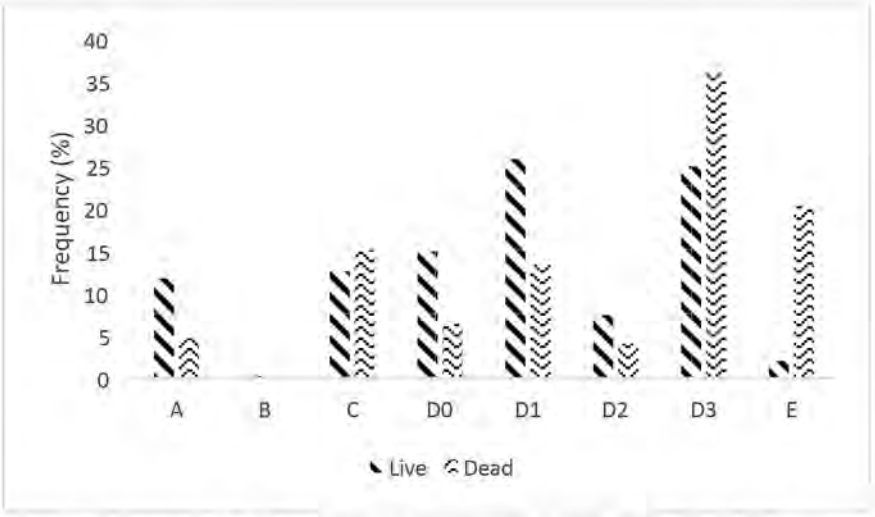

Figure 1: frequency of molting phase of *L. vannamei* cultured in intensive tanks. live refers to shrimp that were sampled alive from the culture tanks (n=348); Dead means shrimp that were collected from the tank as freshly dead animals (n=172).

(Continued on next page)

2. Materials and methods

The research work had been carried out in the experimental RAS facility of Maof Hanegev Ltd in Kibutz Revivim, Israel. The experiment included 3 culture tanks, 5m^3 each, stocked with 5500 shrimps (L. vannamei) per tank, at an average size of 5gr. Dead shrimps were collected continuously from the experimental tanks and were frozen or fixed immediately; this sampling method enabled the analysis of as fresh as possible dead animals. As a reference, normal animals were randomly pooled from the tanks and were stored and analyzed at the same way as the dead shrimps. To determine the molting stage, the physiological condition and the microbiome of the shrimps, the following tests were carried out:

2.1. The molting stage of each sampled animal (dead/alive) was tested by microscopical observation of the uropod.

2.2. Animals (dead/alive) were fixed for histological examination of the different tissues and organs to observe tissue abnormalities.

2.3. Microbiome analysis of the sampled shrimps, by sequencing specific fragment of microbial 16S

3. Results

Shrimps were cultured in the experimental tanks up to size of 16gr. Analysis of the molting stage profile (figure 1) shows that the profile of the dead shrimp is significantly different from the molting profile of the live shrimp population in the culture tanks. In the live population in the tank only 27% of the animals were in late pre-molt and molt phases (D3&E), compared to 57% of the dead shrimps that were found to be in those phases.

The microbiome analyses and the histological tests do not support any conclusion that the dead shrimps were affected from any acute pathogenic infection.

4. Conclusions

The present research shows that a bio-secured RAS can keep shrimps in high densities without any outbreak of acute bacterial diseases. The data collected in this research support the hypothesis that most of the mortality of shrimp in RAS can be related to the molting phase. It is yet unknown if mortality is due to the molting process itself or due to aggressive interactions among the shrimp population in the tank - predation of soft shell, defenseless shrimps.

BIOREMEDIATION OF AQUACULTURE AND BIOGAS SIDE STREAMS USING POLYCHAETES (*Hediste diversicolor*, O.F. MÜLLER, 1776). PART I: GROWTH & MORTALITY

Introduction

"*In a world with growing pressures on resources and the environment, the EU has no choice but to go for the transition to a resource-efficient and ultimately regenerative circular economy*" (EREP, 2014). Bio industries are especially well suited to spearhead circular principles, as biological processes *per se* rely on recycling and reuse of organic and inorganic compounds. Circular approaches can help making aquaculture operation greener, e.g. by producing high quality feed components rather than harvesting them. Polychaetes are a natural part of the diet of many aquatic animals and contains high levels of sought after biochemicals, such as omega-3-fatty acids and proteins. Further, they are detritivores, making them perfectly suited as recyclers of organic side streams. Sludge from RAS aquaculture is an obvious feed source for aquatic vermiculture, and has been shown to be promising (Bischoff et al., 2009; Pajand et al., 2017). As an alternative, biogas production is on the rise, and the solid digestate after methanogenesis might also pose a promising substrate for worm faming.

Material & Methods

We reared the polychaete *Hediste diversicolor* along a gradient spanning from pure sludge from salmon smolt production to pure solid biogas digestate in 33% steps for 30 days. A group receiving fish feeds served as the positive control. Worms reared on these five different diets were analysed for growth, survival and biochemical composition (cf. part two of this study; Malzahn et al).

Results

The polychaetes accepted all diets and displayed positive growth. The worms fed FF showed a significantly higher SGR compared to worms produced on the other diets (0.018 ± 0.003 d^{-1}; $p < 0.05$), whereas there were no significant differences in SGRs between the other treatments (Fig. 1). Previous studies have shown negative growth for *H. diversicolor* when starved (-0.02 ± 0.007 d^{-1}). The survival rate ranged from 82 - 92% between the treatments, and there were no significant dietary effects on mortality (Fig. 2).

Discussion & Conclusion

H. diversicolor is a promising candidate to produce high quality feed components from to-date-considered wastes. However, current regulations on an EU level do not allow to use animal products produced on aquaculture and biogas side streams as feed ingredients. Clearly, regulations must be reviewed to unleash the full potential of circular bio production approaches.

INCREASED TAURINE CONTENT IN START-FEEDING DIET BOOSTS GROWTH IN FARMED ATLANTIC COD (*Gadus morhua*)

Øyvind J. Hansen*, Velmurugu Puvanendran, Jens P. Jøstensen, Atle Mortensen

Nofima, Muninbakken 9-13, NO-9291 Tromsø, Norway
oyvind.j.hansen@nofima.n

Atlantic cod from a selected broodstock (Norwegian National breeding program for cod) were hand stripped to obtain a genetically uniform starting point for start feeding experiment. Effects on survival and growth of taurine content in start-feeding diet for farmed Atlantic cod larvae were measured. Fish fed diets with high and low level of taurine were compared to fish fed a control diet. Dry diet was introduced at 14 days' post hatch and a co-feeding strategy with rotifers and artemia nauplia were used. Treatment ended at day 120 post hatch and all groups were fed standard diet until end of experiment at day 170 post hatch. Fish fed high level of taurine were significantly longer at day 71 and 85 post hatch. Fish fed high content of taurine was significantly heavier than fish from control group at day 94 to end of experiment at 170 days' post hatch. At 170 days' post hatch fish fed high taurine diet were 47 % heavier than fish from control group. There were no significant differences in survival between treatments. The experiment is repeated and data (deformity and histological) from ongoing experiment will be added.

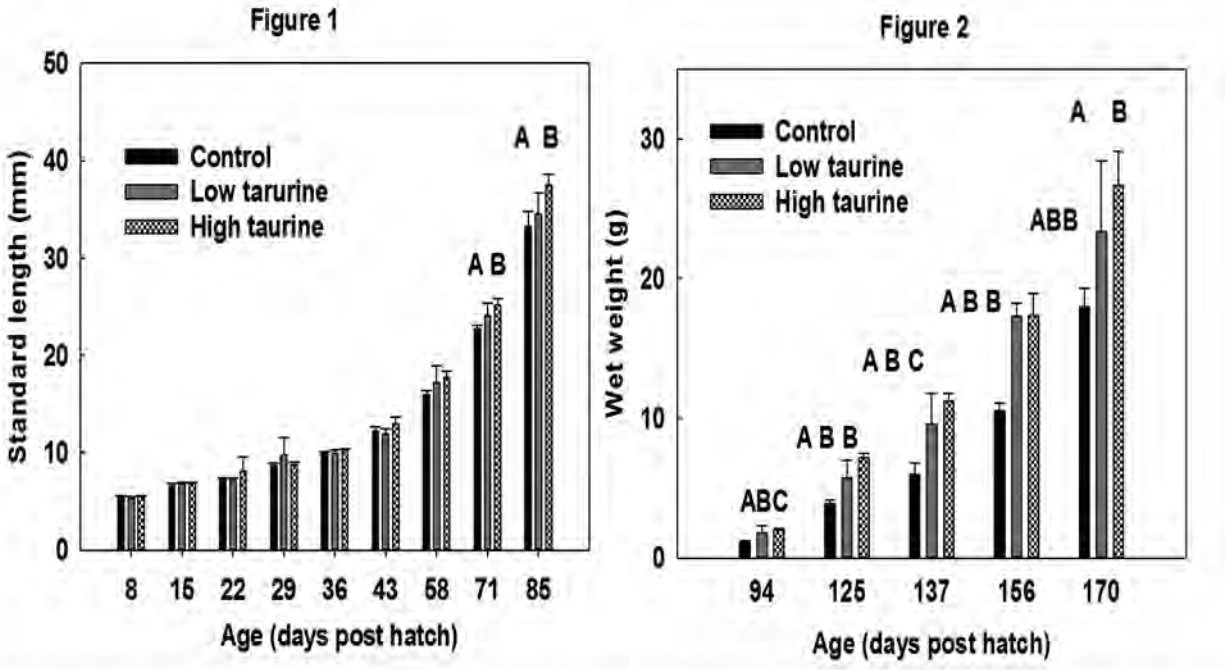

Figure 1: Fish fed high content of taurine were significantly longer than fish from control group at 71 and 85 days' post hatch

DEVELOPMENT OF A HYDRODYNAMIC PARTICLE TRANSPORT MODEL TO STUDY JELLYFISH INTERACTIONS WITH FISH FARMS

Introduction

Fish kill events or gill disorders in marine-farmed fish due to jellyfish sting toxins are a global problem (Rodger et al., 2011; Purcell et al., 2007) with numerous fish-kill events reported in Europe, Asia, North America, and Australia. The economic consequences are significant with annual losses of 68–205 million USD (Kim et al., 2012) and 10 million USD previously estimated for Korea and the Gulf of Mexico (Graham et al., 2003), respectively. In Ireland, in 2017, swarms of jelly wiped out about 80 percent of the salmon stock from several farms in Killary Harbour (Fig 1) and some 10,000 fishes from adjacent waters along the west coast (O'Sullivan, 2017). The present research aims to develop a hydrodynamic coastal model to simulate the transport and fate of jellyfish which can be used to mitigate / prevent adverse interactions of jellyfish with fish farms. Due to its recent problems, Killary Harbour, a fjord on the Irish west coast, was chosen as the case study site for the research.

Materials and methods

A 3D baroclinic model of Killary Harbour has been developed using the Environmental Fluid Dynamics Code (EFDC). The model domain extends 20 km East-West and 16 km N-S and is resolved horizontally at 64 m giving a grid of 320×100 computational cells. Average water depths in the harbour are 20 m and the model uses 20 sigma layers in the vertical direction. The model has been validated against ADCP-measured (446.7 E 5939.7 N) current velocities and water levels (Fig 2) for which good agreement has been achieved. Activities of jellyfish within Killary were recorded in August-September 2015 by releasing tagged jellies and tracking their movement with 8 stationary receivers distributed along the harbour. In this first phase of the research, the jellyfish were modelled as passive drifters using EFDC's particle transport module and the outputs were compared with the measured data. Particles were released in the surface and mid-depth layers at the identical locations and times that tagged jellyfish were released.

Results

In Figure 3, the measured movements of one of the tagged jellyfish is shown by the multi-colored rings. The numbers represent sequential times of detection by receivers (each receiver range was approximately 500m) and the thickness of the rings is representative of the time spent within a detector's range. The figure also shows the positions of modelled particles at two time instances of detection (1 and 9), the first being just a few hours after the release time (indicated by time 0 on the water level insert graph) and the second being approximately 125 hours (ten tidal cycles) after the release. It can be seen that there are particles present at the detection locations (S4 and N1) at the times of detection even though the receivers are located approximately 5 km apart. The plot at time 9 shows a significant difference in the long-term transport of particles released in the middle of the water column compared to those released at the surface. Wind-induced surface currents result in many surface particles being transported west of the release point towards the sea, whereas the sub-surface particles are all transported eastward of the release point.

Discussion and conclusion

Analysis of the jellyfish tracking data has indicated a strong tidal advection influence on jellyfish movements. This agrees with the literature (e.g. Berline et al. (2013) and Yin et al. (2019)) which reports ocean and wind-driven currents to be the main drivers of jellyfish transportation. Simulating the jellyfish in Killary harbour as passive drifters has shown that tidal and wind driven currents alone can indeed cause particles to be transported in a similar manner to the tagged jellyfish which further corroborates the literature. However, further statistical analysis of model results must be conducted. Killary Harbour is home to both salmon and mussel farms and the next phase of the research will involve including jellyfish behaviours and the salmon/mussel farms in the model so that potential jellyfish interactions with farms and their means of prevention can be investigated.

COPING WITH THE INVASIVE JAPANESE OYSTER DRILL (*Ocinebrellus inornatus*) ON OYSTER CULTURE PLOTS

Eva Hartog[1 *], Tony van der Hiele[1], Jouke Heringa[1], Niels Wagenaar[1], Jacob Capelle[2]

[1]HZ University of Applied Sciences, Edisonweg 4, 4382NW, Vlissingen, The Netherlands
[*]email: e.hartog@hz.nl
[2]WMR - Wageningen Marine Research, P.O. Box 77, 4400 AB Yerseke, The Netherlands

Oyster farmers are struggling with large losses due to predation on the oysters by the invasive Japanese oyster drill (*Ocinebrellus inornatus*). By drilling a hole through the shell this marine predatory snail can access and feed on the meat. In the Netherlands, oyster production has steeply declined over the past few years as a consequence of oyster drill predation. Without additional measures the production of oysters will continue to decline and this will have a huge impact on Dutch oyster cultivation, potentially leading to the complete closure of oyster farming companies.

The Japanese oyster drill was first discovered in the Oosterschelde, the Netherlands, in 2007 where it most likely arrived via international oyster transport.

The population of Japanese oyster drills has increased rapidly over time due to the fact that they do not have a natural predator in the area, and have a very high fecundity. The distribution of the Japanese oyster drill is also expanding, and now include Lake Grevelingen and Lake Veere, possibly due to transport of oysters between different cultivation areas.

In 2018 the project ‘Learning to cope with the Japanese oyster drill’ was initiated. In this project Dutch oyster farmers and researchers cooperate to provide oyster farmers with validated methods in order to maintain the oyster cultivation, and increase the survival of oysters on culture plots in the presence of the Japanese oyster drill.

Because little information is available on how the Japanese oyster drill behaves in Dutch waters, research on the biology and behavior of the drill is conducted. This knowledge can be used by oyster farmers to develop effective breeding measures to increase oyster survival.

The current focus within the “Learning to cope with the Japanese oyster drill” project is predation behavior as well as gaining knowledge about the general mobility - a combination of monitoring and in situ manipulative experiments in enclosures.

To explore the feeding behavior of the Japanese oyster drill, the effects of oyster species, morphology and size on predation rate are being investigated.

The general mobility of the oyster drill is also tested, along with the effect of wind, current and prey location on the direction of movement.

The monitoring and experiments are still ongoing and the results will be discussed.

NUTRITIONAL QUALITY OF DIFFERENTLY PROCESSED *Moringa oleifera* SEED BEFORE AND AFTER OIL EXTRACTION FOR INCLUSION IN *Clarias gariepinus* BASED DIETS

Introduction

Previous investigations reported on a range of different fish species fed relatively high inclusions of plant proteins, including African catfish (Goda *et al.,* 2007). The inclusion of plant protein sources in the ration of fish requires investigation on proper processing for effective utilization (Francis *et al.,* 2001). Presence of certain limiting factors in plant ingredients such as high crude fibre content and anti-nutritional factors have been demonstrated (Alegbeleye *et al.*, 2005). The objective of this study was to evaluate the effect of different processing methods on the nutrient and anti-nutrient profiles of *Moringa oleifera* seed.

Materials and Methods

The experiment was conducted in Sokoto, Nigeria on latitude 13^0 07' 47.6''N and longitude 05^0 12'11.3''E in accordance with the University's Research rules and guidelines. Processing and analyses were conducted using standard procedures. For each of the twelve (12) different processing methods two hundred grams (200g) of the seeds were used for proximate analysis, amino acid assay and anti-nutrient determinations.

Results

The anti-nutrients detected in the raw Moringa seeds were Oxalate, saponins, alkaloids, phytic acid, tannin, cyanide and phytate with the following contents; 0.86±0.13, 1.50±0.06, 2.32±0.06, 269.84±1.62, 1.21±0.14, 0.56±0.04 and 69.82±0.86, respectively (Table 1). It was only B90mins/S72hrs that significantly ($p<0.05$) reduced phytic acid to FAO (2009) permissible limit of ≤5mg/kg amongst all the processing methods. As shown in Table 2, treat Moringa had the highest crude protein content of 55.05±0.16.

Discussion and Conclusion

Reduction trend in the anti-nutrients was observed in all the treatments with increasing processing periods in this study. This is in agreement with the finding of Siddhuraju and Becker (2003), who reported reduction in anti-nutritional factors in mucuna seeds with different processing techniques. The results suggest that boiling for 90mins and soaking for 72hrs was the most effective processing method that significantly ($p<0.05$) reduced the phytic acid content. Boiling and soaking treatments observed in this study revealed no significant increase in the crude protein contents of the treated seed. This is contrary to the findings of Mbah *et al.* (2012) who reported increase in protein. The three toasting treatments in this study significantly ($p<0.05$) increased the crude protein contents of the Moringa seed compared with the other treatments. The fat content of the untreated moringa was lower than the value (42%) reported by Ogunsina *et al.* (2011) and higher than 30.36-35.20% observed by Anwar *et al.* (2006) for moringa seed meal. The fat content was also higher than the values reported for other oil seeds, melon seeds (17.36-25.06%) (Ebuchi and Avwobobe 2006).

The significant ($p<0.05$) increase in the protein content in the treated and defatted seed meal recorded in this study could be as a result of the displacement of oil from the seed thereby increasing other parameters. Robinson *et al*. (2001) reported that feed ingredients with crude protein greater than 20% are considered as protein source which qualifies *Moringa oleifera* meal as an alternative protein source. The result further indicates that oil extraction had significant ($p<0.05$) influence on crude protein yield of *Moringa oleifera* seed meal. The crude protein content in the treated and defatted seed meal was relatively higher than the value reported for Moringa cakes after oil extraction (Govardham *et al*., 2013). There was a significant reduction in the fat content of seed meal after oil extraction and this is in tandem with the finding of Govardham *et al*. (2013). This study shows that boiling for 90min and soaking for 72hrs effectively reduce the anti-nutrients to safe levels and revealed the high nutrient profile of *Moringa* seed meal.

WSSV RISK FACTORS OF SHRIMP FARMING IN BANGLADESH: STATISTICAL MODEL-BASED ASSESSMENT

Neaz al Hasan*, Mohammad mahfujul Haque

Department of Aquaculture, Bangladesh Agricultural University, Mymensingh, Bangladesh
E-mail: nah.goldfish@gmail.co

Background
White Spot Syndrome Virus (WSSV), a deadly disease constitutes the main cause of massive mortality in shrimp farming of Bangladesh resulting in huge economic loss every year. Disease prevalence as opposed to virus presence is however uneven, and may be partially dependent on a range of farm management, physical pond parameters and other factors. In this study of 233 farms in South-Western Bangladesh where there range of pond types, culture techniques and farming practices exist in relative close proximity, were surveyed to generate a dataset on relevant variables. A group of potential factors contributing to WSSV prevalence was first analyzed using a univariate logistic regression analysis to identify key variables and then reanalyzed using a multivariate logistic regression analysis following a maximum model to establish incremental risk factors.

Methods
Four categories of data (site/farm characteristics, environmental variables, disease history, and management variables) with associated risk factors were selected following a conceptual framework and participatory rural appraisal tool. Association of the selected factors with WSSV prevalence was examined using log likelihood ratio tests for a univariate analysis and a maximum model following the continuous removal for a multivariate analysis.

Findings
From the surveyed category, extensive farms (65.57%) were more prone to WSSV than that of the semi-extensive (23.81%) one. In both categories of the farm a wide range of variables from site/gher characteristics to management practices act to prevalence and/or transmit the disease within or between the farms. Rice and other cropland converted (63.31%) to large shrimp farms with the possession of loamy soil (71.33%) were more vulnerable to WSSV. WSSV prevalence was also common irrespective of the farm operation because of indiscriminate use of mixed fertilizers (79.41%) and chemical for pond preparation (95%) as well as water treatment. The maximum farmers were found not interested in using aerator, drying the gher, sludge removal, and proper dike repairement after each crop to minimize the production cost. However, these all accelerate the WSSV outbreak in the amalgamated and interconnected shrimp farms. Under the domain of 'water and culture management' different impecunious practices like perilous source of water, frequent water exchange within and between the farms, absent of reservoir, introducing water via other farms and vague source of atrocious PL were also responsible for unexpected occurrence of WSSV. In some farms, WSSV was linked with the usage of adulterated feed and poor biosecurity system. Farms operated by the tenant worker (p: 0.03), mixed use of fertilizer (p: 0.009), indigent water source (p: 0.001), absent of reservoir for water purification (p: <0.001), and frequent exchange of water between a single crop culture (p: <0.001) were significantly associated with either WSSV prevalence index in the multivariate analysis.

Interpretation
Maintaining good biosecurity, feed management, good culture practice, and managing the farm characteristics will not be sufficient on their own to control WSSV prevalence. Improving some features of site/farm management variables, safe source of water, controlled exchange of water and maintaining constant salinity are necessary to reduce WSSV prevalence.

IRRADIATION USING MIDDLE- TO LONG-WAVELENGTH LIGHT INDUCES OVEREXPRESSION OF *GSDF* AND MALE-SPECIFIC GONADAL DIFFERENTIATION IN GENETIC FEMALE MEDAKA (*Oryzias latipes*)

Introduction

Environmental factors such as high temperature, low pH, and rearing density affect gonadal differentiation in fish (Devlin and Nagahama, 2002). Lighting conditions also play an important role in regulating physiology in fish. While the effects of irradiation with specific wavelengths on the growth and reproduction in fish have been demonstrated, their effects on sex differentiation have not been demonstrated. Our previous study demonstrated that green light induces female-to-male sex reversal in medaka (Hayasaka et al., 2019). In the present study, we developed the method further by selecting green light-mediated sex-reversed fish at an early developmental stage and evaluated how light wavelength affected their gonadal differentiation.

Materials and methods

Strain d-rR-Tg (*olvas*-GFP) (Strain ID: TG141) of the medaka (*Oryzias latipes*), supplied by NBRP Medaka (https://shigen.nig.ac.jp/medaka/), was used in this study. Newly hatched medaka larva were irradiated with light at 450nm (white), 462nm (blue), 518nm (green), or 623nm (red), from 0 to 15 days post hatching (dph). The phenotypic sex of the fish was determined by gonad size via GFP fluorescence. Genotypic sex was determined by presence/absence of the sex determination gene *DM domain gene on the Y chromosome* (*dmy*) in genomic PCR. Total RNA was extracted from the phenotypically and genotypically identified fish and performed to real-time PCR for quantification of *gonadal soma derived factor* (*gsdf*).

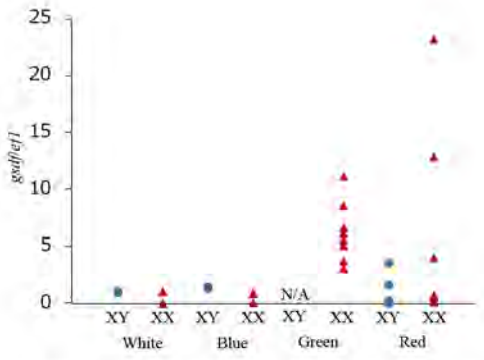

Figure 1. Expression of *gsdf* in fish at 15dph from each LED treatment. XY/XX indicates genetic sex. Each treatment used 3–10 samples.

(Continued on next page)

Results

Gonadal fluorescence clearly demonstrated sexual dysmorphia in the fish at 15dph. The appearance rate of neo-males (male-specific-gonad $dmy^{-/-}$) was higher under green (39%) and red (38%) light treatments than under white (9%) and blue (16%). Moreover, the expression of *gsdf* was high under green and red light treatments (Fig. 1). Notably, XX fish showed higher levels of *gsdf* expression than XY fish under green and red light treatments, especially in genotypic XX fish (Fig. 1).

Discussion and conclusion

The present study showed that sex-reversed fish was successfully detected at 15dph. The rearing trial demonstrated that middle- to long-wavelength (green and red) light induced high expression of *gsdf* and increased the appearance rate of sex-reversed fish. We concluded that irradiation using middle- to long-wavelength light induces masculinization of medaka in the early developmental stage, with fish at 15dph undergoing sex reversal as shown by gene expression and gonadal differentiation. Further research is necessary to clarify the significance of cortisol in the sex-reversal.

Introduction

Increasing intensification of aquaculture has produced higher yields but also higher incidences of disease (Garza et al, 2019), a problem that may be linked to overuse of antibiotics (Watts et al, 2017). In this paper we use questionnaire data from farmers in Bangladesh who are cultivating *Oreochromis niloticus* in ponds using a polyculture method. We examine farming practices to attempt to understand how they may influence disease presence in the ponds

Methods

To gather information about farming practices a questionnaire was performed in the north-central region of Bangladesh in 2018. Data cleaning and data analysis was performed on the results using R and R Studio (RStudio Team, 2016).

Results

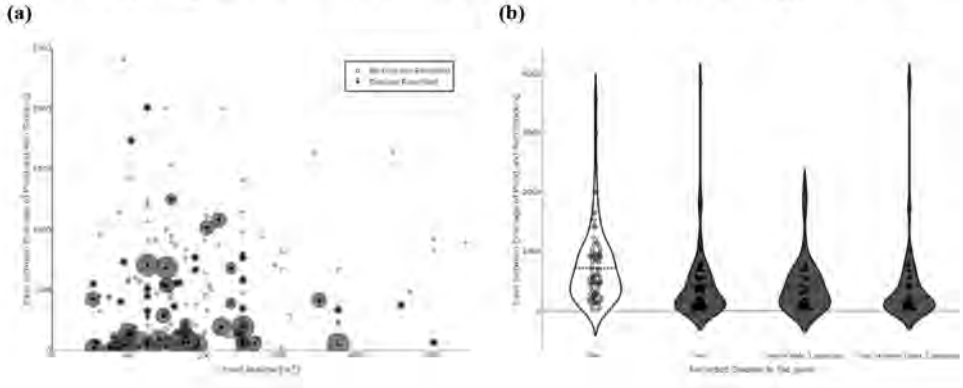
Overview of disease in ponds. From the survey the ponds performing polyculture of *O. niloticus* in Bangladesh had a mean surface area of 3000m^2 and an overall mean stocking density of 6.8 fish per m^2 (Table I). 43% reported signs of disease during production and of these 43% reported disease in tilapia, 54% in pangasius and 44% in carp. Disease was reported in more than 1 species of fish in 20% of the ponds, nearly half (48%) of those ponds that reported disease presence.

Analysis of stocking densities in ponds with recorded diseases. There was no significant difference in mean pond surface area, mean pond volume or overall stocking density (6.95 fish. $^{-2}$ in ponds with disease versus 6.54 fish. $^{-2}$) for those ponds that recorded disease and those that did not. However, the mean stocking density of tilapia was significantly lower in ponds with recorded disease (2.70 fish. $^{-2}$) than those with no recorded disease (3.38 fish. $^{-2}$; $p<0.05$, Kruskal-Wallis rank sum test (KWT)).

Table I *Pond details from survey. Values are mean values ± std.*

Surface area (m^2)	Water depth (m)	Stocking Density (Fish m^{-2})		Volume per fish (m^3)	Fingerling weight (g)		Ponds reporting disease (% of total)	
		Total	Tilapia		All	Tilapia	Any species	Tilapia
3000	1.51	6.72	3.08	0.29	53.5	16.1	43%	19%
±1877	±0.38	±4.28	±1.90	±0.15	±33.1	±19.5		

Figure 1.(a) Effect of recency of pond sludge removal on disease being recorded during production. Here the size of the bubble reflects the number of diseases recorded; (b) Violin plots of the recency of sludge removal and whether the pond had recorded disease during production.



(Continued on next page)

More recently drained ponds were more likely to report disease presence. How recent the pond had been drained and the sludge removed was determined by counting the number of days between the recorded last drainage/sludge removal date and the date that the main stocking of the pond occurred. Figure 1a shows no significant correlation between pond volume and recency of sludge removal ($r = 0.13$). However, this figure and the violin plots in Figure 1b reveal an association between recency of sludge removal and the recorded presence of disease. Ponds that recorded disease during the production cycle had significantly less days since sludge removal than those that did not record disease ($p<0.01$; KWT) and there was no significant difference between ponds recording disease in 1 species only and those recording disease in more than 1 species ($p=0.36$; KWT).

Association between the disease history of the pond and recency of sludge removal. Farmers reported how often disease was observed in their ponds. The responses were stratified into "Frequent" for yearly or more often; "Infrequent" for every 2 to 3 years; or "Rarely" for every 4 to 5 years. Ponds with a frequent occurrence of disease had sludge removed more recently than those that rarely encountered disease (455 versus 734 days) and the incidence of disease in these ponds was higher (84% versus 24%). Furthermore, those ponds that have regular water replacement (at least weekly) appear to have a higher incidence of disease than those where the water is exchanged monthly (56% versus 38%; $p<0.05$; $\square^2$ test); ponds that rarely had disease and where the water was replaced monthly had the lowest proportion of recorded disease and a mean recency of drainage of 880 days.

Discussion

Disease is a long-standing issue in aquaculture and may become a barrier to realizing aquaculture's potential (FAO, 2018). Our evidence suggests that the current overall stocking densities used in polyculture of tilapia in Bangladesh do not increase the likelihood of disease and there may be an opportunity to increase the stocking density of tilapia as this appears to be linked to lower disease prevalence at present.

Analysis of the farmers responses indicates a link between the recency of pond sludge removal and disease. This association may be due to sludge disturbance increasing the possibility of disease, or that ponds that suffer an outbreak of disease are more likely to have sludge removed before restocking, or a combination of both. There is evidence in our data for both processes. Ponds with a high disease incidence were drained more recently prior to stocking than those that rarely encountered disease, suggesting that after disease farmers drain ponds and then restock. However, ponds that rarely encounter disease, but reported disease during production, had sludge removed more recently. This suggests that the action of sludge removal may be linked to disease.

Overall our data suggests that removal of pond sludge does not act as an effective means of reducing disease. In the survey, only 9 ponds reported antibiotic use during production. With increased antibiotic use in fish farming (Watts et al, 2017) this may be due to underreporting, slow uptake or abandonment due to publicised antimicrobial resistance.

Introduction

Increasing food production from the aquaculture sector has been promoted to deal with declining capture fisheries production (FAO, 2018). For a LEDC increased aquaculture also improves food security and provides an additional income for local farmers. In some countries, such as Bangladesh, the sector has grown considerably resulting in intensification and higher yields but also higher incidences of disease (Garza et al, 2019). In this paper we use questionnaire data to compare aquaculture of tilapia in a country intensively farming Nile tilapia (*Oreochromis niloticus* in Bangladesh) with one subsistence farming red-breasted tilapia (*Tilapia rendalli* in Malawi). From this data insights are made about improving yields without increasing disease prevalence.

Methods

To gather information about farming practices a questionnaire was performed in the north-central region of Bangladesh and in 6 districts in Malawi in 2018. Data cleaning and data analysis was performed on the results using R and R Studio (RStudio Team, 2016).

Results

Bangladesh ponds have a larger surface area and a higher stocking density. Ponds culturing tilapia in Bangladesh have significantly larger surface areas than those in Malawi (Table I; 773% larger; $p < 0.01$; Kruskal-Wallis rank sum test (KWT)), have significantly greater densities of fish per m^2 (63% greater; $p<0.01$; KWT) but have a similar water depth ($p=0.35$; KWT). These results compare favourably with those of other studies (Alam et al 2012; Limuwa et al. 2018). Stocking density differences were not the result of polyculture with smaller fish as overall fingerling weight was larger in Bangladeshi ponds ($p<0.01$; KWT) with no difference in tilapia fingerling weights in the 2 countries ($p = 0.48$; KWT)

Table I *Aquaculture practices for tilapia. Unless indicated values are mean ± std.*

Country	Number of Ponds (monoculture)	Surface area (m^2)	Water depth (m)	Stocking Density (Fish m^{-2})	Volume per fish (m^3)	Fingerling weight (g)	
						All	Tilapia
Bangladesh	189(1)	2995 ±1873	1.51 ±0.37	6.79 ±4.67	0.290 ±0.158	53.2 ±33.2	16.1 ±19.5
Malawi	68(17)	343 ±224	1.65 ±0.41	4.16 ±1.89	0.471 ±0.230	10.0 ±6.51	8.94 ±4.64

Table II. *Harvest size and WLR of tilapia in Bangladesh and Malawi. Values are mean ± std (N).*

Harvest Parameter	Bangladesh	Malawi
Mean fish weight (g)	353±147 (189)	245±162 (64)
Mean fish length (cm)	16.6±2.6 (189)	18.6±6.0 (64)
WLR (gcm^{-1})	20.8±7.3 (189)	12.5±7.5 (64)
> median length	22.7±8.4 (95)	21.2±5.8 (33)
< median length	18.8±5.3 (94)	20.5±8.1 (31)
Farmer feed used	23.4±8.4 (16)	(as all tilapia)
Commercial feed	21.4±7.6 (112)	None
Antibiotics used	23.0±10.2 (9)	None
No antibiotics used	20.7±7.1 (179)	12.5±7.5 (68)
Mortality level 0-10%	19.3±6.0 (127)	12.5±7.5 (68)
Mortality level 10-20%	20.8±7.0 (33)	None
Mortality level >20%	27.0±9.4 (29)	None

(Continued on next page)

Nile tilapia show a higher weight to length ratio. Comparison of the weight-to-length ratio (WLR) of tilapia revealed a significantly larger mean WLR in Bangladesh compared to Malawi ($p<0.01$; Student's t-test (STT)) suggesting smaller and heavier harvested fish (Table II). Tilapia above median length in Bangladesh had a higher mean WLR than the smaller fish ($p<0.01$ STT) whereas in Malawi there was no significant difference. Analysis of food input in Bangladesh showed no significant difference in WLR between commercial and own food sources (Table II) and all the ponds in Malawi were fed using food from the farmer. As the amount or type of feed was not reported these factors cannot be completely ruled out. Further, use of antibiotics during production showed no significant increase in the WLR in Bangladesh (Table II; $p = 0.52$, STT).

A higher WLR may be associated with higher pond mortality. All ponds in Malawi reported a mortality level of 0-10% during production whereas in Bangladesh the overall level was 0-10% (67%), 10-20% (17%) and over 20% (15%) indicating a higher level of disease. The WLR for tilapia was found to be higher in those ponds in Bangladesh showing over 20% mortality ($p < 0.05$; STT) indicating that a higher WLR is associated with increased disease prevalence. In Malawi 52% of the ponds observed the presence of disease or parasites during production compared to just 43% in Bangladesh. Considering the increased level of mortality in these ponds this may indicate under-reporting of disease.

Discussion

A survey on tilapia pond aquaculture has indicated a more intensive practice in Bangladesh with larger pond surface areas, higher stocking densities and the almost universal use of polyculture; resulting in ponds with larger volumes of fish in each pond. By contrast, in Malawi ponds are smaller and form part of an integrated agricultural approach where nutrient recycling from farm wastes occurs (Brummett and Jamu, 2011). Fingerlings are sourced locally from farmers (only 4% from hatchery or NGO) and fed using pond primary productivity and added crop wastes. The different growth patterns observed may reflect the different species of tilapia being cultured although previous studies have indicated a higher growth rate in *T.rendalli* (Nyirenda, 2017) not seen in our results. Using commercial fish feeds, increasing stocking densities or using faster growing fish to increase yields should be treated with caution according to our results. These did not affect the harvest weight to length ratio (WLR) of either species and a higher WLR was linked to higher mortality levels in *O.niloticus*. At present aquaculture in Malawi uses little antibiotics (none reported in our survey) and with problems of antibiotic overuse in aquaculture care must be taken when driving intensification of aquaculture

THE INFLUENCE OF STRUCTURE ORIENTATION TO WATER CURRENTS AND WAVES AND THE EFFECT OF WATER DEPTH ON STRUCTURAL STRESS AND SHELLFISH RETENTION IN EXPOSED OCEAN ENVIRONMENTS

Kevin Heasman*, Malcolm Smeaton, Nicholas Scott and Bela H. Buck

*Cawthron Institute, Private Bag 2, Nelson, 7010, New Zealand
Kevin.heasman@cawthron.org.nz

Exposed ocean farming is developing around the world. In New Zealand there is over 10 000 ha of exposed ocean space permitted for shellfish and seaweed farming. The structures which allow for the efficient farming of these exposed sites are developing but generally are in their early stages. The Cawthron Institute in New Zealand has a government funded (Ministry of Business, Innovation and Employment) program designing new shellfish and seaweed structures for exposed ocean sites. This program is assessing several innovative structures by numerically modelling them (using SolidWorks and OrcaFlex), testing scaled down models of them in wave basins and deploying full scale prototypes in the ocean.

Two features that have become very obvious during the assessments of structures with multiple moorings are: (1) the importance of the structures' orientation to waves and water currents and (2) the consequence of the water depth in which they are deployed.

Using a generic structure, the influence and importance of these two factors will be shown and discussed for surfaced and submerged systems in both deeper (50 m) and shallow (20 m) sites.

Introduction

Light influences the entire life cycle of many fishes from embryonic development to sexual maturity (Downing and Litvak, 2001). Several studies have been carried out to investigate fish cultivation under different light intensities (Luchiari et al., 2006, Kozlowski et al., 2010). In recent years, wavelength (light colour) has also increasingly become the focus of research (Luchiari et al., 2009). Previous studies showed that pikeperch prefer low light intensities and grow better under such conditions (Luchiari et al., 2006, Kozlowski et al., 2010). Luchiari et al. (2009) demonstrated that individually reared juvenile pikeperch showed better growth performances under red light compared to fish reared under other light colours (i.e. white, blue, green, yellow). The aim of the present study is to examine the effect of light colour on the performance parameters of pikeperch under production conditions.

Material and methods

A study series with three trials is currently conducted. In the first trial, the light colours red (650nm) and white (4400K) were compared and results are presented for this trial. A second trial during which the colours blue (450nm) and white are examined is currently in progress. In a third trial, all three light colours will be compared in a single study to verify the previous results. Trial two and three will be completed until summer. In the first trial, each four tanks per light colour were stocked at a mean biomass±SD of 31.00±0.26kg. Individual mean weight±SD of pikeperch was 401.32±28.70g. Light intensity was kept at 45 µmol/m²/s. Fish were reared for 5 weeks. After this period, 10 individually marked fish from each tank were sacrificed, measured for total length and weight and the total biomass in each tank was assessed to compare biomass gain, specific growth rate (SGR), absolute growth rate (AGR), Fulton's condition factor (K), coefficient of variation (CV), the gonadosomatic index (GSI), the viscerosomatic index (VSI) and the hepatosomatic index (HSI) among treatments.

Results

Growth was similar between fish reared under red and white light conditions as indicated by similar SGR and AGR (Table 1). Likewise, there was no difference in growth homogeneity between the two light colours as indicated by similar CV (Table 1). Furthermore morpho-anatomical indices (i.e. VSI and HIS) and the gonadal development (i.e. GSI) were not significant di ferent between fish reared under red and white light conditions (able 1).

Table 1: Specific growth rate (SGR), absolute growth rate (AGR), coefficient of variation (CV), Fulton's condition factor (K), gonadosomatic index (GSI), viscerosomatic index (VSI) and hepatosomatic index (HSI) of fishes reared 5 weeks under red and white lighting conditions.

Colour	Red	White	F	df	p
SGR [% d^{-1}]	0.45±0.11	0.51±0.14	0.124	6	0.520
AGR [g d^{-1}]	2.03±0.57	2.31±0.68	0.045	6	0.552
CV	9.40±1.55	9.44±3.60	2.112	6	0.981
Fulton's K	0.78±0.02	0.79±0.04	1.599	6	0.870
HSI [%]	0.87±0.14	0.97±0.05	4.366	6	0.520
GSI [%]	0.75±0.55	0.39±0.16	1.976	6	0.214
VSI [%]	3.07±0.54	3.46±0.75	0.072	6	0.463

(Continued on next page)

Discussion and conclusion

No difference between red and white light on pikeperch performance under production conditions was observed. Small-scale studies showed that red light improves the growth of juvenile pikeperch (Luchiari et al., 2009, Baekelandt et al., 2018). Possibly, the contradictory results are an indication of social hierarchy effects under production conditions (Luchiari et al., 2009).

MICROALGAE CELL WALL RUPTURE WHEN INCORPORATED INTO FISH FEED: EFFECT ON SEA BASS *Dicentrarchus labrax* PERFORMANCE

M.D. Hernández*, A. Álvarez, R. Alcaraz, A. Hernández-Contreras

IMIDA-Aquaculture. Carretera del puerto s/n, 30740, P.O. Box 65, San Pedro del Pinatar, Murcia, Spain

Introduction

The incorporation of microalgae as a substitute for fishmeal or fish oil in fish feed has been studied for decades, since they can improve the nutritional value of fish feed thanks to its chemical composition and the large number of bio-active compounds they contain. The results obtained to date are not clear in terms of growth and intake, and the latter has even been reduced by a supposed problem of palatability (Walker & Berlinsky, 2011). Despite the abundant research on the subject, many of these studies do not address the effect of the different microalgae processing systems prior to their incorporation into diets. In this sense, the rupture of the cell wall of microalgae has attracted the interest of researchers and companies, in view of the studies and the existing patents on it (Prabakaran and Ravindran, 2011; US9358553B2, 2016), having the majority of them the main objective of extracting their oils for industrial purposes. The effect of cell breakage on the digestibility of a great variety of nutrients has been studied in salmon (Tibbetts et al., 2017). However, its effect on performance parameters such as growth or feed conversion has not been studied, despite the predictability of greater bioavailability of nutrients. More specifical y, there is no information on this in mediterranean marine fish, so the objective of this study is to evaluate the effect of cell wall rupture on the main productive performance parameters of seabass *Dicentrarchus labrax*.

Materials and methods

525 juvenile seabass (*Dicentrarchus labrax*) were acclimated at the IMIDA Marine Aquaculture Station, with an initial mean weight of 28.0 ± 4.1g. They were homogeneously distributed in 15 tanks of 612 l that form part of a closed recirculating seawater system, in groups of 35 animals. Five isoproteic and isoenergetic diets were tested in triplicate: Diet 1 (basal diet); Diet 2 (basal diet with 10% of unaltered *Tetraselmis chuii*); Diet 3 (basal diet with 10% *T. chuii* with broken walls); Diet 4 (basal diet with 10% unaltered *Nannochloropsis gaditana*); Diet 5 (basal diet with 10% *N. gaditana* with broken walls). The water temperature was maintained at 23 ± 1 ° C, the photoperiod at 12:12 (L: D), and the dissolved oxygen above 80%. Fish were fed twice a day to apparent satiety. The intake of the animals was monitored daily and the weight of the animals was measured at the beginning and at the end of the experiment. The specific growth rate (SGR), the specific feeding rate (SFR) and the feed conversion rate (FCR) were calculated from these data. The data were compared by means of a one-way ANOVA and the significant di ferences between the means were analysed by the Tukey test.

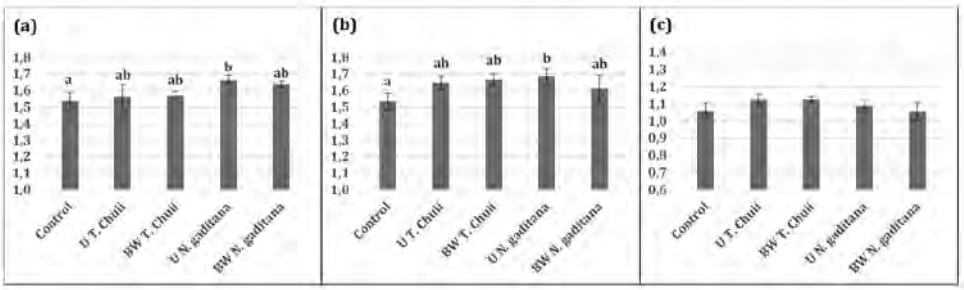

Figure 1. Specific growth rate (SGR), specific feeding rate (SFR) and feed conversion rate (FCR) of seabass (*Dicentrarchus labrax*) fed with experimental diets: Control (basal diet), U *T. chuii* (diet with unaltered *T. chuii*), BW *T. chuii* (diet with *T. chuii* with broken walls), U *N. gaditana* (diet with unaltered *N. gaditana*), BW *N. gaditana* (diet with *N. gaditana* with broken walls).

(Continued on next page)

Results

All diets were well accepted by the fish, being the specific feeding rate (SFR) between 1.53 and 1.69. The group fed with the diet containing unaltered *N. gaditana* showed a higher growth, being the weight gain (WG) (data not shown) and the specific growth rate (SGR) significantly higher than in the control group. The rest of the groups fed with diets containing microalgae also showed a tendency to improve growth although without significant differences. This improvement in growth was associated with higher relative feeding rates (SFR), so the conversion rate was similar, not observing significant differences in it (Figure 1).

Discussion and conclusion

The results contributed by this study can help to design a strategy for the incorporation of microalgae in commercial diets for mediterranean fish, since there is no information on the effect of this type of pre-treatment on these fish species. The results suggest that the treatment to break the cell wall is not able to improve performance parameters of seabass. However, greater bioavailability of nutrients has been demonstrated, including omega-3 long chain polyunsaturated fatty acids after cell breakage (Lemahieu et al., 2016). In addition, cell wall rupture maintains nutrient digestibility to higher levels of inclusion (30%) (Tibbetts et al., 2017).

In conclusion, the results obtained in this study suggest an improvement in the performance of seabass due to the incorporation of these microalgae species, but which does not depend on cell wall rupture. The effect of cell wall rupture on aspects of fish nutrition has been studied with *Chlorella vulgaris* but not with *T. chuii* or with *N. gaditana*, so these results are important for the design of diets containing these microalgae as ingredients. However, it would be interesting to study how this treatment affects the digestibility of the main nutrients in Mediterranean fish diets and other aspects such as the oxidative status or the immune system of fish

VALORIZATION OF AGRI-FOOD INDUSTRY BY-PRODUCTS THROUGH THE PRODUCTION OF INSECT MEAL: "VALORAGRIN" PROJECT

A. Hernández-Contreras*, G.I. Mita, R. Alcaraz, M.D. Hernández

IMIDA-Aquaculture. Carretera del puerto s/n, 30740, P.O. Box 65, San Pedro del Pinatar, Murcia, Spain
*E-mail: angel.hernandez8@carm.es

VALORAGRIN project started in January 2018, being the execution period of 48 months. It is a coordinated project funded by the European Union and regional authorities through RIS3 strategy, with the participation of research institutions, agri-food industry companies, and universities, forming a broad consortium. The general objective of the project is the evaluation of a new process of transformation of by-products and agri-food residues that allows its valorization through the production of insect meal or its high added value by-products. To this end, pilot experiments will be carried out with by-products of agro-food industries as substrates for the cultivation of insects, new knowledge will be acquired for the application of insect meal and its derivatives as raw material in aquaculture feed and, finall , new applications will be designed for the fertilizer generated during the insect culture. This whole project is based on the principles of sustainability, process optimization, revaluation and recycling.

Justification

The inclusion of insect meal in animal diets has already been the subject of research and a great investment worldwide for more than a decade. It is easy to verify the continuous growth of publications in this regard and the involvement of entities of great importance such as the European Commission. The latter recently drafted a regulation in this regard (Commission Regulation 2017/893 of May 24, 2017) which establishes the conditions for the use of insect meal in animal feed. In addition to this, important companies in the fish feed sector worldwide have issued on insect meal utilization in aquaculture, describing them as a "feasible alternative with numerous environmental, health and nutritional benefits" (Alex Obach, Skretting ARC). Despite promising results a priori for its exceptional nutritional profiles, its ability to supply and reuse organic waste, and the apparent influence on the immune system of fish, in-depth research is necessary to accurately determine the viability of these insect meals as a substitute for fishmeal

At the same time, other industries are focusing their attention on the cultivation of insects, both because of their potential as food and because of their ability to recycle by-products and waste. The agri-food industry is of great importance in the south of Europe due to the climate and the availability of land. However, the great development of this industry leads to an increasing production of by-products that are difficult to recycle and could be re-valorised when used as substrates for the cultivation of insects. Therefore, the cooperation of the agri-food and aquaculture industries can provide synergistic solutions promoting the circular economy and environmental sustainability.

Objectives

The main objective of the Project is the evaluation of a new process of transformation of by-products and agri-food residues that allows its valorization through the production of insect meal or its high added value by-products. Partial objectives are as follows: 1. Design the appropriate pretreatments to transform the by-products and residues of the agri-food industry into substrates intended for the cultivation of insects. 2. Acquire new knowledge for the application of insect meal and its derivatives as raw materials in aquaculture feed. 3. Design new specifications and applications for the fertilizer generated during the cultivation of insects.

Work Plan and Consortium

The work plan is divided in 3 work packages divided in several tasks and sub-tasks, WP2 and WP3 will be carried out simultaneously once the insect system culture is designed.

WP1. Insect culture design at pilot scale.

Task 1.1. Design of the insect cultivation system to be tested.

Task 1.2. Evaluation of by-products and waste destined for the cultivation of insects.

Task 1.3.Determination of the necessary pre-treatments for the recovery of by-products and residues through the cultivation of insects.

WP2. Design of an insect meal from by-products of vegetable origin intended for aquaculture.

Task 2.1. Design of the composition of a substrate formed by different vegetable by-products that improves the performance of insect production.

(Continued on next page)

Task 2.2. Determination of the effect of the inclusion of insect meal produced from vegetable substrates in the diet of fish
Task 2.3. Life cycle analysis of the production of insect meal for aquaculture.
WP3. Valorization of substrates of non-vegetable origin through the production of insects.
Task 3.1. Analysis of the viability of the production of insect meal from substrates of non-vegetable origin destined for the foreign market.
Task 3.2. Demonstration of fertilizer production from substrates of non-vegetable origin.
Partners:
Alimentos del Mediterráneo, S.Coop. (ALIMER): plant by-products and fertilizer tests.
Grupo Alimentario De Lorca, S.L. (LACOMARCA): Animal by-products. Insects fed with these by-products will not be used in feeding of fish (EU Regulation)
Estrella de Levante Fábrica de Cerveza, S.A. (ESTRELLA): by-products of beer production.
Juan Jiménez García, S.A.U. (JISAP): slurry and manure from pork production.
Catholic University of Murcia (UCAM): experimental tasks with insects and substrates.
Entomo Agroindustrial (Subcontracting by UCAM): pilot plant and technology transfer.
IMIDA (Agrarian and Food Research and Development Institute of Murcia): The Aquaculture Research Group is dedicated to applied research in aquaculture and will carry out fish nutrition experiments

Acknowledgment
VALORAGRIN project is funded by the regional government of Murcia through the Regional Research and Innovation Strategies for Intelligent Specialization (RIS3), promoted by the European Commission.

EFFECT OF INCREASING DOSES OF *Nannochloropsis gaditana* ON THE IMMUNE SYSTEM OF GILTHEAD SEABREAM *Sparus aurata*

A. Hernández-Contreras*, M.A. Esteban, A. Álvarez, M.D. Hernández

IMIDA-Aquaculture. Carretera del puerto s/n, 30740, P.O. Box 65, San Pedro del Pinatar, Murcia, Spain

Introduction

The incorporation of microalgae in fish feeds has been studied in recent years with several objectives: mainly as an alternative source of protein and omega-3 long chain polyunsaturated fatty acids but also as a probiotic or as a source of immunostimulant compounds. Despite the great quantity and quality of nutrients and immunostimulant compounds they contain, the results in nutrition have not been definitive and the immunostimulating effects depend on the species used. Some species such as *Tetraselmis chuii*, *Phaeodactylum tricornutum*, *Navicula* sp. or *Chlorella* sp. have been shown to improve the immunological status of fish (Cerezuela et al., 2012; Reyes-Becerril et al., 2013; Zhang et al., 2014).

The microalga *Nannochloropsis gaditana* has shown positive effects on the immune system of gilthead seabream in doses of up to 10%. Despite of this, it has not been studied as an immunostimulant at higher doses that may be viable in more sustainable feeds with high levels of fishmeal and fish oil substitution. Based on the above, the objective of this work was to study the effect of the incorporation of increasing levels of *N. gaditana* in gilthead seabream diet, on its humoral and cellular immunity.

Materials and methods

450 gilthead seabream (*Sparus aurata*) were randomly distributed on fifteen tanks and fed with five diets (three replicates by diet): standard diet (control), or standard diet supplemented with microalgae *N. gaditana* at 2.5, 5, 10 and 15%. At the end of the experiment fish were killed and blood and head kidney samples were taken for immunological analysis. The blood samples were left to clot and later the serum was collected after centrifugation. Leucocytes were isolated from head kidney samples and used to determine the respiratory burst, peroxidase and phagocytic activity of leucocytes. Serum samples were used to evaluate the peroxidase activity and IgM levels. Samples of liver and intestine were processed for light microscopy analysis. The data were compared by means of a one-way ANOVA and the significant differences between the means were analysed by the Tukey test.

Results

In terms of cellular immunity, a general increase in the percentage of phagocytic cells was observed in fish fed with microalgae diets, being significant in the group fed with 15% microalgae (Figure 1-A). However, no statistically significant differences were observed in phagocytic capacity (Figure 1-B). Leukocyte respiratory burst activity also showed no significant differences (Figure 1-C). Peroxidase activity was significantly higher in leukocytes from fish fed the diet with 10% microalgae (Figure 1-D).

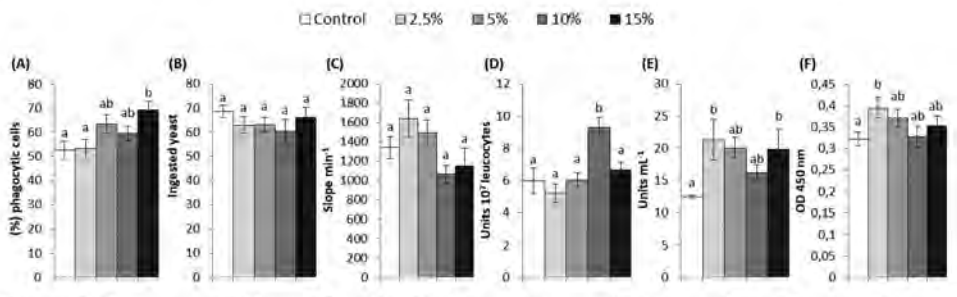

Figure 1. Percentage of phagocytic cells (A), phagocytic capacity (B), respiratory burst activity (C), leucocyte peroxidase activity (D), serum peroxidase activity (E), serum IgM level –450 nm absorvance–(F) in *Sparus aurata* fed with diets containing increasing doses of *N. gaditana* (colour legend).

(Continued on next page)

Regarding humoral immunity serum peroxidase activity was significantly higher in fish fed diets containing 5 and 10% microalgae (Figure 1-E). The immunoglobulin M (IgM) levels in serum increased significantly in the serum of the fish fed with 2.5% microalga, showing a tendency to increase with the rest of the microalgae diets (Figure 1-F). All histology slides from gilthead seabream liver and intestine showed a normal histological pattern from a healthy situation with any of the treatments.

Discussion and conclusions

These results suggest that the incorporation of *N. gaditana* in the diet of sea bream has a certain immunostimulating effect. Other authors have also observed an immunostimulant effect at a dose of 5 and 10% (Cerezuela et al., 2012), which in our case is only the optimal one regarding peroxidase activity in leukocytes -not previously studied-. In general, the main immunostimulant effect at the cellular level can be observed in the percentage of phagocytic cells at high doses (15%) and at the humoral level in the peroxidase activity and in the level of serum IgM. Based on these results, it would be interesting to perform viral, bacterial or parasitic challenges to get a more definitive approach

In conclusion, the incorporation of the microalga *N. gaditana* promotes certain immune activity both at the cellular level and at the humoral level, with the optimal dose being different depending on the parameter studied.

Introduction

Algae constitute a heterogeneous protein source, taking into consideration the vast group of species available, and hence, the actual utilization of the protein contained in a given algae biomass can't be predicted easily. Indeed, great differences in algae cell wall composition, thickness, and structure have been reported, and thus, reasonable doubts might arise related to their digestibility and amino acid bioavailability owing to such disparity. In the last years numerous studies have assessed their potential as dietary protein ingredient in practical diets for different fish species (Vizcaíno et al. 2019). However, to our knowledge, little research has been reported about the way digestive enzymes of fish hydrolyzes algal protein (Tibbetts et al. 2017), and particularly to our knowledge, scarce research has been reported about the rate and extent of the hydrolysis of algae by digestive enzymes of turbot. The aim of this work was to assess the *in vitro* hydrolysis of *Arthrospira platensis* (cyanobacteria), *Chlorella vulgaris* (microalgae), and *Ulva compressa* and *Ulva rigida* (macroalgae) by the digestive proteases of juvenile turbot (*Psetta maxima*).

Materials and methods

The *in vitro* hydrolysis of the algae biomass was carried out in 10mL-jacketed reaction vessels connected to a circulating water bath maintained at a constant temperature of 25°C, under continuous agitation by a magnetic stirrer. For each assay, a known amount of each alga species, providing 80mg crude protein, was suspended in 50mM Tris HCl buffer pH 9.0. After 15min stirring, the protein hydrolysis was initiated by the addition of a previously calculated volume of the turbot digestive enzymatic extract comprising 600U of total alkaline proteolytic activity. The susceptibility of algae protein to be hydrolysed by fish digestive enzymes has been assessed by sequential characterization of the hydrolysis products using sodium dodecyl sulphate polyacrylamide gel electrophoresis (Vízcaíno et al. 2019). Total released amino acids at each sampling time were quantified spectrophotometrically at 340 nm using L-leucine as standard. In addition, total reducing sugars released from microalgae were evaluated using the dinitrosalicylic acid (DNS) method.

Results and discussion

Results obtained evidenced that turbot digestive proteases hydrolyse algae protein (figure 1). Overall, turbot proteases are able to release from 28 to 50% of the total amino acids contained in algae protein after 120min of *in vitro* hydrolysis (figure 2). *Arthrospira* and *Chlorella* showed the highest accumulative values of free amino acids released, 50 and 44%, respectively. The lowest values were obtained in macroalgae, 27 and 31% for *U. compressa* and *U. rigida*, respectively. In this case, the lower protein content and the complex cell wall structure in macroalgae might reduce the accessibility to cleave peptide bonds by turbot digestive proteases. However, these values were similar to those obtained for fishmeal, plant proteins, and even microalgae using similar *in vitro* assays with fish digestive enzymes (Sáenz de Rodrigáñez et al. 2011; Vizcaíno et al. 2019). The amount of glucose equivalents released during the digestive simulation never reached more than 4 g of glucose per 100 g of algae biomass. It was evidenced a negligible contribution of fish digestive carbohydrases but values obtained for macroalgae were lower compared to *Arthrospira* and *Chlorella.*

Conclusions

The results obtained confirmed that algae are potential ingredients for feeding turbot, although the suitability of these algae as feed ingredient in this fish species should be tested by means of *in vivo* feeding trials.

INSECTS IN AQUACULTURE FEEDS: CURRENT STATUS AND SWOT ANALYSIS

G.I. Mita, A. Hernández-Contreras, R. Alcaraz, M.D. Hernández*

IMIDA-Aquaculture, Carretera del puerto s/n, 30740, P.O. Box 65, San Pedro del Pinatar, Murcia, Spain
*E-mail: mdolores.hernandez6@carm.es

Introduction:
Since the beginning of the so-called ¨blue growth¨, the increase in the use of fish oil and meal has become a concern. Oceans have shown not to be an inexhaustible source of fishery resources, as a result, its bio-availability is lowest day by day and its costs also increases, so, for aquaculture industry represents a challenge in terms of its sustainability and their public image. In this sense, efforts in the search for alternative sources have increased, especially the use of insects. From industrialization to its use in feed for aquaculture have shown its benefits, but also their difficulties able 1).

Overview:
Interest on the use of insects for aquaculture feeding was described more than 50 years ago, it was concluded that silkworm might be an important component in diets of carp in Japan and China. Later, in the 1980s, were carried out studies with silkworm in complete diets and substitution of fishmeal for Hybrid Carp (*catla-rohu*) and the use of *Hermetia illucens* in the diet of *Ictalurus punctuatus* and *Oreochromis sp*. (Henry et al., 2015).

Even though these trials based on unprocessed larvae, these proved to be suitable for feeding fish, other nutrition features (e.g. amino acid profile, fatty acid profile), or technologies (e.g. extruded, among others feed use) were not referred to, or, in the case of aquatic species under investigation, digestibility test, utilization of nutrients or their nutritional composition or sensory analysis.

The use of insects as feed in aquaculture has taken more interest from 2010, studied in species of commercial inclination as *Carassius auratus, Clarias anguillaris, Clarias gariepinus, Dicentrarchus labrax, Ictalurus punctatus, Orcorhychus mykiss, Oreochromis niloticus, Pagellus bogaraveo, Psetta maximum, Salmo salar and Sparus aurata* in nutrition, molecular biology, immunology, histology and economics trials (Makkar et al., 2014; Henry et al., 2015; Gasco et al., 2018; Halloran et al., 2018).

Table 1. SWOT analysis of the use of insects for feeding in aquaculture.

Weaknesses. -Its high lipid levels make it difficult for feed formulation, pellet stability and storage when using the full insect or non-defatted meal. -Anti-nutritional factors: chitin. -High inclusion levels affect the sensory quality and decrease PUFAs omega 3 and 6 in fish fillet (Gasco et al., 2018).	**Threats.** -Recent interest may be subject to legislative and policy changes and can affect its sustainability and generate an uncertain scenary. -Currently, insect flour prices ($ 5-10/kg) are higher than the fish (2.37 €/ kg) (www.allaboutfeed.net.).
Strengths. -It requires little land and water for cultivation. -Possibility of using agricultural, urban, or industrial by-products as substrates for the breeding of insects. -Easy management of organic waste, transforming 3 t into 150 kg crop / dry matter. -Its protein and lipid level is high, varies according to insect species, biological stage and substrate. -Insects are part of natural diet in carnivorous fish, (Diener et al., 2009; Gasco et al., 2018)	**Opportunities.** -Regulation EU 2017/893, allows the use of insects and animal feed that contains them for aquaculture. -Sets to black soldier fly (*Hermetia illucens*), common fly (*Musca domestica*), mealworm (*Tenebrio molitor*), bed beetle (*Alphitobius diaperinus*), domestic cricket (*Acheta domesticus)*, striped cricket (*Gryllodes sigillatus*) and bicolor cricket (*Gryllus assimilis*) as suitable for feed in aquaculture species.

(Continued on next page)

What strategies can be applied to reduce these difficulties?

The combination of insect meal with by-products of other animal products such as meat, bone, or blood meal, besides to the combination in diets or use as substrate for cuts, rendered and fish offal have shown comparable results to the diets with fish meal or in some cases higher in terms of growth performance and nutrients utilization in the fish On the other hand, technology for the transformation of insects like deffated meal, protein extract, oils, chitin and Chitosan has shown to fix feed quality and nutritional aspects.

Also, adequate finishing-diets based on fish meal and fish oil for short periods of time in insect meal-fed fish, has demonstrated to promote a rapid return on their levels of essential fatty acids. These strategies must be validated by identifying if there are differences or not in terms of sensory quality.

It was found that chitin reduces digestibility and nutrients utilization from fish fed with insects. However, also has been observed that carnivorous fish have the ability to degrade by digestive enzymes (chitinases). On the other hand, their inclusion has demonstrated immuno-stimulants effects, so it is of interest for the development of functional feed.

Widely variability in nutritional composition was found in insects and new species are investigated to known if can satisfy nutritional requirements of fish around the world. Is the case of silkworm, which has one of the highest levels of protein, amino acids and fatty acids, depending on the substrate that is given to them (e.g. fish offal), compared to other species of insects. Studies on fish have shown good results of digestibility, growth and nutrients utilization in diets to replacement levels from 38% to 100% fishmea (Makkar et al., 2014).

MICROALGAE CELL WALL RUPTURE WHEN INCORPORATED INTO FISH FEED: EFFECT ON SEA BASS *Dicentrarchus labrax* PERFORMANCE

M.D. Hernández*, A. Álvarez, R. Alcaraz, A. Hernández-Contreras

IMIDA-Aquaculture. Carretera del puerto s/n, 30740, P.O. Box 65, San Pedro del Pinatar, Murcia, Spain
*E-mail: mdolores.hernandez6@carm.es

Sea bass (*Dicentrarchus labrax*) were fed for 8 weeks in a seawater recirculation circuit. Five experimental diets in triplicate were used: Diet 1 (basal diet); Diet 2 (basal diet with 10% of *Tetraselmis chuii* complete); Diet 3 (basal diet with 10% *T. chuii* with broken walls); Diet 4 (basal diet with 10% complete *Nannochloropsis gaditana*); Diet 5 (basal diet with 10% *N. gaditana* with broken walls). The intake of the animals was monitored daily and the weight of the animals was measured at the beginning and at the end of the experiment. The rates of growth, intake and feed conversion were calculated. The results obtained showed a greater growth of the animals fed with microalgae compared to the control. Among the groups fed with supplemented diets the growth was higher with *N. gaditana* (with walls and without walls). Higher feeding rates were also observed with diets containing microalgae. Despite this, no differences were observed between the same type of microalgae treated or not to break its wall. In conclusion, although the microalgae studied have a positive effect on growth and intake, the rupture of the cell wall of *T. chuii* and *N. gaditana* before its incorporation into the 10% sea bass feed has no effect on its performance.

MINIMIZING THE IMPACT OF MARINE LITTER AND GEAR IN THE AQUACULTURE INDUSTRY GLOBALLY

Marcelo Hidalgo, Michiel Fransen

marcelo.hidalgo@asc-aqua.org
Standard Coordinator, Aquaculture Stewardship Council (ASC)

Introduction:

Every year 300'000.000 MT of plastic are produced, Our oceans are nearing tipping point and plastic waste is one of the greatest threats to them. Large numbers of plastic bottles and bags float around the earth but there is another, lesser-known, man-made killer plastic lurking in our oceans. Fishing gear is designed to catch and kill marine life, and 'ghost gear' – abandoned, lost or discarded fishing gear - is the most harmful form of marine debris for animals

Each year at least 640,000 tonnes of this 'ghost gear' is lost or left in our oceans. The enormous impacts of ghost gear spell out the need for urgent attention: if this deadly threat to our oceans, marine animals and ecosystems is not addressed, there is a great risk that that ghost gear will interact and combine with other current oceanic threats to create what the UN termed "a destructive cycle of degradation." Ultimately this could mean our oceans simply stop providing for humans in the many ways we now rely on them. Worryingly, the level of ghost gear has increased in recent years and it is likely to grow further as fishing efforts intensify all over the world. Effective solutions are being found locally and nationally, yet I believe only a global approach can enable us to monitor and fight this threat. (aken from Global Ghost Gear Initiative - GGGI)

In 2018, Aquaculture Stewardship Council (ASC) approached to GGGI and assesses how the Aquaculture sector can minimize the impact of using plastic tools in the farms operations. ASC joined GGGI officially in 2018 to support the initiative and developed a criterion to be request to the aquaculture industry globally based on FAO code of conduct for fisheries and in the 3 principles of GGGI

The technologies of the aquaculture are evolving at rapid pace and therefore, the application of the research and development in other fields is welcome to the sector. One of such development is the plastic application in aquaculture. The use of plastics in agriculture / aquaculture in countries have increased rapidly, and have acquired substantial significance in the conversion of material and energy, contributing greatly to the increased production of aquaculture.

The plastics are perhaps the most versatile of the materials known. They being synthetic can be tailor made to meet the very specific performance requirements of the enduse. By virtue of their versatility, plastics are fast replacing the conventional materials such as wood, glass, metals, papers, etc. in vary varied segments like agriculture, irrigation, water management, aquaculture, packaging, etc.

The plastics most commonly used in aquaculture are Low Density Polyethylene
(LDPE), High Density Polyethylene (HDPE), Polyvinyl Chloride (PVC), Polypropylene (PP), Polystyrene (PS), Polyamide (nylon), Polycarbonet (PC), Acrylic (PMMA), Fibre Reinforced Plastics (FRP), etc.

The research in application of the plastics for aquaculture operation certified by ASC has produced list per sector that have been evaluated as farmers fields for their applicability. At present, many of these gadgets are being used in the Aquaculture industry. The overview of these applications will be presented. This policy is affecting and minimizing the discarding of marine litter globally in farms that are producing: Tilapia, Pangasius, Shirmp, Troutfish, Salmon, Seriola, Seabass/ Seabream, Oysters, Abalone and Bivalves.

EFFECTS OF COMBINED ELEVATED TEMPERATURE AND SALINITY ON PROTEIN, ENERGY REQUIREMENTS FOR MAINTENANCE AND FEED UTILIZATION OF RED TILAPIA (*Oreochromis* sp.)

T.T.T. Hien[1*], T.T. Hieu[2] and T.M.Phu[1]

Introduction

Climate change is predicted to affect the biodiversity in Vietnam, particularly in the Mekong Delta. The predictions include an increase in the environmental temperature and rising of sea level, which lead to increased estuary salinity and salinity intrusion into the fresh water bodies. Many studies have been conducted to evaluate the effect of salinity and temperature on the growth, digestibility and feed utilization of different fish species. Other studies on interaction between temperature and salinity in tilapia or red tilapia were conducted in order to investigate the changes in growth performance (Rodriguez *et al*., 2015), feed utilization (Hassan *et al*., 2014), growth (Barreto-Curiel and Durazo, 2015), adaptation and nutrition requirements of tilapia in tropical areas where climate change is being observed apparently. However, the interaction between elevated temperature and salinity has not been investigated on the tilapia, especially in red tilapia (*Oreochromis* sp.). Therefore, this study aimed to determine the interaction between elevated temperature and salinity on protein and energy requirements for maintenance and growth of red tilapia, *Oreochromis* sp.

Materials and methods

Two-factorial experiment was randomly allocated, consisting of 12 treatments. The first factor was the combined temperature and salinity including normal temperature (28°C) and 0ppt; and high temperature (34°C) and 12ppt. The second factor was the three levels of protein in the formulated diets (25, 30 and 35%) combined with the two levels of lipid in the diets (6 and 9%). Each treatment was randomly triplicated. Fish (7.1±0.03g; 30 fish) were stocked in 200 L tanks. Fish was acclimated with salinity and temperature for two weeks before starting the experiment. Fish was fed to satiation two times a day (8AM and 4PM). Temperature and salinity were measured and adjusted daily for each treatment. At the end of experiment, fish was weighed and counted to calculate the growth performance and survival rate (SR). Feed conversion ratio (FCR) and specific growth rate (SGR %) were calculated. Statistical difference in mean of investigated parameters were analyzed by the General linear model followed by the Duncan test at a significance leve of 0.05, using SPSS program 16.0.

Results

Growth performance, there was interaction between feed composition and salinity-temperature on specific growth rate ($p<0.05$), while there was no interaction between feed composition and salinity-temperature on final weight and daily weight gain ($p>0.05$). At the same protein proportion, growth rate of fish were better at dietary 9% lipid level than that in dietary 6% lipid level, especially in 30% protein with 9% lipid the growth performance of red tilapia was the best. Besides, in 12ppt -34^{o}C treatments, the growth performance of red tilapia was better than in freshwater treatments for all diets. The growth performance (Wf, and SGR) was highest in fish fed with feed (9% lipid and 30% protein) in 12ppt-34^{o}C.

Feed efficac , feed composition affects directly to feed utilization efficiency ($p<0.05$). Interestingly, only in feed intake did both feed composition and salinity-temperature influence the amount of feed consumed per day. With the same type of feed, the experimental fish which were reared in higher temperature and salinity consumed higher amount. Besides, with the same level of protein in feed, the fish consumed more feed which have lower lipid level (6%) than the feed that contains higher lipid level (9%).

Fish composition, there was interaction between salinity-temperature and protein composition of diets on fish composition. In 0ppt-28^{o}C, the total moisture in fish body composition is higher than in 12ppt-34^{o}C treatments. The highest total moisture was 77.88±0.96% which was showed in (salinity 0ppt-28^{o}C with diet 6% lipid and 30% protein), and there were interaction between temperature-salinity and protein proportion; protein and lipid in diets ($p<0.05$). In all remain parameters (crude protein, crude lipid and total ash), the same trend was seen, in which the figure was in the same parameter in the same diets in 12ppt-34^{o}C treatments were all higher than salinity 0ppt-28^{o}C treatments.

Discussion and conclusion

In 0ppt salinity-normal temperature condition, the best growth performance of red tilapia was shown by using the diet with lipid 6% and protein 25%.

In 12ppt salinity-34^{o}C condition, the best growth performance of red tilapia was shown by using the diet with lipid 9% and protein 30%.

Introduction

Aquaculture of freshwater carnivorous fish in Vietnam, Cambodia, and the broader Mekong Delta region has been highly dependent on inland fisheries of low value fish for sourcing key dietary nutrient inputs. Hien et al. (2017) at Can Tho University (CTU) found that successful weaning of snakehead larvae using a formulated feed enables farmers to domesticate snakehead culture in Vietnam and Cambodia and eliminate reliance on fish captured from the wild as both seed and feed. The CTU feed formulation was shared with feed mills in the Mekong Delta by CTU researchers, along with further outreach and demonstration projects for farmers in An Giang and Dong Thap provinces. This led to widespread adoption of the formulated pelleted diets by snakehead farmers in Vietnam (Hien et al., 2018) and some early successes. However, the development of the snakehead (*Channa striata*) aquaculture industry in Vietnam and Cambodia depends on additional innovations in supplemental diets. Pangasius fish meal (PFM) made from the by-products of striped catfish is a new fish meal resource for making fish feeds. This study evaluated the possibility of using PFM as alternative feed ingredient for snakehead.

Materials and methods

The study included two experiments: (1) evaluation the digestibility of PFM and marine fish meal (MFM) as feed ingredients for snakehead; and (2) replacement of marine fish meal protein by PFM. In the first experiment, the test ingredients were a reference diet, PFM and MFM. Two diets were formulated using 70% reference diet and 30% of each of the test ingredients. The snakehead reference diet is made by (Hien et al., 2016). Chromic oxide (Cr_2O_3) was added to all diets at a level of 1%. Feces were collected daily, dried at 60°C, and analyzed for crude protein, crude lipid, moisture, and ash. Apparent digestibility coefficient (ADC ingredients) of protein and lipid were analyzed and calculated. In the second experiment, the protein of MFM was replaced by the protein of PFM at levels of 0%, 25%, 50%, 75% and 100%. Each treatment was randomly triplicated. Fish (6g; 30 fish) were stocked in 250 L tanks. Fish were fed to satiation two times per day (8AM and 4PM). At the end of the experiment, fish were weighed and counted to calculate growth performance, feed conversion ratio (FCR), and specific growth rate (SGR%). Statistical difference in the means of investigated parameters were analyzed by the General linear model followed by the Duncan test at a significa ce level of 0.05, using SPSS program 16.0.

Results

Experiment 1:

Apparent digestibility coefficient (ADC) of protein and lipid of PFM were significantly higher than those of MFM. Table 1 shows that ADC of protein in MFM (86.2%) was lower than that of PFM (93.4%). Similarly, lipid digestibility of PFM was higher than that of MFM.

Experiment 2:

Results showed that replacement of MFM by PFM did not affect snakehead survival rate. The highest specific growth rate (SGR) was found in fish fed 100% PFM (3.67%/day). Feed intake (FI) was not significantly different among treatments. There was no significant difference of feed conversion ratio (FCR) and protein efficiency ratio (PER) between treatments using 75% and 100% PFM ($p>0.05$).

Discussion and conclusion

Apparent digestibility coefficie ts of protein and lipid of PFM were significantly higher than those of MFM. Replacement of 100% MFM by PFM showed the highest fish growth performance and feed efficien .

(Continued on next page)

Table 1. Apparent digestibility of MFM and PFM (%)

Feed ingredients	Dry matter (%)	Protein (%)	Lipid (%)
MFM	68.4±0.21[a]	86.2±0.80[a]	77.1±0.90[a]
PFM	69.3±0.70[b]	93.4±0.60[b]	90.6±0.62[b]

QUANTIFYING GENETIC AND ECOLOGICAL EFFECTS OF ESCAPED FARMED SALMON ON WILD SALMON

K. Hindar*

with collaborators from NINA Trondheim, Institute of Marine Research Bergen, Nofima Tromsø and NMBU Ås, Norway
E-mail: kjetil.hindar@nina.no

Introduction

The impact of escaped farmed Atlantic salmon (*Salmo salar*) on conspecific wild populations has been a matter of discussion since the 1980s. In order to attain a facts-based discussion on this topic, the Research Council of Norway in 2011 announced a call for proposals to establish a knowledge platform that included research institutions from environmental, fisheries and aquaculture science to study farmed-wild genetic and ecological interactions. Four Norwegian institutions won the competition for a knowledge platform, QuantEscape, which was established in 2012. By end of 2019, the knowledge platform has run for two 4-yr periods. This talk gives an overview of what has been accomplished and of the type of knowledge that remains to be established.

Methods

QuantEscape uses a mix of different methodologies and approaches to study how escaped farmed salmon and their offspring affect wild populations. First, a method for distinguishing between wild and farmed salmon has been developed by finding a set of Single Nucleotide Polymorphisms and a novel, statistical analytical approach to separate the two groups. This method has been used to quantify the level of genetic introgression in a large number of wild populations reaching 225 populations and more than 90% of the wild Norwegian salmon resource by 2019. Moreover, the method has been used to study how introgression at the individual level affects the life history and body size of wild Atlantic salmon.

Experiments have been used to establish how farmed and farmed-by-wild offspring compete with wild salmon offspring in hatchery, semi-natural and natural environments. Also, the experimental protocol allows testing of naturalised farmed salmon in competition with wild salmon, and how a predator (brown trout, *Salmo trutta*) affects the outcome of the competition.

Modelling has been used to accompany the empirical and experimental studies, both by group-based demographic models, by quantitative genetic models and by individual-based eco-genetic models.

Results

QuantEscape has established that genetic introgression occurs in the majority of wild Atlantic salmon populations in Norway and in a large proportion of the wild Atlantic salmon resource. QuantEscape has further established that at the individual level, genetic introgression leads to changes in growth rate, age at smoltification, age at maturity, behaviour and phenology of migration.

Experiments show that offspring of farmed salmon, by having been selected for fast growth, dominate wild offspring under favourable environmental conditions, and that this also holds true for farmed-by-wild hybrids competing with wild offspring. In the presence of a predator, however, the advantage of farmed offspring is counteracted by their higher vulnerability to the predator. These results point to possible mechanisms for the variable fitness of farmed offspring in nature, which is seen as asymmetries in competitive advantage during different life stages.

Models show that genetic introgression leads to lower average fitness of the wild population, and that intermediate differences between farmed and wild salmon may lead to more dramatic effects than either small or very large differences. An area for further research is whether or not wild populations retain their average fitness if escapes are controlled

(Continued on next page)

Discussion and Implications

The genetic integrity of wild Atlantic salmon populations is threatened by escaped farmed salmon. The enormous success of salmon-based aquaculture industry in Norway has led to problems for wild fish, not only because of interbreeding between escaped farmed and wild salmon, but also because of the associated population growth of disease agents, such as sea lice.

These phenomena have resulted in a large increase of research money to understand and find solutions to aquaculture-related environmental problems, and as a side-track, has also contributed to world-leading new knowledge of salmon biology and more generally, sex-based dominance as a way of maintaining genetic variation in major loci (Barson et al. 2015). Moreover, the knowledge platform was a major contributor to the documentation and advice given by an ICES expert group on the effects of salmon aquaculture of wild salmonids (ICES 2016).

The detailed knowledge acquired by QuantEscape, and its collaboration and dialogue-based structure, points a way to understand and tackle complex environmental problems where vital conservation values and economic development are at stake.

Introduction

European Whitefish (*Coregonus lavaretus)* has been suggested as a novel candidate for further expansion of aquaculture in northern Europe. However, whitefish are highly sensitive to stress. Farmers report that it is difficult to translate farm practices from other farmed salmonids to whitefish as they rapidly respond to stressful events with reduced feed intake and even loss of equilibrium. The stress response result in increased circulating levels of e.g. corticosteroids and catecholamines which elicit adaptive, secondary responses in target tissues. When fish are not allowed sufficient recovery time, maladaptive tertiary responses to repeated stress is a potential threat to homeostasis and thus fish health and welfare (Barton and Iwama, 1991; Wendelaar Bonga, 1997). Measurements of secondary physiological stress responses (e.g. heart rate) can therefore be used as a tool for welfare assessment in fish (Ashley, 2007). To ensure economic sustainability and improved welfare for the fish, it is important to identify and minimize stressors during farming conditions. The use of implantable heart rate loggers for continuous long-term recording of heart rate, in combination with measurements of plasma cortisol concentration, have previously been shown to be a useful tool to detect stressful events in aquaculture for rainbow trout (Brijs et al., 2018). The aim of this study was to assess the effects of anthropogenic stressors on whitefish associated with harvest by measuring heart rate and cortisol levels. This information can facilitate proper farm management of whitefish and safeguard the welfare of the fish.

Materials and methods

The study took place at a commercial fish farm where 20 whitefish were surgically instrumented with heart rate loggers (STAR-Oddi DST milli-HRT) before releasing them back into a sea cage together with 3000 conspecifics. Thereafter, heart rate were recorded and we kept a logbook of all husbandry events and environmental conditions that occurred at the farm during a period of 3 weeks. During the last 2 days the fish were exposed to a series of farming practises related to the harvest of the fish (e.g. crowding, brailing, well-boat transport and CO_2 narcosis). To validate the stress responses during these days, a sub-sample of 100 fish were sampled for haemoglobin, haematocrit and circulating levels of plasma cortisol during each event and compared to a group of “undisturbed” fish prior to harvest.

Results

The results showed that the repeated stress induced by subsequent farming practises had a cumulative effect as heart rate roughly doubled and peaked at ~35 beats min^{-1} above resting heart rate following the combination of crowding, brailing and transportation that commenced the harvest at day 19. After the initial increase in heart rate it remained elevated until they fish where slaughtered. Additionally, haematocrit was significantly increased when fish were exposed to crowding before, and also during, transport in the well boat. At the last stages of harvest, where fish were crowded and brailed and later stunned, mean corpuscular haemoglobin concentration (MCHC) decreased significantl . To our surprise, we also found a clear increase in heart rate 18 days after being released back into the sea cages which was before the harvest had begun. Cortisol data are unavailable at time of abstract deadline, but will be presented at the conference.

Discussion and conclusion

Based on the present results, we conclude that repeated stress has a cumulative effect on whitefish causing an increase in heart rate that remained elevated during a 14 hour recovery-period after transport. We also found a drop in MCHC indicating adrenergically-induced red blood cell swelling. The unexpected rise in heart rate that preceded the handling of the fish indicated a stressful event. From the logbook we could see that a second net cage containing rainbow trout was transported into the bay at this time, which presence may have caused this response. With rainbow trout in their vicinity the heart rate of the whitefish never recovered but remained significantly elevated, 10-15 beats min^{-1} above resting hear rate. These findings are important for management purposes, but also validate how heart rate can be used to monitor how fish perceive events occurring in aquaculture.

Introduction

Skeletal anomalies in farmed teleosts are a world-wide problem in aquaculture as the high rate of malformed fish often results in downgraded product and impacts economic profit (Boglione et al., 2013a). Although many factors have been implicated in skeletal deformities in fish larvae/fry reared in intensive production systems. Recent data provides evidence of the critical role several dietary components (such as crude protein, crude fat, polyunsaturated fatty acids – PUFA etc.) play in the early development of fish (Cahu et al., 2003). The goal of this study was to assess the effects of three different commercial diets (different composition of nutritional ingredients and level of PUFA) on Eurasian perch juveniles growth, survival and frequency of anomalies in their vertebral column.

Materials and methods

The four-week experiment was carried out on 32-day perch post-larvae (average body weight of 0.048±0.027g and average body length of 16.5±2.4mm) fed with three commercial feeds with varied nutritional components: Aller Futura EX (group AF); Perla Eel Protec A (group PE); Perla Larva Proactive 4.0 (group PP). The fish were reared at 20±0.5°C, with a photoperiod of 12L:12D. After the experiment, fish were anaesthetised (MS-222, Sigma-Aldrich Ltd., Poznan, Poland), measured and radiographed using a X-ray apparatus (FAXITRON MX-20, DOTmed.com Inc., New York, USA). The pictures were digitized and the vertebral column of each fish was thoroughly examined. Additionally, analysis of the basic chemical composition (dry matter, crude protein, crude fat and crude ash) of feeds and fish filets were examined according to the procedures proposed by AOAC (2012). The fatty acids profiles of fish feed and muscles were determined by gas chromatography (Christie, 1993).

Results

The study showed the effect of the varied feeds on the growth indexes of the perch juveniles. At the end of the experiment mean body weight (B_w; g) and mean total length (B_L; cm) were significant greater ($P<0.05$) in PE (1.13±0.36 and 4.3±0.5, for B_w and B_L respectively) than AF (0.72±0.24 and 3.9±0.4, for B_w and B_L respectively) and PP (0.72±0.22 and 3.9±0.5, for B_w and B_L respectively). Similarly to B_w and B_L, specific growth rate (SGR; % day^{-1}) was significant higher ($P<0.05$) in PE (11.30±0.26) than AF (9.65±0.25) and PP (9.73±0.06). The survival of fish was comparable in all groups and varied between 42.1% (group AF) to 58.2% (group PE). At the end of the experiment, the overall rate of deformities was at 20.9% (59 individuals). The vertebral column deformities determined as dislocation (Fig. 1A), ankylosis and compression (Fig. 1B) of vertebrae were found in all experimental groups: AF (22.5%; n=9), PE (17.5%; n=21) and PP (23.8%; n=29). Significant differences ($P\leq0.05$) in levels of crude fat (highest in PE group 8.25%) and polyunsaturated fatty acids, mainly eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA)(highest in AF group 5.04% and 6.14%, respectively) in fish muscles, were recorded among groups.

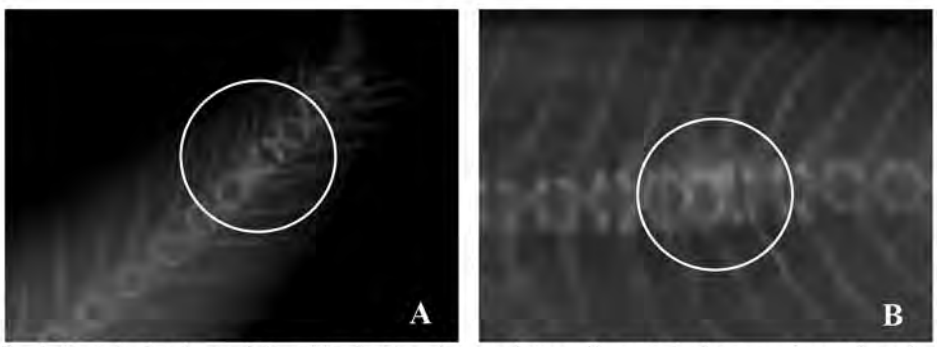

Fig. 1. Vertebral column deformities in Eurasian perch juveniles noted after experimental rearing. Lateral radiographs showing dislocation (A), ankylosis and compression of vertebrae (B).

(Continued on next page)

Discussion

Existing literature indicates that finfis species important to European aquaculture industry could be divided into two groups based on the type, severity and frequency of vertebral anomalies. The first group includes gilthead seabream, European seabass, flatfis and most of the candidate new species like Eurasian perch, whereas the second group includes salmonids. In the non-salmonid group, vertebral axis anomalies are quite frequent in the same lot or species, and concern almost all the recorded types to date (Boglione et al., 2013b). At the same time vertebral deformities are one of the most important causes of losses in the culture of Atlantic salmon (Fjelldal et al., 2007). Our data suggest that differences in level of polyunsaturated fatty acids in tested commercial diets does not affect the prevalence of skeletal malformation in perch juveniles. The percentage of fish with anomalies does not vary greatly among experimental groups though significant differences in growth rate were observed.

High prevalence of vertebral column anomalies noted in our study (~ 20%) suggests the need to improve the knowledge about factors leading to skeletal anomalies under percids intensive culture conditions.

Fisheries is the most vital industry in the Lake Victoria Basin, being a major source of income for the population and an important part of the national economies in the region. However, the lake is under pressure due to overfishing and severe pollution. One solution to the problem of overfishing is aquaculture. Recirculating Aquaculture Systems (RAS) incorporates water treatment and reuses 90-95% of the water. RAS offers a variety of important advantages compared to open pond culture, such as reduced water and land requirements, environmental control, year-round operation, waste management control, and food safety benefits.

VicInAqua, a project under the EU Horizon 2020 programme, has developed a tilapia hatchery in Kisumu, Kenya using RAS adapted to local conditions. The hatchery is designed as a flexible, scalable and modular system. An online monitoring system enables the farmers to access farm data also for the energy system in real time and act quickly when something is out of the ordinary. The hatchery runs predominantly on solar energy making use of a 14.3kWp PV system including 30kWh Li-battery storage.

The purpose of the project is to demonstrate the possible technologies and present a financially feasible upscaled design, ready for the African market. The hatchery is used by the the Department of Livestock, Agriculture and Fisheries as a training and demonstration facility to promote the aquaculture sector and increase awareness, knowledge and skills for fish farmers.

ANTI-INFLAMMATORY FEEDS AND TRYPTOPHAN METABOLIC PATHWAYS TO STRESS RESILIENCE IN FISH

E. Höglund

Norwegian institute of water research (NIVA). Gaustadalléen 21
0349 Oslo (Norway)
E-mail: erik.hoglund@niva.no

Diets of salmon in aquaculture have been changing due to a range of factors including constraints to marine resources, generally resulting in reduced levels of the anti-inflammatory n-3 fatty acid, eicosapentaenoic acid and increased pro-inflammatory n-6 fatty acids. In human medicine there is a surging interest in the beneficial effects of anti-inflammatory feeds on mental health and stress coping ability. This has giving rise to a neuro-immune framework where high n-3 diets are shown to increase immune function and stress resistance by suppressing pro-inflammatory eicosanoids and shunting catabolism of the essential amino acid tryptophan towards neuroprotective serotonin production, Fig 1.

Anti- and pro-inflammatory fatty acids and tryptophan have widespread and evolutionary conserved roles. However, to what degree the emerging mammalian neuro-immune framework is present and activated in teleost fish is currently unknown.

Here, this potential interplay between dietary fatty- and amino- acids compositions affect inflammatory processes, TRP catabolic pathways and brain signaling systems involved in stress coping and resilience in farmed salmon will be presented. Moreover, its applications in aquaculture will be discussed, with focus on stress mitigating aquafeeds targeting critical periods in the production cycle, such as vaccination, transport and seawater transfer.

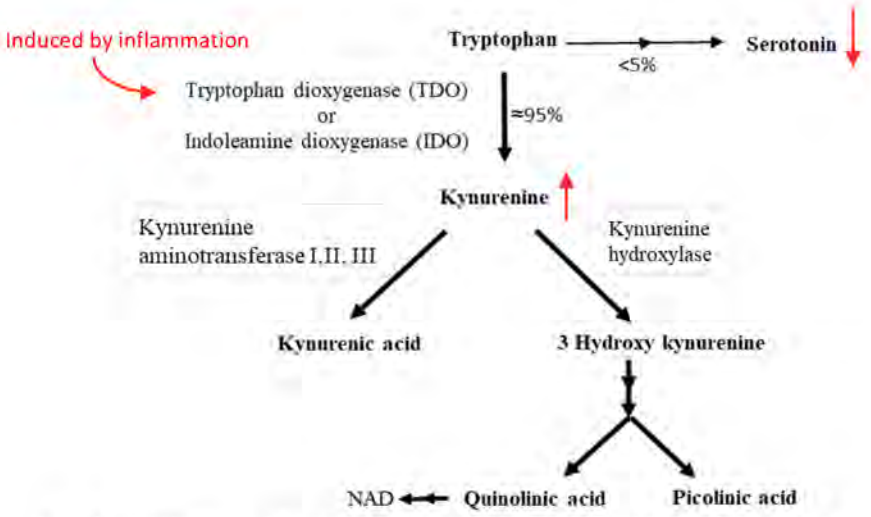

Fig 1. Interaction between the immune system and production of serotonin. A neurotransmitter/modulator having neuroprotective functions.

COMPARISON BETWEEN THE RESULTS FROM THE EU H2020 CERES AND CLIMEFISH PROJECTS ON THE POTENTIAL EFFECTS OF CLIMATE CHANGE FOR AQUACULTURE OF MEDITERRANEAN MUSSEL (*Mytilus galloprovincialis*)

Mediterranean mussel (*Mytilus galloprovincialis*) culture is the top shellfish farming activity in Europe, with an annual production of over 300.000 tons. Given the socioeconomic importance of this culture, the Mediterranean mussel is a target species of the EU H2020 projects “Climate change and European aquatic resource” (CERES) and “Co-creating a decision support framework to ensure sustainable fish production in Europe under climate change” (ClimeFish). The overall aim of CERES and ClimeFish is to forecast the effects of and propose adaption measures to climate change on European fisheries and aquaculture. Particularly, CERES studied Mediterranean mussel farming in SW Portugal and ClimeFish in NW Spain and the Northern Adriatic Sea. The NW Spain and SW Portugal sites belong to the coastal upwelling system of the Western Iberian Peninsula, under the influence of intermittent upwelling-favourable northerly winds during the spring and summer. Coastal upwelling events regulate sea surface temperature and chlorophyll levels. Conversely, the Northern Adriatic Sea is a shallow semi-enclosed basin that receives cold water from many alpine rivers. Although CERES and ClimeFish focus on contrasting sites using different approaches, they are working together for the sustainable production of Mediterranean mussels along the European coast under climate change.

Oral presentations based on Abstracts 930 and 420 in this conference will provide details from the respective studies on Mediterranean mussel in CERES and ClimeFish. This poster will compare the similarities and differences in the results from these two projects.

GOODFISH – A PROJECT FOR THE DEVELOPMENT OF POND AQUACULTURE IN HUNGARY

Introduction

Hungarian aquaculture is primarily a cyprinid-centered pond aquaculture which is characterized by seasonal production mainly for the Christmas market, low production intensity and sale of raw material (live fish) instead of processed products. A consortium of four leading Hungarian institutions of higher education and research has joined their resources to address this problem. The consortim is led by Szent István University and its objective is to improve and intensify the production of common carp (*Cyprinus carpio*), pikeperch (*Sander lucioperca*) and wels catfish *Silurus glanis*) in Hungary.

Materials and Methods

In the wels catfish and pikeperch, a cryopreserved gene bank has been developed of various populations of these species along with population genetic studies of both species. In addition a two-year production technology along with a specific breed of wels catfish is developed for intensive production of the species. In the pikeperch, a complex commercial-scale larviculture and fingerling culture technology is developed to ensure the supply of healthy juveniles for grow-out. Finally in the common carp, production is intensified by developing a two-year production cycle along with a specific carp breed and cost-benefit analyses, development of monosex all-female carp stocks and the development of a veterinary e-tool for the early detection of pathogens and diseases.

Results

A cryopreserved gene bank of wels catfish and pikeperch was developed with more than 1000 straws from catfish over 70 straws in the pikeperch originating from Hungarian and foreign populations. Three panmictic spawning events were conducted in the wels catfish and parents of the best performing progeny were selected based on DNA tests. The technology of broodstock handling, off-season spawning and larviculture of pikeperch is continuously developed. Regarding the two-year carp production, an intensive fingerling rearing technology is under continuous development, experimental feeds are also developed targeting intensification. Monosex carp broodstock is developed to improve production using meiotic gynogenesis as well as sex reversal of the progeny.

Discussion

The consortium is making progress in developing intensive technologies for three commercially important fish species for Hungarian aquaculture. We hope that intensified production will improve the productivity of the Hungarian aquaculture sector.

NITROGEN REMOVAL FROM A SALT-WATER RECIRCULATING AQUACULTURE SYSTEM (RAS) USING A STEP FED BATCH REACTOR (SFBR) OPERATED UNDER EXTERNAL AND INTERNAL CARBON SOURCES

Xiaoyu Huang[a*], Carlos O. Letelier-Gordo[ab]

[a] Technical University of Denmark, DTU Aqua, Section for Aquaculture, North Sea Research Centre, DK-9850 Hirtshals, Denmark
[b]Corr. author Email address: colg@aqua.dtu.dk

Introduction

Following the Marine Strategy Framework Directive (MSFD) to achieve Good Environmental Status by 2020 and Water Framework Directive (WFD), the Baltic Marine Environment Protection Commission (HELCOM) in 2013 agreed upon Country Allocated Reduction Targets (CARTs) to limit the allowable nutrient inputs in Baltic Sea sub-basins. Therefore, the development of recirculating aquaculture systems (RAS) in Baltic area depends on a more sustainable and cost-effective solution. Denitrification as an end-of-pipe treatment technology to reduce nitrogen discharge, gains increasingly more attention in particular for brackish and salt-water RAS (Hamlin et al., 2008; Suhr et al., 2013; van Rijn, 2013). Both external (commercially obtained) and internal (produced within the system) carbon sources can be used by denitrifying bacteria (Letelier-Gordo et al., 2017). Methanol and ethanol are frequently applied in commercial denitrification, but as flammable alcohols they are complicated in transport, storage and usage. In comparison, acetate and propionate as nonalcohol carbon sources can be better options. On the other hand, internal carbon sources originating from fish faeces can also be used for end-of-pipe denitrification in order to save operational costs in RAS (Arbiv and van Rijn, 1995; Suhr et al., 2013).

Materials and Methods

As a potential solution in RAS, the following study evaluated the denitrification capacity of a small scale SFBR working under different operational cycles (2h, 4h and 6h) with acetate, and under 4h operational cycle using external (acetate, propionate and ethanol) and internal (fresh and fermented fish organic waste (FOW & FFOW)) carbon sources from a salt-water RAS.

Results and Discussion

The results (Figure 1) showed that among different carbon sources denitrification with acetate had the best nitrate removal rates (57.64±6.55mg N/h/g bacteria) in SFBR, followed by propionate and ethanol. The differences can be explained by their feasibilities in the tricarboxylic acid cycle (TCA) (Yatong, 1996). The coexistence of fermentation and denitrification described by Sun et al. (2016) were observed in both FOW and FFOW groups, while the latter had higher efficienc . Only internal carbon groups had fluctuant total ammonia nitrogen production along denitrification process. Total hydrogen sulfide production was under control in all groups. Denitrificati n rates with acetate increased as SFBR operational cycle time decreased, might due to the selective pressure (Liu and Tay, 2007; Yatong, 1996). SFBR cycle of 2h with acetate reached a denitrification rate of 99mg N/h/g bacteria and a denitrification capacity of 600g N/d/m^3 working volume. A commercial case study indicated that SFBR using acetate as carbon source had a great potential in denitrification efficienc , reliable operation and required system volume compared to traditional biomedia-based systems.

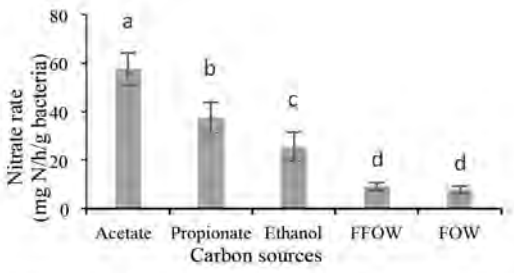

Figure 1. Nitrate rates with different carbon sources (acetate, FOW, FFOW, ethanol and propionate) under 4h SFBR cycle. n=4

Introduction

Long-chain polyunsaturated fatty acids (LC-PUFA), such as DHA and EPA, are important for growth and health of farmed fish. However, the required level of LC-PUFA and their proportion to dietary lipid or absolute intake levels are not well understood. A previous study on rainbow trout found that more PUFA (i.e. alpha-Linolenic acid) was required when feeding higher levels of lipids, which suggests PUFA requirements are proportional to lipid (or energy) intake (Watanabe, 1982). Furthermore, the demand for LC-PUFA may be influenced by environmental factors, such as low oxygen (hypoxia), that are relatively common in commercial aquaculture systems. Hypoxia has been found to reduce feed intake by rainbow trout while protein and energy utilisation efficiency remained unchanged (Glencross, 2009). Minor changes in nutrient uptake and steroid synthesis into the blood may explain interactions between diet, stressors and fish performance. The objective of this study was to determine the effect of dietary lipid, LC-PUFA and dissolved oxygen on the growth performance, feed digestibility, nutrient retention, haematology, plasma biochemistry and steroid synthesis of juvenile Atlantic salmon.

Materials and methods

Atlantic salmon post-smolts of 184 g initial weight were reared in 24 circular tanks (32 fish/tank) for 138 days (20 weeks) at the University of Stirling's Marine Environmental Research Lab (Machrihanish, UK). In triplicate, each tank of fish was fed one of four extruded diets that were isoenergetic and isonitrogenous, where diets A and C had a higher total lipid level (230 compared with 180 g/kg) and diets C and D had a higher LC-PUFA level (14 compared with 7 g/kg). Protein was also varied to ensure diets were isoenergetic. Yttrium oxide was included as a digestibility marker in the diets. In half the tanks, the flow rate was decreased to lower the dissolved oxygen from approximately 90% to 70% saturation in order to subject the fish to a chronic hypoxic stress. Fish were sedated with MS222 and weighed at day 0, 56 and 138. Faeces were stripped from all fish, pooled and frozen on dry ice. Four fish per tank were euthanised and caudal blood and whole carcass were frozen on dry ice. Proximate, fatty acid and mineral composition of the diets, carcasses and faeces were performed using Kjeldahl, Folch, GC of FAMEs and ICP-MS methods at the Institute of Aquaculture (Stirling, UK). Haematology and plasma biochemistry were analysed at Scotland's Rural College (Edinburgh, UK) and plasma steroids were analysed at University of Edinburgh. For statistical analyses, normality tests and linear mixed effects model (LME) were performed using R software.

Results

Weight gain was significantly reduced for fish reared in low dissolved oxygen and fish fed high levels of lipids and LC-PUFA had the highest weight gain after 138 days (Fig. 1). FCR was not significantly affected by lipid, LC-PUFA or oxygen levels, whereas protein intake was affected by all three factors. In high oxygen, protein digestibility increased when fed high lipid or LC-PUFA whereas the opposite was found for lipid digestibility. Fish fed high lipid diets had higher protein retention while lipid retention was unaffected. For blood and plasma, differences in lipid, LC-PUFA and/or oxygen resulted in significant changes to levels of creatinine, total protein, cholesterol and mean corpuscular haemoglobin (MCHC), although fewer effects were found at day 138 compared to day 56 (Table 1). At day 56, both androstenedione and its derivative were affected by lipid and oxygen level, but PC-PUFA had no effects on any steroid synthesis.

Discussion and conclusion

The results indicate that hypoxia was the most influential of the three factors as it reduced feed intake, weight gain, lipid digestibility, androstenedione synthesis and elevated plasma creatinine. In both hypoxia and normoxia, fish fed diets with high lipid and high LC-PUFA levels had the highest weight gain (Fig. 1) and only fish fed the low lipid diet under hypoxia resulted in significantl lower weight gain. This result is in agreement with previous research (Watanabe, 1982)

(Continued on next page)

and provides further evidence that the level of LC-PUFA required by Atlantic salmon is proportional/relative to the total lipid level rather than the absolute level in the diet. This effect seems to be enhanced when fish are exposed to a chronic stressor, where both high lipid and LC-PUFA can improve growth. In contrast to rainbow trout, hypoxia significantly affected protein and lipid digestibility coefficients of Atlantic salmon in the present study (Glencross, 2009). Fish fed high lipid and LC-PUFA diets consistently had higher levels of total protein, cholesterol, MCHC and androstenedione in the blood, which may explain higher weight gain. In conclusion, these results indicate that LC-PUFA requirements for Atlantic salmon should be considered as proportional to total lipid in the diet and this demand can be influenced by hypoxia

The use of cleaner fish, such as lumpfish (*Cyclopterus lumpus*), is common practice in the salmon industry to control sea lice in seacages. They are an effective biological control compared to chemical treatments which sea lice have largely become resistant to. They are of particular relevance in organic farming of salmon, where there are limitations on the number of chemical treatments permitted. Despite their widespread use in the industry, there are limited studies on their nutritional requirements or the effect that commercial formulated diets have on lumpsucker. To further understand this, two feeding trials were carried out to determine the protein requirements and the potential for alternative protein sources in the diets of juvenile lumpfish.

The first feeding trial was carried out on juvenile lumpfish to investigate optimal dietary protein levels. Four protein levels were tested, with three replicates per treatment. The second feeding trial focused on the use of mealworm and black soldier fly larvae as an alternative source of protein. Similar to the first trail there four feed treatments with three replicates of each. The feed treatments consisted of control, mealworm, black solder fl , and a mix of both mealworm and black solder fly diets.

This paper is an overview of some of the nutrition work being carried out by ANARU, with a focus on experiments on alternate protein sources (insect meals) and optimal levels of dietary protein required for juvenile lumpfish

POTENTIAL EFFECTS OF CLIMATE¨ CHANGE ON OFFSHORE AQUACULTURE OF MEDITERRANEAN MUSSEL (*mytilus galloprovincialis*) ON THE SW COAST OF PORTUGAL

J. Icely*, A.Cubillo**, M.Elliot, J.Ferreira, B.Fragoso, P. Kamermans, S.Kay, A.Kennerley, C.Kreis, A.Marques, D.Matias, M.Peck, J.Pinnegar, H.Rambo, K.Smyth, V.Stetzenmüller and N.Taylor

Introduction

There is increasing interest in the development of offshore aquaculture in Europe. In the case of Portugal, *Mytilus galloprovincialis* , the Mediterranean mussel (Med.mussel), is an endemic species and is well adapted to the local environment; the seed can be collected naturally from this environment with suspended ropes as collectors, and it grows relatively quickly with limited handling (O'Hagan et al., 2017). Although Med. Mussel is probably not critically vulnerable to climate change, their capacity as a farmed species will be sensitive to warming under scenarios of future climate change. For SW Portugal, the primary production is regulated by the occurrence of upwelling which brings cold and nutrient rich water promoting increased chlorophyll (proxy for primary production). During periods of upwelling relaxation, there is an increase in temperature and a reduction in temperature; extended periods of these conditions is reflected by a loss in mussel condition and an increased susceptibility to disease. Furthermore, fluctuations in environmental conditions will also modify the patterns related to Harmful Algal Blooms (HAB) and the recruitment of mussel seed.

Development of the Med.mussel 'story line' from the EU CERES project

As part of the EU project Climate change and European Aquatic RESource (CERES) to forecast and anticipate the effects of climate change (CC) on fisheries and aquaculture, the offshore aquaculture of Med.mussel in SW Portugal has been developed as one of the 'story lines' to explore how this industry might be affected by the effects of future CC. Essentially, two scenarios have been selected for the future Representative Concentration Pathway (RCP) of carbon emissions: with RCP 8.5, emissions create concentrations of carbon up to 1370 ppm (causing a radiative forcing higher than 8.5Wm^{-2}); and with RCP 4.5, the total radiative forcing and carbon concentrations are stabilised at 4.5Wm^{-2} and ~650 ppm, respectively, shortly after 2100 due to more rapid reduction of carbon emissions (IPCC 2001, Kay *et al.*, 2018). The 'story line' starts with a review of the species background and the current economic activity related to the culture of Med.mussel. Using this current information on expected projections under CC, potential future socio-economic scenarios are analysed such as 'world market', 'local stewardship, and 'global sustainability' (Pinnegar *et al.* 2018). Using the review of the literature and some specific CERES research on future CC effects, individual and local-scale models have been validated against the current culture practices for offshore aquaculture of Med.mussel in Portugal (Ferreira *et al.*, 2019)

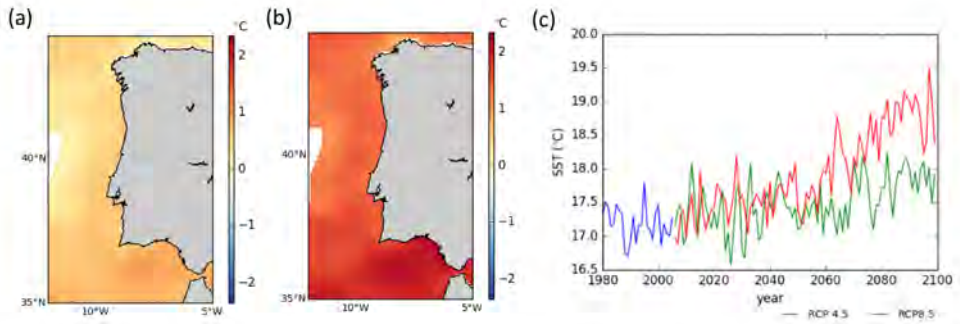

Fig 1. Projected change in sea surface temperature for the Portugal region. (a,b) Difference in 20-year mean temperatures for 2080-2099 compared to 2000-2019 under (a) RCP 4.5 and (b) RCP 8.5. (c) Annual mean for the same region (with thanks to Susan Kay).

(Continued on next page)

The sensitivity of the Med.mussel aquaculture to future CC is considered further with an analysis of the adaptive capacity in the system to accommodate change, using different approaches including, quantifying the resultant and residual vulnerability to decrease future potential problems from CC. The bottom-up approach using Bow tie analysis (Cormier et al 2019) is a risk analysis technique adopted from IEC/ISO 31010 that uses local stakeholders to define, in the case of Med,mussel, what are the principle issues affecting losses and mortality from the offshore aquaculture in Portugal. Also, the Bayesian Belief Network approach has been implemented; this is an innovative meta-analytical approach using Bayesian hierarchical models to use "data-rich" information to infer responses about "data-poor" information. The information from all these techniques is the core of the CERES project, as the data defines and addresses the risks from future CC that allows for the development of practical and operational solutions in collaboration with the aquaculture industry.

Some of the outcomes from the Med.mussel 'story line' in the EU CERES project

Due to both shortage of space for the Abstract and time for the talk, only two examples of the results from the Med. mussel 'story line' are presented here, but acknowledgement through the Authors list are given to all the contributors to this extensive work that will be presented in a future Deliverable of the project .

CERES climate change projections suggest that waters around the Portuguese coast will warm by up to 2°C by the end of the century under RCP 8.5, with the largest increases in the south (Fig.1). Increases under RCP 4.5 are lower, up to 1°C. Whilst projected changes in net primary production (PP), using chlorophyll as a proxy, are less distinct between the RCP scenarios, with a general trend of slightly increasing production under both RCP 4.5 and RCP 8.5. Historical *in-situ* measurements in SW Portugal indicate a decrease in PP with increasing temperature and, therefore, the future projections of changes in PP should be treated as uncertain (Kay *et al*. 2018).

Physiological models including the AquaShell model modified for individual Med.musssels and incorporated into the local scale Farm Aquaculture Resource Management (FARM) model that has been used to examine direct climate driven responses on harvest and environment effects (Ferreira *et al.* 2019). Three time slices have been selected: present (2000-2019), near-future (2040-2059), and far-future (2080-2099). The time slices are related to the two emission scenarios: the more conservative RCP 4.5 and the more severe RCP 8.5. The individual growth model has been run for 20 years within each time slice, and the years which yield the minimum and maximum individual biomass have been selected to give an idea of the statistical spread. Mussel weight at harvest is very similar under both emission scenarios. Similarly, production yield and profit show no significant differences between RCP 4.5 and 8.5 at any time slice, although the average values are greater under the 8.5. The better growth performance under the high-emission scenarios is reflected in the greater consumption of food and lower energy expenditure of these mussels and can be mainly explained by greater chlorophyll concentrations. Slightly better average yields and profits have been obtained from the mid-term time slice (Ferreira *et al*, 2019)

Conclusion

The Med.mussel 'story line' has helped to define the current and future risks for offshore aquaculture and is providing practical and operational solutions in collaboration with the aquaculture industry to reduce future losses to the Blue Economy in SW Portugal.

Introduction

There is concern that aquaculture is not developing at the same pace in Europe as other regions of the world (FAO,2018). With this situation in mind, the EU has funded projects to encourage expansion of aquaculture in Europe including the Horizon 2020 project GAIN (Green Aquaculture Intensificatio in Europe). GAIN is designed to support the ecological intensification of aquaculture in the European Union, with the dual objectives of increasing production and competitiveness of the industry, while ensuring sustainability and compliance with EU regulations on food safety and environment. This poster focuses on how to improve the management of shellfish farms in SW Portugal using environmental data from *in situ* sensors that can be integrated with appropriate data from Earth Observation. The ultimate objective is to implement a Management System for the farms that can use large volumes of information (Big Data) processed in real time.

Methods

Fig 1 (left panel) shows the location of the offshore concessions for mussel aquaculture licensed to Finisterra L[da]. Using one of Finisterra's signal bouys moored within in the aquaculture concession, Sagremarisco L[da] SGM has installed a solar powered data logger with sensors for solar irradiance above the sea surface, and sensors for temperature, chlorophyll fluorescence, turbidity (transmissometer), and optical conditions below the sea surface (Fig.1, right panel). Data from these sensors are transmitted every two hours to be incorporate in a common cloud-based data management and services platform. The overall objective is to offer unified access to information which not only includes the *in situ* sensor data, satellite data, relevant public data, model hindcasts, nowcasts, and forecasts, as well operational data from the farm.

SGM has also set up an experiment that monitors a cohort of mussel spat collected in June 2019 from the shoreline facing the concession (Fig 1, left panel) that simulates Finisterra's current production protocol for mussel production on long-lines. The experimental mussels are grown on one of the long-lines adjacent to the commercial production where temperature and salinity is also recorded every 30 minutes HOBO sensors. Mortality and growth from sub-samples of the experimental cohort of mussels is monitored monthly. As the submerged sensors need to be cleaned regularly, a CTD (conductivity, temperature and depth) is deployed at each visit to obtain temperature and salinity profiles in the water column and water samples are collected for estimates of chlorophyll, total suspended matter, nutrients and identification f phytoplankton.

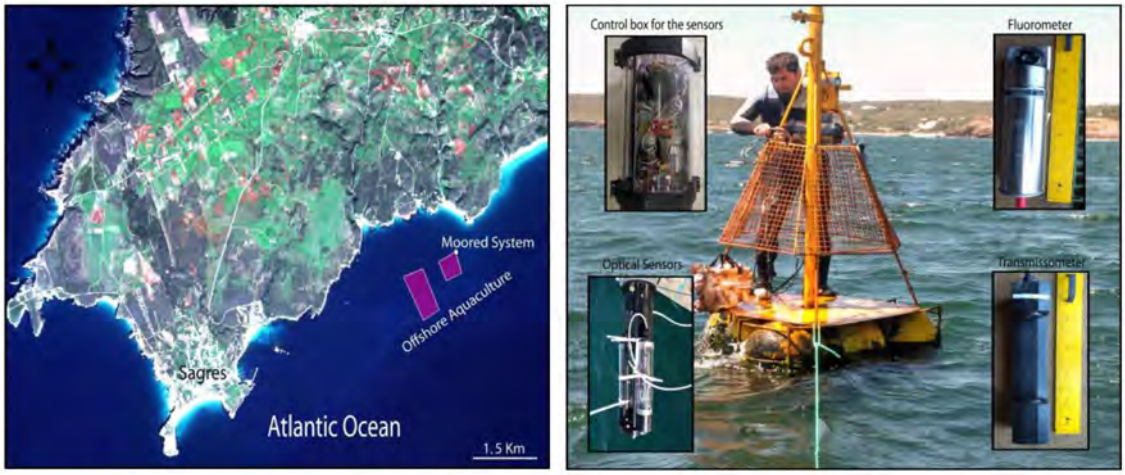

Fig.1 Left panel: geographical location of offshore aquaculture at Sagres (Sentinel-2 Level 1 satellite image provided by Copernicus). Right panel: moored signal bouy providing real time data from a range of sensors powered with a solar control box.

(Continued on next page)

Results and Discussion

Fig 2 shows an example of the environmental *in situ* data that is being recorded at the site and uploaded to the cloud platform.

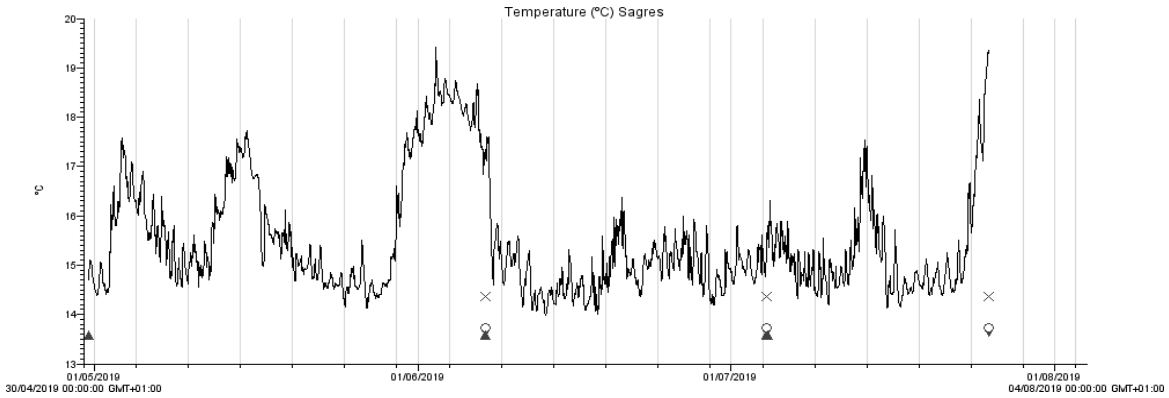

Fig 2 Temperature trace at 5 metres depth from a HOBO sensor deployed with the growth and mortality experiment for mussel initiated in June 2019. X shows when mussels where sampled for mortality and growth.

The *in situ* data set will be complemented with remotely sensed environmental data harvested from publicly available portals, such as the Copernicus Marine Service; these additional data will be relevant in particular for shellfish culture, as some products are a good proxy of food availability, and therefore of shellfish potential growth rates. Also, there are other important issues such as Harmful Algal Blooms (HAB), storm conditions and mussel spat recruitment that might be understood and predicted by integrating large volumes of data from these heterogeneous sources. There is already a substantial body of published Earth Observation data obtained at the Finisterra concession (e.g Icely et al. 2013; Goela et al, 2015,2016; Cristina et al. 2016).

In conclusion, the work at Sagres contributes to one of the objectives of the GAIN project, namely, to implement a cloud based Information Management System (IMS) by combining sensors, key performance indicators, Big Data analysis, and predictive mathematical models for production and environmental effects. The IMS should enable the daily management of precision aquaculture at shellfish farms (GAIN project https://cordis.europa.eu/project/rcn/216474/en)

WASTE FROM DISCARDS: SOCIO-ECONOMIC CHALLENGES OF ARTISANAL FISH PRODUCTION IN NIGERIA

Igejongbo, Toyosi Fadekemi* Ajayi, Clementina Oluwafunke

Department of Fisheries and Aquaculture Technology. Federal University of Technology Akure
E mail: toyosi.adeyemi@yahoo.com

Introduction

Fish is an important source of protein to the teeming population in Nigeria. According to Adekoya (2004), Fish represents about 55% of the protein sources intake of Nigerians. In spite of her enormous oil wealth, Nigeria is confronted with a number of developmental challenges especially in the areas of reducing poverty and meeting adequate nutritive requirement of its 200 million people (Business Day, 2016). The major compelling factor for the development of the sector is the huge domestic market with an existing demand of about 1.5 million metric tonnes per annum. Incidentally, domestic fish catch which comes mostly from artisanal sources with its dwindling fortunes (Ojo and Fagbenro, 2004) is just 511,700 metric tonnes leaving a wide gap of 988,300 metric tons that could possibly be bridged through fish farming. Discards are the waste incurred from incidental capture of non-targeted fish and this part of the catch is usually unregulated. The capture of by-catch may pose a threat to species diversity and ecosystem health (Eayrs, 2007). Discards mostly consists of juvenile food-fish species and is therefore a threat to food security and sustainable fisheries production. There is an awareness that waste from discards is a global problem that must be addressed therefore the need to examine the economic implication of waste reduction, acknowledging the need for general awareness on the need to conserve fisheries resources to ensure food security.

Research Methodology

The study was carried out in river Igbokoda which is one of the longest water body in the country. Primary data source was only employed for the study. The data were collected with the aid of structured questionnaire administered by snowballing. Hundred (100) questionnaires were prepared but nine six (96) were valid and distributed to the targeted respondents. Samples and Data were collected for six months starting from March to August 2017. The data on the socio-economic characteristics of the respondents, marketing costs returns, processing cost and data on fishing operations; as well as constraints militating against fish marketing in the study area, were collected. Data was analyzed using SPSS (14.0) package Descriptive statistics such as measures of central tendency and dispersion and frequency distribution were used to analyze respondents and perceived awareness of bycatch and its reduction devices. The data gathered were fitted to different regression models then the lead equation with the best fit was then chosen.

Table I. Awareness characteristics of waste from discards among artisanal fishers in the study area

Variable	Dominant Indicator
Awareness of discards	10.26% very much aware, 58.33% aware, 31.41% not aware
Occurrence of discards	32.69% always, 67.31% sometimes.
Common discarded species	Snake fish, Crabs, Shrimp/prawn, fin fish, sea turtle, Crayfish, Oyster, electric fish, Periwinkle, black snail, Water snail, white fish, Turtle, crocodile, Cockle, Whelk, Squid, Octopus,
What they do with discards	78.85% sell as additional income, 21.15% cook for household
Value realized from discards	₦18, 583.33 peak season, ₦11, 076.19 moderate, ₦4963.10 low
Reasons for getting discards	Small quantity of harvest, storage and preservation, sorting and preparation, low market, low demand
Fishing gear used	44.23% cast net, 32.69% gill net, 12.9% Dragnet, 12.18% hook and line, traps and basket.

Source: Field survey (2017)

(Continued on next page)

Results

Table l showed the awareness characteristics of discards among artisanal fishers in the study area. It is important to note that these were the only options that were selected by respondents, other options such as 'return them to the waters after catch,' 'discard them but not to the waters,' 'sort and prepare them as foods for animals' and 'sort and give them away to community people' were not selected.

Discussion and Conclusion

In the study of characteristics of discards as shown above, the fisher folks were using fishing gears that make reduction of waste from discards difficult. However, when asked about the knowledge and use of bycatch reduction devices, most of the respondents linked reduction devices to commercial trawlers. Majority (95%) also revealed that the introduction of a bycatch reduction device to artisanal fishers will raise the unit cost of effort and this cost increase will induce a reduction in the profit maximizing level of effort and also reduces profit. This is in consonance with (Eayrs, 2007) that the fishermen are strongly urged to use appropriate bycatch reduction measures to help maintain the productivity of the fishery and the long-term prosperity of the fishing industry. He stated further that by appropriately, fishermen could help to protect the marine environment and assist global food security both now and in the future. While this problem of cost increment with the use of bycatch reduction devices should not be ignored, there is an urgent need to sensitize the fishermen on the implication of non-discard reduction device. The economic implication of the findings is that in the long run, the fishing households in the study area may become food insecure. Therefore, there is a crucial need for interventions that will reduce bycatch and discarding, improve selectivity and therefore lead to better managed fisheries while not neglecting sustainable food security of the fishing households and consumers and alternative means of livelihoods for those that are mainly discards and bycatch fisherfolks

EFFECT OF FEEDING STRATEGY WITH ROTIFERS *(Brachionus plicatilis)* ON PIKEPERCH (*Sander lucioperca)* LARVAL PERFOMANCE

Aiman Imentai*, Christoph Steinbach, Carlos Yanes-Roca, Tomas Policar

University of South Bohemia in Ceske Budejovice, Faculty of Fisheries and Protection of Waters, South Bohemian Research Center of Aquaculture and Biodiversity of Hydrocenoses, Zátiší 728/II, 389 25, Vodňany, Czech Republic
E-mail: aimentai@frov.jcu.cz

Introduction

Rotifers are commonly used in marine larval culture (Girin 1975; Nash and Kuo 1975; Yufera, Pascual et al. 1993; Howell 1997) and recently reintroduced for pikeperch larviculture. Their smaller size and higher level of DHA and LA values compared to *Artemia* proved them as a suitable first diet for pikeperch larvae (Yanes-Roca et al. 2018). However, larval feeding with rotifers is expensive and labor demanding. Therefore, the aim of the present study was to optimize the duration of pikeperch larval first feeding with rotifers under the controlled conditions.

Materials and methods

Experimental culture of pikeperch larvae with rotifers *B. plicatilis* was performed in the Experimental Fish Facility of the Faculty of Fisheries and Protection of Waters (FFPW), University of South Bohemia. The rotifer (mean length 280 µm) were cultured in flat-bottomed, polyethylene tanks of 50-l capacity using a batch culture protocol fed with microalgae paste of *Nannochloropsis* sp. (Nanno 3600, ReedMariculture Inc., USA) at a rate of 1 ml of paste per liter of culture twice a day. Pikeperch larvae (TL= 5.69 ± 0.26 mm, BW=6.68±0.42 mg, 4 DPH) were stocked randomly into each 2-l rearing tank at initial density 100 larvae L^{-1}. The larvae were divided into five experimental groups (Table 1), each in four replicates and reared until 17 DPH. Microalgae *Nannochloropsis sp*. was added twice per day throughout the experiment. The larvae were fed with rotifers *B. plicatilis* or/and *Artemia* nauplii three times a day. Light regime was set at 13L: 11D. Light intensity on the water surface ranged from 90 to 100 lux. The tanks were cleaned twice daily by siphoning to remove excrements, dead larvae and uneaten food. The water temperature, pH and the concentration of dissolved oxygen were measured before each feeding with an oximeter (OxyGuard International A/S, Farum, Denmark) and pH tester (HI98129, Hanna Combo) and the average values were: temperature (17.86±0.63°C), pH (7.38 ± 0.17) and DO (88.55 ± 9.50%). Ammonium concentration was below 0.1 mg L^{-1} and nitrite concentration was below 0.01 mg L^{-1}. Survival, SGR_{TL} and morphometric parameters were measured and calculated. All data were statistically analyzed using RStudio while differences were considered significant at $p<0.05$ using one-way ANOVA followed by Tukey post hoc test.

Results

The highest survival rates mean (±SD) of larvae at 17 DPH was in groups D (68±5.51%) and C (53±5.43%) and significantly different compared to larvae in groups B (50±7.2%), A (36±9.2%) and K (33±6.9%). The highest TL of pikeperch larvae at the end of experiment was in group D (8.57±0.57 mm) and significantly different compared to larvae in groups C (8.23±0.50 mm), A (8.22±0.52 mm), B (8.22±0.46 mm) and K (8.21±0.56 mm). The highest SGR_{TL} at 17 DPH was in groups D (20.76±4.61 % d^{-1}), C (18.28±3.74 % d^{-1}), B (18.26±3.66 % d^{-1}) and A (18.22±4.49% d^{-1}) and significantly differed compared to larvae in group K (18.18± 4.20% d^{-1}).

Table 1. Feeding regime of experimental groups

	5-7 DPH	8-10 DPH	11-13 DPH	14-16 DPH
Group A	rotifers	rotifers	rotifers	Artemia
Group B	rotifers	rotifers	Artemia	Artemia
Group C	rotifers	Artemia	Artemia	Artemia
Group D	rotifers	rotifers+ Artemia	rotifers+ Artemia	rotifers+ Artemia
Group K	rotifers	rotifers	rotifers	rotifers

(Continued on next page)

Discussion

The success in larval production generally depends on the first feeding (Ostaszewska, 2005). The study shows that pikeperch larvae fed with rotifers during first three days and then replacing with *Artemia* (group C) or combination with *Artemia* (group D) resulted in the best performance for fish survival and growth. Similar results were obtained in a study of Yanes-Roca et al. (2018) where larvae had mixed diet of rotifers and *Artemia*. This study can conclude that feeding pikeperch with rotifers during first three days (from 5 DPH till 8 DPH) and afterwards replacing with *Artemia* is proper feeding regime that supports larval development with minimal investments in live feed and labor.

EFFECT OF VISUAL ENVIRONMENTAL ENRICHMENT ON THE WELFARE OF FARMED RAINBOW TROUT (*Oncorhynchus mykiss*)

Introduction

In conjunction with an increasing significance of animal welfare in our society, research on how to improve husbandry conditions in commercial fish farms is also gaining importance. One way of contributing to this is to study various forms of environmental enrichment. While structural enrichment can have several benefits on fish welfare and health, it also reduces tank hygiene with an associated increase in infectious diseases, increases the risk of injuries and is an overall practicability impediment for fish farmers (Näslund and Johnsson, 2016). Therefore, the present study tests the implementation of a purely visual form of enrichment and its effects on welfare, health and condition on farmed rainbow trout. While eliminating several drawbacks, this method maintains a complex visual environment. An improved sensory and cognitive stimulation is believed to play a key role in the neuroendocrine development in fish (Salvanes et al., 2013), which regulates important functions such as immunocompetence and stress tolerance. In consequence, enhancement of these functions would achieve an overall increase in fish welfare

Material and methods

Eight tanks, holding 1m^3 of water each, were stocked with 12kg of rainbow trout (mean weight 20.5g). Previously, four of the tanks have been equipped with surfaces imitating the look of a natural riverbed, while the remaining four control tanks have been lined with a structureless monochromatic green motive. After the acclimation phase, stocking density was kept at 30kg/m^3. Regular samplings of 10 fish per replicate were perf rmed in three-week intervals over a period of 5 months.

As indicators of fish stress, plasma cortisol and glucose levels as well as a differential blood cell count were determined. The fin damage index according to Hoyle et al. (2007) served as additional parameter to quantify fish welfare. Fish health was evaluated by necropsy, including parasitological and bacteriological examinations. Growth rate, condition factor and bacterial load of tank water were determined. Complementary, fish behaviour was examined by video observations

For a second phase of our study, the trout of four tanks were marked with fluorescent pigment (Siebenthal et al., 2017) and were transferred to a commercial fish farm. The remaining trout stayed in their respective tanks at their initial location. On the fish farm, trout of an enriched tank were pooled with trout of a control tank, resulting in two mixed groups. Each group was put in a custom-built cage in the farms raceway, one cage exhibiting the same kind of enrichment as the tanks in the previous phase and the other one featuring a monochromatic green motive serving as a control. After the transfer, sampling continued in both locations for another 5 months.

Results

First results will be presented at the Aquaculture Europe 2019 conference in Berlin.

Discussion and conclusion

Findings of this study will show if purely visual environmental enrichment in farmed rainbow trout has any discernible benefits concerning fish welfare, health or condition. If this is the case, an easy to apply visual modification of fish tanks or raceways would be a valid alternative to other forms of enrichment, without compromising hygiene. Additionally, by mixing fish exposed to the different treatments, the influence of visual enrichment on the ability to cope with neophobia could be evaluated.

Introduction

AquaVitae is a new four year H2020 project with the overall objective of increasing aquaculture production in and around the Atlantic Ocean in a sustainable way by developing new and emerging low trophic species and by optimising production in existing aquaculture value chains. AquaVitae will conduct research and facilitate innovation in five value chains (VCs) selected with regard to their potential for contributing to improved, sustainable food production and their lasting, significant impacts, specifically

VC I: Macroalgal production; New species, offshore production, and post-harvest processes
VC II: Integrated Multi-Trophic Aquaculture (IMTA); land-based and sea-based, new species and systems
VC III: New echinoderm species: Sea urchins and sea cucumbers
VC IV: Existing shellfish species: Oysters and mussels
VC V: Optimised production of selected existing finfish species; freshwater and mari

A series of cross-cutting Work Packages (WPs) will include research on biosensors, Internet of Things (IoT), product characteristics, consumer attitudes, market potential, sustainability, environmental monitoring, risk assessment, analysis of value chains, profitabilit , and other socioeconomic aspects.

AquaVitae will contribute to various policy dialogues and produce briefs on policy and governance issues. The AquaVitae consortium consists of 36 full partners from Europe and countries bordering the Atlantic Ocean, in addition to an Industry Reference group, a Policy Advice Group, and an External Advisory Group. AquaVitae supports extensive communication and outreach activities, employs a multi-actor approach to ensure stakeholder engagement in all phases of the project, and will set up a durable aquaculture industry and research network around the Atlantic Ocean. Industry partners are present in all case studies, and they have a special responsibility for exploitation and commercialization of the project research results and outcomes. AquaVitae will have a lasting impact on society through the introduction of new species, and through the development of new processes and products based on a circular economy / zero waste approach with improved sustainability. AquaVitae will produce Good Practice standards, facilitate industry apprenticeship and student exchange, support extensive training programs for industry, academia, and the public, and contribute to the implementation of the EU-Brazil-South Africa Belém Statement. This presentation will give an outline of how the project will be conducted and will highlight examples from the Case Studies within the project.

JOURNEY FROM INTRODUCTION TILL LOCAL PRODUCTION OF SOY-BASED FLOATING EXTRUDED AQUAFEED IN PAKISTAN; A REVOLUTION IN AQUACULTURE INDUSTRY

R.S.N. Janjua*[1], Shafaq Fatima[2] Sehar Munawar[3]

[1]SoyPak (American Soybean Association/WISHH/Pakistan)
[2 & 3] Lahore College For Women University, Lahore, Pakistan

SoyPak(ASA/WISHH)
Karachi-Pakistan
janjua@soypak.org

In Pakistan, Aquaculture is a rather recent activity and is in a phase of transformatioin from extensive fish farming to semi-intenstive fish farming; nevertheless there is an immense potential for development of this sector. Major challenge faced by this industry hindering progress of this sector had been lack of commercial floating fish feed. Soy-based extruded floating aquafeed was introduced for the first time in Pakistan by United States Department of Agriculture (USDA) in 2012. The imported feed was trialled at various commercial farms by FEEEDING Pakistan Program of American Soybean Association (ASA)/WISHH funded by USDA to convince farmers about nutritional and commercial value of this feed for multiple species.

Amongst these several research trials, FEEDING Pakistan Program carried out a trial (June – November, 2017) to study the effects of locally produced extruded floating pelleted soybean meal (SBM) feed on the growth of genetically improved farmed tilapia (GIFT) *Oreochromis niloticus* at two commercial earthen ponds (n= 4,560 each pond), average stocking weight = 110 g. During this trial, fish were fed with floating soy based feed containing 32% of crude protein (CP) for the first 90 days and 28% CP for next 90 days. Control group was fed with conventional mixture of mash feed; 32% CP for first 90 days and 28% CP for next 90 days without SBM. Thirty days after commencement of trial, a significant increase of 93% was observed in total body weight of fish in treatment group as compared to those in control group. At end of the trial, an increase of 55% was observed in total body weight of treatment group as compared to control group. Feed Convesion ration (FCR) of 1.2 was observed in treatment group and 4.10 in control group. High success of extruded soy-based floating feed in improvement of fish growth was a breakthrough for local aquaculture industry develpment. After strenuous hard efforts of two years, FEEEDING Pakistan Program successfully collaborated with local industry to establish the first floating soy-based aquafeeed mills in 2013. Number of soy based floating aquafeed mills has been increased up to five by 2018. Total production of soy based aquafeed was recorded to be 11,000 metric tonnes in 2017 which has increased up to 21,750 metric tonnes by the end of 2018.

Introduction

An increasing number of studies have been published on the composition of the bacterial microbiota in Atlantic salmon. However, few studies have been made to discriminate between optimal, well-performing communities and suboptimal, "unbalanced" bacterial communities in the intestine. Identificati n of such dysbiosis markers in the salmon gut microbiota, as well as markers of optimal gut community function, would be a vitally important tool in the development of new functional feeds targeting gut health.

The GutBioM project is an initiative that aims to identify and use quantifiable microbiota-related markers as indicators of gut health and intestinal function for the development of functional feeds. The project will increase our knowledge on host-microbiota interactions in fish, by identifying and describing microbiota-related markers such as single bacterial groups, metabolites in blood or feces or specific host responses associated with normal or abnormal health status.

Material and Methods

The first part of the project involved a long-term sea water feeding trial with Atlantic salmon to detect quantifiable microbiota-related markers for gut health and intestinal function. To meet this aim, 28 healthy fish were fed on a standard commercial grower feed diet. These fish were then sampled from the same net pen and divided into two groups based on weight, i.e. fourteen large (High performers, average weight 3.709 kg) and fourteen small (Low performers, average weight 2.111 kg) based on growth performance. The second part of the project focuses on the interplay among functional feed ingredients, gut microbiota, intestinal health, and fish performance, and will assess whether functional feeds can improve the re-establishment of a healthy gut environment after dysbiosis events caused by chemotherapeutic agents such as antibiotics.

The variables chosen for identification of microbiota-related markers of intestinal health and evaluate host response were fish performance, intestinal bacterial microbiota profiling using 16S rRNA gene sequencing, targeted and untargeted metabolomics and short chain fatty acid profiling of fecal and blood plasma samples, targeted and untargeted gene expression profiling and histopathological evaluation of the intestine. Data from the different endpoints will be integrated to identify microbiota-related markers of gut health and function.

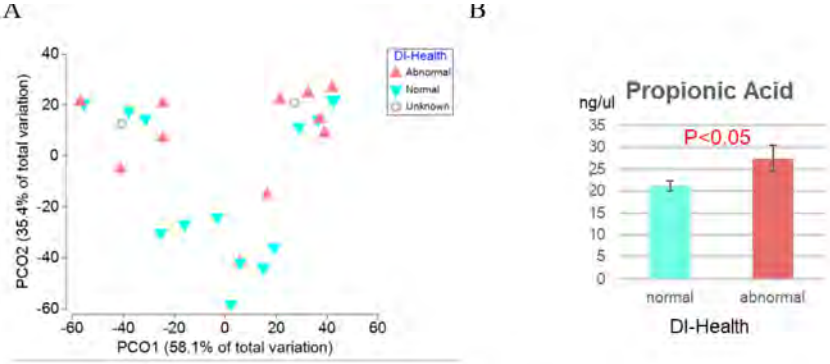

Figure 1. Differences in digesta-associated microbiota according to beta diversity PcoA (Bray-Curtis) (A) and blood plasma propionic acid levels (B) between fish with normal and abnormal distal intestine (DI) histological score.

(Continued on next page)

Results and Discussion

Results from the trial conducted to evaluate intestinal markers of large and small fish indicated that despite that the sampling was conducted in apparently healthy individuals a large number (46%) of the fish showed changes that ranged from mild to marked inflammation in the distal intestine. However, these changes were not associated with fish size. Metabolic differentiation between the two fish groups (large vs small) appeared to be pronounced within the blood plasma, but not in fecal samples. These differences in the plasma were mainly due to changes in metabolites related to glucose utilization and lipid and creatinine metabolism. Short chain fatty acid profiles between large and small fish were similar in fecal and plasma samples except for acetic acid that was significantly higher in the fecal content of large fish. Microbiota profiling showed high dominance of *Aliivibrio*, *Photobacterium* and unidentified member family *mycoplasmataceae* in both the mucosa and digesta. No significant differences in the diversity and overall bacterial structure were observed between large and small fish. Nonetheless, fish with signs of inflammation in the distal intestine had a different digesta-associated microbiota than the fish with a healthy intestine (Figure 1A). Fish with no sign of enteritis had also lower levels of propionic acid in the plasma (Figure 1B). Analyses of samples from the trials conducted in the second part of the project aiming to evaluate functional feeds are on-going and will be presented at the conference.

Conclusion

Signs of suboptimal gut health were apparent in both large and small fish. There were a number of differences in the metabolic profiles between the two groups of fish, possibly reflecting differences in growth rates and energy utilization. Gut bacterial communities were similar for the two groups of fish. Fish with signs of intestinal inflammation showed different bacterial communities, gene expression levels, and short chain fatty acid profiles compared to healthy individuals. The study has provided novel information on intestinal microbiota and metabolic profiles in Atlantic salmon, and identified certain metabolites and bacterial groups associated with high growth and intestinal inflammation that should be targeted in future studies.

EFFECTS OF DIETARY PHOSPHOLIPIDS ON EARLY STAGE ATLANTIC SALMON (*Salmo salar*) PERFORMANCE: A COMPARISON AMONGST PHOSPHOLIPID SOURCES

J. Jaxion-Harm*

TripleNine Group, Trafikhavnskaj 9, 6700 Esbje g, Denmark
E-mail: jjh@999.dk

Introduction

The present study aimed to confirm that additional phospholipids are needed in Atlantic Salmon (*Salmo salar*) fry diet for optimal growth. Furthermore, comparisons were made between two marine-based phospholipids- krill oil and marine phospholipids extracted from fishmeal. Marine-based ingredients are sustainable, but limited; therefore, it is important that many numerous, effective ingredient sources are available for the aquaculture industry.

Materials and Methods

First feeding fish were fed a fishmeal-based diet with 54% protein and 19% fat. Phospholipid (PL) levels in diets were adjusted by using fishmeals with differing levels of PL content and adding either krill oil or fish-based PL oil to levels of 1.3% (low PL control diet), 1.9% (control diet) and 3.5% (diets with added PL). The diets were balanced with regards to astaxanthin and EPA/DHA levels, so the focus was on PL source and level.

Atlantic Salmon fry (0.14g) were distributed in four 60x60cm tanks per diet, and mean water temperature was 13°C during the experiment. Diets were randomly distributed amongst tanks. Fish were sampled after 30 days and 60 days via individual weighing, while number of dead fish was recorded daily. At the termination of the trial, fish were preserved in order to perform intestine histology.

Results and Discussion

Growth of fry fed with diets with added krill oil and fish-based PL oil (3,5% PL) were significantly higher than both control diets with fry fed the lowest PL diet showing the lowest SGR. Final weight of fry fed marine-based PL were more than 12% (fish based PL) and 9% (krill oil) heavier than the control diet (Figure 1). Overall survival was high (more than 93%) and was significantly correlated with PL concentration. Previous research also shows Atlantic Salmon fish larvae (up to 2.5g) fed diets with 2.6, 3.2, 3.6, and 4.2% PL (added krill oil) had higher growth rates and lower mortality than the un-supplemented baseline diet of 1.5% PL (Taylor et al., 2015). Taylor et al. (2015) also found intestinal steatosis in early stage Atlantic Salmon fry when fed the baseline diet and no steatosis in any of the krill oil supplemented diets. Intestinal steatosis analysed via histology in the present study will also be discussed. The results verify that Atlantic salmon have a dietary requirement of PL in their early stage. These results correspond with previous work on multiple species of fish larvae and juveniles (Couteau et al., 1997; Tocher et al., 2008; Dapra et al., 2011; Taylor et al., 2015). Most importantly, growth of these fry increased with addition of marine-based PL, regardless of the marine-based source.

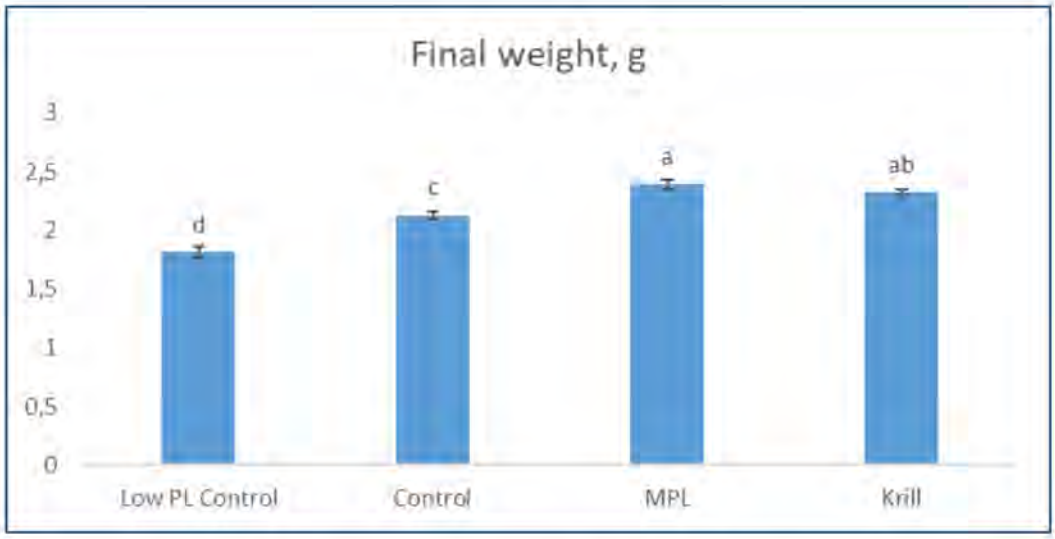

Fig. 1. Final weight of Atlantic Salmon first feeding fry (0.14g) after 60 days at 13°C. Diets were in quadruplicate and fish were individually weighed

INTEGRATION OF FISHERIES AND AQUACULTURE INTO A MORE HOLISTIC SEAFOOD PRODUCTION SYSTEM

Keith Jeffery*, Stephen Mangi, Heather Conejo-Watt, Angela Muench & Kieran Hyder

Centre for Environment, Fisheries & Aquaculture Science, Barrack Road, The Nothe, Weymouth
Dorset, DT4 8UB, UK
Keith.Jeffery@Cefas.co.uk

Background

Food security has been highlighted as one of the major global challenges to 2050 with fisheries and aquaculture identified as key contributors to this challenge. Sustainable aquaculture needs to fit with and supplement sustainable fisheries. An increasingly large share of fish entering global markets derives from aquaculture; the world's fastest growing food production sector for more than four decades, making it roughly equal to global capture fishery production. The two production systems have important complementary roles in meeting rising demand for fish and other products (such as animal feed and fish oil) and enhancing incomes and nutrition. However, policies associated with the two are not always complementary. The aim of our two-year project was to strengthen Cefas knowledge in future integration of fisheries and aquaculture.

Key Objectives

1) Have literature of what is happening across Europe and perhaps globally with respect to fishermen diversifying/ integrating into aquaculture;
2) Have the results of a series of workshops with UK fishermen
3) Have information on any social and economic barriers to this happening;
4) Write at least two papers on results.

Methods

Year 1 An internal workshop including fisheries, aquaculture and socio-economist personnel was followed by a snowball literature search and subsequently a systematic literature for agreed search terms. The results were then sorted, selected and placed into Mendeley software before being allocated and read by project members.

In addition, a parallel grey literature search contacted key personnel involved in both aquaculture and fisheries and asked them for case studies where fishermen had
1. Switched from fishing into aquacultur
2. Combined fishery activities with aquaculture
3. Used aquaculture technology for their benefit within the capture fishe .

The case study results from the grey literature search were then tabulated by type of aquaculture and region.

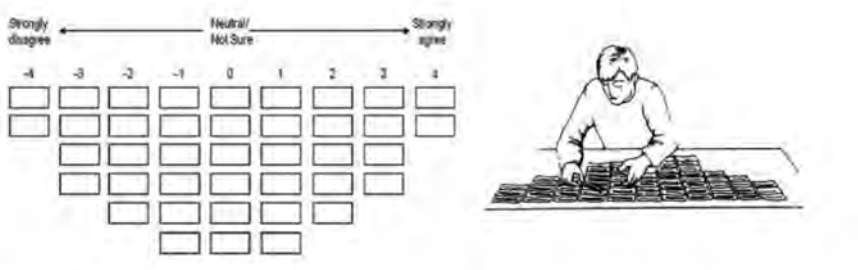

Figure 1 Q-Sort methodology.

(Continued on next page)

Year 2 The summarised findings from both literature searches were used within workshops with fishermen to canvas their views and identify any social, technical, financial, economic or other barriers that may affect greater integration of the two sectors. The workshops (which focussed on the UK inshore fleet) were organised within fishing ports with differing types of local fisher .

- Hastings (sole, plaice, skate, cod, bass)
- Mevagissey (mackerel, pollock, mullet, bass, pilchards, bream, flatfish, herrin
- Kingsbridge (shellfish

A fourth workshop in Bridlington resulted in no show due to a spell of calm weather.

The approach during the workshops was use of the Q-method. The fishermen were presented with 30 statements obtained from the literature reviews and preliminary interviews with 5 fishermen. The statements were grouped into five themes: Social, Economic, Training/skills, Regulatory/policy & Environmental. They were then asked to sort them into those they either strongly agreed or disagreed with.

The 30 statements were sorted into distribution (shaped as a normal distribution curve.) so that we could conduct principal component analysis that allowed us to identify common groupings of responses amongst the participants (that we call factors).

Results / Outcome

The year 1 literature search provided some emerging themes such as economies of scale, complementarity with marine livelihoods, social acceptance and individual skills and attributes. The grey literature search provided some excellent examples for all three categories from many parts of the UK coastline showing that to some extent the diversification and movement towards a more holistic seafood chain has already happened or is in progress. The year 2 workshops with fishermen demonstrated the benefit of using the Q methodology via successful engagement of the fishermen and the resulting data sets for analysis. Our analysis identified four factors within the inshore fishing communi .

Factor 1 (The professional fisherman Contra
Occupational pride and family tradition.
Factor 2 (The worrier) Pro
Concerned about economic aspects and having the relevant equipment.
Factor 3 (The thrill seeker) Contra
Value the enjoyment they receive from fishing – which they feel would not be the same with aquaculture (less "hunting" more "farming").
Factor 4 (The inexperienced) Pro
Have heard success stories but would need more information/training and skills to start up an aquaculture business.

Summary

To enable closer integration of fisheries and aquaculture into a more holistic seafood chain, policy teams and funding bodies could consider providing financial incentives for fishermen within factor 2 and training and information for those within factor 4. The project has identified socio-economic barriers and provided valuable background information for helping facilitate closer integration of fisheries and aquaculture. Two papers are in draft as a result of this project.

Acknowledgements

Thanks to Cefas for funding and providing resources for this project, to the aquaculture industry experts who contributed to the grey literature search and all the fishermen and their representatives in Mevagissey, Kingsbridge, Hastings and Bridlington that contributed to the workshops.

DETERMINING THE HERITABILITY OF GROWTH TRAITS IN CULTURED EUROPEAN LOBSTERS USING GENOMICS

T.L. Jenkins[1], C.E. Ellis[1,2], C.L. Daniels[2], E.M. Santos[1], J.R. Stevens[1]

[1]Department of Biosciences, College of Life and Environmental Sciences, University of Exeter, Exeter, UK
[2]National Lobster Hatchery, South Quay, Padstow, Cornwall, UK.
Email: t.l.jenkins@exeter.ac.uk

Since the early 2000s, there has been a steep rise in aquaculture production, a trend driven in part by technological advances and socio-economic factors such as food security and the stagnation or overexploitation of many wild fisheries. This has led to a common goal among aquaculture managers, scientists and governments, namely, to enhance productivity and maximise yield in species targeted for aquaculture. Growth is an economically important trait in aquaculture, and while it has been studied extensively in agriculture and some pioneering aquatic species (e.g. salmon) for selective breeding, the heritability of growth traits in species emerging as appealing aquaculture candidates, such as lobsters, is generally not well understood. The European lobster (*Homarus gammarus*) is a prized seafood product in the UK, where it is one of the highest value export species by weight (£14.06kg^{-1} on average in 2017 – more than triple that of cod), making it an extremely attractive option for aquaculture. However, although molecular techniques have been applied in the species (i.e. to elucidate genetic structure and paternity ecology in *H. gammarus* populations), the heritability of growth traits in this species remains unknown. A recently completed project (Lobster Grower 2) revealed that hatchery-reared lobsters cultured at sea in passive systems from an early post-larval stage show considerable variation in growth over the same time period (Fig. 1). In this study, therefore, we are conducting a genome-wide association study (GWAS) on these cultured lobsters, with the aim of identifying loci (if any) that are associated with growth traits. In particular, a genotyping-by-sequencing approach will be implemented on ~180 individuals to screen for single nucleotide polymorphisms (SNPs) that significantly associate with growth measurements. Furthermore, because the life history of each animal is known, this means that variation as a result of rearing batch or environmental conditions can be controlled for in the GWAS. The results of this study will provide novel information about the heritability of growth traits in the European lobster and will potentially provide a valuable tool to inform future development of aquaculture and selective breeding programmes in this species.

DOMESTICATION-ASSOCIATED LIPID METABOLISM REGULATION IN ATLANTIC SALMON

Introduction

Atlantic salmon (*salmo salar*) has been domesticated in Norway since 1971 and has been selected for better growth and performance for 11 generations. This has resulted in a farmed strain with larger size and growth rate, but genetically and morphologically diverged from the wild populations (Fleming, Einum, 1997).

Long chain polyunsaturated fatty acids (LC-PUFA) such as docosahexaenoic acid (DHA, 22:6n-3), eicosapentaenoic acid (EPA, 20:5n-3) and arachidonic acid (ARA, 20:4n-6) are especially important for salmon. Farmed salmon are getting less LC-PUFA in the past 15 years since they are fed more vegetable oil (VO) rather than traditional fish oil (FO) in diets. The present strains of farmed salmon should be better adapted to VO diet compared to earlier generations, but whether this includes higher LC-PUFA synthesis abilities is unclear. Dietary phospholipids (PL) are more efficient at delivering LC-PUFA into fish body rather than triacylglycerols (Olsen, et al., 2014). The efficiency of utilizing dietary PL could be different between farmed and wild salmon.

The present study has compared the whole transcriptomic and fatty acid differences between farmed and wild salmon feeding either FO, VO or PL diets, aiming to identify 1) differences in transcriptomic state between farmed and wild salmon and 2) domestication associate changes in lipid metabolism regulation when feeding contrasting diets rich in either FO, VO or PL.

Materials and methods

The farmed and wild salmon were separated into 12 tanks (2 fish strains x 3 diet treatments x 2 replicate tanks) and started feeding at the same time. The fish was given three contrasting diets from start feeding up to 94 days, either a FO diet high in LC-PUFA, or a VO diet low in LC-PUFA, or a PL diet with high LC-PUFA in PL. Fish was sampled at day 0 (before start-feeding), day 65 and day 94 after first feeding. The pyloric caeca and liver tissues were sampled and used for RNAseq and fatty acid analysis. Differential expressed analysis was applied between wild and farmed salmon under any contrast of developmental stages and dietary treatments. The cut-off of differential expressed genes (DEGs) was q<0.05 and log2 fold change >1 or <-1 at any contrasts group.

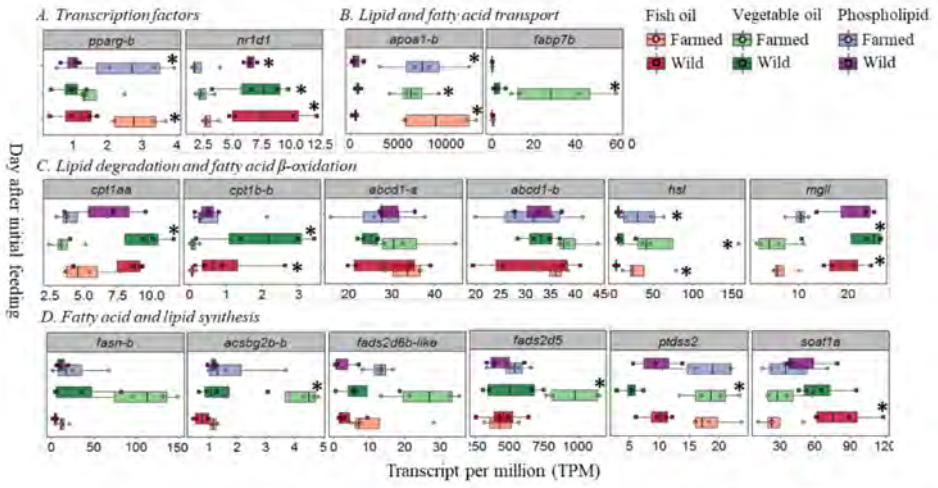

Figure 1 Expression of genes involved in lipid metabolism in liver of wild and farmed salmon at day 94 after feeding FO, VO and PL. Gene expression was shown as transcript per million (TPM) which was normalized by library size and mRNA length. Asterisk indicates DEGs between farmed and wild salmon under each strain and dietary treatment.

(Continued on next page)

Results and Discussions

After 93 days of feeding, the farmed salmon reached 4.5g, while wild salmon was 2.6g. No difference was found on the weight of farmed salmon when fed FO, VO and PL diets. However, the growth of wild fish seemed more sensitive to dietary lipids, with PL-fed fish having the best growth followed by FO-fed fish and then VO-fed fish. We found 4418 DEGs in pyloric caeca and 2137 DEGs in liver across all dietary treatments. DEGs with higher expression in farmed salmon were enriched energy metabolism, amino acid and lipid synthesis pathways, suggesting more efficient energy conversion via protein and lipids synthesis.

Several genes of lipid metabolism were differentially expressed between liver of farmed and wild salmon (Figure 1). Gene *apoa1-b* and *hsl* was always higher expressed in farmed salmon, suggesting that they have higher ability of lipid transport, lipid turnover and phosphatidylserine synthesis. Genes of transcriptional regulation (*srebp1a* and *pparg-b*), peroxisome oxidation (*abcd1a* and *abcd1b*), fatty acid transport (*fabp7b*) and fatty acids synthesis (*fasn-b*, *acsbg2b-b*, *fads2d6b-like* and *fads2d5*) was only differentially expressed between farmed and wild salmon when fed VO diet. This shows that farmed salmon is able to modify its fatty acid metabolism to compensate for the shortage of essential LC-PUFA in the diet, while such ability is very low in wild salmon. Meanwhile, higher content of DHA, ARA and EPA and lower content of 18:3n3 and 18:2n6 was found in phospholipid of liver in farmed salmon than wild only when they were given VO diet. This was likely an effect of *fads2d5* and *fads2d6b-like* genes (Monroig, et al., 2010).

Conclusion

The higher growth and development of farmed salmon was likely due to combination of various genetic advantages including better uptake, transport and biosynthesis of nutrients. Moreover, farmed salmon had higher regulatory plasticity when given a VO diet with less essential fatty acids, while such ability is very low in wild salmon.

THE EFFECT OF WAVES ON VERTICAL DISTRIBUTION OF ATLANTIC SALMON (*Salmo salar*) IN AN EXPOSED SALMON CAGE

A. Johannesen*, P. Klebert, Øy. Patursson

Fiskaaling, við Áir 11, FO-430 Hvalvík, Faroe Islands
asajoh@fiskaaling.f

Introduction

As salmon aquaculture expands into more exposed locations, the environmental conditions become more extreme with stronger currents and larger waves. Atlantic Salmon (*Salmo salar*) are well equipped to cope with both currents and waves, but the nature of salmon cages can compromise their ability to cope in poor conditions. This study considers to what extent salmon are able to use behavioural coping mechanisms when exposed to large waves.

Materials and methods

One salmon cage was monitored for the duration of two months in a wave exposed salmon farm on the Faroe Islands (Miðvágur farm location). Observations were timed to allow for monitoring during poor and good weather conditions (from late February to early April) and the chosen cage was located such that it had maximal exposure to waves. The salmon were approximately 2kg in size and night lights were located in the cage to prevent sexual maturation.

Two current profilers outside of the farm and a single point current meter inside the cage were used to monitor water conditions. Two echo sounders located underneath the cage and looking up were used to monitor vertical distribution as well as horizontal movement of salmon within the cage. Both echo sounders were located approximately half way between the centre and the edge of the cage, one at the side where waves entered the cage ("front") and one at the side where the waves exited the cage ("back"). The echo sounders looked through approximately 15 metres from the bottom of the cage to the water surface in a cone shaped beam and at the surface, they covered an area of approximately 11m Ø.

Four video cameras were in place to monitor detailed behaviour, such as shoaling and swimming effort.

Results

Wave data indicated that wave intensity or power decreased rapidly with depth with much lower water movement speeds at 10m depth than at the surface. The data coincided fairly well with the data from the single point current metre within the cage, so the wave data are fairly representative of conditions within the cage. At wind directions from 90 to 180 degrees, wave height correlated with wind speed, whereas there was no correlation at other wind directions. This allowed us to use wind as a proxy for wave height at the relevant directions.

Salmon had a general tendency to seek further down when waves grew taller. This effect was countered by wave period, with a longer period being associated with salmon moving higher up in the water column. This indicates that the large waves caused by bad weather (which typically have sort periods) are those that affect salmon most. This is corroborated by the fact that there is a similar response in vertical distribution of salmon when wind is used as a proxy for wave height while vertical distribution is differently, but not unaffected by wind speed at the other wind directions.

As relevant wind speed increased, tail beats per minute decreased and became less regular. Video footage indicates that the salmon switched from using their tails for propulsion to instead balancing within the waves and moving forward very slowly.

Salmon also showed a tendency to switch swimming direction as wind speed increased.

Discussion

The cage depth was only 15m at the deepest monitored point. Salmon were often seen at this depth, and it is unclear if they would have chosen to move further down if they had the option. Salmon behaviour differed at the front and back echo sounders. The cause of this difference is unclear, but if it is due to restriction due to cage deformation, then consideration of the effect of short period, large waves must be taken into account when designing cages for exposed locations.

ECOINTENSIFICATION OF AQUACULTURE: CAPTURE AND VALORISATION OF SLUDGE FROM AQUACULTURE WASTEWATER

Johan Johansen*, Lars Svenningsson and Hallstein Baarset

Salten Havbrukspark, 8120 Nygårdsjøen, Norway
E-mail: johan@havbruksparken.no

Aquaculture is expected to contribute to fill the foreseen gap in food supply towards 2050 and beyond. Hurdles to overcome to allow for an industrial growth of relevant scale relates to economic, environmental and social sustainability, and the solutions sought must be correspondingly multi-disciplinary.

GAIN (Green Aquaculture Intensification in Europe), a recently awarded Horizon 2020 project, aspire to deliver services and technologies to market within the project period to contribute to the ecointensification of European aquaculture production. Resource efficienc , reduced environmental impact, increased precision and valorisation throughout the production chain are all key elements in the approach to improve seafood self-proficiency and regional stabilit .

As intensificati n of aquaculture warrants reduced environmental impact, parts of our efforts are focused on capturing dissolved and particulate matter in wastewater from landbased aquaculture. Valorisation of the resulting products provides incentive for the industry to invest in environmental technologies, augmenting resource efficiency and facilitating circular economy.

A GAIN demonstration facility has been established at a Norwegian Atlantic salmon smolt producer, for evaluation, documentation and professional training on relevant substrate in industrial scale. Results from the characterisation of wastewater and sludge, and evaluation of different valorisation pathways will be presented. Technologies to be demonstrated are identified as having potential for superior performance, cost- and energy-efficienc , autonomous and resilient towards fluctuations in o ganic loading.

We will present some encountered obstacles for circularity and the most promising value chain perspectives.

This project has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement N° 773330

INTEGRATED MULTITROPHIC AQUACULTURE SYSTEM PAVES SUSTAINABLE WAY TO MITIGATE THE BIOEFFLUENT

Introduction

Combination of fed aquaculture with inorganic extractive (and organic extractive aquiculture to generate balanced systems for environment remediation, economic stability and social acceptability is called Integrated Multitrophic Aquaculture System (IMTA). For example, farmers can combine fed species, like salmon, with seaweeds, suspension feeders, such as scallops and mussels, and or organic deposit feeders such as sea-cucumbers to increase production efficiency and decrease waste.

Fed aquaculture system:

Feed cost covers maximum input to the operation cost. But, Integrated Multitrophic Aquaculture System containing fish can provide dissolved and particulate nutrients to one to another species. Hence, combined species can effectively utilize the nutrients without lose. The quantity and form of these nutrients is depends on species size and feed formulation among other factors. Feed formulation provides perhaps the most obvious route for fish effluent modification for the extractive computes conversely other trades in the aqua feeds industry may impact fish effluent quality for an I A system.

Pros and Cons of Integrated Multitrophic Aquaculture System

Proper species selection to this system can mitigate the bio effluents through absorption of suspended and dissolved nutrients which minimize the nutrient discharge and feed cost. By adopting this technology can promote the economy and generate better profit. One system can produce three species with low feed input. Product diversification may office financial protection and decrease economic risks when price fluctuations occur if one of the alp is lost to dies or increment weather. Prevention or reduction of disease among farmed fish can be provided by certain seaweeds due to their antibacterial activity again fish pathogenic benefits. Potential for differentiation of the IMTA product through eco labelling or organic certification program

Higher investment is required to establish this technology. Integrated farming in open sea request a higher level of technological and engineering sophisticated and up forty investment. Difficulty in coordination, if practiced by means of different working in concern, it would require cools collaboration and coordination of management and production activities.

Integrated Multitrophic Aquaculture System is an emerging research carried out by several central institute of India. It will enhance the production without affecting environment. Recently this technology operated in freshwater which is called Freshwater Integrated Multitrophic Aquaculture System (FIMTA).

SALMON LICE (*Lepeophtheirus salmonis*) INDUCED MORTALITY OF ATLANTIC SALMON (*Salmo salar*) SURING POST-SMOLT MIGRATION IN NORWAY

Ingrid A. Johnsen*[1], Alison Harvey[1], Anne D. Sandvik[1], Ola Ugedal[2], Pål Næverlid Sævik, Bjørn Ådlandsvik[1], Vidar Wennevik[1], Kevin A. Glover[1] & Ørjan Karlsen[1]

Introduction

Marine aquaculture in open-cages has resulted in diverse environmental challenges. In Norway, the sustainability of aquaculture is evaluated in 13 management areas along the coastline. The environmental impact with respect to salmon lice is evaluated in the "Traffic Light System", whereby a management area is determined as "green" if lice are estimated to cause < 10% mortality of wild salmonids, "yellow" if estimated mortality is 10-30%, and "red" if estimated mortality is > 30%. These colours refer to that the status: permit further expansion, no change, or production reduction, respectively (St. Meld. 16, 2014-2015).

For wild Atlantic salmon post-smolts that migrate from their rivers to the ocean, the first phase of their journey, in fjords and the coastal zone where aquaculture occurs, is considered as the critical and potentially population-regulatory phase with respect to exposure to lice (Torrisen et al.; 2013; Taranger et al.. 2015; Glover et al., 2017; Forseth et al., 2017). Therefore, to estimate lice-induced mortality of wild salmon post-smolts in Norway, we developed a novel model system predicting the lice infestation pressure level and mortality for over 400 rivers covering all of the Norwegian coastline. Thereafter, the modelled lice infestation pressure was used to estimate the mortality of Atlantic salmon post-smolt. These estimated mortalities were used to evaluate the sustainability of the aquaculture production in 13 management areas along the coastline, considering the influence of salmon lice

Material and methods

To estimate salmon lice induced mortality of wild salmon post-smolts migrating towards the ocean, we built a virtual post-smolt (VPS) migration model using knowledge of migration speed and timing from empirical observations. To include the lice infestation on the VPS, we combined data from a fine-scal distribution of lice in time and space from a previously published lice dispersion model (Johnsen et al., 2016; Sandvik et al., 2016, Myksvoll et al., 2018). The infestation level in the model was calibrated using measurements of lice infestation levels of wild salmon post-smolts that had been captured in the sea in 2015-2017. The river of origin for the wild post-smolts captured by trawling was determined by genetic assignment to provide the optimal dataset for model calibration (Harvey et al., submitted). Further, observations from trawl-captured post-smolts in 2018 was used to validate the model outputs.

Finally, by assuming tolerance of lice as given by Taranger et al. (2015), lice induced mortality was estimated for all salmon rivers along the Norwegian coastline using the model.

Results

The lice level on modelled post-smolts, using the tuned infestation level, was strongly correlated (spearman rank order correlation coefficient = 0.8, $p>0.01$) to the lice level observed on captured wild post-smolts. Mortality for the 401 salmon rivers was calculated and ranged from 0 to 83% among rivers in 2018. The highest mortality estimates were found for the rivers situated in the western part of the country and in particular in the inner part of the long fjords. The estimated mortality categorized in three classes with low (<10%), medium (10-30%) and high (>30%) mortality is presented in green, yellow and red respectively in Figure 1. Of the 401 rivers, 299 of them were found to be in the low category, 64 medium and 38 at high mortality levels for 2018.

Concluding remarks

Salmon lice induced mortality has a negative effect on wild Atlantic salmon post-smolts in areas of intensive salmonid aquaculture. The effect is now well documented (Skilbrei et al., 2013; Vollset et al.,2016), but can be hard to evaluate for all rivers in Norway and on an annual basis. Here, we developed a unique virtual post-smolt (VPS) model that estimates the lice induced mortality of out-migrating salmon post-smolts. The VPS model estimates presented here provides the regulatory authorities with an objective measure of the influence salmon lice have on wild fish in a time period, and in areas that the post-smolts are likely to migrate through.

FJORD BASIN WATER EXCHANGE IN SILL NORWEGIAN FJORDS

Ingrid A. Johnsen*[1]

[1]Institute of Marine Research (IMR), Norway
*Corresponding author, e-mail: ingrid.johnsen@hi.no

Introduction

The global change in climate is expected to have large ecological implications, although knowledge of such changes in fjords and coastal waters is sparse. A fjord is characterised by the presence of a shallow sill at its mouth that cuts off basin water below the sill depth from direct communication with the continental shelf and the ocean water.

The exchange of the basin water will only occur when the oceanic water at sill depth is denser than the fjord basin water. Between exchange episodes the fjord basin water density is continuously decreasing due to vertical mixing processes. The time intervals between exchanges of deep fjord water depends on several factors, like sill depth, conditions of water mass both inside and outside the sill, freshwater supply, tides and wind conditions (Inall et al., 2010). Generally, the fjord basin exchange occurs less frequently in fjords with shallow sills, and more frequently in northern Norway (annually) compared to southern Norway (8-9 years in between) (Sælen 1950, 1967, 1976, Gade 1973, Aure et al. 2007).

A shift in the environmental conditions provide beneficial conditions for some species, for other species it can degrade previously suitable habitats (Pörtner & Peck, 2010).To increase the knowledge of climatic alterations in the fjord basins, we have investigated how the environment is altered through warming, increased stratification and reduced water exchange resulting in less frequent re-oxygenation of the deep fjord basins in the last 50 years. This knowledge is essential for studying variability in and the potential changes to these ecosystems, and to evaluate the sustainability of aquaculture activity in sill fjords to obtain a predictable environmentally sustainable production that is demanded (St. Meld. 16, 2015).

Material and method

Information of the water column at the coast was analysed from the IMRs coastal stations observing salinity and temperature weekly going back to the late 1930s. Additional information of the coastal environment will was provided by analysis of the wedge between coastal and Atlantic water, mapped from the sections marked in blue in Figure 1, mapped 4-6 times a year. Alterations in the structure of the water masses during the latter 50 years was analysed. The wind close to surface was analysed for temporal trends and set in context to the vertical depth of the interface between Atlantic and Coastal water.
Fjord basin exchange episodes was recognised in time series of salinity and oxygen from the historical fjord surveys containing observations of temperature, salinity, oxygen and more from 139 stations, in 32 fjords from south to north from the time period 1975 – 1997. The monitoring of fjords continued less systematically after this at the western part of Norway. However, in Northern Norway the fjords have been monitored for the latter 100 years (Mankettikkara R. 2013). This long term the dataset made it possible to evaluate the long-term levels, trends, and fluctuations in temperature, salinity, and oxygen the fjords basins.

Results

The coastal station observations showed that there has been an environmental change since the 1990s. The temperature in the upper 200 m has increased in the latter 30 years at all stations, with the increase largest close to the surface at the southern stations (Figure 1). At Utsira (59.5°N) the average temperature at 20 m depth from 2010-2015 was 10°C compared to under 8°C during the 1985-1990 period. The observations from the coastal stations clearly show that the water column has a stronger vertical temperature gradient in the southern station (Utsira) compared to the northern station (Ingøy, 71°N) (Figure 1).

At the southern station (Utsira) the upper water salinity has decreased with increasing temperatures, resulting in less dense water (not shown). During the last 30 years, the density at 20 m depth at Utsira has decreased one sigma unit, increasing the stability of the water column. In contrast, the density at Ingøy has stayed relatively constant.

The alterations in the coastal environment was reflected in the fjord basins with respect to temperature (not shown). It is hypothesised that the increased stratification at the coast will impact the fjord basin exchange rate in sill fjords, however this remains undocumented.

E-mail: ajo@aqua.dtu.dk

Rainbow trout farming and in particular organic rainbow trout farms are critically challenged by the relatively high prevalence of skin/gill infections caused by various pathogens, especially the parasite Costia (*Ichthyobodo necator*) and amoebae, which are ultimately lethal for fry/smaller fish. In addition, a *Midichloria*-like bacterium causes the non-lethal skin disease Red Mark Syndrome (RMS), which results in downgrading/rejection of up to 30% of the fish when placed on the market. Treatment by use of antibiotics/parasitics/ auxiliary compounds is only possible to a limited extent in organic trout production. Hence, solutions to prevent and/or treat costia, amoebae and RMS are urgently needed, not only to secure production of organic rainbow trout in Denmark, but also enable a larger and more cost efficient production with high animal welfare and minimal environmental impact.

ShelterFish will focus on solutions addressing the interactions between fish - pathogens – farming environment and water quality; including 1) Test of artificial shelters (shade) to enrich environmental conditions and lower stress; 2) Test of biological herb extracts and a new bacterial surfactant to minimize gill/skin parasite infections; 3) Test of induced immunity to Red Mark Syndrome (RMS) by early exposure; and 4) Test of tools to reduce organic matter load in organic trout farms and hereby improve water quality, fish health/welfare

TRANSPORT STRESS IN BALLAN WRASSE (*Labrus bergylta*) AND LUMPFISH (*Cyclopterus lumpus*)

T.M. Jonassen*, A. Foss, M. Remen, E.J. Watts, T.A. Hangstad

Akvaplan-niva, Framsenteret, 9296 Tromsø (Norway)
E-mail: tmj@akvaplan.niva.no

Introduction

Ballan wrasse and lumpfish produced in land-based systems are used in sea cages to reduce sea lice infestation. The transport to sea by truck or boat and physical disturbances associated with loading, transport, and discharge will cause stress of varying degree, possibly leading to long-term health impairment. Hence, it is important to understand the physiological response to transport to ensure acceptable fish welfare and the fish s ability to adapt to the new environment in salmon cages.

Materials and methods

Primary stress response (plasma cortisol) from four commercial transports of Ballan wrasse and lumpfish, was analyzed and discussed in relation to transport conditions. For each species, two transports were by truck and two by boat. Blood from five fish in each transport groups were sampled before transport and after primary transport. For two groups of Ballan wrasse with a two-step transport (truck + boat) fish were also sampled after the secondary transport. In addition, five fish from each groups were sampled 7-10 days after transfer to sea cages. Good water quality condition (89-124 % oxygen and pH 8,8 – 7,0) was reported for all transports. A two-way nested ANOVA (group nested in time) followed by SNK-test ($\alpha = 0,05$) was used to test changes of plasma cortisol over time. A one-way ANOVA was used to test differences between groups at each sampling time.

Results

Lumpfish showed a significant increase in plasm cortisol after transport for all groups ($p<0,001$), with the highest increase in fish transported by boat (T3 and T4, transport time 6 and 5 h) compared to truck (T1 and T2, transport time 6 and 5 h). 7-10 days after transfer to sea T2 and T3 returned to levels slightly higher than before transport, while T1 and T4 returned to stress levels significantly lower than before transport ($p<0,05$)

With the exception of T1, there was an increase in plasma cortisol after primary transport compared to pre-transport levels and a stabilization (T4) or slight decrease (T3) after the secondary transport. T1 had the highest cortisol level before transport compared to after transport and 7-10 days in sea. For the other groups (T2-T4), the fish did not regulate plasma cortisol to pre-transport levels after 7-10 days in sea. T2 showed an exceptionally high plasma cortisol in sea cages.

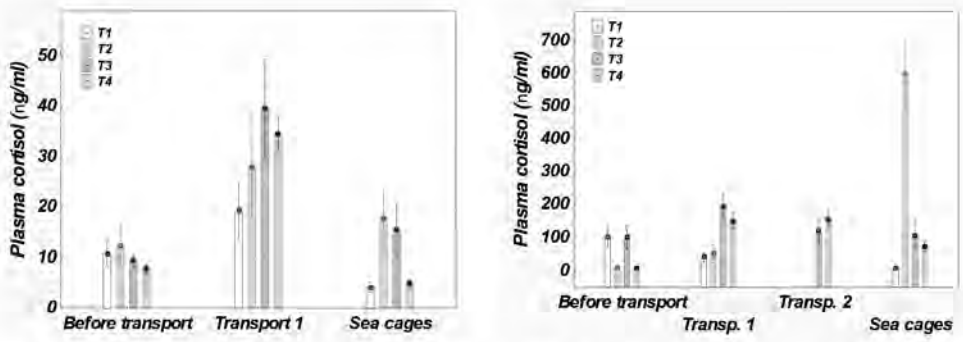

Fig. 1. Development of plasma cortisol (ng/ml) in four transport groups (T1 – T4) of lumpfish (left) and Ballan wrasse (right) before and after transport, and 7-10 days after discharge to sea cages. Vertical lines on bars indicate standard error of mean (SEM). Transport 1 = primary transport, Transport 2 = secondary transport.

(Continued on next page)

Discussion and conclusion

In general, the level of transport stress in lumpfish was lower than previous reported from 15 commercial transports of lumpfish, mainly truck transports (Remen et al. 2017), indicating recent improvements in transport practice and conditions. The tendency of higher stress after boat transport of lumpfish compared to truck transport was most likely a result of the shorter transportation time by boat, as increased transport time under good conditions increase time for recovery after handling-stress (Iversen et al. 2005). Independent of transport conditions the seawater conditions or site characteristics seemed to influence the acclimation of the lumpfish after discharged to sea cages. The higher stress levels in T2 and T3 7-10 days after transport compared to T1 and T4 may be associated with the higher water current at the sites for release.
This is the first recordings of stress during transport of Ballan wrasse. The low pre-transport levels are similar to (T4) or slightly higher (T3) than resting levels previously measured in tank experiments with Ballan wrasse (Epmark et al. 2017). The cortisol levels in T3 and T4 after primary and secondary transport are similar to 1-hour pre-stress levels after exposing Ballan wrasse for 20 min. tank draining (Iversen 2016). Based on the elevated levels of plasma cortisol in T3 and T4 compared to T1 and T2 after the primary transport, truck transport seemed more stressful to Ballan wrasse compared to boat transport, but was reduced following a 16 hour secondary transport by boat (T3). The pre-transport sampling from T1 was, unlike the other groups, done after the water level in the tank was drained (lowered) to prepare for pumping fis to transport tanks. Hence, the elevated stress level was probably a response to crowding, indicating that a significant part of the stress associated with transport of Ballan wrasse is related to pre transport procedures. The exceptionally high stress level in T2 after transferred to sea, was followed by an accumulated mortality of 19% after 7 days in sea. This suggests that high seawater temperatures (16-18 ˚C) under stressful conditions caused the elevated mortality.

This investigation of stress response of lumpfish and Ballan wrasse to different transport conditions indicate generally good welfare during transport, but that special considerations should be payed to pre-transport conditions and handling, and reduced environmental challenges after transfer to sea cages.

Introduction

The aquaculture production of European eel has declined due to stock depletion and low abundance of juvenile glass eels used as fry in eel farming. Captive breeding and larval rearing to the glass eel stage would overcome this obstacle. Yet, eels do not reproduce in captivity due to a dopaminergic inhibition of the follicle stimulating hormone (FSH) and luteinizing hormone (LH) at the brain-pituitary level, preventing sexual maturation (Vidal et al., 2004). However, weekly hormonal treatment with pituitary extract from salmon (SPE) or carp (CPE) to stimulate ovarian development can overcome these maturational barriers (Mylonas et al., 2010). Such breeding protocols for anguillid species were established using different treatment schemes for SPE and CPE (Bezdenezhnykh & Prokhorchik, 1988; Ohta et al., 1997). Thus for European eel, breeding protocols generally use a constant dose scheme for SPE, while treatment with CPE often use a stepwise increasing scheme starting at a low dose. Nevertheless, the efficacy of these treatment schemes needs to be validated. In the present study, we investigated differences in egg quality and reproduction success when using a constant CPE dose versus an increasing dose, while considering the underlying molecular mechanisms involved in the progression of vitellogenesis.

Materials and methods

CPE was administrated weekly to farmed broodstock females (n=87) to artificially induce maturation. Two treatments were compared: 1) Constant dose of 20 mg kg^{-1} of CPE until ovulation (n=38) and 2) Increasing dose of CPE (i.e., 5, 10, and 15 mg kg^{-1} for nine weeks, three weeks per dose, followed by 20mg kg^{-1} until ovulation; n=41). Morphometry (i.e., gonado-somatic index (GSI) and liver index (LI)) and histology was used to follow the development and growth of ovaries and livers for the two treatments. Females were dissected at day 0 (n=8), and after 6, 9, and 12 weeks eels (n=8 per treatment) as well as after spawning (remaining females). Organs were weighed and tissue samples were obtained for histology and molecular analyses. Ovarian tissues were stained with periodic acid Schiff's (PAS) hematoxylin and metanil yellow (Quintero-Hunter, Grier & Muscato, 1991). Oocytes were categorized into developmental stages within the phases pre-vitellogenesis (LV3 and LV4), vitellogenesis (VT1-3), and final maturation and hydration (HYD) (da Silva et al. 2016). Evaluation of ovarian maturation was based on the most advanced oocyte stage present in the sample. In addition, expression of ovarian gonadotropin receptors (*fshr, lhr1* and *lhr2*), estrogen receptors (*erα, erβ1, erβ2, gper1* and *gper2*), androgen receptors (*aa-ara* and *ara-arb*), and vitellogenin genes (*vtg1* and *vtg2*) in ovaries and livers was analyzed through real-time polymerase chain reaction (qPCR) and compared between treatments and over time. The remaining females (n=31) were spawned and ovulated eggs were fertilized. Spawning success (i.e., successful ovulation of eggs), fertilization-, hatch-, and larval deformity rate were calculated for the treatments to evaluate egg quality.

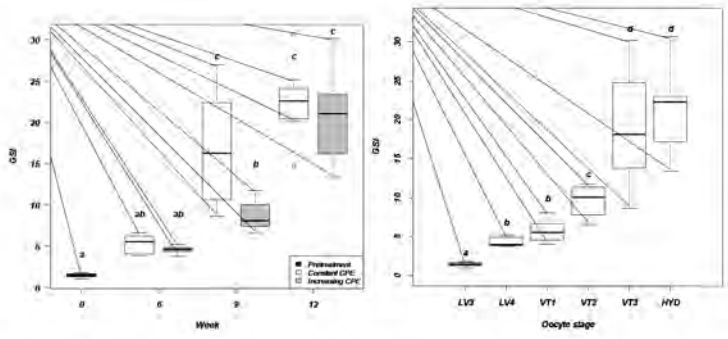

Fig. 1. Boxplots of gonado-somatic index (GSI) according to treatment and sampling week (left) and oocyte developmental stage (right). The top and bottom edges of the box represents 75th and 25th percentile data; line within the box medians; whiskers 90th and 10th percentile data; circles outliers. Boxes labelled with the same letter are not significantly different (P>0.05).

(Continued on next page)

Results and discussion

The progression of ovarian development differed between treatments with a significant difference in GSI at week 9 (Fig. 1). The constant dose group had accelerated ovarian growth compared to the increasing dose group. Nevertheless, the latter caught up to the former when the full dose of CPE was administered at 10 week, eliminating any detectable difference between the treatments at week 12, when all fish had reached final maturation. Aligning ovarian development independent of treatment revealed that development based on the furthest advanced oocyte stage was similar (Fig. 1) with stages being significantly different between treatments only at week 9. Here, the constant dose group was at the end of vitellogenesis approaching final maturation, while the increasing dose group was still in early vitellogenesis. Nevertheless, both groups were in the final maturation phase at week 12. Results of the gene expression analysis support these results and substantiate our understanding of mechanisms involved. Lastly, spawning success and egg quality was similar among treatments.

Conclusion

The results indicate the hormones FSH and LH in the pituitary extract do not correspond to the requirements at the specific developmental phases and may either be in excess or demand resulting in a difference in the speed of ovarian development for the two treatments. The spawning results, on the other hand, did not show any difference between the two treatments regarding spawning success and egg quality.

MICROALGAL MIXOTROPHY AS A SOURCE OF FEED FOR *Mytilus edulis* LARVAE

J. Penhaul Smith[1*], C. Beveridge[1], VA. Laudicello, L. McEvoy[2], AD. Hughes[1], JG. Day[1]

Mytilus edulis aquaculture represents an important section of the UK and EU economies. Current production mechanisms rely on the supply of wild larvae to be settled upon longlines and subsequently on-grown. This leaves larval collect and production of adult blue mussels reliant upon larval supply and so is one of a number of limiting factors in upscaling production. In Scotland 7000 tonnes of mussels were produced in 2015 and mussel growers aim to double production by 2020. To do so, the limiting factor of larval supply must be overcome. One method of doing this is the creation of a *M. edulis* larval hatchery. The costs associated with microalgal culture, for use as feed, in a larval hatchery are currently around 40% of total costs. As a result the creation of a larval hatchery is not economically viable (Hickman, 1992). This is due to the requirement for live microalgae, mussel larvae do not feed on dead cells. This study aims to address this limiting factor through use of mixotrophically cultured microalgae as a feed source.

Microalgae are classically considered to be photoautotrophic and are cultured in the light, in seawater with additional nitrate and phosphate. Mixotrophy is the ability of a microalga to uptake organic nutrients, such as carbon or nitrogen, in addition to, or as an alternative to, photoautotrophic fixation of carbon. This ability to be cultured mixotrophically is considered to be ubiquitous in the marine environment (Borowitzka, 2013) and has a number of advantages. Mixotrophic culture often results in greater cell numbers and dry weight, as well as an increased culture stability (Morales-Sánchez & Martinez-Rodriguez, 2015). Furthermore, dependent upon the method of culture and the carbon source utilised, the biochemical profile can be tailored to create a "designer" feed.

Over the course of three feeding trials this study takes current "industry standard" microalgal species and compares larval growth and survival to mixotrophic "designer" microalgal feeds, then subsequently optimises the diet used. The "designer" feed can be considered to be as effective as the standard benchmark feed and subsequent optimisation shows that a diet that is tailored towards the development performs the most effectively in terms of larval growth. Mixotrophic culture requires an additional organic carbon source which has a significant cost implication. Therefore using first order modelling, the economics of use of mixotrophy as an alternative to photoautotrophic culture reveals a more complex picture in terms of the optimal methods of culture. Culture optimization, a move to semi-continuous culture and alternative, low cost carbon sources potentially reveal a way forwards.

Introduction

Vibriosis is one of the most prevalent bacterial fish diseases in the Adriatic region (Thompson et al., 2003). It is caused by certain species and strains of heterotrophic bacteria from the genus *Vibrio.* These bacteria are indigenous to the marine environment, but different environmental factors regulate their growth and distribution (Asplund, 2013). The aim of this study was to investigate seasonal variations of *Vibrio* sp. in marine cage areas of the Bay of Mali Ston, and to determine the influence of di ferent environmental parameters on their growth.

Materials and Methods

The sampling was carried out at the fish cage farm located in the Kabli, outer part of the Mali Ston Bay (Eastern Adriatic) and at the control site situated 2 km away from the farm in Mali Ston Channel. Samples were collected quarterly during 2017. Temperature, dissolved oxygen, pH, salinity and total dissolved solids were recorded at each sampling site by Metler probe in situ, while water samples for microbiology, total nitrogen, phosphorus and particulate matter analyses were collected using 8L Niskin bottle at four depths (0.5m, 5m and 10m, and 0.5m above the sea bottom). Water samples were further processed and analyzed in the laboratory. For *Vibrio* enumeration, serial dilutions of the water were applied onto selective medium Difco™ TCBS (BD) agar and incubated at 22°C for 3-5 days. Bacterial isolates were further processed on MALDI TOF MS for identification. The results of the *Vibrio* counts were expressed as colony forming units (cfu)/mL. Seston quantity parameters (total-TPM, organic - POM and inorganic particulate matter -PIM) were analyzed according to the method described by Peterson et al. (2003). Samples for total phosphorus and nitrogen determination were digested using a Hach DRB200 reactor. Total phosphorus was determined on Hach dr 6000 spectrophotometer by using Hach kits (PhosVer 3 Acigd Persulfate Digestion procedure), while total nitrogen was determined on a Hach colorimeter DR/870 by using a Hach kit (TNT Persulfate Digestion method). Person's correlation coefficients were calculated to evaluate the relationship between the *Vibrio* sp. count and each environmental variable.

Results and Discussion

The highest mean *Vibrio* sp. counts in the water column were found at both sites in September (170 cfu/mL at the fish farm, and 412 cfu/mL at control site), while the lowest counts were in samples from June (Table 1). The abundance of these bacteria showed the strongest positive correlation with total nitrogen, TPM and salinity (Table 2). According to MALDI TOF MS identification, *Vibrio pomeroyi* and *Aliivibrio* (*Vibrio*) *fischeri* were the dominant *Vibrio* species in the water column at fish farm site, while at control site *Vibrio pomeroyi*, *Vibrio harveyi* and *Vibrio fortis* prevailed. Comparing the results from both sampling sites, it seems that the fish farm is not the main source of *Vibrio* sp., and does not present the main source of nutrients promoting their growth.

QRT-PCR ANALYSIS OF *Parvicapsula sp.* IN DIFFERENT ORGANS FROM EMACIATED OLIVE FLOUNDER, *Paralichthys olivaceus* IN KOREA

Lyu jin Jun*, Seung min Kim and Joon bum Jeong

Faculty of Marine Biomedical Science, Jeju National University, Jeju 63243, Korea

E-mail: loujin@hanmail.net

Introduction

In Korea, the emaciation disease of olive flounder (*Paralichthys olivaceus*) are causing serious economic losses on the aquaculture industry every year. Fishes that were infected by this illness showed symptoms such as darkening body colors, decreases in body weight, and bleeding. The causative agent of this disease was identified as *Parvicapsula* sp. (Kim et al., 2015). In this study, we analyzed the copy number of pathogens in different organs using the real-time PCR.

Materials and methods

Olive flounders with emaciation symptoms, such as the darkening of the body color, the emaciation of the abdomen and the loss of weight (length 19.8±2 cm, weight 70±5 g) from 2 farms in Jeju Island of Korea were selected as the experimental group, while healthy olive flounders (length 20±3 cm, weight 90±10 g) from 1 farm without any history of emaciation disease were selected as the control group. The kidney, intestine, spleen, brain and liver of each fish were extracted, and signs of infection were checked using PCR (Kim et al., 2015). Real-time qPCR was performed using a LightCycler^{R} Nano Instrument for real-time PCR (Roche, USA) and the marker used was SYBR Green I dye (Faststart Essential DNA Green Master, Roche, USA). PCR reactions were performed in 20 ↑ volumes consisting of 0.5 ↑ of each RTEM-F(5'-GGATACATGTTGGTCGAC-3'), RTEM-R(5'-CGAATCGCATTAATTATC-3'), 10 ↑ of SYBR Green I master mix, 2 ↑ of DNA and 7 ↑ of Deionized sterile distilled water.

Results and discussion

Real-time PCR was performed using DNA extracted directly from the internal organs (kidney, intestine, spleen, brain and liver) of emaciated fishes (farm 1 and 2) and normal fish (farm 3). The highest DNA copy number (1.7×10^{7} copies/mg tissue) was detected in kidney of the emaciated olive flounder of farm 2, while the DNA copy number was below detection limit in all the organs of the olive flounder of farm 1. There was not positive result in all organs isolated from olive flounder of farm 3. PCR and histopathological analysis were also performed using the same specimen and showed same results as those by real-time PCR.

DEVELOPMENT OF ANTIBIOTIC RESISTANCES IN BACTERIA ISOLATED FROM ORNAMENTAL FISH AND FISH FOR FOOD PRODUCTION BETWEEN 2005 AND 2017

Verena Jung-Schroers[1*], Arne Jung[2], Julia Bauer[1], Felix Teitge[1], Dieter Steinhagen[1]

[1] Fish Disease Research Unit, Institute for Parasitology, University of Veterinary Medicine, Buenteweg 17, 30559 Hannover, Germany
[2] Clinic for Poultry, University of Veterinary Medicine, Buenteweg 17, 30559 Hannover, Germany
E-Mail: verena.jung-schroers@tiho-hannover.de

Introduction

Antibiotic resistance is one of the biggest threats to human and animal health. Antibiotic resistances can occur naturally, but misuse of antibiotics is accelerating the process. As resistances against antibiotics occur in bacteria isolated from fish as well, it is recommendable to perform a sensitivity test for the detected bacteria before treatment of fish.

Materials and methods

All bacteria isolated from diagnostic samples between 2005 and 2017 at the Fish Disease Research Unit were analysed for resistance against antibiotic substances. In total 19 substances were tested, whereas some substances were tested during the whole period of 13 years and others were tested only for two to 12 years.

The antimicrobial susceptibilities of bacterial isolates were determined by the use of the disk diffusion method. Bacterial isolates were inoculated on blood agar plates. Antibiotic disks containing amoxicillin (10 µg), ampicillin (10 µg) chloramphenicol (30 µg), chlortetracycline (30 µg), colistin (50 µg), doxycyclin (30 µg), enrofloxacin (5 µg), erythromycin (15 µg), florfenicol (30 µg), flumequine (30 µg), furazolidone (100 µg), gentamicin (10 µg), kanamycin (30 µg), neomycin (10 µg), oxolinic acid (10 µg), oxytetracycline (30 µg), trimethoprim/sulfonamide (25 µg) tulathromycin (30 µg), or tylosin (30 µg) were used according to the manufacturer's instructions. Inhibition zone diameters were measured and evaluated inspired by CSLI if possible. According to the diameter of the inhibition zone, the results were given in resistant (R), intermediate (I) and sensitive (S).

Results and discussion

The results show that the detected bacteria showed mainly resistances against amoxicillin, ampicillin, neomycin, oxolinic acid and tylosin. Yet, over the last 13 years, resistances of bacteria against antibiotic agents were decreasing in total and for most substances the resistance situation improved. Only for single substances, like trimethoprim/sulphonamide, the number of resistant bacteria increased.

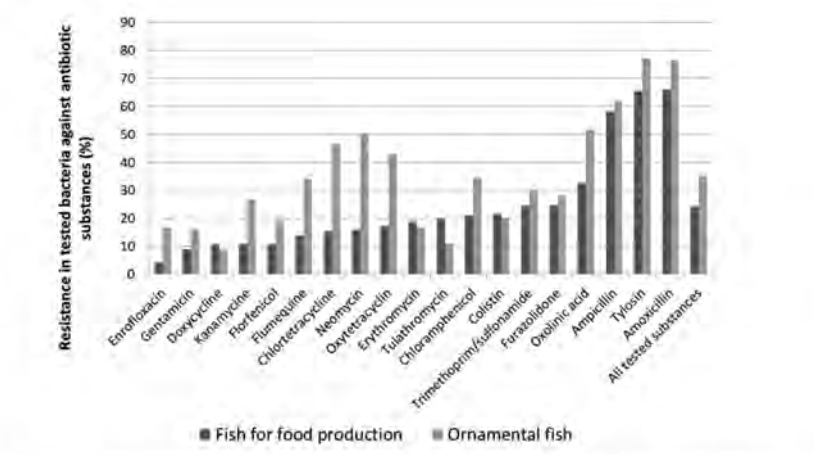

Fig 1. Resistances in tested bacteria isolated from fish for food production and from ornamental fish against 19 antibiotic substances.

(Continued on next page)

Differences were seen in bacteria isolated from fish from different keeping units. Especially in bacteria isolated from ornamental fish at wholesaler facilities more resistances were detected, whereas in bacteria isolated from fish for human consumption fewer resistances were found. Differences were also detected in the resistances of specific bacterial species. Especially Flavobacteria, some species of motile Aeromonads and Pseudomonads showed frequently resistances against a number of antibiotic substances.

Conclusion

Between 2005 and 2017 resistances against antibiotic substances of bacteria isolated from fish were decreasing in general. Only for single substances, like trimethoprim / sulfonamide, the number of resistant bacteria increased Bacteria isolated from ornamental fish showed more often resistances against antibiotic substances compared to bacteria isolated from fish for food production.

INFLUENCE OF A NANOFILTRATION - REACTOR ON THE BACTERIAL MICROFLORA AND ON *Ichthyophthirius multifiliis* THERONTS IN RECIRCULATING AQUACULTURE SYSTEMS

Verena Jung-Schroers[1*], Mikolaj Adamek[1], Angela Boley[2], Julia Bauer[1], Anna Korshun[2], Felix Teitge[1], Dieter Steinhagen[1]

[1] Fish Disease Research Unit, Institute for Parasitology, University of Veterinary Medicine, Buenteweg 17, 30559 Hannover, Germany
[2] Institute for Sanitary Engineering, Water Quality and Solid Waste Management, University of Stuttgart, Bandtäle 2, 70569 Stuttgart, Germany
E-Mail: verena.jung-schroers@tiho-hannover.de

Introduction

Recirculating aquaculture systems offer the opportunity to keep high numbers of fish without the need of high amounts of fresh water due to recirculation and filtration of tank water. Problems can occur if the amount of nitrate, bacteria or parasites in the water increases. To maintain a good water quality, nanofiltration of the water is described as one method to reduce the amount of bacteria in the water and to keep the chemical water parameters in an optimal range.

Materials and methods

We tested nanofiltration reactors with integrated denitrificatio membranes in four different recirculation aquaculture facilities. One system in each facility was run with a membrane denitrification reactor (MDR) and as control identical systems without reactor were used. The aquaculture facilities were stocked either with carp, sturgeons, golden orfes or rainbow trout and the systems were run at a water temperature between 20 and 25°C. In three facilities the bacterial microflora was analysed in tank water, biofilms of tanks and partly also of the filters and on skin and gills of fish kept in the systems. In one of the systems cortisol measurements in the water and in the blood of fish were performed to determine the stress level of the animals in the system. In the fourth system fish were examined for infection with the parasite *Ichthyophthirius multifiliis* and the effectivity of nanofiltration against the theronts of this ciliate was determined.

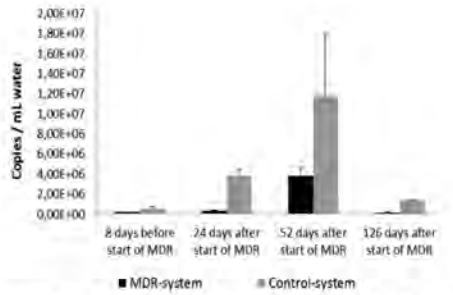

Fig 1. Total number of bacteria in the water of RAS with and without the MDR. Shown are the total bacteria numbers measured by the copy number of the 16S rDNA using quantitative PCR Shown are the mean values and standard deviations from two sampling points per system and time-point.

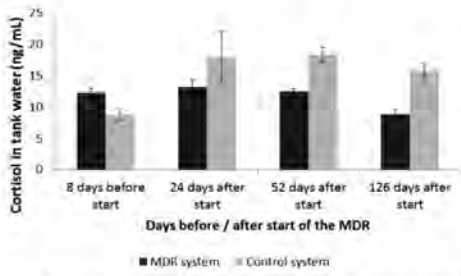

Fig 2. Amount of cortisol (ng/mL) in the tank water from the MDR system and the control system. Shown are the mean values and standard deviations from three measurements per time-point and system.

(Continued on next page)

Results and discussion

Overall it could be shown that the reactor with a filtrating membrane could decrease the total amount of bacteria in the tank water of a recirculating aquaculture system (Jung-Schroers et al, 2019). Also the amount of bacteria on the gills of fish was decreased in the systems with installed reactor.

The diversity of bacteria was higher in the systems with installed reactor and the fish in this system seemed to have less stress.

A reduction of stages of *Ichthyophthirius multifiliis* could also be detected in a system with installed reactor. One challenge was the increasing water temperature in systems with installed reactor and the operation of the reactor itself is time consuming.

Conclusion

The usage of a reactor with filtrating-membrane can have a positive influence on fish health and welfare (Boley et al 2017, Jung-Schroers et al. 2019).

Introduction

In Germany stunning of animals in general is regulated in a directive and special requirements for stunning of fish are given. For all fish species these regulations prescribe stunning by percussion or electric current. Only for salmonids, additionally stunning by CO_2 exposure in a water bath is authorised. Precise instructions on how these methods should be used are not available. It is known that stunning of special fish species, like common carp, is difficult by using the authorised methods.

Materials and methods

In total 24 fish farms throughout Germany were visited and the whole process of stunning and slaughtering was evaluated. Some of these farms were slaughtering carp and trout; others were slaughtering only one of these species. Therefore the process of stunning and killing was documented 22 times in aquaculture farms for trout and 17 times in farms for carp. If possible catching of fish from the ponds was documented. In all farms, keeping fish in special tanks before slaughter and the transport of fish from these tanks to the stunning site was evaluated. Also in all farms stunning and killing of fish was documented.
An evaluation score with 93 points was established which includes all measured parameters and data about the process. Different evaluation factors were multiplied with scores assessing their importance. By combining the scores from different aspects of the harvesting process, an overall evaluation score was calculated. With the overall evaluation score a gradual classification and an assessment of different techniques and methods for stunning and killing of rainbow trout and carp was possible.

Results and discussion

Most of the rainbow trout were stunned by electric current, followed by percussion. In two farms trout were stunned by a combination of both and in one farm CO_2 was used for stunning. In contrast, in most of the documented cases carp were stunned by a combination of electric current and percussion. Stunning by percussion was used in 3 cases and stunning by electric current was uses in four cases. Most of the rainbow trout were successfully stunned by all evaluated methods. Only around 60% of carp were successfully stunned by electric current and around 80% of carp were successfully stunned by percussion (Retter et al, 2018). Only a combination of both methods was leading to successfully stunned carp. With the collected data it could be shown, that for stunning by electric current, the conductibility of the water, the stunning time and the size and shape of the stunning tank can have an important influence of the success of stunning. Short stunning times of less than 2 minutes and water conductibility lower than 500µS/cm or higher than 1000µS/cm were leading to problems with stunning of especially carp.

Conclusion

In conclusion, a combination of stunning by electric current with adequate conductibility and adequate stunning time and by percussion seems to be the best method for stunning of rainbow trout and carp.

Introduction

Infections with the carp edema virus, a pox virus, are known from Japanese koi populations since 1974. Lethargy is one characteristic clinical sign associated with the infection is and therefore the disease is called “koi sleepy disease”. For a long period of time, disease outbreaks seemed to be restricted to Japan. During the last years clinical outbreaks of koi sleepy disease also occurred in many European countries (Jung-Schroers et al, 2015, Way et al, 2017). Koi sleepy disease seems to pose a potential risk to carp aquaculture and koi trade also in Europe.

Materials and methods

During the years 2015 and 2016 an epidemiological study on the occurrence of CEV in fish in Germany was performed. In total 421 gill samples were analyzed. Most of these samples were taken from common carp or koi carp, only a few samples were taken from additional fish species that were kept together with carp.

Results and discussion

In 194 samples CEV genome fragments were detected. Most detections, in total 179, were made in samples from koi carp (*Cyprinus carpio*), in 61 samples of common carp (*Cyprinus carpio*) CEV was detected and in 1-2 samples each of *Ctenopharyngodon idella*, *Esox lucius*, *Gymnocephalus cernua*, *Perca fluviatilis*, *Sander lucioperca* genome fragments of CEV were found in low amounts (1.10E+00 – 1.19E+03). Highest amounts of viral DNA were detected in samples of koi carp (1.00E+00 – 4.82E+06) and common carp (1.00E+00 – 4.03E+06). Sequencing of the DNA fragments revealed that there are at least two different genogroups of the virus are present and that almost all isolates detected in common carp are belonging to genogroup 1 whereas almost all isolates detected in koi carp are belonging to genogroup IIa.

Characteristic symptoms for an infection with CEV were enophthalmus, anorexia, gill necrosis, gill swelling and lethargic behavior. Mostly in spring, between May and July, CEV was detected. In koi carp disease outbreaks due to CEV were mostly seen when the water temperature was between 17-18°C, whereas in common carp at water temperatures between 9-13°C CEV was detected most frequently.

In 46.66% of samples taken from clinically healthy koi or carp from retailers, CEV was detected. Taken all samples from clinically healthy koi and carp, CEV could also be detected, but only in 26.32% of all examined fish. Therefore purchasing new fish from retailers might be one risk factor for the introduction of CEV in a pond. In common carp more frequently diseases signs and mortalities were recorded compared to koi carp. The probability of losses of more than 50% in a system was around 5 times higher in common carp aquaculture than in facilities for koi carp.

Conclusion

Fish health services should therefore be aware of the presence of CEV which may result in high losses in carp aquaculture and testing of koi and carp for CEV should become part of fish disease surveillance programs of national and regional fish disease laboratories.

STUNNING OF AFRICAN CATFISH (*Clarias gariepinus*) BY A PENETRATIVE CAPTIVE BOLT DEVICE

Verena Jung-Schroers[1*], Felix Teitge[1], Julia Bauer[1], Vanessa Guddorf[2], Dieter Steinhagen[1]

Introduction

African catfish (*Clarias gariepinus*) are particularly suitable for keeping in recirculating aquaculture systems because the not utilised heat from biogas plants can be used to heat the tank water. However, with the innovation of "exotic" fish for food production, new challenges are facing aquaculture farms and the regulatory authorities. Especially the development of an ethical method of stunning and slaughtering of African catfish is needed. In Germany, stunning of animals in general is regulated in a directive and special requirements for stunning of fish are given. For all fish species these regulations prescribe stunning by percussion or electric current. Due to anatomical and physiological peculiarities, both these methods are problematic for the stunning of African catfish. For example, the skull anatomy of this species hinders rapid percussion stunning. Anaesthesia is achieved with this procedure only if the impact is made with considerable force on a precise localization. If the blow does not hit the skull at the correct location, it will not cause anaesthesia, but respiratory tract damage. The situation is similar with electrical stunning. From practice and the scientific literature (Sattari, Lambooij et al., 2010) it is known that satisfactory stunning cannot be achieved with conventional electric stunning devices and that high current densities are required, which pose a threat to occupational safety.

Materials and methods

A penetrative captive bolt device was used to stun 14 African catfish with a mean body length of 55.5 ± 4.9cm and a mean weight of 1900.4 ± 610.3g. Previous investigations of African catfish showed that on the skull externally visible adhesion zones of skull plates were recognizable. The positional relationship of these structures to the brain could be visualized during dissection of slaughtered catfish and by using three-dimensional computer models of the skulls. The anterior fusion zone, which was covered with connective tissue, was located rostrally in front of the brain, while the posterior fusion zone was caudodorsal to the brain. For the localization of the brain, a line in the median of the skull was used for orientation on the basis of the present anatomical findings. This line was drawn in conjunction with the two congenital zones of the skull, which are usually not ossified. It runs from rostral to caudal in the median over the skull and divides it into two equal halves. In the rear third between these zones the brain was located. This point was used for placing the captive bolt device. After shooting, the skulls of the catfish were x-rayed to control the correct localization of the bolt.

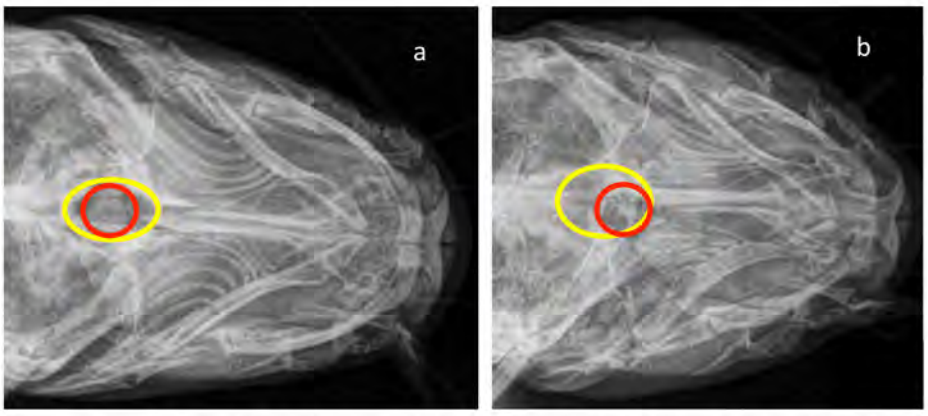

Fig 1. X-ray of an African catfish hit by the captive bolt device in the middle of the brain (a) and X-ray of an African catfish with a shorter skull hit in the rostral part of the brain. The localization of the brain is marked in yellow and the localization of the punch hole is marked in red.

(Continued on next page)

Results and discussion

All fish were stunned successfully by the captive bolt device. After shooting the fish were showing tremors of muscles in the back and of the fins for up to 30 seconds. After this time movement was no longer observed. On the X-rays it could be seen that the brain was destroyed in all fish. Nevertheless, in fish with a shorter skull, the captive bolt device was hitting the brain slightly too rostrally (fig. 1).

Conclusion

Stunning of African catfish with a captive bolt device is an effective and reliable method to achieve unconsciousness in the fish before slaughtering. The exact position of the brain has to be known and the procedure has to be adapted in fish showing alterations of the skull morphology, like shorter skulls. Nevertheless, also in these fish the brains were destroyed almost completely and a successful stunning could be achieved.

Introduction

Numerous diseases continue to cause economic and ecological problems in aquaculture. Injection vaccination of fish entails high effort and fish stress and many nations resort to other, ecologically questionable treatment methods. An ideal fish vaccination method is oral vaccination and research on the topic has been performed since the 80s with limited success. Although good immune responses can be achieved using the oral route (Romalde *et al.* 2004, Ballesteros *et al.* 2014) crucial long-term protection could not be induced. One of the bottlenecks of oral vaccination is the ingestion and digestion of the vaccine-particle (Ballesteros *et al.* 2015). The aim of this study is to investigate the early stages of an oral vaccination process and elaborate the optimal feeding regime for salmonids. At present, a large amount of research is dedicated to feed intake and feed composition of salmonids. However, little attention was drawn to the variance of feed uptake amongst and between individual fish, which is key to consistent vaccination. The information presented in this study is intended to form the foundation for successful induction of herd immunity for salmonids in aquaculture using effective oral vaccines

Materials and Methods

To evaluate the feeding regime, three trials were conducted, focusing on starvation period, portions size and daily feeding events. Fish weight ranged from 23g, 27g and 31g for the trials, respectively. Rearing temperature was 15°C and aeration was 0.1l • h^{-1} for each replicate. To determine the individual feed intake and the intake variance, quadruplicates were used with seven marked fish in each replicate. All feeding events were video-recorded and evaluated post-experiment. To evaluate the video files of each trial, the consumption of the food pellet was assigned for every fish independent .

Results and Discussion

Results of the starvation experiment showed no significant differences in pellet uptake, however a correlation of intake variance and starvation period was present. At this point of time, the video evaluation is still in progress. Initial results indicate significant differences in individual feed intake variance, while minimal effect is observed due to the starvation period.

Conclusion and Impact

Even though research on feeding regimes for salmonids has been performed, progress in oral vaccination requires a different approach than those experiments already undertaken and must include optimisation of oral uptake. The impact of an applicable oral vaccine will have a great impact on fish heath, welfare and labour matters in the global aquaculture industry. Consequently, the increase in fish robustness would decrease the pollution to the ocean by antibiotics in open-water systems.

Argyrosomus regius IN THE MEDITERRANEAN AQUACULTURE: IS IT A SILENT CARRIER AND CONTAMINANT SPECIES FOR THE TWO GRAM POSITIVE BACTERIAL TYPES NAMELY MYCOBACTERIUM & NOCARDIA? WHAT ARE THE IMPLICATIONS TO MARINE FARMING?

Kantham K. Papanna

Nireus Aquaculture SA., 19400 Koropi, Greece
E.mail. k.papanna@nireus.com

Production of *Argyrosomus regius*, introduced as a new species in to Mediterranean mariculture has spread widely in the last 15 years. It was introduced as a supplementary new species in to the traditional seabass and seabream producing hatcheries and cage farms.

Its culture as a futuristic fast-growing fish to take over an over unexpected niche market on a wider scale has faced with technical and biological problems leading to a slow abandonment of this species culture by most small-scale farmers and a number of larger farmers due to decimation of enthusiasm as a whole.

Apart from the technical problems of culturing this species in parallel with existing sea bass and seabream farms, at required low stocking densities (requiring larger cage space for a given biomass), growth and FCR issues have not been satisfactory. Due to limited market demand, need to harvest small volumes in irregular frequencies, makes this species mass culture more uneconomical in general based on all the above said factors.

While Biological constraints due to serious parasitic, bacterial and nutritional diseases have caused greater concern to the future viability of this species sustainability, serious Biosecurity concerns have surfaced exposing other species such as Sea bass and cultured sparids to gram positive bacterial infections.

The work will present the Disease problems faced in *Argyrosomus regius* aquaculture since its inception, and the serious biosecurity risks to the traditional Mediterranean Aquaculture species.

EFFECTS OF RAPESEED PROTEIN PRODUCTS SUPPLEMENTED WITH GLUCOSINOLATES AND PHYTIC ACID ON THE GROWTH PERFORMANCE OF RAINBOW TROUTS (*Oncorhynchus mykiss*)

Introduction

With growing demands and a limited availability of fishmeal, the search for suitable alternatives has never been more urgent (Tacon et al. 2010; Hermann et al. 2016). Proteins from rapeseed and canola have been extensively studied in the past; however, anti-nutritive substances like glucosinolates and phytic acid present in rapeseed have limited its use as an ingredient in fish feeds (Francis et al. 2001; Thiessen et al. 2004). The present study focusses on determining thresholds at which aforementioned anti-nutritive substances are no longer impairing growth performance of rainbow trout (*Oncorhynchus mykiss*).

Materials and methods

Juvenile rainbow trout (mean weight 12g) were fed twice a day to apparent satiation for 38 days with nine basal diets containing rapeseed protein concentrate, supplemented with different levels of glucosinolates (GLS 0.5; GLS 1; GLS 1.8 in µmol/g) and phytic acid (PA 1.7; PA 2; PA 2.6; PA 2.9; PA 3 in %) and one control diet without rapeseed protein concentrate. Fish were held in a recirculation system with freshwater at 13°C and an average pH of 7.4.

Results

Results show a significant decrease in growth performance with increasing inclusion levels of phytic acid

The inclusion of 3% phytic acid shows a significantly lower daily feed intake (DFI, figure 1) and subsequently significantly lowered specific growth rate (SGR, figure 1) and final body weight compared with the rapeseed protein control group (CD RP).

There was no significant difference between the rapeseed protein control group and any of the glucosinolate groups (GLS0.5, GLS1, GLS1.8) in terms of growth performance.

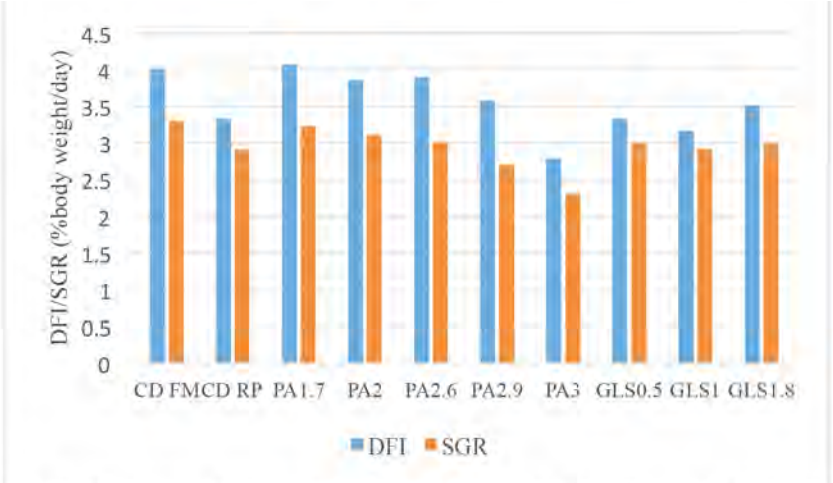

Figure 1: Daily feed intake and specific growth rate of rainbow trout for each treatment after 38 days of feeding. Specific growth rate = (Ln(final body weight)-Ln(initial body weight))/number of feeding days*100, daily feed intake = FCR*SGR.

(Continued on next page)

Discussion

Since no significant differences could be observed in feed conversion ratio (FCR), differences in growth performance most likely result from reduced feed intake. A reduced daily feed intake has been observed in different studies when rapeseed protein was used as a fish feed ingredient (Nagel et al. 2012; Bu et al. 2017). Glucosinolates, tannins and sinapine are considered to impair the organoleptic properties of certain ingredients in different species (Francis 2001 et al. 2001; Tan et al. 2011). However, effects on growth performance were most commonly observed by inclusion of different rapeseed proteins in fish feed, hampering to find which anti-nutritive substances are responsible for a reduced feed intake. Denstadli et al. (2006) also observed a reduction in daily feed intake when feeding Atlantic salmon (*Salmo salar*) graded levels of phytic acid. Atlantic salmon showed a significantly reduced daily feed intake at 2.07% inclusion after 80 days of feeding (Denstadli et al. 2006).

Since our results show no significant impact of glucosinolates on growth performance, phytic acid might be a main anti-nutritive substance influencing daily feed intake and therefore growth performance at certain inclusion levels of both anti-nutritive substances.

Introduction

Among carotenoids, astaxanthin (AX) is the most used in aquaculture nutrition, principally as a pigmenting feed additive. Recently, more attention has been paid to the potential health benefits of AX in part related to its free radical scavenging, singlet oxygen quenching and antioxidant properties (Dose et al., 2016). Aquaculture species are continuously exposed to several types of challenging conditions, all generators of oxidative stress. Based on the hypothesis that dietary AX provides physiological benefits to rainbow trout antioxidant response, the present study aimed to compare the liver oxidative status of this species fed an astaxanthin depleted diet (CTRL) and fed an astaxanthin diet (CARO), under normoxia conditions and in response to episodic hyperoxia (termed 8HYP:16NOR). In addition, we assessed if the antioxidant response of rainbow trout was associated with carotenoid-based pigmentation of the skin and muscle.

Material and methods

Two iso-nitrogenous, iso-lipidic and iso-caloric feeds were tested with triplicate groups of rainbow trout juveniles of 30 fish per 800-L tank (initial weight ~ 308.5g). The differences among experimental diets was the AX content, CTRL diet had no AX and the CARO diet was supplemented with 100 mg AX (DSM-Carophyll Pink) per kilogram of feed. This feeding trial was conducted for a period of 92 days; the first 85 days, fish were fed on the respective CTRL or CARO diet and reared under normoxic conditions. The following seven days, fish continued to be fed with the same diet and were exposed to hyperoxia. For hyperoxic conditions, oxygen supply was increased from 8 to 13 mg/l and between 9:00 to 17:30, afterwards oxygen levels returned to normoxic conditions. A factorial design 2x2 was performed, comparing normoxia treated fish (termed N) and hyperoxia (termed H), fed two distinct diets (CTRL and CARO) to produce four experimental treatments N-CTRL, N-CARO, H-CTRL, H-CARO.

(Continued on next page)

Results

Skin redness was only influenced by the diet (Table 1). In the muscle, environment, diet, and their interaction enhanced ($P<0.05$) muscle redness, having H-Caro fish significantly higher values. TBARs values in muscle and liver were affected by the diet; being lower in CARO fish. In contrast, environment also influenced TBARs in muscle, being higher with hyperoxia. A negative correlation was observed between skin a*-values and TBARs in muscle ($P<0.01$; $r=-0.32$) and liver ($P<0.05$; $r=-0.32$); furthermore, between muscle a*-values and TBARS in muscle ($P<0.05$; $r=-0.35$) and liver ($P<0.05$; $r=-0.36$). From the genes studied, CARO diet exerted an up-regulating effect on glutathione reductase (GR), glutamate-cysteine ligase catalytic subunit (Gclc) and thioredoxin reductase (TR). Correlations were found between liver GR gene expression and skin ($P<0.05$; $r=0.35$) and muscle ($P<0.01$; $r=0.48$) a*-values, and between TR and skin ($P<0.05$; $r=0.34$) and muscle ($P<0.05$; $r=0.42$) a*-values. In the case of Gclc, only a significant correlation was observed with muscle a*-values ($P<0.05$; $r=0.36$). Environment lowered liver antioxidant activity of SOD, CAT and GR. GR was also influenced by diet, rainbow trout fed on the CARO diet presented significantly higher values than CTRL treatment. A correlation was only found between liver GR activity and skin a*-values ($P<0.05$; $r=0.4$).

Discussion and conclusions

Reduced and oxidized glutathione (GSH/GSSG) and thioredoxin (Trx/TrxSS) redox couples play important roles in antioxidant defense (Circu et al., 2011). In this study dietary AX up regulated important hepatic GR and TR both key enzymes in restoring reduced forms of glutathione and thioredoxin, respectively; and Gclc an active participant in de novo GSH synthesis. However, the activities of other enzymes were not affected by dietary AX, being lower in trout undergoing hyperoxia. Regarding muscle and skin color, there seems to be no trade-off in the allocation of AX between avoidance of oxidative stress and color expression. In accordance to our results, birds exposed to mild levels of oxidative challenge also developed redder ornaments (García-de Blas et al., 2016). In conclusion, results in this study suggest that dietary AX can enhance rainbow trout liver antioxidant response.

Introduction

Infections with the ciliate parasite *Ichthyophthirius multifiliis* regularly lead to serious losses in fish farms worldwide. At present, there are no effective means available against this pathogen in the EU. Thus, there is a therapeutic emergency for this disease up to date, which is unacceptable in terms of animal welfare and considering the economic risks. In the course of this project, the interference in host transmission of the fish-infecting theront stages using solubilized active component mixtures for water treatment was tested as an alternative control strategy against *I. multifiliis* in trout farms without the use of pharmaceutical therapeutics.

Materials and methods

Basis for the trials was the identification of natural substrates that activate the unique host search movement-pattern in vital theronts. This fast rotating swimming activation and host recognition behaviour was intended to disturb host transmission either by a decoy effect, failure of recognition or by the greatly increased energy consumption due to motility and subsequently earlier onset of vitality loss.

An initial small scale experiment with brown trout (*Salmo trutta*, 4-5 cm) fingerlings utilized direct dispersion of substances activating theront host finding behaviour to disrupt transmission success. For this purpose, 10 fish each were exposed as separate groups in control/preincubated or theront solutions (3.5 l) at 16°C and were transferred to 15 l aquaria after 5 hours. Active substance addition was conducted on one hand with simultaneous addition of active ingredient solution (A) and fish to parasite containing infection compartments, on the other hand with exposure of the fish only after preincubation with active ingredient for seven hours before fish addition. The admixture of active ingredient to the batches was done stepwise hourly. The trial was ended after 7 days. For the large-scale experiments, six rectangle tanks (280 x 60 x 60cm) were used and every group was arranged in triplicates. The tanks (production volume: 0.5m^3) were arranged as flow through system at 10°C. All rearing units were continuously aerated during the experiments and water quality corresponded with physiological requirements for trout fingerlings. For exposure, 11 500 theronts were added per tank with flow-through closed and 60g of active ingredient were stirred-in as solid in the treated group. After 24 hours, six rainbow trout fingerlings were stocked per tank and incubated overnight before flow-through was turned on. The trial was ended after 10 days. In both trials, all experimental fish were euthanized and fixed in 70% ethanol for later parasite stage enumeration on the body surface by stereomicrocopy.

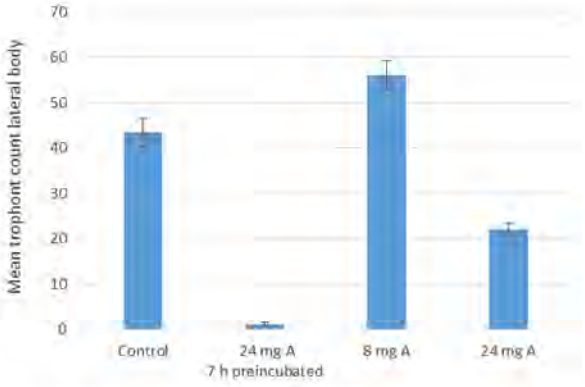

Fig. 1. Mean trophont numbers (± SEM) on rainbow trout fingerling body surface after 7 d incubation upon prior exposure to equal amounts *I. multifiliis* theronts. Fish were exposed to theronts under repeated cumulative addition of Activation Solution Mixture (A, mg final concentration per infection compartment) or after preincubation of theronts to A without fish (preincubated).

(Continued on next page)

Results

Counting the infestation rate at one week in the small-scale setup showed a highly significant reduction in epidermal trophic stages down to a fraction of those on the untreated group after 7 hours pre-incubation of theronts with active compound administration (Fig.1). Control theronts incubated the same period under equal conditions remained vital. The simultaneous addition of experimental fish and active substance with repeated administration to a final concentration of 24 mg per infection compartment (~7 mg/L) already resulted in a significant reduction of the infection rate by more than 50%. However, there seemed to be a critical concentration threshold, since lower final concentrations of 8 mg A did rather promote host invasion rates when fish and parasites were added simultaneousl .

In the large scale experiment, the result of the small-scale preincubation trial could be further confirmed, since the number of *I. multifiliis* trophonts on fish exposed in the group with prior dispersal of active substances could be significantly reduced compared to the control group. Individuals from treated tanks had over four times less trophonts on their body surface ($P < 0.0001$; Tukey t-test, $N = 18$ per group).

Discussion and Conclusion

Mortality by Ichthiophthiriasis is usually caused by overinfection via quick reinfection mostly at elevated temperatures. However, theronts are short-lived transmission stages that bear limited resources to achieve successful transmission. They rely on a distinct behavioural pattern for host finding and recognition upon chemical and physical stimulants (Haas et al. 1999, Hofmann 1995). This means may serve as a possibility that could be utilized for alternative control strategies, without the use of pharmaceuticals. Our results show that only by artificial activation of the natural behaviour of theronts in vicinity of a putative host can interrupt transmission to a considerable degree. This offers a chance for fish to cope with reduced numbers of parasites while acquiring a stable immunity status during this critical phase. These findings can be exploited in future management and control efforts.

IMTA AND SMARTER MONITORING FOR GREENER AQUACULTURE.

Frank Kane*, and Joanne Casserly

Marine Institute, Rinville, Oranmore, Co. Galway, Ireland
Email: frank.kane@marine.ie

Introduction

The major challenges to EU aquaculture growth can be summarised to adaptation to market changes and competition, as well as need for technical improvements (maintaining health / welfare of livestock, integration of activity with the environment, optimizing resource use and spatial planning) (Anon. 2014). The production of aquaculture food and equipment must be supported by the most advanced research and technology, and the EU must maintain a strong research and technological edge to stay at the forefront, and improve the competitiveness, of the aquaculture sector by using innovative technologies and management techniques (Anon, 2009).

IMTA offers an attractive approach to aquaculture with the benefits of; environmental sustainability through bio-mitigation; economic stability through product diversification and risk reduction; spatial optimisation by increasing site productivity and; social acceptability through better management practices. The management of large-scale IMTA areas remains difficult, even in countries where it is currently practiced commercially (Fang *et al*, 2016), due in principal to limited knowledge of how the separate components in the IMTA ecosystem interact and function as a whole, as well as the impact on the environment and the broader ecosystem. Using new and emerging technologies and innovations in the monitoring and management systems can provide data and guidance to adaptively manage IMTA systems to ensure on-going sustainability.

Methods

The H2020 Impaqt project, Intelligent Management system for integrated multi-trophic Aquaculture, aims to maximise the growth rate and minimise the production costs, through the optimisation of production systems, while ensuring seafood product quality, optimal resource use, and minimisation of environmental impact. It will develop and validate in-situ a multi-purpose (inland, coastal and offshore productions), multi-sensing (heterogeneous sensors and new/emerging technologies) and multi-functional (advanced monitoring, modelling, data analytics and decision making) management platform for sustainable IMTA production.

The project is developing three main interacting subsystems:

1. the autonomous data acquisition and communication system - data sources from chemical, physical and attached sensors, remote sensing algorithms and satellite observation, crowd-sourcing observation and in vitro species characterisation.
2. the advanced IMTA model - yielding spatially explicit information on the interaction of farm components with the environment on the ecosystem scale, for management and regulatory planning.
3. the integrated management system - operating at the farm scale, comprising data and predictive analytics, decision making and actuation to enable improved operational decisions for animal welfare, production optimisation, environmental protection, food quality and sustainable productivity.

Results and Discussion

Impaqt will help to identify and quantify the benefits to be gained from IMTA and combining trophic levels. Impacts and interactions will be specifically assessed at an ecosystem scale, rather than just at the scale of individual farms. The integrated management system will also enable real time assessment of current conditions and respond to production and environmental challenges timely at the farm scale. It will enable a more efficient IMTA practice, informing the selection of optimal sites and optimal spatial configuration for the various aquaculture components

Impaqt will rely on an Open Systems approach and an "everything-as-a-service" thinking, while Semantic Aquaculture Data Interoperability and Harmonization will enable data federation and knowledge exchange between different systems.

This high level ambition is to drive a paradigm shift in the European Industry and its acceptance of IMTA as a viable approach, paving the way to a more environmentally friendly and more efficient/higher yielding European Industr .

(Continued on next page)

This project has received funding from the EU H2020 research and innovation programme under Grant Agreement No 774109.

Introduction

Marine larval feed technology is a fast changing field with great progress in manufacture technology. The challenge is to produce small enough feed particles that cover the nutritional needs of newly hatched larvae and have high acceptability and palatability, water stability and low nutrient leaching (Hardy and Barrows, 2002). Nowadays, many of the fish larval feed industries do provide such small-sized dry feeds which, in the hatchery practice of gilthead seabream *Sparus aurata*, are progressively introduced to fish larvae not earlier than 15 days post hatch (dph) with the concomitant use of live feeds (rotifers, *Artemia*) until weaning. However, compared to live feed, dry feeds appropriately manufactured (i.e. physical and nutritional properties) are expected to better provide for all nutritional needs of altricial fish species, such as gilthead seabream. The aim of the present study was to investigate the introduction of dry feed as early as on 4 dph on growth and digestive physiology of gilthead seabream larvae, as well as to monitor fish growth performance after metamorphosis

Materials and methods

The experimental trial was conducted in two stages: Stage 1, Hatchery rearing (Hr), was performed in a commercial marine fish hatchery. Four tanks of 10 m^3 were stocked with eggs within three days. In two of the tanks a commercial dry feed (Larviva Prostart, Biomar) was introduced on 4 dph (DF4), while in the other two tanks the dry feed was introduced on 15 dph (DF15). In all experimental tanks, the larvae were fed with rotifers from 4 dph up to 24 dph and with *Artemia* from 13 dph up to 58 dph. From 59 dph larvae were fed dry feed only. Feeding with live and dry feed followed the hatchery protocol and larvae samples were observed under microscope to confirm food consumption. During larval rearing, water quality was monitored daily and larvae were sampled every 5 days from 5 to 60 dph, to estimate larvae length, phenotypic deformities and digestive function (i.e. lipase, amylase, trypsin, chymotrypsin, pepsin specific activities). Stage 2, Laboratory rearing (Lr), was performed in a recirculating seawater system. On 61-62 dph fish larvae of each duplicated tank were graded on hatchery to two size classes (Big, Small). The Big and Small fish of each duplicated hatchery tank were pooled and transferred to laboratory installations (on 64-66 dph). Nine hundred and seventy-six (976) fish from each size class and Hr treatment (DF4-Big, DF4-Small, DF15-Big, DF15-Small) were group weighed and randomly distributed in duplicated tanks (on 66-68 dph). Fish growth (i.e. body mass, survival, specific growth rate-SGR, thermal growth coefficient-TGC, mass variation) was monitored for two (2) months. All fish were fed the same commercial diet *ad libitum*. Water quality was monitored daily and fish were group weighed (app. 15-20 fish per group) every 15 days, while at the end of rearing fish were individually subjected to weighing and length measurement. Phenotypic deformities were also individually recorded. During the second month of rearing, food consumption was recorded to estimate feed efficiency (food conversion ratio-FCR).

Results

Stage 1, Hatchery rearing (Hr): Larval length on 60 dph was similar among experimental treatments. DF4 larvae had significantly lower variability in length and lower phenotypic deformities than DF15. Survival, as estimated upon grading on 61-62 dph, was similar (30-33%), but DF4 treatment provided more Big fish (56%) than DF15 treatment (42%). Lipase, amylase, trypsin and chymotrypsin specific activities showed similar patterns during 5-60 dph in both treatments. However, pepsin was first detected on 55 dph for DF4 larvae and on 60 dph for DF15 larvae. Stage 2, Laboratory rearing (Lr): First weighing (66-68 dph) showed that DF4-Big larvae were significantly larger (0.087 g) than DF15-Big larvae (0.074 g). Differences in body mass for Small fish were not significan (DF4-Small: 0.051 g, DF15-Small: 0.049 g). At the end of the two months rearing period, DF4-Big fish retained their growth advantage being significantly larger (5.36 g) than DF15-Big fish (4.84 g), while DF4-Small and DF15-Small fish body mass was similar. SGR, TGC and FCR showed no differences for DF4 and DF15 fish, either Big or Small. Total survival and total deformities were significantly higher and lower respectively in DF4 larvae than in DF15 larvae, no matter size class. Finally, body mass distribution was significantly different for DF4-Big and DF15-Big fish, DF4 fish resulting in higher percentage of the most numerous l ge size class.

(Continued on next page)

Discussion and conclusion

Present results showed that the early introduction of dry feed on 4 dph, instead on the most commonly used 15 dph, resulted in lower variation among larvae and reduced incidence of deformed fish. Seabream larvae ingested the feed and their digestive function was similar to patterns observed for gilthead seabream and other Sparidae species (Moyano et al., 1996; Suzer et al., 2008; Yúfera et al., 2011), thus confirming normal exogenous feeding. Gastric acid digestion (i.e. pepsin) was evidenced slightly earlier in DF4 and slightly earlier than previously reported (i.e. >60 dph: Elbal et al., 2004; Yúfera et al., 2011). Upon grading, DF4 treatment resulted in higher body mass of Big fish and higher percentages of Big fish than DF15, advantage that was maintained during further rearing up to 123-125 dph. Taking into consideration the better survival and the lower incidence of deformities that both Big and Small fish showed for DF4 treatment, obtained results suggest that the early introduction of dry feeds has benefits and indicate that a change of dry feed protocol during development may have significant e fects on subsequent post-larval production stages (e.g. Koedijk et al., 2010).

ESTIMATING GENETIC INTROGRESSION OF FARMED SALMON – *P(wild)*; METHODOLOGY, ACHIEVEMENTS AND PROSPECTS

Sten Karlsson*, Tonje Aronsen, Geir Bolstad, Ola H. Diserud, Ingerid J. Hagen, Kjetil Hindar

[1]Norwegian Institute for Nature Research, Høgskoleringen 9, 7034 Trondheim, Norway
E-mail: sten.karlsson@nina.no

Genetic introgression of escaped farmed salmon is a large threat to the viability of wild salmon populations. Development of molecular genetic tools to trace farmed to wild genetic introgression has been a prerequisite for understanding, not only the magnitude, but also how this genetic introgression affects important life history traits in wild salmon populations, how natural selection acts against farmed genetic introgression, which conditions determine the success of escaped farmed salmon, and how broodfish of farmed ancestry in stock enhancement programs might impact wild populations. Without the development of these genetic tools, none of these central topics could have been addressed.

Although a large effort has been put into uncovering the magnitude and consequences of farmed to wild genetic introgression, this work needs to continue; a second generation set of markers for estimating genetic introgression is under development. This new set of genetic markers will enable us to monitor farmed to wild genetic introgression with higher precision, its consequences and to understand the relative importance of different factors in determining the success of escaped farmed salmon in different rivers and populations.

Methodology
In 2011, the first set of genetic markers specifically identified for generically differentiating between Norwegian farmed and Norwegian wild salmon populations was published (Karlsson et al. 2011), and in 2014 a statistical method was developed for quantifying farmed ancestry in individual salmon (Karlsson et al. 2014).

Achievements
The method for tracing farmed ancestry in wild salmon has been used extensively in many different projects: 1.The level of genetic introgression of escaped farmed salmon in Norwegian wild salmon populations has been quantified (Karlsson et al. 2016), and include analyses of more than 40 000 individuals from 225 populations (Diserud et al. 2019). 2. By relating individual data of genetic introgression and data from scale reading we demonstrated that genetic introgression has a large effect on age at maturity and growth, and that the effect of farmed genetic introgression depended on the phylogenetic origin (Bolstad et al. 2017) 3. Tracing farmed ancestry in naturally born salmon has since 2014 been included as a mandatory test of all brood-salmon used for stocking to exclude salmon of non-wild origin 4. We have demonstrated that hatcheries have inadvertently used brood-salmon of farmed ancestry for stock enhancement and that under hatchery conditions these have outcompeted salmon of pure wild origin (Hagen et al. 2019). 5. By estimating the level of introgression in a cohort, at different ages, we have demonstrated a lower survival of individuals of farmed ancestry (Aronsen et al. 2017). 6. By relating the level of genetic introgression and proportion of escaped farmed salmon in a river with different river specific and population specific parameters we have improved our understanding of why some populations show a higher level of genetic introgression that others.

Prospects
A second generation set of markers for tracing farmed to wild genetic introgression is under development. This set of markers will improve the precision when estimating the level of farmed to wild genetic introgression and will enable us to better understand the consequences on the viability of the wild salmon populations, and the role of natural selection in counteracting negative effects of the genetic introgression.

Introduction

Studies on innate immune signal transducers hold paramount importance in fish vaccine development (Priyathilaka et al., 2018), wherein this study, economically important rockfish (Md Mizanur and Bai, 2014), signal transducing adaptor molecule Myd88 (*SsMyD88*) was characterized *in silico*, *in vivo* and *in vitro*.

Materials and methods

Cording sequence of *MyD88* was identified from a previously constructed rockfish transcriptome database. To evaluate the expression under no immune stimulant, tissue samples were obtained from healthy rockfish. To evaluate immune stimulants, rockfish were injected with immune stimulants including polyinosinic-polycytidylic acid (poly I:C), lipopolysaccharide (LPS) and *Streptococcus iniae* (*S.iniae*) then the post injected spleen tissue samples were obtained. RNA extraction followed by cDNA synthesis were carried out and the relative gene expression were determined by the qPCR. *SsMyD88* bearing vector was transiently transfected into the FHM cells along with vector bearing NF-κB luciferase construct for the luciferase reporter assay.

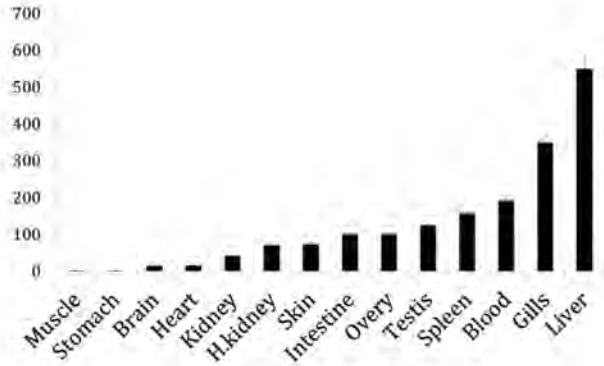

Fig. 1. Unchallenged expression of the SsMyD88 in different tissues/organs of the fish. Rockfish elongation factor-1-α was used as the internal control.

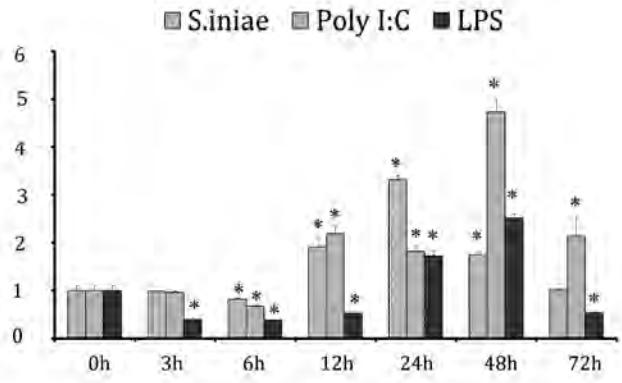

Fig. 2. Challenge expression of the SsMyD88 in spleen. Rockfish was challenged with three immune stimulants including *S.iniae*, Poly I:C and LPS. Rockfish elongation factor-1-α was used as the internal control.

(Continued on next page)

Results

SsMyD88 is a protein with 288 amino-acids, its pI and molecular weights respectively, 5.1 and 33.1 KDa. SsMyD88 is observed to contain two main domains, N-terminal death domain (DD) and C-terminal Toll/interleukin-1 receptor (TIR) domain. Expression under no immune stimulant revealed highest expression of *SsMyD88* in liver, whereas other important immune organs similarly, spleen and gills disclosed relatively high expression (Fig. 1.). Immune challenge experiment revealed upregulation of transcription resulted by poly I:C, LPS as well as *S.iniae* in spleen (Fig. 2.). According to the luciferase assay rockfish MyD88 has shown a significant and enhanced activation of N κB compared to the control.

Discussion and conclusion

SsMyD88 was found to express in enhanced levels in important immune organs compared to non-immune organs, revelling its importance in immune pathways. According to the immune challenge, *SsMyD88* expression was induced by all the distinct immune stimulants used, therefore SsMyD88 may be involved in diverse range of immune pathways. Luciferase assay results further confirmed the capability of SsMyD88 to activate the NF-κB. All these findings reassure diverse and important immune role of the SsMyD88 during the innate immune defence.

Introduction

Norway is the biggest aquaculture producer in Europe, contributing 66% of the total production volume, of which Atlantic salmon (*Salmo salar)* is the predominant species (Rico et al., 2018). In recent years this aquaculture industry has intensified and expanded considerably, entailing an increased likelihood of major disease problems (Bondad-Reantaso et al., 2005). In order to promote optimal fish health conditions, a variety of therapeutants are used on Norwegian salmon farms. This research project will focus on the substances used to treat sea lice (*Lepeophtheirus salmoni*), including hydrogen peroxide, emamectin benzoate, deltamethrin, azamethiphos and cypermethrin. Another common problem Norwegian salmon farmers are facing is biofouling, which can also have significant production impacts, as the fouling restricts water exchange in cages, causes deformation of cages and increases disease risk (Fitridge et al., 2012). Copper-based antifoulants are mainly used to mitigate the effect of biofouling (Guardiola et al., 2012). However, concerns have been raised about the possible environmental impacts of the use of therapeutants and copper (Guardiola et al., 2012; Rico & Van den Brink, 2014). These chemicals may harm the biodiversity and functioning of aquatic ecosystems surrounding aquaculture farms, and may compromise the environmental sustainability of the aquaculture sector (Guardiola et al., 2012; Rico & Van den Brink, 2014). This research project was undertaken as part of the EU H2020 TAPAS project (Tools for Assessment and Planning of Aquaculture Sustainability) in order to assess the environmental impact of therapeutants and copper by investigating the relationship between copper and therapeutants and the benthic species biodiversity surrounding Norwegian salmon farms.

Materials & methods

As part of the certification process of the Aquaculture Stewardship Council (ASC), the ASC requests salmon producers to submit a comprehensive set of farm data to them. Included in this data are the results of benthic sampling for biotic diversity and copper concentrations. This data will be used to assess the impact of copper and therapeutants on the benthic biodiversity surrounding Norwegian salmon farms. The used benthic quality data includes biotic indices, copper concentrations and counts of macrofaunal taxa. Data concerning therapeutant use will also be used in this research project. A bivariate statistical analysis will be conducted to analyse the relationships between both the benthic copper concentrations and therapeutant dosage and the Shannon-Wiener (SW) index. Another aspect of this research project will look at whether the MAMPEC model is suitable, given the salmon data collected to date by the ASC, to assess environmental impacts of copper and therapeutants. The MAMPEC model is a chemical fate model, designed to predict environmental concentration of antifoulants, and may also be adapted to perform risk assessments of therapeutants used in aquaculture (Rico et al., 2018).

Results

Data analysis is still ongoing this stage of the research project, therefore the complete results will be presented in the updated abstract.

(Continued on next page)

Conclusion and discussion

As mentioned above, data analysis is still ongoing therefore no conclusions can be drawn yet. These will instead be presented in the updated abstract. Statistical testing of the associations or correlations between different concentrations of therapeutants and copper and the benthic species biodiversity will help to further scientific understanding of the environmental impacts of therapeutant and copper use on marine cage salmon farms. Use of environmental risk assessments in aquaculture is currently somewhat limited in many European countries (Rico et al., 2018), meaning it is important to improve chemical exposure and effect assessments of therapeutants and copper in order to help assure the sustainability of the aquaculture sector.

Based on this research, it may be possible for the ASC to alter its data collection system in a way that this data can be fitted into environmental impact models such as MAMPEC. This research project and further research therefore not only makes a contribution to the work of TAPAS, but also to the work of the ASC in appraising their collected salmon farm data.

AquaIMPACT - GENOMIC AND NUTRITIONAL INNOVATIONS FOR GENETICALLY SUPERIOR FARMED FISH

A. Kause, the AquaIMPACT consortium

Natural Resources Institute Finland (Luke)
E-mail: antti.kause@luke.fi; ww .luke.fi/aquaimpact; Twitter: @aqua_impact

Introduction

AquaIMPACT is a Innovation Action project funded by EU's Horizon 2020 programme under the call 'Sustainable European aquaculture 4.0: Nutrition and Breeding'.

AquaIMPACT is a major effort to integrate the fields of fish breeding and nutrition to increase the competiveness of EU's aquaculture of Atlantic salmon, rainbow trout, gilthead seabream and European seabass, to ensure food and nutrition security and to satisfy consumer demands for high-quality seafood with limited environmental impact. AquaIMPACT is also the initiator of digitalisation to make aquaculture operations more cost-effective and with new services and products.

The AquaIMPACT concept is (Fig. 1):
• To demonstrate implementation of **genomic selection technology** in commercial breeding programmes, focusing especially in improving the traits related to feed utilisation, nutritional quality and disease resistance.
• To quantify the way current breeding programmes have changed fish traits, and to quantify the consequent need for associated changes in present and future fish nutrition, and to demonstrate the already-realised benefits for **the industry profit and environment**.
• To tailor-make **feed formulae and feeding practices for the genetically selected fish improved by breeding programmes**, based on their nutritional needs, focusing especially on improving the traits related to feed utilisation, nutritional quality, disease resistance and their interactions.
• Using the current breeding programmes as a starting point, to quantify **the break-even points and cost-efficiency ratios for investing, and to find optimized designs** to implement the novel genomic methods.
• **Develop methods for digitalisation, spectroscopy, smart-software, machine learning, and IoT**, especially for recording novel added-value traits, reducing costs of recording fish traits, reducing costs of genotyping, and to develop feed formulae to produce added-value fish products (with higher omega-3, balanced body composition, minimum waste) without the need to grow the fish in practice
• To interactively **communicate with stakeholders and end users** to promote the use of the developed methods for solving industry, societal and environmental challenges, and **increase awareness of consumers** on sustainable aquaculture practices.

Expected impact

In AquaIMPACT, we follow the Innovation Action principles to validate and demonstrate the use of existing knowledge, pre-products and technologies within companies, by overcoming the bottlenecks of their implementation, to meet the demands of companies, consumers, and society. The expected impacts are:

• Productive and resilient breeding and feed industry, and increased self-sufficiency in blue bioeconomy within E
• Increased potential for emerging raw materials (algae, single-celled, insect meals), novel additives in feeds, and novel technologies
• Environmental impact, fish welfare and resource efficien .
• Increased awareness and acceptability on aquaculture, fish breeding, genomics and nutrition

The consortium

The consortium consists of 11 companies and 13 research institutes, with solid track-record for developing technological advancement for the benefit of industries and consumers. The consortium members come from 9 countries: Finland, Norway, France, Spain, Portugal, Italy, Netherlands, Belgium and United Kingdom. The Stakeholder Group consists of FEAP - Federation of European Aquaculture Producers, FEFAC - European Feed Manufacturers' Federation, and EAS - European Aquaculture Society. The consortium is described at our website www.luke.fi/aquaimpact

AquaIMPACT has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No 818367.

FISH CELL CULTURES AS A ROBUST TEST SYSTEM IN AQUACULTURE RESEARCH

Y. Kaya[1]* and G.P. Franz[1], P. Ciba[2], B. Grunow[1]

Leibniz-Institute for Farm Animal Biology, Institute of Muscle Biology and Growth; Wilhelm-Stahl-Allee 2, 18196 Dummerstorf (Germany)

Introduction

Fish culture and production is the fastest growing area of food production with a steady expansion of 8.4% since the 1970s (FAO 2016), aiming to improve the food supply for the increasing world population. In order to establish a sustainable aquaculture production with high product quality and adequate animal welfare, the understanding of fish growth and its development needs to be deepened. For this purpose, the external influences that fish larvae are exposed to during development, like changing abiotic parameters due to climate change, environmental pollution or illnesses, need to be investigated. Already in the early ‘60s the first fish cell line was established by Wolf & Quimbly (1962) to examine these factors. Since then, the number of fin fish cell lines has strongly increased, reflecting the scientific interest in these species.

Even though capabilities of *in vitro* models have greatly improved, the numbers of fish species used in research is very low. The Federal Ministry of Food and Agriculture declared that in between 2015 and 2016 the number of used fishes in research increased by 72% (https://speakingofresearch.com/facts/animal-research-statistics/german-animal-research-statistics/). During the last years, we showed that these cell lines can be useful tools for studying the effects of different biotic and abiotic factors (Grunow et al., 2011a, Grunow et al., 2012, Grunow et al., 2015), like temperature changes and viral-host-pathogen interactions and pathogenesis (Noguera et al., 2017).The aim of our work is to investigate cell lines established from different economically important fish, like Atlantic sturgeon (Acipenser oxyrinchus), rainbow trout (Oncorhynchus mykiss), maraena whitefish (Coregonus mareana) and Atlantic salmon (Salmo salar), regarding their potential to serve as relevant *in vitro* models in aquaculture related research.

Methods

Cell cultures obtained from the eye-point egg stage or yolk-sac larvae of the fish species of interest were generated. Additionally, cell cultures were obtained from the German Cell Bank for Wildlife “CRYO-BREHM”. To elucidate the effect of temperature changes on cell growth, the proliferation of cells generated from Atl. sturgeon, trout and mareana was examined at 4 different temperatures (16°C, 20°C, 25°C, 28°C). These analyses were performed via impedance measurements using the xCELLigence RTCA SP instrument. Additionally, spontaneously contracting cardiac cell aggregates (SCC) were generated in order to examine the effects of temperature changes on cardiac cells. Further analyses were performed by using qPCR, immunocytochemistry as well as Mass Spectroscopy and Electron microscopy. As a last step, SCCs were infected with cardiotropic viruses (Infectious salmon anaemia virus and Salmonid alphavirus) and the viral gene expression was analyzed by qPCR.

Results

We established a well proliferating cell population which have been passaged and propagated over several years showing a uniform cell morphology with increasing numbers of passages. The cells from Atlantic sturgeon revealed the highest cell indices and therefore the optimal growth conditions at 25°C with a cell impedance of 19.68 reached after 35.22h of incubation. Using cells from sturgeon that were kept at 20°C, the highest cell impedance level was reached three-times in the following, having an index 5.3% lower than at 25°C (Grunow et al., 2011b). During passage 0, the generation of spontaneously contracting cell aggregates (SCC) could be observed after cell isolation of several fish larval species, like trout, salmon, sturgeon and maraena, with up to five SCCs per specimen (Grunow et al., 2011a, Grunow et al., 2012). The characterization of the cells exposed fully developed myocardial as well as endothelial and fibroblastic cells which were electrical and mechanical connected to each other (Grunow et al., 2011a, Grunow et al., 2015, Noguera et al., 2017). SCCs can be maintained with minimal support retaining their contraction capacity and displaying beating frequencies similar to the fish heart for up to 6 months in culture. The influence of the temperature showed that the spontaneously beating frequency of SCC generated from rainbow trout larvae will increase from 59.5±15.6 bpm at 16°C to 90±24.38 bpm at 25°C showing an increase of 66%. Furthermore, viral infection analysis via qPCR revealed that SCCs can be infected with different SAV (F93-125, MS 4640 and F97-220) and ISAV isolates (ISA 390-98) (Noguera et al., 2017).

(Continued on next page)

Discussion

Fin fishes possess an enormous diversity as well as different fish species will react in a disparate manner to external influences. Therefore, fish cells are an ideal tool to study various influencing factors in a closed and verifiable environment. We were able to show that *in vitro* models represent a bioethical and cost effective tool to study the impact of changing climate factors or the interaction between the host and viral pathogen. Our observations confirmed that cells will react differently based on their source of isolation. For forthcoming, our goal is to establish stable cell lines from a taxonomic broad range of fish species and to answer the question, whether adapted *in vitro* tools can narrow the gap between *in vitro* and *in vivo* models.

SALMOSIM: BUILDING ARTIFICIAL ATLANTIC SALMON (*SALMO SALAR*) GUT SYSTEM

R. Kazlauskaite*, B. Cheaib, J. Kaufmann, C. Heys, A. Kitts and M. Llewellyn

The University of Glasgow, Graham Kerr Building, G12 8QQ, Glasgow (United Kingdom)
E-mail: R.kazlauskaite.1@research.gla.ac.uk

Introduction

The aquaculture in Scotland is dominated by Atlantic salmon, which has increasing significance both in terms of economics and food sustainability. The constant decline in wild Atlantic salmon stocks has resulted in an increasing demand for farmed fish, however, the expansion of the Salmonid aquaculture industry is unsustainable due to two reasons: the reliance on over-exploited wild fish stocks as the main protein and lipid food source, and, the poor growth efficiency on alternative plant-based feeds (Ytrestøyl, Aas and Åsgård, 2015; Hemre *et al.*, 2016)two regression experiments, with parr and post-smolt, were conducted. A control diet was included to evaluate if ingredients supplied sufficient nutrients without any added nutrient package (NP. In order to overcome both of these problems the growth efficiency of fish fed on plant-based diets must be improved, and this requires a novel experimental approach.

We are developing a synthetic, continuous salmon gut microbial fermentation system, called SalmoSim, simulating salmon gut compartments representing generalized marine lifecycle stages. The SalmoSim project aims to provide an in vitro platform to study the link between the gut microbiota and digestion in Atlantic salmon (Salmo salar).

Materials and methods

SalmoSim is comprised of three series-linked Applikon MiniBio 500 reactors running anaerobically, simulating three major compartments in salmon gut: stomach, pyloric caecum and mid intestine. They are characterised by a constant flow of media, constant reactor volume, constant temperature and pH control of the individual reactor vessels. The bioreactor vessels are inoculated using a small homogenate of the gut contents collected from the corresponding gut compartments of adult farmed Atlantic salmon.

In order to validate the SalmoSim system, samples from a feed trial performed by Marine Harvest in Averøy were used. During this trial adult salmon were fed a fish meal positive (FM+) diet until they reached 1.5kg, and then they were switched to a fish meal zero (FM0) diet until they doubled in size. This experimental procedure was replicated within the SalmoSim system. Reactors inoculated with the gut contents from fish fed on the FM+ diet were left to stabilise over a 20 day period, whilst continually supplied with FM+ media. They were then switched to a FM0 diet over a following 20 day period, in order to see if the bacterial community changes seen in real salmon, can be replicated inside the SalmoSim system.

During the length of the validation experiment samplings were performed every second day, during which bacterial activity (protein, ammonia and volatile fatty acids concentrations) and bacterial population changes (qPCR and next generation sequencing) were measured.

Results

Preliminary results indicate that in both real salmon and SalmoSim the switch in feed from FM+ to FM0 diet results in similar response in several different bacterial groups, such as Actinobacteria, Betaproteobacteria, Firmicutes, Gammaproteobacteria, Lactobacillus and Mycoplasma. Currently next generation analysis on real salmon and SalmoSim samples is being performed, in order to see more detailed results. Results from this experiment and others in progress will be presented.

Discussion and conclusion

The observed similar bacterial community changes during the switch of the fish meal from FM+ to FM0 in both real salmon gut and SalmoSim system, indicate that artificial salmon gut system is functioning as expected. Once the system is validated, it has the potential to provide a platform with a broad range of applications including the study of microbial population dynamics, the evaluation of the performance of different feed formulations, the comparison of the fermentative capacity of the gut microbiome of lean and obese fish (possibly leading to oral transplant studies), the evaluation of the effects of antibiotic/disinfectant/antiparasitic treatments on microbial gut population composition, the evaluation of pro- and syn-biotic approaches as well as the study of antimicrobial resistance transfer. The system's physicochemical parameters can also be adjusted to simulate the gastrointestinal tract of other teleost fish of commercial or biological interest

Discussion and conclusion

Introduction

Fisheries and fish farming are important global contributors to the production of seafood for human consumption. These industries are also known for substantially higher HSE risks and work-related injury frequencies which implies that increasing the automation level of high-risk operations within fisheries and aquaculture would lead not only to economical but also social and ethical benefits [1]. Using intelligent machines and robots to replace humans in challenging and dangerous environments may improve the HSE situation in these industries, which will benefit society. Increased automation will improve the level of control humans have over operations in aquaculture by facilitating increased future use of autonomous underwater robots in the industry [2]. This paper aims to address challenges on how autonomous operations in complex and dynamically changing environments can be realized by enabling underwater robots to adapt their actions by considering interaction with fish, deformable flexible structures and environmental disturbances. This harmonises with the currently emerging Precision Fish Farming (PFF) concept, which outlines how innovative technologies and automation principles may be used to industrialise, digitise and improve operations in fish farming [3]

Material and Methods

The CageReporter project (RCN 269087) headed by SINTEF Ocean AS aims to develop a tetherless permanent resident underwater robotic system [4]. The integrated system consisting of an advanced underwater positioning system, a vision system able to obtain high quality data and novel control functions is developed in order to perform data capture in interaction with the fish, infrastructure and production environment. To this end, adaptive and bio-interactive control concepts have been developed for underwater robots performing autonomous operations. The concern of the bio-interactive based inspection and intervention operations/tasks is addressed in the context of intelligent bio-interactive path planning, which is the task of planning a path that allows the vehicle to inspect the area of interest while avoiding collision with the infrastructure inside the fish cage and avoid 'scaring the fish during each operation

Results

The developed control framework consists of three components: a) estimation of cage structure and fish behavior, b) path planning and c) path following control approach. Estimation techniques combining measurements from underwater positioning system have been used to estimate the deformation of the structure during planned operations in fish farms. In particular, the obtained positions of different locators installed at different places of the fish cage have been combined with a prior knowledge of the fish cage shape in order to estimate the current profile and thus the deformation of fish cages at each time step (Figure 2). For the estimation of fish behavior, underwater vision sensors combined with advanced image processing techniques have been used in order to calculate the fish swimming speed and the distance of the vehicle from the fish (Figure 3). Afterwards, the knowledge of the structural deformation and the fish related behavior have been used in order to propose bio-interactive path planning concept in this paper. To accomplish the planned operation, the off-line path has been generated using a prior knowledge of the fish cage structure. Then, the adaptation of the generated path is performed at each time step considering the inputs for the constraint functions obtained by using the online estimation of structural deformation and fish behavior. The estimated path is fed to the control systecm as reference point to be followed using the proposed path following control approach during the planned operations (Figure 2).

Discussions and Conclusion

Underwater robots are today used in a variety of different applications in different industrial segments (e.g. oil and gas, shipping and conservation/oceanography). In most present applications, the vehicle is beneath the wave zone, where environmental impacts are less challenging, and relates to fixed features (e.g. seabed, permanent bottom installations and rigid ship bodies). However, the external features a robotic system faces in an aquaculture situation differ from those encountered in conventional operations. Motivated by the PFF concept and following the needs of future unmanned aquaculture operations, this paper targets a novel research area by investigating the challenges of using underwater robots in "application-realistic" environments such as fish farms, where structures are flexible, and robotic systems must interact with animals during operations.

INVESTIGATION OF THE BIODEGRADATION EFFICIENCY OF T-2 MYCOTOXIN-DEGRADING BACTERIA BY MICROINJECTION ON ZEBRAFISH (*Danio rerio*) EMBRYOS

Flóra Kerekes *, Edina Garai, Anita Risa, Mátyás Cserháti, Emese Varga, Béla Urbányi, Zsolt Csenki-Bakos

Szent István University, Institute of Aquaculture and Environmental Safety, Department of Aquaculture,
1 Páter K. Street, Gödöllő 2100 (Hungary)
Email: kerekesflo@gmail.co

Introduction

Extreme weather conditions resulting from climate change greatly influence the appearance of microscopic molds and the amount of mycotoxins produced on agricultural crops (e.g. fruits). Mycotoxins are not only the reason of economic losses but also a source of public health threats. One of the most promising methods of mycotoxin decontamination is degradation and detoxification by microorganisms or by their enzymes. The method allows the removal of mycotoxins without using harmful chemicals and without significant loss in nutritional value. According to EFSA's recommendation, in addition to the degradation potential of the microbes used for this purpose, the metabolites from the parent compound should also be investigated by ecotoxicological tests. Not all toxins and microbes have a fast, reliable and cost-effective bioassay/ecoassay, this is also relevant for the T-2 toxin we tested, which is one of the most important mycotoxins from an agricultural point of view. Due to its immunological, dermato- and neurotoxic effects, it represents a potential hazard to both human and animal health.

Materials and methods

Our study covers if the seven selected T-2 degrading microbial strains have biodetoxification potential. The aim of our experiments was the bacterial degradation and biodetoxification of T-2, so the elimination of its harmful effect. The residual biological activity of the degradation samples was tested on zebrafish embryos by microinjection (120 hour test).

Results

Based on the results of our experiments, it can be stated that only the normal metabolite and the degradation by-product of *R. erythropolis* NI1 were not toxic to the treated fish. The normal metabolite of *R. rhodochrous* NI2 was found to be harmful, whereas the degradation by-product was not.

Conclusion

In conclusion, metabolic products produced by degrading bacteria under normal living conditions are also important to study, and considering the EFSA recommendation is recommended in all similar cases. In addition, the strain NI1 may be used in the future to decontaminate contaminated feed indoors.

ECOSYSTEM SERVICES PROVIDED BY FRESHWATER FISHPONDS IN RELATION TO CLIMATE CHANGE

E. Kerepeczki* P. Palásti and G. Gyalog

National Agricultural Research and Innovation Centre Research Institute for Fisheries and Aquaculture,
35 Anna-liget H-5540 Szarvas (Hungary)
E-mail: kerepeczki.eva@haki.naik.hu

Introduction

Fishponds in Central and Eastern Europe are centuries-old human constructions, however, beyond using them for fish production freshwater ponds are sites of valuable functions which are essential to society. Ecosystem services, defined as 'benefits people obtain from ecosystems' (MA, 2005), are often unrecognized in the case of fishponds. As nature-like shallow waters, fishponds are highly exposed to recent and forecasted changes in climate and therefore the ecosystem services may suffer considerable drawbacks. The objectives of our study were to identify ecosystem services (ESs) provided by the second largest pond system in Hungary and survey its importance for local residents. Moreover, we estimated the impact of climate change on identified ESs.

Materials and methods

The study area was the Biharugra Fishponds, located in the southeast of Hungary with a territory of 1920 hectares. The ponds are semi-intensively managed with an average stocking density of 350kg ha^{-1} in polyculture of warm water species, like common carp, silver carp, grass carp, European catfish, pike and pikeperch. During the three-year growing period, supplementary grain feeding is applied accompanied by manuring to enhance natural food resources. Because the favourable living and feeding conditions, fishponds are suitable for a great number of waterbirds and have a significant nature conservation value. To identify the fishponds ecosystem services we interviewed local key-informants of various stakeholder groups. Habitat mapping according to the Hungarian landscape types was implemented (Bölöni et al, 2011) as a base for ESs' visualisation. Biophysical and socio-cultural assessments were conducted on the revealed ESs. For biophysical evaluation, we have assigned indicators to every quantifiable service to determine their supply in a 3-5 years interval. During the socio-cultural assessment, we have performed 70 questionnaires among the people of the neighbouring settlement, to reveal local demand for services and their perceptions towards ESs. To assess ES capacity, we used a matrix model based mapping (Jacobs et al., 2015). To identify climate change effects on ESs the survey proposed by Foley et al (2018) was conducted by an expert panel.

Table I Ranking of identified ESs at Biharugra Fishponds and the effects of climate change (CC) (+ positive, - negative, +/- both)

Ecosystem service	Rank	CC effect
Fish production	1	+/-
Recreation	2	na
Aesthetics	3	-
Presence of protected/rare species	4	-
Reed production	5	+
Habitats for protected/rare species	6	-
Education	7	+
Air quality regulation	8	na
CO_2 absorption	9	+
Inspiration	10	+
Water storage	11	+
Groundwater recharge	12	+
Water quality regulation	13	+/-
Opportunities for research	14	+/-

(Continued on next page)

Results

Fourteen site-specific ESs were revealed through interviews with diverse stakeholders which were then ranked by the people of Biharugra the nearest village in the area (Table I). Our results showed that fish production, recreation and habitat provision were the most highlighted services (Palasti et al., 2018). Additionally, the interviews exposed the importance of other ESs like air quality regulation, education or water quality control. The potential use of the 14 services was mapped based on a matrix model and the actual use of ESs was also mapped and valued in biophysical terms in the described sub-habitats of the pond system which allowed us to build in stakeholders' ecological knowledge, as well.

According to the expert panel, almost all ESs will be impacted by climate change. Hungarian aquaculture will most likely benefit from higher temperatures in general through accelerated growth rates and elongated production seasons. However, increased occurrence of extreme weather events, new pathogens will stress fish and food organisms and also may amortize physical infrastructure. Altered precipitation patterns, especially drought will cause water scarcity and conflicts between fish farmers and operators of the irrigation sector. Assumed positive effects in some cases (education, water storage, inspiration) predict a need for increased efforts and attention towards semi-natural aquatic and wetland ecosystems.

Conclusions

The numerous ESs identified in our study site prove that freshwater fishponds are important ecosystems in rural areas in Hungary and in Central Europe as well. Climate change, even if positive effects were found, requires special planning and management efforts and additional costs to keep sustainable this segment. Working with diverse stakeholder groups also revealed future possibilities for further utilization such as water storage, ecotourism and environmental education.

Introduction

Silver Prussian Carp (*Carassius auratus gibelio,* Bloch, 1782) is a non-native, invasive fish species in the Hungarian water bodies. Because of their gynogenetic reproduction they spread very fast and mean a serious food competitor to native fishes and economically important species, like the carps. In spite of these our knowledge very limited about their population genetic background. The aim of the present study to analyse the genetic diversity of the silver Prussian carp populations on the water basin of lake Balaton and some additional Hungarian populations, based on mitochondrial D-loop sequences.

Materials and methods

134 samples were collected from six places in Hungary, the inner region of the Lake Balaton (Siófok;n=29), two regions of the Kis-Balaton (Ingó (n=18), Kányavár (n=18), Hőgyész (n=31), Török (n=19) and Őszödi-berek (n=19). From the samples, DNA was isolated by E.Z.N.A Tissue DNA Kit following the producer protocol. PCR was made with a general D-loop primers from Cyprinidae, Carp-pro2-F (5'-TCACCCC TGGCTCCCAAAGC-3') and Carp-Phe2-R (5'-CTAGGACTCATCTTAGCATCTTCA GTG-3') (Wang et al. 2010).

The purified amplification product was sequenced by using Big Dye Terminator v. 3.1 Cycle Sequencing kit (Applied Biosystems) and ABI PRISM® 3100 Genetic Analyzer. Sequence alignments were made by ClustalW algorithm with MegaX software (Kumar, 2018). Based on the polymorphic sites haplotype groups were calculated by DnaSP6 version 6. software and polymorphic tree was made by MegaX software. Different haplotypes were compared and checked in the NCBI database.

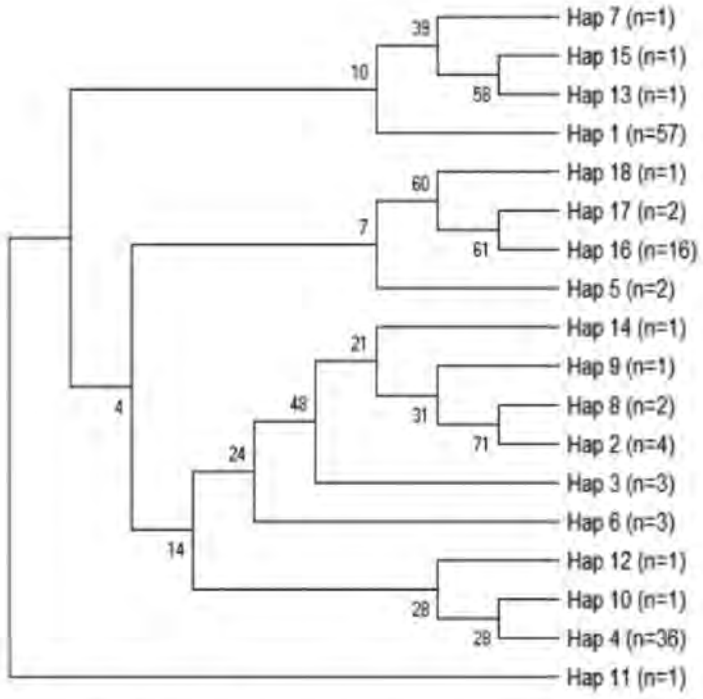

Fig 1. Silver Prussian Carp haplotypes in Hungary

(Continued on next page)

Results

A total of 18 haplotypes were identified in the 134 sequences with 50 variable sites. Haplotype diversity was 0,735. The most common group were contained (Haplotype 1) 57, the second (Haplotype 4) 36 and the third 16 individuals (Figure 1.). The remaining 15 haplotypes were present only 1, 2 or 3 samples. Populations from the different area were distributed mixed in the haplotypes expect the samples from Öszödi-berek. The Haplotype 17 and Haplotype 19 were found only in this population. Based on the NCBI Blast, there were 4 groups which despite their phenotypes show higher similarity with other *carassius* subspecies, than the *Carassius auratus gibelio*.

Discussion and conclusion

In conclusion, 18 haplotypes were successfully identified in six *Carassius auratus gibelio* populations in Hungary. More than one haplotypes were identified in all populations showing the maternal lines in populations. Probably live connections are present between the Balaton and its influencers based on the distribution of haplotypes. Only the Öszödi-berek forms an independent group. Interestingly 5 individuals carried goldfish originated haplotypes (*C. a auratus; C.a. buergeri*) showing signs of hybridization with other carassius species. However, these ornamental species are not natives in Hungary they can survive in nature and escape or release from ornamental ponds are proved several times. There was not identified the native *Carassius carassius* specific haplotypes. Larger sample size and nuclear genomic analyses are required for more detailed analyses of hybridization with the native relatives.

Introduction

Currently, genetic evaluation of slaughter quality of Atlantic salmon (*Salmo salar*) is based on costly, time-consuming and laborious yearly test-slaughter of thousands of siblings of the breeding candidates. The potential of genetic progress in slaughter traits is limited, as the traits are recorded only from relatives, and because the manual dissection phenotypes are likely to be coupled with a measurement error.

Earlier studies have reported that computerized tomography (CT) scans accurately predict fat and protein percentage in rainbow trout (Gjerde, 1987) and Atlantic salmon (Rye, 1991), but so far this methodology is not implemented in salmonid breeding programs. Our objective is to create a link between the manual slaughter traits and CT scanning of live fish to assess the potential benefit of utilizing C technology for breeding evaluation of slaughter quality in Atlantic salmon.

The first part of the project focused on coupling traditional test slaughter measurements of body weight and fat with the CT-scan phenotypes to get deeper insight of the genetic variation in body composition, and to assess whether the ranking of the families relative to slaughter traits is similar using these two measuring approaches.

Material and methods

Data comprised records from 2692 (1685) individually tagged progeny of 144 (112) sires and 276 (178) dams from manual dissection (CT). The average weight of the fish at slaughter was 4.2kg. For each individual harvest weight (MHWT), gutted weight (MGWT) and fillet weight (MFWT) were recorded, and fat percentage (MFAT) in the fillet was measured using near infrared spectroscopy (NIR).

All CT scans was performed using a Toshiba Aquilion 16 CT scanner (Toshiba Medical Systems, Japan). The CT protocol selected for the salmon was with an energy of 100kVp, X-Ray tube current of 150mA, 750ms exposure time, standard reconstruction kernel (FC01), 2mm slice thickness and an in-plane-pixel spacing of 0.781/0.781mm. The data processing was conducted using a custom-made program removing the organs and cutting the head and tail off by applying a virtual three-dimensional mask to the CT scan. Individual scans were further segmented into volume of different tissue types (fat, meat and bone) for whole, headed-gutted fish and for the fillet, and multiplied by densities estimated from the round weight to convert into weight of the virtual cuts. Virtual phenotypes of fillet weight (FWT_CT), fillet fat percentage (FFAT_CT) and intestinal fat (INTFAT_CT) are presented in this abstract.

Genetic parameters were estimated using ASReml (Gilmore et al. 2015) with a bivariate animal model:

$$\begin{vmatrix} \mathbf{y}_1 \\ \mathbf{y}_2 \end{vmatrix} = \begin{bmatrix} \mathbf{X}_1 & \mathbf{0} \\ \mathbf{0} & \mathbf{X}_2 \end{bmatrix} \begin{vmatrix} \mathbf{b}_1 \\ \mathbf{b}_2 \end{vmatrix} + \begin{bmatrix} \mathbf{Z}_{1_A} & \mathbf{0} \\ \mathbf{0} & \mathbf{Z}_{2_A} \end{bmatrix} \begin{vmatrix} \mathbf{a}_1 \\ \mathbf{a}_2 \end{vmatrix} + \begin{vmatrix} \mathbf{e}_1 \\ \mathbf{e}_2 \end{vmatrix} \begin{vmatrix} \mathbf{y}_1 \\ \mathbf{y}_2 \end{vmatrix} = \begin{bmatrix} \mathbf{X}_1 & \mathbf{0} \\ \mathbf{0} & \mathbf{X}_2 \end{bmatrix} \begin{bmatrix} \mathbf{b}_1 \\ \mathbf{b}_2 \end{bmatrix} + \begin{bmatrix} \mathbf{Z}_{1_A} & \mathbf{0} \\ \mathbf{0} & \mathbf{Z}_{2_A} \end{bmatrix} \begin{vmatrix} \mathbf{a}_1 \\ \mathbf{a}_2 \end{vmatrix} + \begin{vmatrix} \mathbf{e}_1 \\ \mathbf{e}_2 \end{vmatrix},$$

where, $\mathbf{yy}$ is the vector of the phenotypic observations; $\mathbf{bb}$ is the vector of fixed effect of sex (male and female); $\mathbf{aa}$ is the vector of random additive genetic effects; $\mathbf{ee}$ is the vector of random residual effects. The $\mathbf{XX}$ and $\mathbf{Z}_A\mathbf{Z}_A$ are the design matrices assigning observations to the levels of fixed effect and additive genetic effects, respectively. Variance components were also estimated with a univariate animal model, and an additional random family effect was fitted for manual slaughter traits.

Results

Estimates of heritability for MHWT, MGWT, MFWT and MFAT from a univariate model were moderate, ranging from 0.28 to 0.32. Proportion of family variance from phenotypic variance varied between 0.04-0.07 and connected with a high standard error. Genetic correlations between the body weight traits were close to unity (0.96-0.99).

(Continued on next page)

Estimate of heritability for FWT_CT was similar (0.30) and for FFAT_CT higher (0.63) than for traits measured in the manual dissection. Heritability estimate for INTFAT_CT was 0.35.

MHWT and FWT_CT were genetically the same trait. Genetic correlations between MFAT and MHWT/MFWT were moderate (0.42-0.53), whereas high correlations were estimated between FFAT_CT and MHWT/MFWT (0.82-0.83). FFAT_CT and MFAT were phenotypically and genetically highly correlated with estimates of 0.64 and 0.91, respectively. Weight traits MHWT, MFWT and FWT_CT were all unfavourably phenotypically (0.51-0.63) and in lesser extent genetically (0.28-0.53) correlated with INTFAT_CT.

Discussion

The results presented here are part of a large project assessing the potential of using CT scans to evaluate the breeding candidates relative to the slaughter quality in Atlantic salmon. If successful, CT technology would enable finetuning the optimisation of body composition and slaughter quality of salmon through selection and offer potential for incorporation of non-invasive new phenotypes as selection criteria without resource- demanding test-slaughter.

As a first step, we performed a test-slaughter combining CT-scanned and manually dissected phenotypes. The genetic parameters show clearly the potential of using virtual cuts from CT scanning as selection criteria for improved slaughter quality. Unity genetic correlation between MHWT and FWT_CT verifies the difficulty of genetic improvement of fillet yield when selecting for body weight. MFAT has been shown to be highly correlated with chemical references (Segtnan et al. 2009). High genetic correlation between MFAT and FFAT_CT implies reliable ranking of individuals on MFAT based on non-invasive FFAT_CT phenotypes. Selection for rapid growth causes genetic increase in MFAT in lesser extent than in FAT_CT. Difference may arise from the definition of CT phenotypes (voxel threshold value and conversion through density) or that CT phenotype captures components other than lipids, which are highly genetically correlated with rapid growth.

In the next phase of the project we will CT scan live fish to validate the methodology and estimate the genetic correlations between live fish virtual cuts with manual dissection. High genetic correlations would speak for replacement of manual slaughter and sib information by live CT scanning of breeding candidates to recorded individual phenotypes for slaughter quality.

POWER CALCULATIONS FOR OPTIMISATION OF THE EXPERIMENTAL DESIGN TO DETECT G X E: SALMON EXPERIMENTS IN FUTUREEUAQUA

A. Kettunen[1]* and M. Lillehammer[1]

[1]Nofima AS, P.O. Box 210, N-1431 Ås, Norway

Introduction

The objective of the WP1 in FutureEUAqua is to assess how the current breeding programmes for salmon, seabass, seabream and rainbow trout can respond to future demands for novel feed compositions, and to make further improvements to disease resistance, climate resilience and animal welfare. For Atlantic salmon (*Salmo salar*) we estimate the genotype by diet/climate interactions (GxE) in semi-commercial salmon production system and validate best selection methods in salmon breeding programs by comparing traditional BLUP selection with GS/MAS for production and robustness traits. Estimated correlations will be taken as indicators of the magnitude of re-ranking of genotypes across diets/environments.

Power calculations are elementary part of the experimental design but unfortunately often de-prioritized, compromising the critical interpretation of the results. *A priori* power calculations of genetic studies are characterized with multiple uncertainties, such as true relationship structure, number of families and individuals at the time of registration and unknown heritability of the traits of interest. This said, we argue that by performing a range of power calculations it is possible to frame the true power of the experiment and improve the probability of executing scientifically solid experiments with given restrictions of resources. We demonstrate the optimisation of the experimental design in order to have adequate power to detect significant GxE (diet/climate aggregate) given FutureEUAqua WP1 resources.

Material and methods

WP1 experiments will be run on two geographical locations in order to study both genotype by feed and genotype by climate interactions. Given the WP1 resources each treatment will be run in two parallels. We assessed the power of detecting heritability (0.05-0.35) in experiments using different number of families utilizing the maximum cage capacity of 750 fish. Same range of true trait heritability and true genetic correlation ranging from 0.1 to 0.9 was used to estimate power detecting genetic correlation (r_g) different from 1 (one). Standard error of heritability was calculated assuming full-sib family structure, thus multiplying the standard error of the intraclass correlation by two: $\sigma_{h^2} = 2\sigma_t = 2\sqrt{\frac{2[1+(n-1)t]^2(1-t)^2}{n(n-1)(N-1)}}$ $\sigma_{h^2} = 2\sigma_t = 2\sqrt{\frac{2[1+(n-1)t]^2(1-t)^2}{n(n-1)(N-1)}}$ (Falconer 1989, p182). Standard error of the genetic correlation is dependent on the heritability of the traits (assumed identical), the standard error of the heritability and the genetic correlation: $\sigma_{(r_A)} = \frac{1-r_A^2}{\sqrt{2}}\sqrt{\frac{\sigma_{(h_x^2)}\sigma_{(h_y^2)}}{h_x^2 h_y^2}}\sigma_{(r_A)} = \frac{1-r_A^2}{\sqrt{2}}\sqrt{\frac{\sigma_{(h_x^2)}\sigma_{(h_y^2)}}{h_x^2 h_y^2}}$ (Falconer 1989, p317). Power was calculated in the context of one-tailed test and 0.95 cumulative probability.

Results

Assuming equal full-sib family size, power of 0.8 to detect true heritability of 0.15 or above was achieved with 20 or more families. To obtain similar power to detect significant GxE ($r_g \leq 0.8$) a minimum of 35 families was required when both traits have true heritability of 0.2 or larger, (figure 1). For genetic parameter estimation it is common to choose the design aiming at 10 fish/famil at registration. With this design and 0.2 heritability, we would be able to detect significant GxE for $r_g \leq 0.9$ or below with power of 0.80, whereas for heritability 0.15 true genetic correlation of 0.6 is needed to detect significant re-ranking of genotypes with identical power.

If the available capacity is only 500 fish, the power of detection of 0.15 heritability would drop down to 0.75. Alike, the maximum probability of detecting significant GxE ($r_g \leq 0.8$) for trait heritability 0.2 reduces to 0.7. For 10 fish/family design, $r_g \leq 0.55$ or $r_g \leq 0.30$ would allow to conclude re-ranking of genotypes with 80% power for traits with trait heritability of 0.2 and 0.15, respectively.

(Continued on next page)

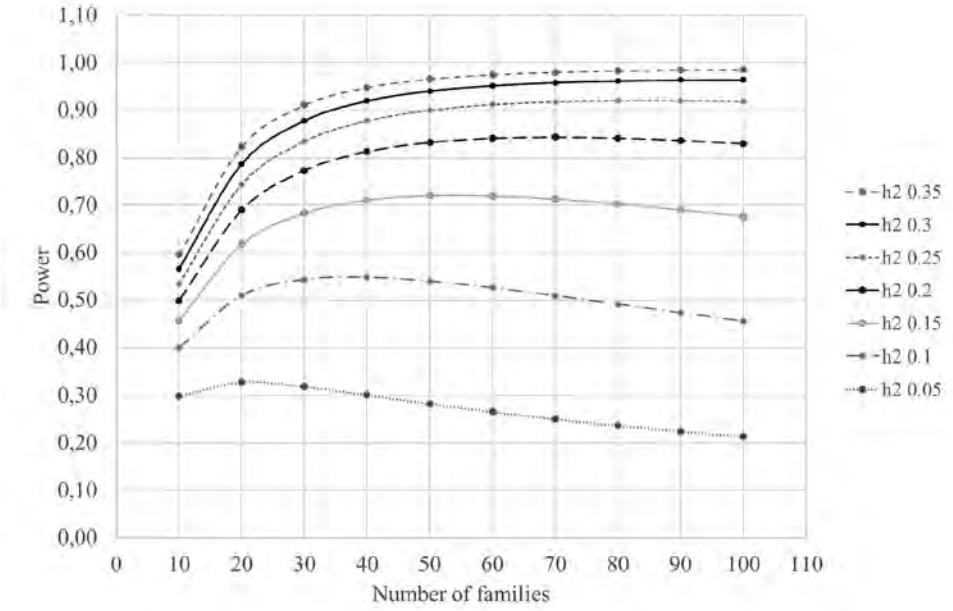

Fig. 1. Power to detect significant GxE, defined as r_g=0.8 (and below), with different number of families and true trait heritability given total capacity of 750 fish.

Discussion

Power calculations, demonstrated here, will allow appropriate reflections of the magnitude of r_g relative to the existence of GxE. The estimates presented here are based on full-sib family structure. In practical breeding programs the genetic material includes half-sib groups and/or related parents. Additionally, relationships are increasingly based on genomic information. Half-sib family structure will reduce the power, counteracted by the genomic relationship information. The true experimental design includes parallel cages to be able to detect treatment effects, whereas we have presented conservative calculations based on one cage only. Despite uncertainties, by performing a range of power calculations it is possible to frame the true power of the experiment with given restrictions of resources. Magnitude of power considered acceptable should be reflected and aligned with the overall objectives and resources of the project

SYNERGETIC EFFECT OF DIETARY ESSENTIAL AMINO ACIDS (LYSINE & METHIONINE) ON THE GROWTH, BODY COMPOSITION AND ENZYMES ACTIVITIES OF GENETICALLY MALE TILAPIA (GMT)

Noor Khan* and Hira Waris

*Department of Fisheries & Aquaculture, University of Veterinary and Animal Sciences, Lahore-Pakistan
Email: noorkhan@uvas.edu.pk

This study was conducted on genetically male tilapia (GMT) fry reared in glass aquariums for three months to examine the synergetic effect of essential amino acids (EAA) supplementation on growth, body composition and enzyme activities. Fish having average body weight of 16.56±0.42g were fed twice a day on artificial feed (20% crude protein) procured from Oryza Organics (commercial feed) supplemented with EAA; methionine (M) and lysine (L) designated as T1 (0.3%M & 2%L), T2 (0.6%M & 4%L), T3 (0.9%M & 6%L) and control without EAA. Significantly higher growth performance was observed in T1 followed by T2, T3 and control. The results showed that whole-body dry matter and crude protein were significantly higher ($P \leq 0.05$) in T3 (0.9% & 6%) feeding fish, while the crude fat was lower ($P \leq 0.05$) in the same group of fish. Additionally, protease, amylase and lipase activities were also observed maximum ($P \leq 0.05$) in response to T3 than other treatments and control. However, the essential and non-essential amino acids, especially methionine and lysine were found significantly higher ($P \leq 0.05$) in T1 compared to other treatments. Conclusively, the addition of EAA methionine and lysine in feed not only significantly enhanced the growth performance of GMT fry, but also improved body proximate composition and essential amino acid profile.

PROGRESS IN HĀPUKU (*Polyprion oxygeneios*) PRODUCTION FROM F1 BROODSTOCK

Khan, J.R.[1]*, Setiawan, A.N.[1], Wylie, M.J.[2], Symonds, J.E.[3] and Pether, S.[1]

[2]Institute for Plant and Food Research, Nelson, New Zealand
[3]Cawthron Institute, Nelson, New Zealand

The wreckfish hāpuku (*Polyprion oxygeneios*) is a high-value commercial species found in the waters of the southern hemisphere. A research breeding program was started to develop the species as for aquaculture in New Zealand, that showed the amenableness of wild caught broodstock to reproduce in captivity, with the key production bottleneck being the highly variable and often very low fingerling survival. However, sufficient numbers of F1 were obtained which were subsequently raised as broodstock. Here, we provide a broad description of the development of reproductive performance of F1 broodstock relative to wild-caught broodstock.

Wild and F1 broodstock were kept in 20-70 m^3 photothermal controlled tanks. Wild and F1 broodstock were given wet feed and pelleted feed, respectively. Spawning occurred between August and December, with sufficiently viable eggs carried through incubation and larvae rearing. The 2008 F1 cohort was part of a study to describe the physiological control of reproduction and were periodically handled for gonad biopsies, measurements, blood sampling and hormonal induction (GnRHa and hCG). The 2010 cohort acted as a minimal disturbance group for comparison. Production and quality parameters of eggs and larvae for each batch (e.g., fertilization, hatch and survival rates) were recorded.

F1 broodstock can be induced to spawn in captivity from 5-6 years using GnRHa implants, with yearly improvements in egg fecundity and quality. After 7 years, particularly when disturbance was kept minimal in the preceding years, F1 broodstock consistently outperform wild broodstock in terms of fingerling survival (5-7% yearly average) by a factor of 5. At 8 - 9 years, spontaneous spawning occurred without exogenous hormone. The high fingerling production subsequently revealed another bottleneck at the early juvenile stage associated with *Vibrio* proliferation, which was overcome by improvements in microbial control practices. Thus, we achieved fingerling and juvenile survival of 6.6% and 4.1% in the last production season from F1 broodstock.

Conclusion

The ongoing research program has now demonstrated that captive-bred (F1) broodstock are a viable and sustainable source for high quality gametes in hāpuku. However, commercial-level natural production does not take place until at least 7 years.

COMPARISON OF SURVIVAL AND GROWTH RATES OF ABALONE, *Haliotis discus hannai*, IN THE DISCHARGE AND INTAKE CHANNELS OF IN POWER PLANT

Taeho Kim*

Division of Marine Technology
Chonnam National University
Yeosu 58754, Republic of Korea
E-mail: kimth@jnu.ac.kr

Introduction

The aquaculture potential offered by the thermal discharges of power stations is widely recognized. Their suitability for fish farming largely depends on the cooling water sources and on the design and operation of the power station. Water of varying quality and salinity is used to generate steam and drive the turbines, which then drive the generators, and the waste steam is fed to a condenser and discharged as thermal effluent.

The heated water that is discharged from steam-electric generating stations has been considered a nuisance and a direct threat to aquatic life. The survival rates of caged fish in discharge canals have been extremely poor, and, thus, it is necessary to develop an aquaculture system for culturing new species such as abalone that can tolerate high-temperature environments relatively well compared to fish. This development would transform "waste water" into an aquaculture resource.

Materials and methods

Survival and growth rates of abalone were investigated in the cages installed in the discharge and intake channels for a total of 98 days from December 17, 2014 to March 25, 2015. The total number of abalone stocked in the 240 shelters installed in the container system was approximately 115,000, with about 479 abalone per shelter. The average shell length of each abalone was 37.87 ± 3.29 mm, and the mean wet weight was 6.29 ± 1.74 g. In order to compare the survival and growth rates of the abalone in the hot-water drainage channel and the intake channel, one cage for the control was installed in the intake channel. In the control cage, 500 abalones were enclosed within the abalone shelter, with an average shell length of 38.31 ± 3.35 mm and an average wet weight of 6.62 ± 1.86 g. Feeding was done about once every 10 days. To prevent deterioration of water quality in the shelter of the cage facilities, the abalone was fed and the remaining feed was removed at the next feed. Bubbles and biofouling that occur in the channels would interfere with the flow in the container; therefore, the containers were raised above the water surface and cleaned at three- or four-day intervals using a high-pressure washer.

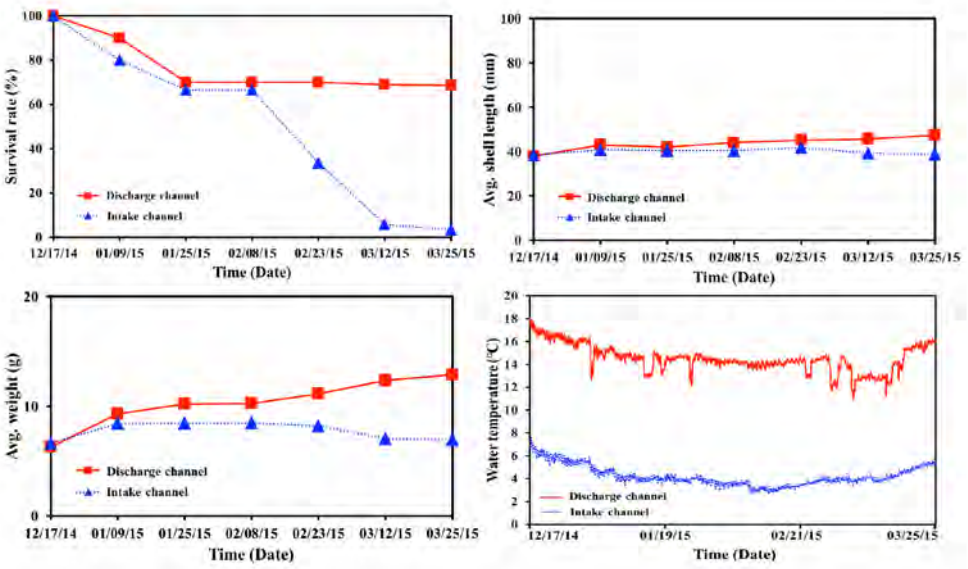

Fig. 1. Survival and growth rates of abalone plotted with changes in water temperature in the discharge and intake channels.

(Continued on next page)

Results and discussion

About 10 percent of the total stocks (approximately 11,500) were dead three days after stocking the abalone in the discharge channel, and most of the individuals with poor initial health died. After the initial 10 percent die-off, the mortality rate increased, and the final survival rate of abalone was estimated to be 68.71 percent in the discha ge-channel cage.

The survival rate of abalone in the control cage located in the intake channel began to decrease rapidly from February 23, 68 days after the abalone stocking, and the final survival rate of control abalone was 3.4 percent.

In terms of growth rate for the abalone in the discharge channel, the average shell length was 47.34 mm, representing a growth of 9.47 mm (125 percent), compared with 37.87 mm for the control cage. The average wet weight increased by 6.66 g (193.54 percent), from 6.29 to 12.89 g.

In contrast, the average shell length of abalone in the control cage grew from 38.31 to 38.9 mm, an increase of 0.59 mm (101.54 percent). The average wet weight of abalone in the intake channel increased by 0.28 g (104.84 percent), from 6.62 g to 6.94 g.

Conclusion

The successful performance of the abalone cage system in the discharge channel during the tests shows promise for feasibility in aquaculture to maximize growth rates of abalone in the winter season.

EFFECT OF DIETARY MONOBASIC POTASSIUM PHOSPHATE (MKP) ON GROWTH OF FAR EASTERN CATFISH (*Silurus asotus*) AND LEAFY VEGETABLES IN HBFT (HYBRID BFT) AQUAPONIC SYSTEM

J.D. Kim[1*], D.H. Lee[2], S.R. Lim[2], D.Y. Kim[2] and J.Y. Kim[3]

Introduction

To date, recirculating aquaculture system (RAS) and biofloc technology (BFT) have been the representative methods of aquatic animal production through the reuse of water in the rearing tank (Avnimelech et al., 2015). Aquaponics is an integrated production system which combines the aquaculture of fisheries with hydroponics of agriculture. In the system, around 30% of feeds supplied to animals such as fish and prawn are assimilated in their body. The remaining 70% are excreted outside the body (Emerenciano et al., 2017) and decomposed and formed into various minerals and nitrates. Successively, such nutrients are utilized by plants and water quality is optimally maintained. In general, plants require 13 kinds of nutrients (N, P, K, S, Ca, Mg, Fe, Mn, Cu, Zn, B, Mo and Al) for their growth in aquaponics but aquafeed contains a limited levels of Ca, K, Fe and P for growth of plants (Bittsanszky et al., 2016). The UVI (University of Virgin islands) aquaponic system has been proposed to artificially add the above-mentioned deficient nutrients for plant growth (Rakocy et al., 2006). The purpose of this study was to suggest a direction to simplify the present aquaponic system by supplying nutrients to the plants through diet only. Therefore, we tried to improve productivity of both of fish and plant by replacing the phosphate source being used in conventional diet with monobasic potassium phosphate (MKP) as P and K sources.

Materials and methods

Graded MKP of 1, 2, 3 and 4% was added to each of the experimental diets containing 45% protein and 7% lipid designated to MKP1, MKP2, MKP3, and MKP4. The first experiment (Exp. 1) was conducted to investigate the differences among three commercial diets (CA, CB and CC) and one experimental diet (MKP2) for growth of Far Eastern catfish (*Silulus asotus*) and two leafy vegetables (Lollo-bionda and Lollo-rossa). Following a 24 h fasting, 400 fish with a mean body weight of 225 g were randomly allotted to 4 groups in two replicates, whereby 8 tanks (1.5 × 1.5 × 0.6 m, water level of 1.35 ton) and 8 plant beds (1.5 × 1.5 × 0.1 m, water level of 0.22 ton) were employed. Diets at the level of 0.8% body weight/d were supplied twice a day at 08:00 h and 17:00 h, respectively, for 4 weeks. Subsequently, the second experiment (Exp. 2) was designed to determine the optimum levels of MKP as growth promoter for fish and four leafy vegetables (Lollo-rossa, Avatar, Caipira and Heuk-Romaine) during 10 weeks. Using the same system as the Exp. 1, 480 fish with a mean body weight of 186 g were randomly allotted to 4 groups in two replicates. Diets at the level of 0.5% body weight/d were supplied twice a day at 08:00 h and 17:00 h, respectively, for 10 weeks.

Results

After 4-week feeding trial of the Exp 1, there were no significant differences in weight gain (WG), feed efficiency (FE), specific growth rate (SGR) and protein efficiency ratio (PER) among fish groups fed MKP2, CA and CC ($P>0.05$) except CB. Growth (total leaf weight) of two leafy vegetables (Lollo-bionda and Lollo-rossa) was the highest in fish group fed MKP2 among treatments (Table 1). After 10-week feeding trial in the Exp 2, WG, FE, SGR and PER were higher in fish groups fed MKP2 and MKP3 than in other groups ($P<0.05$). Similarly, growth of four leafy vegetables was higher in fish groups fed MKP2 and MKP3 than in other groups.

Discussion and conclusion

The productivity (total leaf weight, g) of two leafy vegetables was higher in the MKP2 diet group compared to the three commercial diet groups (CA,CB and CC) in the Exp 1 and it was suggested that the addition of monobasic potassium phosphate (MKP) to the diet could improve plant productivity. In the Exp 2, all leafy vegetables grew well to such an extent that whole harvest was possible 23 days after the initial seeding. It was suggested that the supplementation of the MKP in diet would increase the levels of P and K in the system. Second order polynomial regression model analysis indicated that the dietary optimal MKP level could be 2.77% to 2.89% on the basis of WG of far eastern catfish and four leafy vegetables (Fig. 1 and Fig. 2).

Introduction

Aquaponic system is designed to keep water quality optimal for growth of both of fish and plants and water quality control has been carried out by a mechanical filtration filter which removes solids and a biological filtration which induces a nitrification process. Biofloc tech (BFT) is a recirculating aquaculture method that was introduced in South Korea in the 2000's. One of the pollutants generated by aquaculture is ammonia (NH_3-N) and the ammonia is removed by using organic carbon (molasses, glucose, etc.) to induce proliferation of microorganisms through C:N ratio (15:1 or more) control. To date, recirculating aquaculture system (RAS) does not completely reuse rearing tank water and it is common that less than 10% of the total circulation is replenished every day. RAS is slow to proceed with industrial expansion due to high initial capital investment. For this reason, fresh water aquaculture farms with a simple pollutant settling facility in South Korea prefer the use of the flowing water taken from river and underground. Farms that operate the RAS system are restricted to rearing high-priced fish species such as eel. The UVI (University of Virgin islands) aquaponic system, which has been universally adopted, has been operated in a way that combined hydroponic cultivation with the RAS production method of aquaculture (Bailey and Ferrarezi, 2017) but it has included a problem of facility cost and complexity of system operation. The purpose of this study was to investigate a low pH aquaponic system that utilizes useful microorganisms mixed with heterotrophs and autotrophs to increase the production efficiency and to simplify the current universalized system

Materials and methods

Far Eastern catfish (*Silulus asotus*) of 480 with a mean body weight of 186 g were randomly allotted to 4 groups in two replicates, whereby 8 tanks (1.5 × 1.5 × 0.6 m, water level of 1.35 ton) and 8 plant beds (1.5 × 1.5 × 0.1 m, water level of 0.22 ton) were employed. Diets (graded monobasic potassium phosphate of 1, 2, 3 and 4% was added to the experimental diet containing 45% protein and 7% lipid designated to MKP1, MKP2, MKP3, and MKP4) at the level of 0.5% body weight/d were fed twice a day at 08:00 h and 17:00 h, respectively, for 10 weeks. Product of BFT-ST (EgeeTech, Ltd., USA) was used for low-pH aquaponics water quality management. BFT method (Emerenciano et al., 2017) was applied for 14 days after fish stocking and glucose as carbon source was added into water. Then, the supply of organic carbon was stopped and a certain amount of carbon dioxide (inorganic carbon source) was continuously supplied into the sump tank until the pH dropped below 6.0 using an automatic regulator. From pH 6.0 or lower, useful microorganisms were added when NO_2-N increased and stopped when water quality maintained stable. Water quality (DO, pH, water temperature, electrical conductivity, turbidity, TAN, NO_2-N, NO_3-N, and PO_4-P) measurement was performed 6 times a week using a portable water quality meter (YSI PRODSS, YSI Inc., USA) and reagent measurement (DR5000, HACH Ltd., USA). Blood samples were taken from the caudal vessels of six fish from each group by using a heparinized syringe after fish were starved for 24 h and anesthetized with MS-222.

Results

In present study, the pH value began to decrease following 3 weeks and maintained less than 6.0 from 6 weeks later in all experimental groups. The values of TAN (4.58-20.40 mg/L), NO_3-N (24.12-52.40 m /L), and PO_4-P (20.38-48.48 mg/L) increased and NO_2-N value remained below 0.1 mg / L (Table 1). Blood analysis of fish was shown in Table 2.

Discussion and conclusion

The most important characteristic of the low pH aquaponic system with hybrid BFT is the change of TAN, NO_2-N and NO_3-N according to the nitrific tion process. The results of this experiment which were different from the previous study (Thorarinsdottir, 2015) showed that TAN and nitrate were elevated at the same time and this is presumed to be the result of the nitrificat on process by the heterotrophic bacterium such as genus *Bacillus* at low pH (5.0~6.0) condition. The largest hematologic features are PCV and Hb values which are main indicators of oxygen transport capacity and nutritional anemia, respectively, in fish. Compared to previous researchers, the high value of these two items seems to be the result of adaptation to the environment due to the low pH state of the closed environment.

ROLE OF SMART AQUACULTURE RESEARCH CENTER IN REPUBLIC OF KOREA

Taeho Kim*, Sungju Jung, Hyi-thaek Chong, Jihoon Lee, Eun-sik Kim, Wi-sik Kim and Inyeong Kwon

Smart Aquaculture Research Center
Chonnam National University
Yeosu 58754, Republic of Korea
E-mail: kimth@jnu.ac.kr

Smart Aquaculture Research Center (SARC) as a part of professional human resource training project of Ministry of Oceans and Fisheries is aiming to revitalize high-tech aquaculture industry and cultivate convergent professional manpower through the development of core smart aquaculture technologies and the cultivation of professional human resource.

SARC plans to develop the following three core technologies for smart health-care based on aquaculture biology. First, integrated monitoring and optimal feeding system based on ICT (Information and Communications Technologies)/ IoT (Internet of Things) function for control of breeding environment, growth, working environment, and aquaculture structure in aquaculture ground will be developed to increase productivity and reduce labor force. Second, water treatment technologies to increase re-use rate of breeding water in land based aquaculture will be developed such as nutrient treatment technology of breeding water, process development for efficien removal of waste products, and optimization technology of disinfection process of breeding water. SARC also commercialize IoT-based water quality factor analysis technology to treat pollution sources of aquaculture farm and will develop big data-based water quality analysis and prediction technology. Third, smart aquaculture environment technology to maximize production and for efficient production and management of safe and healthy on cultured fish will be developed by applying ICT to aquaculture process and optimizing breeding methods. SARC build big data on the growth factors of cultured fish growth stages and will develop big data-based health care model on fish growth stages. Moreover, ICT-based high sensitivity rapid diagnostic kit (Point-of-Care Tesing; POCT) and standard manuals for smart health-care will be developed.

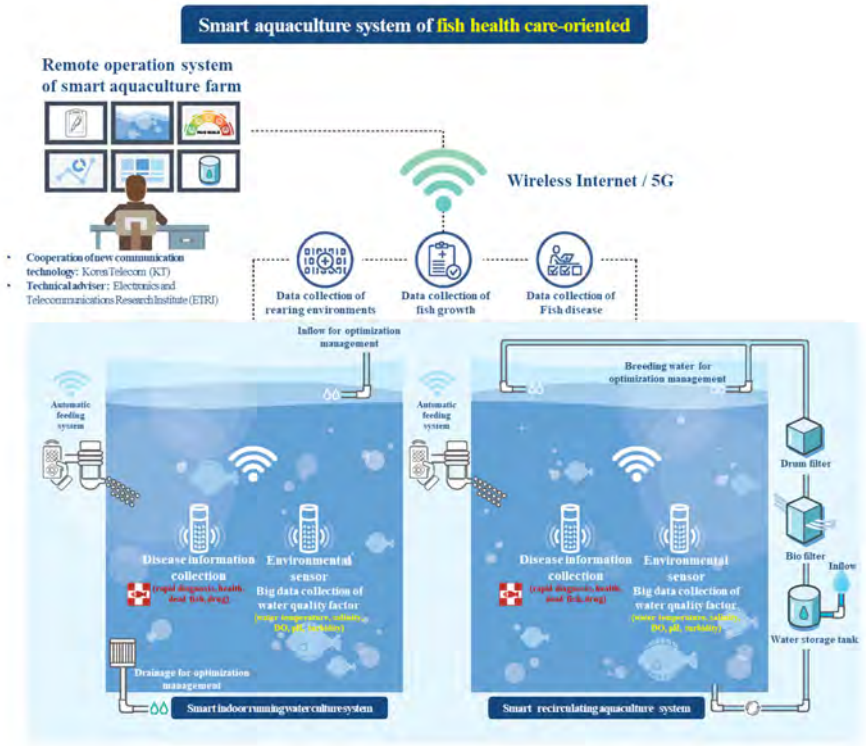

Fig. 1. Concept of smart aquaculture system.

(Continued on next page)

As above, the core goal of this project is to cultivate convergent professional human resource through training and technology transfer for the technologies developed at our center. The Smart Aquaculture Research Center plans to develop AI-C (Advanced Intelligent - Convergence) type professional human resource programs and operate three type programs such as advanced programs for attracting undergraduate students to graduate courses, intelligent programs for strengthening the research power of graduate students of master's and doctoral courses, and convergence programs for strengthening the practice through re-training of industrial manpower and for employment an start-up. In addition, a certification system for smart aquaculture training will be introduced in order to verify the ability of professional human resources who have completed the training of the AI-C type programs.

It is expected that there will be economic and technological ripple effect and job creation effect of Korea's fisheries industry through the development of smart fishery aquaculture technology and fostering of professional manpower that are aimed at Smart Aquaculture Research Center.

A STUDY ON POLY-CULTURE OF SEA Squirt *Halocynthia roretzi* AND SEA CUCUMBER *Apostichopus japonicus* UNDER A HANGING CULTURE SYSTEM

Young Dae Kim[1], Yun Kyung Shin[2], Yong Hyun Do[2], Hee Jung LEE[2]

Changes in the natural environment and high density aquaculture in limited fisheries ground resulted in lower productivity and mass mortality. Sustainable aquaculture farms based on eco-friendly style are needed. Therefore, it is necessary to develop aquaculture technology to improve the up-bottom use of water and the environment in the sea cucumber polyculture. We have developed polyculture techniques using oysters, sea squirts, and sea cucumbers.

The rate of inhabit test in Tongyeong was 45.6% in the oyster shell test, 30.1% in the black tube test, and 33.1% in the rubber tube. In the summer, the oyster shell test was 20.4%, the black tube test was 22.2%, the octopus port shelter test was 17.7% and the rubber tube test was 15.5%. The oyster shell test - 79.6%, black tube test -77.8%, octopus port shelter - 82.3% and rubber tube test plots - 84.5%. In August, the rate of inhabit began to increase gradually. In the November survey, 29.4% in oyster shell test, 35.4% in black tube test, 27.5% in octopus port shelter and 29.2% in rubber tube test. In December, the rate of oyster test was 34.4%, that of black tube test was 37.5%, that of octopus port shelter was 31.7%, and that of and rubber tube test was 32.5%.

The discharge density at the beginning of the test at Tongyeong - si oyster farm ground was 2.51 per m^2. In the March survey, which was one month period, the densities of the oyster shells were 1.06 m^2, 0.75 m^2 for the oyster shell, 1.13 m^2 for the octopus port shelter, and 0.83 m^2 for the rubber tube. The densities of the August survey in summer were the lowest at 0.51 m^2 for oyster test, 0.55 m^2 for black tube test, 0.44 $m^2$for octopus port shelter, and 0.39 m^2 for rubber tube. In October, when the water temperature dropped, the density gradually increased from 0.68 m^2 in the oyster shell test area, 0.83 m^2in the black tube test area, 0.58 m^2 in the octopus port sheltert area, and 0.59 m^2 in the rubber tub test area. In the December survey, the density was 0.86 m^2 in oyster shell test, 0.94 m^2 in black tube test, 0.79 m^2 in octopus port shelter, and 0.81 m^2 in rubber tube, showing similar density as March.

MOLECULAR CHARATERIZATION OF OMEGA AND KAPPA CLASS GLUTATHIONE S-TRANSFERASE FROM REDLIP MULLET (*Liza haematocheilus*) AND ENZYME KINETICS, OPTIMUM CONDITIONS

Jaewon Kim *, D.S Liyanage, W.M GayashaniSandamalika, Jehee Lee

Department of Marine Life Sciences & Fish Vaccine Research Center, Jeju National University
Jeju Self-Governing Province 63243, Republic of Korea
E-mail: jake0927@naver.com

Introduction

The redlip mullet (*Liza haematocheilus*) is a saltwater fish which holds paramount importance as food fish worldwide as well as in Korea. Present study, we characterized the GST kappa (LzGSTκ) and omega (LhGSTω) from redlip mullet. Functional studies were carried out with the recombinant protein to determine its enzymatic and antioxidant properties. In addition, the transcriptional levels of *LzGSTκ*, *LzGSTω* were determined under normal physiological conditions and immunologically challenged conditions.

Materials and methods

The transcriptome database of mullet cDNA sequences was developed using de novo assembly. Mullet fish (~100g, length 24 cm) purchased from Sangdeok fish farm in Hadong, Korea. The fish were acclimatized in the laboratory aquarium tanks at 20 °C for a week prior to the experiment. Total RNA was extracted by using RNAiso plus (TaKaRa, Japan) and cleaned with RNeasy spin column (Qiagen, Germany). Quantitative real-time PCR (qPCR), with specifically designed primers were performed to analyze the expression profile of *LzGSTκ, LzGSTω*. The coding sequence (CDS) of the cDNA fragment was amplified by using gene-specific cloning primers. The size of the amplicon were 687 bp (LzGSTκ) and 720 bp (LzGSTω) respectively. Digested PCR products were ligated into the pMAL-c5X vector. The ligated product was then transformed into *Escherichia coli* (*E.coli*) DH5α and the coding sequence was confirmed by sequencing. To express the recombinant LzGSTκ, LzGSTω protein (rLzGSTκ, rLzGSTω), the pMal-c5X/ LzGSTκ, LzGSTω construct was transformed into *E. coli* BL21 and incubated at 37 °C in LB broth medium containing 100 μg/mL ampicillin, until the OD600 reach 0.6. Isopropyl-β-galactoside (IPTG) was then added to the culture (final concentration 0.5 mM) and incubated for 24 h at 15 °C to induce the expression of the recombinant protein. After incubation, the cells were harvested by centrifugation. The rLzGSTκ, rLzGSTω protein was purified from the supernatant using maltose affinity chromatography. Enzyme activity was measured separately using CDNB as substrates. The absorbance of the reaction was measured, immediately and 5 min after addition of the substrate.

Result

To understand the potential endogenous functions of LzGSTκ, LzGSTω, its relative expression was examined in different tissues. Analysis of the expression profiles from the redlip mullet revealed that *LzGSTκ* was strongly expressed in the heart, while the lowest expression was observed in the head kidney (Fig.1.A). *LzGSTω* was strongly expressed in intestine, whereas the lowest expression was observed in the head kidney. (Fig.2.A) Activities of rLzGSTκ, rLzGSTω and MBP against different substrates, including CDNB(2,4-Dinitrochlorobenzene), DCNB(2,4-Dinitrochlorobenzene), 4-NPB(4-nitrophenethyl bromide), 4-NBC(4-nitrobenzyl chloride), and ECA(ethacrynic acid**)** were then measured. Only detectable activity was observed, when CDNB used as the substrate. No significant activity was detected for MBP against any of the substrates and therefore it was treated as a control. rLzGSTκ was shown to have GSH:CDNB conjugating activity at pH range 6 to 8 (Fig.1.B). Its highest activity was observed at pH 7. For RLzGSTω, GSH:CDNB conjugating activity observed at pH range 6 to 9 (Fig.2.B), wherein the highest activities were observed on pH 8.

LOCAL ACCEPTANCE OF MUSSEL CULTIVATION IN THE BALTIC SEA

Lars Kjerulf Petersen*[a], Nardine Stybel[b]

[a] Aarhus University, Department of Environmental Science, Frederiksborgvej 399, DK-4000 Roskilde
lkp@envs.au.dk
[b] EUCC – The Coastal Union Germany, Friedrich-Barnewitz-Str. 3, D-18119 Rostock

Introduction

It is a recurring problem in land use management, including also coastal management, that the location of all kinds of infrastructural installations and production plants can cause conflicts. Such siting conflicts arise even when new facilities provide general societal benefits such as reduction of greenhouse gas emissions or of nutrient loads in fjords and seas. Discrepancies between greater societal concerns and local resistance sometimes lead to accusations of so-called NIMBYism – i.e. 'Not in my back yard'-ism – implying that local interests are egoistic when they acknowledge the greater good of a facility but just want it located elsewhere. The term is, however, more useful as abuse than as analysis, because it completely blocks any consideration of the legitimacy of local concerns and also blocks the integration and negotiation of such concerns in land use planning (Devine-Wright 2009).

The accumulated experience regarding facility siting has revealed a pattern of recurring issues that are at the root of potential conflicts. Thus, residents, permanent as well as seasonal, can feel a strong attachment to the place in which they reside. This is not least true of seasonal residents, i.e. summerhouse owners and other recurring visitors in an area who may have a longer connection to the area than they have to their permanent residence, and who are particularly concerned about the landscape of their leisure time not being ruined by any changes (Stedman 2006; Trentelman 2009).

It can therefore be perceived as an intrusion when a new facility causes significant changes in the landscape and scenery, whether it is as foul smell, noise, increased traffic, large unappealing structures, increased exposure to health risks, reduced air or water quality or something else. Local residents and visitors may also feel that while they have to live with the nuisances and damages of a facility, its benefits are located elsewhere. Moreover, a new facility can potentially disrupt existing activities and business interests, for instance if fish banks are disturbed by offshore wind farms or if the access to a harbour is disturbed by an aqua culture facility (Michler-Cieluch & Kodeih 2008).

On the other hand, local residents may also embrace the location of a new facility, when they feel involved in the planning process, if they believe a facility is in accordance with local values and if they think the facility in other ways will benefit themselves and their community. Following the EU strategy to increase the Blue growth of the marine and maritime sector, e.g. new aquaculture facilities, it is therefore important to consider and adapt to local reactions to the siting of a new facility in their area. (Barrington et al. 2010)

Material and methods

As part of the BONUS OPTIMUS project, we have investigated the issue of local acceptance in three case areas, where mussel farms have been established: one in Hagensche Wiek as part of the Greifswald Bay in Germany and two in Denmark - in As Vig, which is part of Horsens Fjord and in Skive Fjord, which is part of Limjorden. Here we have conducted expert interviews, questionnaire surveys of summerhouse owners and seasonal residents as well as stakeholder workshops and media analysis of local newspapers in the period from autumn 2017 until spring 2019.

Results and discussion

It appears from the studies that mussel cultivation has a chance of being met with local acceptance, although locations of the facilities have to consider various concerns and interests. It should be mentioned that mussel cultivation has a longer history in Denmark than in Germany. This means that in Denmark there are already local experience with mussel farms, but also with other forms of aquaculture.

In both case areas there is a level of ignorance about mussel cultivation. Respondents are to some extent unaware that there is a mussel farm in their vicinity. Another recurring pattern is the importance attributed by respondents to the quality of water and beach. Especially for the Danes, water clarity was very important. Half of the Danish respondents also found that water quality had deteriorated over the years. Danes in particular blamed fish farms (and not mussel farms) in the bay for the reduction in water quality. 82 % indicated that fish farming reduces water quality, 67 % indicated that mussel

(Continued on next page)

farms to some or to a high extent spoil their experience of the landscape, 57 % find that aquaculture facilities spoil their view a little or a lot, and in their open replies they blamed fish farms for cloudy water, for a muddy, slimy seabed and for the disappearance of flatfis in the bay. Some of this frustration with fish farms may have rubbed off on their somewhat more sceptical attitude towards mussel cultivation. While 74 % of the German respondents agreed partly or fully with the statement "I don't mind that there is mussel farming in this area", only 30 % of Danes agreed and 41 % disagreed fully or partly. From our media study, we also learned that there is a concern in the local public that mussel farms, due to their water cleansing capacity, will be used as a lever to introduce even more fish farms in Horsens Fjord including As Vig.

In conclusion, we would suggest that a strong emphasis on water quality would be useful, if developers of mussel cultivation want the acceptance of local stakeholders as well as local seasonal and permanent residents and want to include them in processes of planning, establishing and managing mussel farms.

MULTIVARIATE GENOMIC MODEL FOR DIPLOID AND TRIPLOID GROWTH PERFORMACE IN ATLANTIC SALMON (*Salmo salar*)

S. Kjøglum*[,1], K.E. Grashei[1], S.A. Korsvoll[1], M.Mommens[1] and J. Ødegård[1]

[1]AquaGen AS, P.O. Box 1240, Torgard, N-7462 Trondheim, Norway
E-mail: sissel.kjoglum@aquagen.no

Introduction

Triploid salmon is to date the only available product, for producing sterile Atlantic salmon. To our knowledge there exists no genetic program specifically selecting for triploid performance in Atlantic salmon, and selective breeding is thus based on the assumption that triploid and diploid genetic effects are closely correlated. This has yet to be shown in a proper genetic model.

Studies on salmonids have investigated performance traits among families or strains in response to triploidy, with some re-ranking of families being observed when going from diploid to triploid genotypes (Blanc et al. 2001; Johnson et al. 2004). But here has been a dissidence in conclusion on whether the selection should be on triploid phenotype (Friars et al., 2001), or not (Taylor et al. 2013; Harvey et.al 2017; Leeds et al. 2019).

One of the problems of genetic analysis of triploids is that the genetic contribution of sires and dams are different, as the dam contribute with two copies of each chromosome, while the sire contribute with one copy of each chromosome (as in diploids). Hence, triploid and diploid family members are indeed genetically different, and substantial re-ranking among families should be expected even if the traits as such are genetically equivalent. Furthermore, the two chromosomes inherited from the dam are not independent and will only differ through recombination (depending on recombination rate and location of recombinations). The variance of the Mendelian sampling deviation is thus unknown, unless modelled though a proper genomic model. Finally, genotyping of triploids using standard software packages for genotype calling has so far not been possible. A new software tool was therefore developed for this purpose.

The aim of this study is to evaluate the genetic correlation between performance on growth for diploid and triploid, by the use of proper genomic relationships involving both diploid and triploid full-sib groups, evaluated for growth performance within the same environment.

Material and methods

A random subset of eggs from approx. 75 families of the year class 2014 nucleus of AquaGen, where immediately after fertilization treated with hydrostatic pressure (5 min of 9500 psi) to induce triploidy. The triploid group of approx. 2000 animals were reared as a separate group until they were mixed with diploid full sibs after vaccination. As smolt the fish were put into a single cage at sea were the fraction of triploids where 3%. The group were on-growing in one cage until harvest.

Growth performance were measured by individual weight registrations after 14 months in sea, and tissue samples for genotyping where sampled and genotyped using a 70K SNP-chip. Special software was used to call genotypes for triploids, and methods were developed to assign triploid offspring to diploid parents.

Table I. Descriptive statistics, number of observations, mean etc of families with diploid and triploid offspring.

Group	N	Mean	Std Dev	Minimum	Maximum	CV
Triploid	743	3687	850.4	1080	5740	23.06
Diploid	7883	4588	949.2	200	10240	20.69

(Continued on next page)

A genomic animal model will be used to model diploid and triploid performance:

$$\begin{bmatrix}\mathbf{y_{2X}}\\ \mathbf{y_{3X}}\end{bmatrix} = \begin{bmatrix}\mathbf{1_{2X}} & \mathbf{0}\\ \mathbf{0} & \mathbf{1_{3X}}\end{bmatrix}\begin{bmatrix}\mu_{2X}\\ \mu_{3X}\end{bmatrix} + \mathbf{Z}\begin{bmatrix}\mathbf{g_{2X}}\\ \mathbf{g_{3X}}\end{bmatrix} + \begin{bmatrix}\mathbf{e_{2X}}\\ \mathbf{e_{3X}}\end{bmatrix}$$

where $\begin{bmatrix}\mu_{2X}\\ \mu_{3X}\end{bmatrix}$ are the overall means of diploid and triploid salmon, $\begin{bmatrix}\mathbf{g_{2X}}\\ \mathbf{g_{3X}}\end{bmatrix} \sim N(\mathbf{0}, \mathbf{G_0} \otimes \mathbf{G})$ is a vector of random diploid and triploid additive genetic effects with respect to growth, $\mathbf{Z}$ is the associate incidence matrix, $\begin{bmatrix}\mathbf{e_{2X}}\\ \mathbf{e_{3X}}\end{bmatrix} \sim N\left(\mathbf{0}, \begin{bmatrix}\mathbf{I_{2X}}\sigma^2_{2X_e} & \mathbf{0}\\ \mathbf{0} & \mathbf{I_{3X}}\sigma^2_{3X_e}\end{bmatrix}\right)$ is a vector of random residuals, $\mathbf{G} = \frac{1}{\mathbf{2p(1-p)'}}\mathbf{MM'}$ is the genomic relationship matrix, $\mathbf{G_0}$ is the additive genetic (co)variance matrix, $\mathbf{M}$ is a matrix of centered marker genotypes, including both diploid and triploid individuals. The centered genotypes of an individual *i* (*i*th row in $\mathbf{M}$) is defined as:

$$\mathbf{m_i} = \mathbf{q_i} - t_i\mathbf{p}$$

where $\mathbf{q_i}$ = row vector of genotypes for the individual, t_i = ploidy of the individual, $\mathbf{p}$ = row vector of allele frequencies for all loci.

Results

The triploid group of salmon were offspring of 65 sires and 63 dams, and weight was measured on 1063 triploid salmon with average of 3635g. The average weight of the diploid was 4257g. Comparison of weight and variation for offspring from the same families are given in table I.

Genetic correlation between performance on growth for diploid and triploid will be presented.

TURBULENCE AND FLOW FIELD ALTERATION IN THE WAKE OF AQUACULTURE SEA CAGE

P. Klebert* and B. Su

Sintef Ocean, 7465 Trondheim
Email: pascal.klebert@sintef.no

Introduction

Current flow dynamics within and surrounding fish cages are highly complex (Klebert et al. 2014, 2015). Flow regimes within cages are dependent on both the incoming current (Klebert et al. 2012, Gansel et al. 2012, Rasmussen et al. 2014) and fish behavior (Johansson et al. 2014), however no clear flow pattern has been found due to flow-net-fis interactions driving complex 3D turbulent regimes. Physical factors that influence hydrodynamic flows at the farm-scale include water depth, current flow velocity, and water stratification (salinity and temperature). The present study was undertaken to characterize the flow pattern and the 3D turbulence regime in the wake of aquaculture sea cages

Materials and methods

By using different sensors, such as a 3D current flow profiler (ADCP), micro-turbulence profile , and High precision CTD (Conductivity, Temperature, and Depth) instruments, echosounders (fish distribution in cages), full-scale measurements of detailed 3D current flow patterns have been carried out on the wake of salmon-farming sea cages with and without fish. The cages were using a skirt in the upper 10 m of the water column in order to prevent Sea-lice infestation.

Results

The field observations mapping spatial and temporal variations in the hydrodynamic flows surrounding the cages showed a strong variation of the turbulence levels in the lee of the cage across a range of different background flow conditions. Turbulence levels over the upper 20 m of the water column (depth of cage) and in the lee adjacent to the cage, showed highly elevated rates of turbulence up to several orders of magnitude greater than those observed several hundred meters upstream of the cage. More precisely, higher turbulence levels were also measured over the upper 10 m of the water column just behind the cage, corresponding to the depth of the skirt, compared to upstream values and depths below the cage. In addition, measurements with a moving ADCP, shown a current flow reduction in the vicinity of the cage. These results show that the presence of stocked aquaculture sea cages significantly and consistently altered the intensity and distribution of turbulence levels, and hence the mixing regime, on the wake of cages: this will strongly affect the spatial and temporal distribution of particulate organic matters in the vicinity of the fish farm

Introduction

With increasing production of farmed animals, treatment of their effluents becomes crucial for the ecological sustainability of the industry. In many countries the nitrate load of soil and groundwater already is critical or exceeds the official guideline values. The random distribution of manure as fertilizer accounts for large parts of this load. Land based aquaculture producers contribute to that to some extent by spreading process sludge on agricultural grounds. However efforts are being made to treat effluents streams on site and recycle the process water effectively. However, filtration often requires sophisticated technology and may be very energy consuming. Aquaponic producers are using fish based excretions as nutrient source for plant culture and cycle those within their system. However, only the dissolved nutrients are being used at the moment and some nutrients are often lacking in the solution. The solids usually are disposed within the municipal sewage system or being spread on agricultural grounds. Nutrients in effluent sludge are carbon-bound and have to be treated in order to make the nutrients available for crop production. A very promising on-site and low-energy treatment option for aquacultural sludge could be vermifiltration, hence worm digestion of effluents from fish production. Former studies showed high potential of this technique regarding physical and biological filtration and mineralization of non-solvent plant nutrients (Sinha et al., 2007 & Gardner et al., 2009).

Material and Methods

System Design

Nine individual vermifiltration devices were set up. The devices were made out of plastic boxes (36 x36x12cm) and arranged in a drawer system style. Each system had 4 drawers and a liquid catch tank. Three drawers per device were filled with 12 liter beech wood chips each as worm substrate and the remaining drawer, inaccessible to the worms, was filled with "Kaldnes K1 Micro" Moving Bed Filtermedium.

Out of the nine systems three groups were formed and stocked with different worm densities. The intensive group was stocked with 25 g/l substrate volume. The extensive group was stocked with 15 g/l substrate volume and the third group (control) was not stocked with worm biomass. Each filtration device was fed African Catfish RAS sludge. The sludge/water was recirculated twice a day via a pump sitting in the catch tank and spread again on the top drawer, from where it took three hours to trickle down to the catch tank again.

Sludge was collected at the semi-intensive aquaculture unit in the FishGlassHouse at the Faculty of Agriculture and Enviromental Sciences at the University of Rostock stocked with 630 African catfish with ≙ 500 g fis $^{-1}$. The experiment was carried out for four weeks and at the end fish biomass within the system was ≙ 441 kg. Dry matter content within the fed sludge varied between 2, 68 and 3, 52 %. The sludge was collected from the sedimenter units. Fish were fed with Coppens Meerval Special PRO EF feed.

Analysis and Sampling

Each filtration device was fed with 3l sludge per week. After one week the liquid fraction was collected at the catch tank and kept for sampling. Solids remained trapped within the filter substrate

The chemo-physical water parameters (dissolved oxygen level (DO), pH-value, temperature, redox potential, conductivity and salinity) were measured with a multimeter (HACH LANGE HQ40d) in input sludge and output effluent after one week of filtration.

Conducted and planned analysis include Chemical Oxygen Demand (COD), Total Organic Carbon (TOC), Total Nitrogen bound (TNb), Macronutrients for input sludge and output effluent. Furthermore the compost value (rotting degree, bound and solvent nutrients) and dry matter plus organic dry matter will be analysed within the substrate after the experiment.

(Continued on next page)

Results

Most of the analysis is yet to be done. First results are promising. Both intensive and semi-intensive vermisystems were able to reduce the organic load. TOC values were reduced up to 30 % and COD values up to 53 % more than in control filters (no worms). Furthermore the vermifiltration systems have strong pH regulating effects on input sludge/water. The pH in the vermisystems evened out at neutral levels around 7, whereas the control group filters were not able to significantly change input pH. Substrate condition was significantly impacted by worm burrowing activities, too. Substrate in vermifilters was loose and kept aerated, whereas substrate in control group was dense, compact and clogged.

Discussion and conclusion

To analyze the potential of vermifiltration for aquaculture and aquaponics a pilot-scale setup was build. This study shows that "worm filtration" effectively reduces Chemical Oxygen Demand (COD) Total Organic Carbon (TOC) and Total Nitrogen bound (TNb) loads in aquaculture effluents. Regarding this, the application of worms and microorganisms can be seen as a low energy additional filtration device for aquaculture operations.

Whether worms and microorganism together are able to transform aquacultural sludge and filter substrate into high quality biological fertilizer or worm digestion supports the mineralization of organic bound nutrients, has yet to be proved (analysis of compost value will start in Mid-May) .

For future studies one should not neglect the fact, that several authors mention worm filtration could be used to remove contaminants from organic effluents due to bioaccumulation (Taylor, 2003). Also the worm biomass, which contains high-quality lysine-rich protein (Xing, 2006), may act as a suitable source for substituting fishmeal in future fish diet

THE NATIONAL ALGAEPILOT MONGSTAD: PRODUCTION OF MICROALGAE FOR AQUACULTURE

Dorinde M.M. Kleinegris*[1], Jeroen H. de Vree[2], Pia Steinrücken[2], Hanna Böpple[1], Hans T. Kleivdal[1,2]

[1] NORCE Environment, Bergen, Norway
[2] University of Bergen, Department of Biological Sciences, Bergen, Norway
* E-mail: Dorinde.kleinegris@norceresearch.no

Goal of the National Algaepilot Mongstad is to produce different microalgae species and optimize the production process, using CO_2 captured by the co-sited Technology Centre Mongstad. The pilot facility is used for upscaling the cultivation work of the microalgae research group in Bergen, a close collaboration between NORCE and the Department of Biological Sciences of the University of Bergen. The microalgae group focusses on developing a commercial and sustainable production chain for industrial application of microalgae, such as aquaculture feed, food products and chemicals.

Most of our research projects are interdisciplinary, aiming at integration of production and processing chain into final products, including use of waste streams as nutrient sources. This encompasses captured CO_2 from flue gas, but also recovery of nutrients from waste streams from aquaculture (fish manure), insect production (insect frass) and municipality waste, where we achieved promising results. We work on bioprospecting, strain selection and optimization, cultivation and process optimization. For bioprospecting, we make use of interesting inhabitants of local fjords and cold coastal Arctic waters, looking for cold-adapted species high in omega-3 fatty acids and other interesting components. Within two projects, CO2Food and Algae2Future, we have been optimizing the production process for a local *Phaeodactylum tricornutum* strain, and compared it to the production of two commercial strains; *Nannochloropsis gaditana* and *Tetraselmis chuii*. Moreover, biomass of these strains was produced for feed trials with salmon. Together with research and industrial partners in food and feed processing and the aquaculture sector, we produced and processed microalgal biomass into aquafeed and performed feed trials to determine suitability of omega-3 rich microalgae to replace fishoil and fishmeal. The first results appear to be very promising, though there are significant differences between algae species and e.g. the digestibility in salmon. Next to salmon feed, also applications as greenwater and rotifer feed have been tested, in the production of Ballan wrasse.

Through these application tests, the value of the microalgae biomass was determined. This information was combined with a detailed techno-economic analysis of the production chain, where production costs of the microalgae feed ingredient were calculated for production sites of 1, 10 and 100 ha in Spain and Norway. The experimental data gathered at the National Algaepilot Mongstad were used for the cost projections, combined with data from literature, directly from suppliers, or standard engineering estimates. Current production prices are still higher than both fish oil and omega-3 rich oil from heterotrophic microalgae, but we foresee that through further strain and process optimization the cost price can become significantly lower than both fish oil and heterotrophic microalgae oil. Using the techno-economic analysis, we could pinpoint the major cost factors that we will address in follow-up projects to achieve the desired cost price reduction.

USE OF BACTERIOPHAGES TO CONTROL *Yersinia ruckeri* IN SALMON FARMING

Eirik Baardsen, Juan J. J. Martínez, Ingrid S. Larsen, Cyril Frantzen and Hans Petter Kleppen*

ACD Pharmaceuticals AS, Storgata 9, 8376 Leknes, Norway
Email: hans.kleppen@acdpharma.com

Bacterial pathogens cause serious challenges in all aquaculture farming industries. *Yersinia ruckeri* is one important pathogen in salmonid farming, where it causes ERM/yersiniosis. The disease is usually controlled by keeping a healthy balance between infection pressure (e.g. hygiene, biosecurity and water quality) and the animal's tolerance for the pathogen (e.g. vaccination and good animal welfare). However, some farm operations, such as sorting, vaccination and transport, challenge this critical balance and can trigger disease outbreaks. During such operations, *Yersinia ruckeri*-specific bacteriophages can be used to control of the infection pressure from the pathogen, thereby maintaining the critical balance and avoiding disease outbreak.

Bacteriophages, viruses which infect and kill bacteria, are nature's own biocontrol tool, making sure no one bacterium becomes too dominant in an environment. Since bacteriophages have been specialized through an evolutionary arms race against their host bacteria, each bacteriophage shows very limited host range. Most phages can only infect and kill one specific bacterial species, some are limited to single bacterial strains. This trait makes bacteriophages particularly suited for use in environments where protection of the commensal microflora is equally important as removing the unwanted

Here, we present data from field trials carried out at salmon farms in Norway, showing that a novel bacteriophage-based product, CUSTUS™$_{YRS,}$ can effectively control infection pressure from *Yersinia ruckeri* in water, and thus avoid bacterial infection and disease outbreaks after stressful farm operations.

AQUAPONICS (S.L.) PRODUCTION OF SPEARMINT (*Mentha spicata*) AND BASIL (*Ocimum basilicum*) WITH BIOHUMIN® AND AFRICAN CATFISH (*Clarias gariepinus*)

U. Knaus*, H.-D. D. Hübner, H. W. Palm

Aquaculture and Sea-Ranching, Faculty of Agricultural and Environmental Sciences, University of Rostock, Justus-von-Liebig-Weg 6, 18059 Rostock, Germany

Introduction

The quality of plants in aquaponics depends on the nutrient composition of the process water, which generally differs from standard hydroponic solutions or soils for plant production. Specific macro- and micro-elements are usually higher in hydroponics such as N, K^+, PO_4^{3-}, Mn^{2+}, Fe^{2+} and Mo (Bittsanszky et al., 2016). Nevertheless a better incorporation of calcium, potassium, magnesium and sodium was recorded from leafs of romaine lettuce (*Lactuca sativa* L. cv Integral) under aquaponics with partly comparable chlorophyll values (SPAD) to lettuce grown under hydroponics (Pantanella, 2012).

In aquaponics, the output and quality of plants increases by partial addition of fertilizers. Ru et al. (2017) described 1.8 times more yield (or 83.6%) of pak choi (*Brassica campestris* L. subsp. *chinensis*) in coupled aquaponics with tilapia (*Oreochromis niloticus*) and the supplementation of partial optimized micro- and macro-nutrient solution with K, Ca, Mg, B, Mn, Zn, Cu, Mo and Fe, respectively. On the other hand, artifi ial fertilizer addition contradicts the "organic" production in aquaponics.

A cost-effective sustainable alternative to liquid fertilizer is Biohumin® (Bioverde AG, Switzerland), a 100% natural product from livestock farming, forestry and soil science. Main components are carbon (30%), calcium (5%), silicium (30%), organic matter (30%) and different natural macro- and micro-nutrients as well as vital cell substances. In this study we evaluated the effectiveness of 15% Biohumin® as a peat substitute on the growth of spearmint (*Mentha spicata*) and basil (*Ocimum basilicum*) under aquaponics (*s.l.*) farming conditions ("gardening plants") following Palm et al. (2018) and the EU Aquaponics Hub COST Action FA1305.

Material and Methods

The experiment was conducted in the FishGlassHouse, an experimental aquaponic facility in Northern Germany (Mecklenburg-West Pomerania, University of Rostock) in spring 2018. Fish were fed with Alltech Coppens Special Pro 4.5mm (42.0% protein, 13% fat, 1.5% crude fibe , 7.5% ash, 1.02% total P) and *C. gariepinus* was held extensive (EAU: 35 fish $tank^{-1}$) and intensive (IAU: 140 fish $tank^{-1}$) in two different aquaculture units. Garden pots with peat soil and seedlings of mint (*M. spicata*) and basil (*O. basilicum*) were repotted in a mix of ≈ 15% Biohumin® natural humus substrate (mean 37.55g = 15.05%, N = 33) and ≈ 85% zero-nutrient-soil substrate (211.89g = 84.94%, N = 11; "Typ 0", Einheitserdewerke Patzer GmbH & Co. KG, Germany).

The plants were cultivated on ebb-and-flood tables with 15 plants per group in triplicates (45 plants per group, 135 plants in total). The hydroponic control group (Control) was adjusted with commercial fertilizer Universol® Orange 16–5–25+3MgO+TE (Everris International BV, The Netherlands) to an electric conductivity of 2 000 µS cm^{-1} (± 50). Nutrient solutions in hydroponics were adapted to pH of 6.0 (± 0.2) by automated Bluelab controllers (New Zealand, USA).

parameters	Control	EAU	IAU	M (I)	M (II)	M (III)
SPAD mint	53.8 ± 7.3^{a}	38.9 ± 2.7^{c}	43.4 ± 3.0^{b}	41.1 ± 3.1^{bc}	43.7 ± 3.1^{b}	29.5 ± 3.2^{d}
height (cm)	63.0 ± 10.5^{a}	51.5 ± 4.3^{b}	53.5 ± 4.7^{b}	33.5	35.5	22.8
SPAD basil	37.3 ± 3.0^{a}	33.6 ± 3.1^{b}	33.9 ± 3.1^{b}	46.7 ± 14.1^{a}	50.0 ± 11.4^{a}	33.3 ± 5.2^{b}
height (cm)	61.2 ± 5.5^{a}	40.5 ± 3.8^{c}	48.2 ± 5.4^{b}	28.5	25.9	-

(Continued on next page)

Plant quality was compared to plant samples from local markets (Grönfingers GmbH, Germany; Fossa Eugenia, The Netherlands; Kaufland Dienstleistung GmbH & Co. KG, Germany) by using the SPAD-index (SPAD-502Plus Chlorophyll-Meter, Konica Minolta).

Results and Discussion

Plant quality of *M. spicata* cultured in aquaponics (*s.l.*) with 15% Biohumin® natural humus substrate reached SPAD values of 38.9 (EAU) and 43.4 (IAU) compared with market samples (41.1-43.7, Table I). SPAD levels with water from the intensive *C. gariepinus* production were insignificant while the water from extensive production resulted in significant less SPAD values compared with one market plant sample (except M III). *O. basilicum* SPAD values were comparable to cutted leaves but not to marketed plants. Plant growth and quality parameters of the control groups were better due to the high nutrient content of the fertilized water that was obviously above the required EC level for the marketed mint plants (Table I).

The positive qualitative (SPAD) effect of Biohumin® in combination with nutrient water from *C. gariepinus* production was more evident in mint (different SPAD of EAU & IAU; equal plant height). In basil, the height of the IAU was significant better compared with the EAU, however, much less than the control group. The relative agronomic efficiency of the plant heights compared with the fertilizer control groups (according to Brod et al., 2017) was higher in mint (EAU: 81.7%; IAU: 84.9%) compared with basil (EAU: 66.2%; IAU: 78.8%). Consequently, Biohumin® is a useful supplement for mint in extensive and intensive aquaponics (*s.l.*) production while the chosen amount of 15% peat replacement appeared to be too low to reach adequate basil growth and quality. Biohumin® is a new option to increase plant quality and growth in aquaponics (*s.l.*) and should be tested in more detail in future experiments to develop marketable aquaponics (*s.l.*) produce.

Introduction
Aquaculture is among the most rapidly growing food production sectors in the world. However, in Germany production growth is hampered by conflicting policy frameworks. In particular, strict environmental, water and building restrictions are sometimes at odds with the national sector development goals. Furthermore, missing international level playing fields with regard to standards and subsidies contribute to this trend. An extensive overview on the current situation and perspectives for Germany can be found in the German study by AFC&COFAD (2017). Nevertheless, marked differences exist between individual fish farms, with other farms growing at impressive rates. This heterogeneity begs the question what drivers are underlying this behaviour, and in particular, whether individual management capacities or regional regulatory pressures are more important. The aim of this study is to provide an overview on the production and marketing structures including efficiency analysis in this market and to support producers and authorities in future investment, management and regulatory decisions.

Method
Against this background, a questionnaire-based production survey with a sample of 39 representative rainbow trout farms in north-west Germany was conducted in 2019. The in-person interviews were usually connected with farm visits, which showed a representative view into the operation conditions of the farms. Here, further problems beyond the scope of the questionnaire could be discussed. This unique dataset allows an in depth view into specific aquaculture technologies and the effects of various external factors. The data depicts the production process in detail from hatching to sale. Additionally, key external impact factors like the time spent on mandatory regulatory requirements and environmental factors were included. Another important part of the survey was to investigate the effects of the extreme weather conditions of 2018 on the farms` performances. Here, one goal was to see if the best performing farms also showed a higher resilience against the extreme weather conditions. Following the efficiency literature in the aquaculture sector (see for example Asche.et.al (2009)) the data was then used to estimate the farms` efficiency using the Data Envelopment Analysis (DEA) approach. This method has the advantage to perform well despite the great diversity in production in the sector. Here, the best performing farms are used to estimate a frontier against which all other farms are benchmarked.

Results
First results demonstrate the sector's great diversity. Interviewed farms range from part-time enterprises with a few tons output to big farms with hundreds of tons of output and more than 10 employees. Production systems and distribution also greatly differs. While some divert large shares of their working hours to processing or selling their goods on farmer's markets, others concentrate on rearing the fish until slaughter. This often relates to the farm size, water rights and the intensity of production. Furthermore, the data also shows the trend to outsource the reproduction, with 75% of farms exclusively buying eggs or juvenile fish from other farms to fatten up

Regarding the extreme weather conditions of 2018 only a minor part experienced the effects as an existential thread for the viability of their businesses. Furthermore, most farms stated reduced yields and mortalities below 10% with only a few mentioning up to 60%.

Discussion and Outlook
The research indicates the great diversity in north-west German rainbow trout production affecting the future development and the expectations and goals of the different farmer. What unifies many of them is the uncertainty about the future of their operations regarding regulatory changes and the water availability. These are stated to be the main constraints decreasing their willingness to invest, thereby limiting the possible sector development. In depth efficiency analysis will shed light on the underlying interactions between the different drivers.

(Continued on next page)

The future will tell if the sector will see a similar structural change as it is going on in the agricultural sector.

Due to climate change, the competition for water resources between aquaculture and agriculture production constitutes an increasing field of conflict and unpredictability. The elimination of major uncertainties is paramount in order to foster key investments needed to reach the national strategic goals. To assist authorities and farmers in estimating the effects of their decisions this research will concentrate on the underlying interactions regarding the production and further external factors.

In the future the environmental interactions will be taken into account next to the results of the research project which focus on the replacement of fishmeal and oil by algae and insects

In regard to policy implementations it can be said that the sector would profit from a unified administration which clarifies and simplifies the decision making and predictability for all actors. For example, the state of Schleswig-Holstein took a step in this direction by establishing the competence network of aquaculture (KNAQ).

Introduction

Over the last decades fishmeal substitutes has been an essential element in the production of new formulated fish diets and oilseed cake-based substitutes are a promising new ingredient with a lot of attention in the past decade. Cold pressed oilseed cake is not only rich of lipids, proteins, vitamins and anti-oxidants but also contains antinutritional factors (ANF) like fibre, phenols, phytohormones and further secondary plant materials (Francis *et al.* 2001). ANF´s can have a negative effect on fish growth and health, meat quality, as well as food acceptance. Therefore it is important to keep the proportion of ANF´s as low as possible. This study was conducted to observe the impact of fibre-reduced rapeseed cake as substitute for fishmeal. Two main questions should be answered. How much fishmeal can be substituted with rapeseed cake in formulated diets for rainbow trouts (*Oncorhynchus mykiss*) until the negative effects of ANF´s take over the positive aspects? And secondly, how do the different concentrations of rapeseed cake in diets impact the growth performance and health of rainbow trouts?

Materials and methods

The experiment took place in the trout farm of the Institute of Fisheries (IFI) of the Bavarian State Research Center for Agriculture (LfL) in Starnberg, Germany. Two production lines (F and T) based on different formulated basal diets were produced. Each line consisted of a reference diet and two experimental diets. Line F was produced at the Fraunhofer Institute for Process Engineering and Packaging using cold pressed cake of organically grown rapeseed. While line T was produced at the "Teutoburger Ölpressmühle" and an organically grown premium rapeseed cake was utilized. Therefore, a total of six groups were monitored during the 9 week experiment. Each group was replicated four times. Twenty-four circular tanks, with a production volume of 450 l each, were stocked with 40 rainbow trouts with an initial weight of 161 ± 0.5 g. Feeding was done by hand once a day at 9 a.m. up to a maximum of 1.2% LW/day. Afterwards the oxygen content and temperature were measured and the daily consumed diet per group was calculated. Every three weeks the growth of ten trouts per tank was examined. At the end of the trial all fish were weighed and a representative number of fish per group were processed for further analysis of length, FCR, organ and general health condition, slaughter yield, body composition and fatty-acid profile.

Table 1: Performance parameters of each diet after 9 weeks.
Statistical analysis was performed using JASP v.0.8.2, Post hoc-Test = Tukey, α = 0.05.

Diet	F REF	F 9 %	F 18 %	T REF	T 17 %	T 34 %
Initial Weight [g]	160.9 ± 8.24	161.2 ± 7.85	161.1 ± 7.94	160.9 ± 7.38	160.7 ± 7.72	160.7 ± 7.95
Final Weight [g]	338.2^{a} ± 34.05	$332.4^{a,b}$ ± 35.86	338.6^{a} ± 32.17	341.3^{a} ± 33.73	$329.4^{a,b}$ ± 34.91	319.9^{b} ± 34.28
Growth [g]	$177.6^{a,b}$ ± 8.16	$166.8^{b,c}$ ± 5.52	$177.5^{a,b}$ ± 7.27	180.4^{a} ± 3.86	$168.8^{a,b,c}$ ± 4.37	$159.3^{b,c}$ ± 5.12
Mean Intake per Group [g/d]	106.5 ± 22.61	107.1 ± 22.95	112.8 ± 22.13	107.1 ± 22.65	104.9 ± 21.59	105.5 ± 23.44
FCR	0.60^{a} ± 0.013	0.64^{b} ± 0.020	0.64^{b} ± 0.012	0.60^{a} ± 0.015	$0.62^{a,b}$ ± 0.010	0.66^{c} ± 0.007
Specific Growth Rate [%/d]	$1.2^{a,b}$ ± 0.04	$1.1^{b,c}$ ± 0.03	$1.2^{a,b}$ ± 0.03	1.2^{a} ± 0.02	$1,1^{a,b,c}$ ± 0.02	$1.1^{b,c}$ ± 0.03

[a,b,c] lowercase letters indicate statistically significant differences between groups.

(Continued on next page)

Results

The conditions of the experiment fulfilled the common physiological requirements o
rainbow trout. The data of the performance parameters which were collected at the end of the experiment are listed below in Tab. 1:

The results of the health, nutrient and fatty acid of the whole body and muscle analysis will be completed in the first half of 2019.

Both reference diets achieved the best results for all parameters. Treatment diet F 18 % showed the same specific growth rate as both reference diets, whereas diet T 17 % achieved the best FCR of all treatment groups which was only 0.2 lower as the FCR of both reference groups. Diet T 34 % showed the most significant differences in final weight, growth, FCR and Specific Growth Rate to all groups.

Discussion and conclusion

All fish achieved a satisfying performance, irrespective of their diet. The statistically significant differences in the growth, FCR and Specific Growth Rate between all treatment diets were still in the margin of high-performing industrial diets. The impact of the ANF´s on the performance and growth of trouts seems to start from a percentage of ~ 34 % rapeseed cake on the dry weight. This can be attributed to the rising proportion of fibre, which provided no nutritional value for the trouts.

Over the last five years the price of rapeseed cake was relatively stable and costs ca. 1.000 USD/t less than fishmeal which is sold at 1,486.35 USD/t (IndexMundi March 2019). Therefore, rapeseed cake appears to be a promising partial substitute for fishmeal in high-performance fish diets with an overall lower ecological and economical impac

Introduction

Praziquantel (PZQ) is a broad-spectrum anthelmintic used in both human and veterinary medicine. In captive fish, PZQ has proven an effective chemotherapeutic against monogeneans infecting the gills, skin and branchial cavities (Hirazawa et al., 2004; Sharp et al., 2004). Orally administered PZQ preparations at doses of 50 to 400mg/kg BW daily for up to 20d have been tested in a variety of cultured fish species (Kim et al., 2001; 2003; Tubbs and Tingle, 2006; Shirakashi et al., 2012). In order to design an effective oral dosing regimen, plasma and tissue (especially at the site of activity) PZQ concentrations can be a useful tool. However, to our knowledge, there is no literature examining the pharmacokinetic properties of PZQ in greater amberjack, *Seriola dumerili* which is a promising emerging farmed finfis species for the Mediterranean area suffering from monogenean infections such as those caused by *Zeuxapta seriolae*. Thus, the aim of this study was to investigate the distribution profile of dietary administered PZQ in greater amberjack following a multiple oral dosing as a first step to optimise PZQ dosing regimens for this species

Materials and methods

Three hundred and twelve healthy greater amberjack of an average body weight of 84±12g were distributed in four land-based seawater cages (78fish/cage) and allowed to acclimate for ten days prior to the beginning of the trial. Both studies were performed at 24.5±0.5°C. During acclimatization fish were received a drug-free commercial diet in amounts of 2% BW per day and starved for 24h prior to administering the medicated feeds. Two distinct medicated diets were made by mixing the active substance (0.75g PZQ/kg feed for the first feed and 1.5g PZQ/1kg feed for the second one) homogeneously with all the dietary ingredients prior to the cold pelleting process with a Hobart food pellet mill. The final dosing regimens of administered PZQ were 75mg/kg BW (Trial A) and 150mg/kg BW (Trial B). Fish were fed the two experimental diets daily for 5 consecutive days. On the first day of treatment, plasma samples were collected from 2h to 24h, while on the other intervention days, plasma samples were collected after 24h of drug administration. Approximately, 2ml of blood was drawn from the caudal vein of from 5 individuals/sampling point. Plasma was separated from blood samples by centrifugation at 14000rpm for 10min at 4°C. An HPLC-UV method has been developed for PZQ measurements in plasma samples of individual fish at each time point. Separation was performed on a Luna-C18 column using an isocratic mixture of 35:65v/v acetonitrile: water as the mobile phase with a constant flow rate of 1ml/min. Eluant was monitored at 210nm.

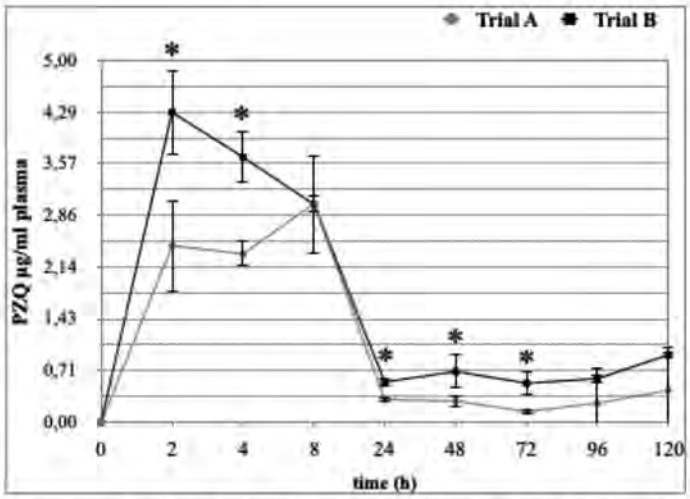

Fig 1 Plasma concentration (µg/ml) of two PZQ doses (Trial A=75mg/kg BW, Trial B=150mg/kg BW) in greater amberjack following multiple dose administration at 24h intervals. Values shown are mean±stdev (N=5). * indicates a statistically significant difference. Significance level was set at $P < 0.05$.

(Continued on next page)

Results

The recovery rates of PZQ for plasma samples were 88.5%-101.6%. PZQ was readily detected in all plasma samples. Plasma concentrations of PZQ in greater amberjack revealed values around 2.6μg/ml and 2.3μg/ml at 2 and 4h post feeding, respectively for Trial A and 4.3μg/ml and 3.7μg/ml at 2 and 4h post feeding, respectively for Trial B. Maximum plasma concentrations (C_{max}) of PZQ for fish fed 75mg/kg BW were achieved at 8h post feeding (3.0μg/ml), while C_{max} of PZQ for fish fed 150mg/kg BW were achieved 2h post feeding (4.3μg/ml). This indicates that the clearance of PZQ for Trial A did not follow a simple decay model. Additionally, a two-fold increase in the administered dose only led to an approximately 76% increase in the mean plasma concentration of PZQ 2h post-treatment. Due to the large variance, no significant differences were found between the mean PZQ concentrations of the two doses at 8h post feeding. Withdrawal of PZQ occurred rapidly in greater amberjack as its concentrations diminished 24h post-treatment in circulation (0.15-0.44μg/ml and 0.54-0.93μg/ml for Trial A and Trial B, respectively). Furthermore, no significant differences were found between the mean PZQ concentrations of either the 75mg/kg or 150mg/kg dose during days of treatment. However, as it shown in Fig. 1, mean plasma concentrations of PZQ were higher on the 5th day of treatment compared with the first, indicating that some low accumulation of the drug occurred during this period for both dosing regimens.

Discussion & conclusion

The results of the present study showed that PZQ was readily absorbed in plasma of greater amberjack while its accumulation was limited for both dosing regimens examined. Rapid absorption of orally administered PZQ preparations has been also demonstrated in other *Seriola spp.* such as kingfish, *S. lalandi* (Tubbs and Tingle, 2006). Low PZQ accumulation was evident in the present work which has been seen also in other farmed fish such as rockfish, *Sebastes schlegeli* (Kim et al., 2001; 2003). This kinetic profile is most probably related to the rapid clearance of the drug, rather than poor absorption. In conclusion, the results of present study revealed that under a 24h dosing interval for 5 consecutive days, the anthelmintic concentrations exhibit significant fluctuations in greater amberjack plasma. Based on the information obtained from the PZQ analysis there is an apparent benefit from the double dosing schedule (split in 2 feedings per day) as seen from the higher achieved plasma PZQ levels and thus this would be the suggested dosing against *Z. seriolae*. Its efficacy however remains to be confirmed in field trial

Introduction

Effective antifouling technologies are critical to maintain the fuel consumption efficiency of ships, minimizing the release of greenhouse gasses and other hazardous air pollutants and also for minimizing possible translocation of aquatic species through maritime trade (Schultz et al., 2007). In order to develop more effective antifouling paints for preventing biofouling of ships, it is very important to test and quantify the efficacy of new antifouling systems including antifouling agents. It is said that antifouling paints have been evaluated in the past mostly through field experiments on rafts and by patch-tests on ship hulls. In this manner, conditions of the marine environment influence test results (Berntsson et al., 2003). Consequently, biofouling data obtained from the field experiments conducted at different sites and in different seasons exhibit large variations, making it insufficient to conduct an objective and quantitatively evaluation of various antifouling paints. In this regard, it is necessary to establish a bioassay to assess antifouling paints under controlled laboratory conditions. The purpose of this study is to confirm whether the efficacy of the antifouling paints is directly reflected in an appropriate manner in a newly proposed evaluation method. In this study, the authors prepared test plates coated with different antifouling paints and tested their antifouling efficac es with a flow-through water system using macro algae. Furthermore, the validation by comparing results of the laboratory bioassay with antifouling efficacy results from field experiments on raft was also considered (Kojima et al., 2016).

Material and methods

5 types of antifouling paints with hydration type coatings and containing 0, 5, 10, 20 and 40wt.% of Cu_2O were prepared as test paints. Polyvinyl chloride plates used in a laboratory bioassay were 50mm x 50mm x 2mm in size. The test plates were coated on one side with the test paint. The panels were aged using a dynamic rotating device under controlled condition (water temperature: 20ºC, rotation speed: 10konts, period: 45days) prior to the laboratory bioassay (Figure1).

The unialgal culture strain of a filamentous brown alga, *Ectocarpus siliculosus*, which is one of the most common fouling macroalgae in biofouling of ships, was housed in Kobe University Macroalgal Culture Collection (KU-MACC) as KU-1372 for test organism. *E. siliculosus* was cultured on a nitro cellulose membrane filter (*f*=47mm, pore size 8.0mm, Millipore) in medium (PESI medium without tris-sodium glycerophosphate) at a temperature of 15ºC for about 7days in a still water condition before their use in the bioassay. The bioassay system consisted of the medium storage tank (volume capacity of 20L), peristatic pump, polypropylene bioassay tank (ca. 2L), and reservoir tank for waste medium. The laboratory bioassay with a flow-through water system was conducted under controlled conditions (flow rate: ca. 500ml/h, water temperature: 15ºC, light cycle: 12h. light/ 12h. dark with 1000 lux, period: 7days). The efficacy of antifouling paints was evaluated by the fluorescence strength of chlorophyll-*a* extracted from the adhered *E. siliculosus* on the surface of filter membranes on each test panel after incubation.

Results

The fluorescence strength generally decreased with an increasing of Cu_2O content. Statistical analysis showed that an inhibition of fluorescence emission was clearly observed at 20wt.% of Cu_2O concentration ($p<0.05$), and the significance difference between the control was extremely different at 40wt.% of Cu_2O concentration ($p<0.0001$) (Figure 2, A). Furthermore, the validation of the bioassay was evaluated compared to field experiments and showed the good agreement between them (Figure 2, B).

(Continued on next page)

Fig. 1. Photographs of the dynamic aging apparatus. (A): the cylinder with test plates fixed on it, and (B): the cylinder with a light shielding sheet while aging.

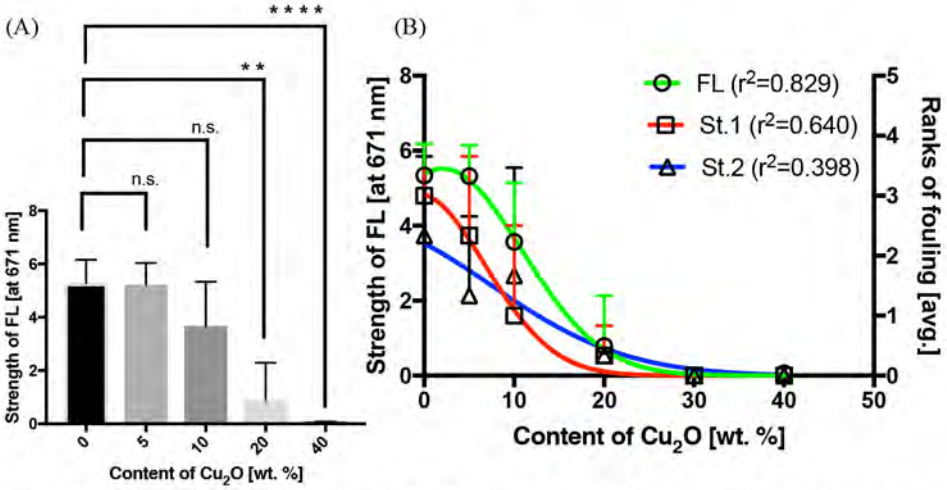

Fig. 2. The validation of the bioassay. (A): The variation of the fluorescence strength from *E. siliculosus* against content of Cu_2O, and (B): relationship between the fluorescence strength vs ranks of fouling (St.1: Miyajima, Hiroshima, Japan, St.2: Tamano, Okayama, Japan).

Discussion and conclusion

A reproduceable and effective laboratory bioassay was established by evaluating the antifouling efficacy of test paints that were prepared with varying contents of Cu_2O. To simulate the actual condition of ship hulls, dynamic aging of test plates was conducted. A positive correlation between the Cu_2O content and the repellant effect of the paint on macro algae was observed at the concentration of more than 20wt.%. Comparison of the results between laboratory bioassay using algae and of filed experiments revealed a highly consistent relationship between the two. This study also proved to be a significantly consistent method for assessing the effectiveness of present or future antifouling paints.

Introduction

Rigid cell walls may limit the availability of valuable nutrients in microalgae biomass for food and feed applications. Cell wall disruption may improve nutrient availability but also increase the risk of oxidative degradation of perishable compounds. Optimisation of cell wall disruption for *Phaeodactylum tricornutum* (*P. tricornutum*) and *Tetraselmis chuii* (*T. chuii*) by bead milling was previously studied by Kokkali et al. (2018a) and Kousoulaki et al. (2018). In the present study, we identified biomass phenolic compounds and their release following bead milling, along with lipids and proteins. Effects of processing on other quality characteristics of the differentially disrupted biomasses, such as viscosity, microbial load in *P. tricornutum,* total phenolics, antioxidant capacity and total carotenoids in both *P. tricornutum* and *T. chuii* processed by bead milling were also estimated, and selected data are presented below.

Material and methods

The microalgae biomass (*P. tricornutum* B58 and *T. chuii* UTEX LB232) were produced at the National Algae pilot Mongstad (NAM) (Mongstad, Norway) in a fed-batch process in four 800L photobioreactor systems (GemTube MK2-750, LGem b.v), harvested twice a week, concentrated by centrifugation to a paste (Evodos 50, Evodos b.v), vacuum packed and directly frozen at -20 ºC before further processing. The microalgae paste was thawed, diluted to different dry matter contents (12.5-22%) and processed by single passes through a Dyno-Mill Multi Lab bead mill (WAB, Muttenz, Switzerland) using a 0.6l chamber, glass or zirconium beads (0.25-0.4 and 0.3mm, respectively) at 80% chamber filling, following factorial designs, varying in a systematic way, besides biomass dry matter, also agitator tip speed (8-12 m/sec) and biomass flow rate (ca. 7-23kg/h). Samples from di ferent processing settings were frozen until further analyses.

Results and discussion

In *T. chuii* the polyphenols capsaicin, dihydro-p-coumaric acid, ethyl vanillin, benzoic acid, methoxyphenylacetic acid, 4-vinylphenol and 4-hydroxybenzaldehyde, sinapic acid were identified by AB SCIEX TripleTOF™ 5600 LC/MS/MS (Figure 1). In the case of *P. tricornutum*, lower number of polyphenols were present compared to *T. chuii*, and the main one was cinnamic acid, a known potent antioxidant, which was released in a linear way as compared to cell wall disruption % (P=0.001) (Figure 2). Aerobic bacteria in *P. tricornutum* culture were reduced by up to 86.9% from 980 000 to 128 000CFU/g wet biomass by bead milling using 0.3mm zirconium beads, with significant effects of flow rate and interaction between biomass dry matter and flow rate (P=0.000)

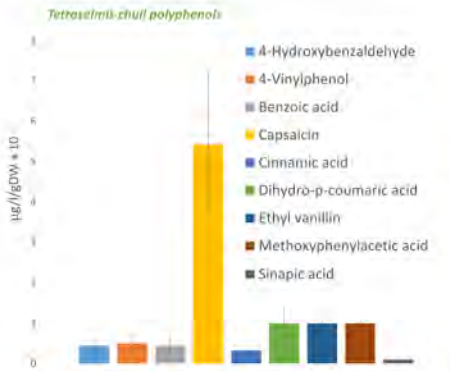

Figure 1 *T. chuii* polyphenols. Values are mean and standard deviation of analysed compound amounts in differentially disrupted samples by bead milling.

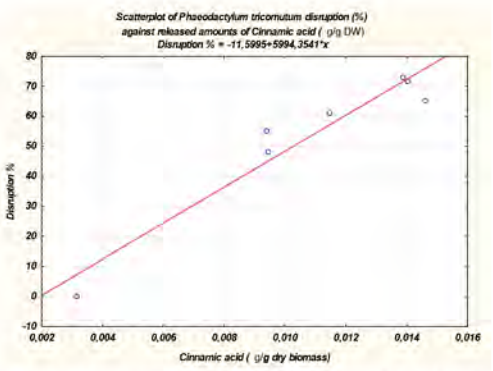

Figure 2 Identified levels of cinnamic acid in differentially disrupted *P. tricornutum* biomass, by bead milling.

(Continued on next page)

Conclusion

The *P. tricornutum* and *T. chuii* biomasses were further used for salmon feed and bread production, respectively. Thus, purity and availability of antioxidants and other nutrients and bioactive compounds are of outmost importance for commercial use of the biomasses, and all these parameters where improved by efficient cell wall disruption using bead milling

Introduction

The constant increase in animal production in order to supply the growing population demands, has led to an extensive use of antibiotic in the livestock industries, as well as aquaculture. Antibiotics are used as growth promotors or to prevent and treat diseases, with adverse implications on the environment, animal health, as well as the commensal gut microbes (Okocha et al., 2018). Gut microbes are known to be important for many physiological functions of the host, thus evaluating such an impact is highly crucial. Examining the antibiotic impact on gut segments with different physiological roles, may provide significant insight into the effect of antibiotics on bacterial taxa in these microhabitats. Hence, we aimed to evaluate and understand the effect of commonly used feed-administrated antibiotics on the composition and metabolic potential of the microbial communities distributed along the gut of the European seabass (*Dicentrarchus labrax*), an important aquaculture species to be used as an experimental model. In the present study, we evaluated the impact of regular and high levels of in-feed antibiotics on the gut microbiome of European seabass juveniles, using quantitative PCR to measure the bacterial copy numbers and amplicon sequencing of the 16S rRNA gene to describe microbial community composition along the gut.

Materials and Methods

European seabass juveniles were housed in 250-L experimental indoor tanks equipped with recirculating systems. Five different treatment groups of fish were formed in triplicates: a group fed with the commercial diet (control group) and four groups fed with the commercial diets coated with two different mixtures of antibiotics of different range at concentrations 5 mg gr-1 of feed and 30 mg gr-1 of feed (excess): **Mixture 1**-Ampicillin, Kanamycin, Erythromycin, Ciproflaxine, Vancomycin; **Mixture 2**- Penicillin, Streptomycin, Lincomycin, Ciproflaxine, Vancomycin. The experiment lasted 7 days and at the end, pyloric caeca, midgut and hindgut were dissected from three randomly selected fish per tank

Bacterial DNA isolation, PCR amplification and 16S rRNA gene sequencing were performed using the protocol described by Kokou et al. 2018. Quantitative real-time PCR analysis was performed to investigate the relative abundance of bacteria inside each intestinal sample through amplification of their copy of the 16S rRNA gene. The microbiome composition along the gut was assessed by PCR amplification and sequencing of the V4 region of 16S rRNA using a MiSeq 2000 Next Generation system (Illumina). Data quality control and analyses were performed using the QIIME pipeline (Caporaso et al. 2011) with the default settings. In order to predict the functional content of the gut microbiome originating from the different groups, we used the PICRUSt tool (Phylogenetic Investigation of Communities by Reconstruction of Unobserved States; PICRUSt (Langille et al. 2013). Statistical analysis was performed in R.

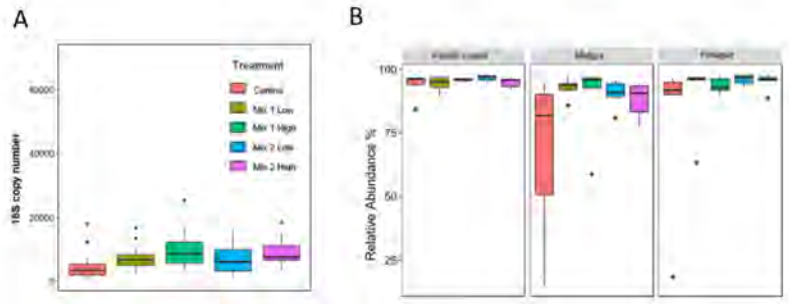

Figure 1. A. Quantitative PCR reveals an increase in the bacterial copy numbers with antibiotic resistance. **B.** European seabass possesses a highly abundant core microbiome which is represented by few bacterial species, that is resilient to antibiotic treatment.

(Continued on next page)

Results and Discussion

The results revealed that the antibiotics had a differential effect on the microbial composition across the fish gut, highlighting the variability of microbial niches. Antibiotic intake overall increased the bacterial counts compared to the control, mostly in Mixture 1 and in the high dosage of Mixture 2, suggesting a higher availability of microbial niches after antibiotic treatments, with opportunities for species expansion or invasion (Figure 1A). No differences were observed in the microbial diversity as revealed by the sequencing analysis, but an effect on the midgut and hindgut microbiome composition was found (Figure 1B). Analysis into the functional potential of the microbiome showed an increase in the antibiotic resistant genes in the treated groups, suggesting the presence of antibiotic resistant bacteria within the seabass gut. Lastly, our study reveals a highly abundant core microbiome in European seabass (<80% of the total microbiome abundance) that seem to be resilient to the examined antibiotic mixtures, thus indicating a high stability of the fish gut microbiome composition to perturbations.

INVESTIGATION OF THE PROTECTIVE ROLE OF THE SEMINAL PLASMA IN COMMON CARP (*Cyprinus carpio*) SPERM

T. Kollár*, B. Pataki, B. Urbányi, Á. Horváth

Department of Aquaculture, Szent István University, Páter Károly u. 1., H-2100 Gödöllő, Hungary
E-mail: timi.kollar@gmail.com

Introduction

In vitro test systems are more and more widespread in ecotoxicology because of their ethical and practical advantages as well as their time- and cost-efficienc . Fish sperm is a feasible model for *in vitro* toxicology tests due to its easily measurable parameters (motility, antioxidant response etc.). Numerous studies have been published in this topic in the last years, however, they are different in many aspects. The most important difference in these is the presence or absence of seminal plasma. In several publications, seminal plasma was removed and only spermatozoa were exposed to the toxic substance in order to eliminate the protective role of the seminal plasma (Hulak et al. 2013, Shaliutina et al. 2017). However, in other experiments, the sperm including seminal plasma (not only the spermatozoa) was treated with xenobiotics (Chyb et al. 2001, Kollár et al. 2018ab) which raises difficulties to compare the results. Our goal was to investigate the protective role of seminal plasma in common carp (*Cyprinus carpio*) sperm.

Materials and methods

Common carp sperm was stripped individually (N=3) 24-48 hours after hormonal treatment. Three sub-groups were created from the sperm of one individual: one group was exposed to Hg in 1:1 (v/v) ratio (Treatment1). The two other groups were centrifuged (500 g, 10 min) and the seminal plasma was removed: in one group, seminal plasma was replaced by cyprinid immobilising solution before spermatozoa were exposed to Hg in 1:1 (v/v) ratio (Treatment2), while in the other group, seminal plasma was not replaced, only the spermatozoa were exposed to Hg in 1:1 (v/v) ratio (Treatment3). In each case, 4 concentrations of Hg (0.5, 1, 2.5, 5 mg/L) and one control group were tested. During the exposure period, progressive motility of sperm (PMOT, %) was measured in 30^{th}, 120^{th} and 240^{th} minutes by Computer-assisted Sperm Analysis system.

Results

No significant differences were found between Treatment1 and Treatment3 at any of the examined exposure times. Treatment2 differed significantl from Treatment1 at 1 and 2.5 mg/L concentrations at each exposure duration as well as at 1 mg/L in the 30^{th} minutes.

Discussion and conclusion

No differences were found between the groups where seminal plasma was removed and where it was not removed prior to Hg exposure. The only difference appeared when seminal plasma was replaced by cyprinid immobilising solution prior to exposure. It can be concluded that seminal plasma does not have a protective role against Hg exposure, however, its replacement with immobilising solution could significantly decrease the progressive motility of common carp sperm. Thus, the removal of seminal plasma is not justified during toxicology tests as it does not a fect the results.

Introduction

Aquaculture is the fastest growing area of food production with a steady expansion of more than 8% per year since the 70s (Burbridge et al. 2001; Knaus 2012). Besides this, fish flesh quality has gained importance among consumers and in the aquaculture industry due to its directly related impact on human health and nutrition. But so far, fish flesh quality of only few species (e.g. *Oncorhynchus mykiss, Salmo salar)* has been examined and this mostly in regard of the chemical composition. These results exhibited that lipid and protein composition in fish muscle varies greatly between species and is depending on age, sex, environment and season (Johnston 2001). Presently, there are no established methods and regulations to measure the physical properties of fish flesh. Therefore, our aim is to establish methods for a defined analysis of fish flesh quality and to adapt the protocols that are presently in use for beef, pork and chicken to fish, to analyze the physical parameters of fish flesh. For a first description two economically important fish species, the European perch (*Perca fluviatilis*, Percidae) and marena whitefish (*Coregonus maraena*, Salmonidae), were analyzed. Both species are present targets for aquaculture cultivation which will ensure the sustainability of our protocols for the future.

Methods

Fishes were cultured in a recirculation system in the Institute of Fisheries in Born, Germany. Adults of both sexes from *P. fluviatilis* (PFL, n = 15) and *C. maraena* (CMA, n = 15) were slaughtered by standard procedure in accordance to the German Animal Welfare Act (§ 4(3) TierSchG). Morphometric measurements of animals and filets as well as the physical measurements were taken immediately after death. Quality parameters of muscle like pH, isoelectrical conductivity and impulse-impedance were measured at 5 min and 1 h post-mortem using pH-Star (Matthäus), LF-Star (Matthäus), and Meat Check 150 (Sigma Electronic), respectively. The filet firmness was measured directly after death by Texture Analyser TA.XTplus (Winopal) with Warner Bratzler blade on the posterior filet, lateral on the horizontal septum, in triplicate. Color of muscle was measured three times with CR-300 Chroma Meter (Minolta) for the epaxial and hypaxial muscles separately. The water holding capacity (WHC) was determined by filte -press-method via Hypress (Grau and Hamm, 1953), in triplicate. Morphometric and quality parameters were statistical analyzed using SAS (v.9.2).

Results

At slaughter, PFL had a total length of 37.58 ± 0.37 cm and a weight of 777.07 ± 0.30 g. CMA exhibited a total length of 32.58 ± 0.27 cm and a total weight of 327.07 ± 7.59 g. For the consumers, especially the amount of free water in the fish filet, defined as WHC and texture, represented by the maximal shear force, is of interest. Under the present fish cultivation condition, the results showed a firmer texture (53.89 ± 7.76 N) with lower WHC (16.45 ± 7.76%) in the PFL filets. Compared to this, the CMA filets exhibit a softer texture with 24.74 ± 0.65 N and a higher WHC (20.90 ± 1.29%). Furthermore, also the impulse impedance showed higher values in PFL filets (able I).

Table I: Physical parameters of fish quality in European perch (*Perca fluviatilis*, PFL) and marena whitefish (*Coregonus maraena*, CMA) in aquaculture of Mecklenburg-Vorpommern.

PFL (n = 15)			CMA (n = 15)	
physical parameter	mean	SEM	mean	SEM
brightness	42.70	0.70	43.64	0.91

impulse-impedance (5min)	70.93	1.54	60.33	1.30
water holding capacity [%]	16.45	0.60	20.90	1.26
shear force max. [N]	53.89	1.76[a]	24.74	0.65[b]

(Continued on next page)

Discussion

In the meat production, strict regulations for pork, beef, and poultry meat quality exist. Due to the high diversity of fish species, regulations for fish muscle quality have not been defined so far. With the present study, we showed that an adaptation of the used physical methods can be transferred to fishes as well. Therefore, the obtained results are a first step in order to develop consistent regulations and statements regarding the physical values of fish filet to define the quality of fish flesh

GENETIC EVALUATION OF RESIDUAL FEED INTAKE IN THE PACIFIC WHITE SHRIMP *Litopenaeus vannamei* USING PHENOTYPIC, PEDIGREE AND GENOMIC INFORMATION

J. Kong, P. Dai and S. Luan

Yellow Sea Fisheries Research Institute, Chinese Academy of Fishery Sciences, Qingdao 266071 (China)
E-mail: kongjie@ysfri.ac.cn

Introduction

Use of residual feed intake (RFI) as a measure of feed efficien y in animal production has raised much interest. Genetic evaluation of important traits in breeding programs of livestock and aquatic species traditionally use only phenotypic data and pedigree information. With the development of high-throughout SNP markers, genomic relatedness from high-throughput genotyping may offer more accuracy to genetic evaluation than pedigree information. The first genetic evaluation of RFI for *Litopenaeus vannamei* was implemented in the breeding population using phenotypic, pedigree and genomic information via a single-step genomic BLUP method (ssGBLUP).

Materials and Methods

Shrimp from 34 families were housed individually and residual feed intake was recorded during three weeks. A total of 479 individuals were genotyped using the 2b-RAD method. Two methods were used in the genetic evaluation. BLUP only used the classical pedigree-based relationship matrix A. ssGBLUP considered both genotypes at the SNP sets and pedigree, in which a combined pedigree-genomic relationship matrix H was constructed by augmenting the pedigree-based relationship matrix with the genomic relationship matrix G (Aguilar et al., 2010; Christensen and Lund, 2010).

Results

Shown in the heatmap (Figure 1), kinships estimated using both genomic and pedigree information were more accurate than those based on only pedigree, which also provides more reference information in genetic evaluation. Prediction accuracies of estimated breeding values (EBVs) for RFI based on A matrix and H matrix were carried out by the tenfold cross-validation (Figure 2), and prediction accuracy based on H matrix (0.41) was higher than that based on A matrix (0.340).

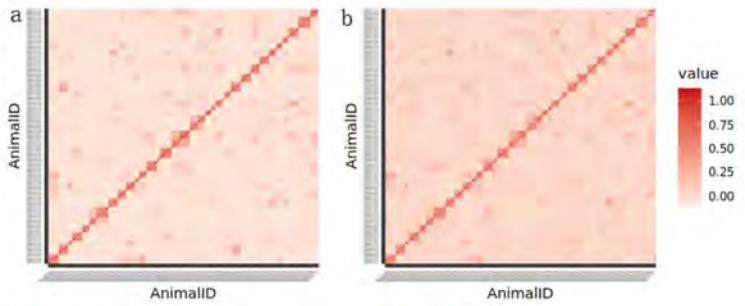

Fig. 1. Heatmap of kinships between individuals estimated using A matrix (a) and H matrix (b).

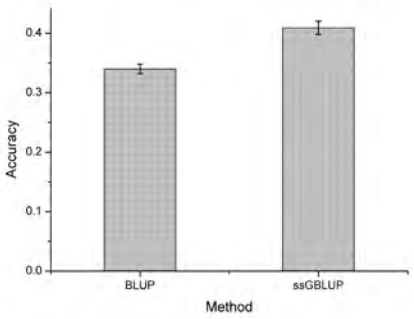

Fig. 2. Prediction accuracies of BLUP and ssGBLUP for EBVs of residual feed intake with standard error.

(Continued on next page)

Discussion and conclusion

In most cases, it is assumed that in a pedigree founder animals comprising the earliest generation do not share genes from older ancestors. Relationships from later generations are estimated as deviations from the founders' relatedness. In fact, however, founders are likely to share genes identical by descent, and if so, the results estimated from original assumption will be biased. Intuitively, pedigree errors may be expected to cause a bias of both heritability estimates and genetic covariances. Introduction of genomic information could reconstruct more real and right relatedness among some individuals (such as full-sib or half-sib individuals), which is expected to contribute to the improvement of evaluation accuracy. The cross-validation analysis implies that accuracy of EBVs of RFI increased by 20.59% using ssGBLUP compared to BLUP. As for its practical implementation, the use of ssGBLUP will depend on a cost-benefit analysis of individual genotyping against the expected gains of accuracy in breeding values.

Introduction

Protein is usually the most expensive macro-nutrient of a fish diet. Its retention into body tissue largely determines aquaculture resource-use efficie cy. Protein deposition is an energy-demanding process. Thus, for a given protein intake, raising energy intake leads to increased protein deposition (Haidar et al. 2018). Animal nutritionists aim at minimizing the use of dietary amino acids (i.e. protein) as energy substrates to improve resource and cost efficiency and minimize environmental impact. In terrestrial monogastric farm species such as pigs and poultry, protein deposition is often described by a linear-plateau model (Campbell et al., 1985). In these species, protein deposition increases with protein intake until energy intake becomes limiting. This model has important implications for animal feed formulation as it helps animal nutritionists balancing dietary protein, lipids and carbohydrates content to maximise protein deposition. The validity of such a linear-plateau model has not been tested in Nile tilapia. The present study intended to describe the interplay between protein and protein-free energy intake on protein deposition in Nile tilapia above 60 g of body weight.

Material and methods

The experiment consisted of a 42 days balance trial during which 16 diets were fed to all-male Nile tilapia with initial body weight = 63.4 g (SD = 1.3g). The diets were formulated and fed restrictively to achieve the following 2*8 factorial design: 2 levels of daily individual protein-free energy intake (18.3 and 25.6 kJ.d^{-1}) * 8 levels of individual daily protein intake (ranging from 0.5 to 1.35 g.d^{-1}). Each of the 16 diets was hand-fed twice daily to two randomly assigned 70-l tanks (30 fish per tank). All tanks were connected to a single water recirculation system. Initial and final body composition were measured from 20 fish and 10 fish per tank, respectively. Apparent digestibility was measured by the indirect method (using yttrium oxide as indigestible marker) based on faeces collected during the 2nd, 4th and 6th week of the trial. Generalized linear modelling was employed to analyse the data. Significance of model e fects was set at $P < 0.05$.

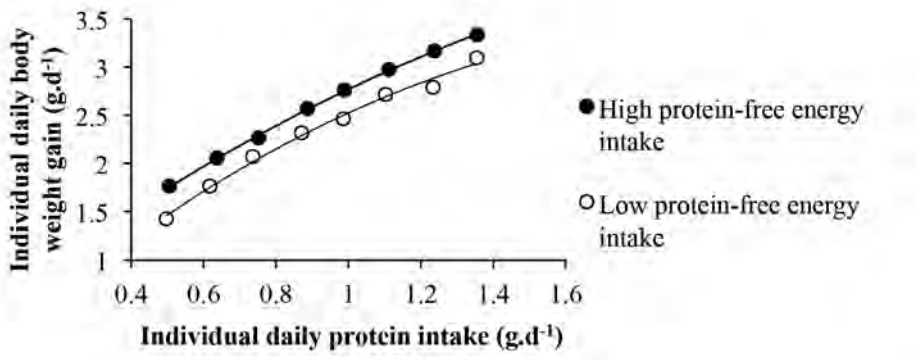

Figure 1. Daily body weight gain increases linearly with increasing protein intake.

(Continued on next page)

Results and discussion

Preliminary results indicate a linear increase of daily body weight gain (BWG, $g.d^{-1}$) with increasing protein intake (PI, $g.d^{-1}$), at both high (Eq. 1) and low (Eq. 2) protein-free energy intake:

$$BWG = 0.86\ (SE\ 0.05) + 1.87\ (SE\ 0.05) * PI \qquad r^2 = 0.99 \quad (1)$$

$$BWG = 0.62\ (SE\ 0.08) + 1.84\ (SE\ 0.08) * PI \qquad r^2 = 0.97 \quad (2)$$

At similar daily protein intake, fish receiving a high protein-free energy intake showed higher daily body weight gain than those receiving a low protein-free energy intake (figure 1). This clearly shows the protein-sparing effect induced by increasing protein-free energy intake which was already showed in Nile tilapia (Haidar et al., 2018; Saravanan et al., 2012).

The linearity of the relation between daily protein intake and daily body weight gain (figure 1) suggests that protein deposition does not follow a linear-plateau model as observed in terrestrial monogastric farm species. However, previous studies showed that Nile tilapia body composition – especially fat content – can be strongly affected by diet composition (Haidar et al., 2018). Body weight gain is therefore not the best read-out parameter for a cross-species comparison. Complete nutrient balances (including nutrient digestibility and body composition data) will provide a more precise description of the interplay between protein and energy intake on nutrient deposition rates and retention efficiencies during this experiment.

EFFECTS OF HEAT-TREATED SOY & SUNFLOWER FLOUR FOR FISH MEAL SUBSTITUTION ON ENERGY RESERVES AND ANTIOXIDANT & DIGESTIVE ENZYMES IN THE GILTHEAD SEA BREAM (*Sparus aurata*)

M. Kotsiri*, E. Cotou, E. Fountoulaki, and K. Charalabous

Inst. Mar. Biol. Biot. & Aquaculture, HCMR, Agios Kosmas, 16777 Hellinikon, Athens (Greece)
E-mail: mkotsiri@hcmr.gr

Introduction

Aquaculture has become one of the fastest growing food-producing sectors (FAO, 2018). However, the shortage and cost of fish meal supplies is limiting the further development of aquaculture. Thus, alternative protein sources have been studied in order to replace fishmeal in aqua-feeds. The potential alternatives of plant-derived nutrient sources are known to contain a wide variety of anti nutritional factors (ANFs) (Francis et al., 2001). Thermal processing is recognized to be a very successful method for inactivation of ANFs (Arndt et al., 1999; Ari et al., 2012).

Materials and Methods

Three isoenergetic and isonitrogenous experimental diets were formulated including a control (30% fish meal, 0% soy & sunflower), an untreated (12% fish meal, 25% soy+15% sunflower) and a treated (12% fish meal, heat-treated 25% soy+15% sunflower). Heat treatment included addition of 20-30% hot water (80-90^{o}C) to soy and sunflower flour and mixing, cooking at 60-65^{o}C for 15min with continues mixing and drying at 50^{o}C for two hours. A 14-week feeding trial with three groups of *S. aurata* juveniles (26.4 ± 0.5g) was conducted in 100 l tanks (28 fishes/tank). Livers and intestines were excised after properly sampling, placed in liquid N_2 and stored at -80^{o}C until analysis. Biomarkers responses of energy reserves (HSI) and antioxidant (GSH content and GPx, GR, GST activities) and intestine (ALP, Trypsin, Aminopeptidase activities) enzymes were determined.

Results and Discussion

Hepatosomatic index (HSI) values were affected by diet composition and treatment. HSI was higher in treated compared to untreated diet but significantl lower compared to control diet (Table 1.). GR & GST activities significantly induced in treated compared to untreated diet with a significant induction of GST indicated in treated diet compared to control. GSH content did not differ significantly in treated from untreated and control diet, whereas a significant reduction is showed in untreated compared to control diet (Fig.1). GPx activity was similar in treated compared to untreated diet but it was significantly reduced compared to control diet (Fig 1). In general, induction of antioxidant enzymes reflects activation of a compensatory mechanism to prevent a rising oxidative stress. Heat-treatment was positively affected some antioxidant enzymes.

Alkaline phosphatase (ALP) & aminopeptidase activity exhibited similar pattern. A significant reduction of ALP & aminopeptidase is shown in treated and untreated diets compared to control. Reduction in ALP activity is indicative of malnutrition (Estensoro et al., 2016). Trypsin activity was similar in all diets (Fig. 2). Trypsin activity can be

used for the prediction of digestive ability of the fish, which may in turn lead to differences in growth rate (Sunde et al., 2004). Heat-treatment had no effect on digestive enzymes.

Introduction

The catadromous European eel, *Anguilla anguilla*, has an unusual life cycle including a 5000-6000 km long migration to spawning areas in the Sargasso Sea. Whilst inhabiting continental habitats, complex hormonal mechanisms inhibit gonadotropic function (Vidal et al., 2004). This inhibition must be released in nature when reaching spawning habitats. Thus, captive reproduction apply exogenous administration of gonadotropins (Mylonas et al., 2010). Generally, female breeding protocols of anguillid species have been established using pituitary extracts of either carp (CPE) or salmon (SPE) varying in dosage. Such hormonal treatment schemes affect female reproductive developmental success and offspring quality (Mylonas et al., 2010). This study compares for the first time effects of applying either CPE or SPE to induce vitellogenesis in female European eel broodstock and evaluates efficiency as well as offspring quality under controlled experimental conditions. Expression of developmental genes are used to explore the largely unknown mechanisms affecting embryonic survival.

Material and methods

The experiment included migrating female silver eels caught at lower Bann, Toomebridge, Ireland (n = 28), migrating female silver eels from Lake Vandet, Denmark (n = 26) and male eels farmed from glass eels at a commercial fish farm. Vitellogenesis in the female broodstock was induced by weekly intramuscular injections of either CPE or SPE, each at 18.75mg kg^{-1} initial BW for 10-21 wks depending on response. Both treatment groups received 17α,20ß-dihydroxy-4-pregnen-3-one (DHP) as maturation inducing hormone, while males received human chorionic gonadotropin (hCG). Females were strip-spawned and eggs *in vitro* fertilized (Butts et al., 2014). Eggs from the floating layer were incubated in glass beakers (1 L) filled with filtered UV-treated seawater (FUV seawater; filter size: 10, 5, 1 µm) and supplemented with rifampicin and ampicillin (each 50 mg L^{-1}, Sigma-Aldrich, Missouri, USA) under controlled conditions at 36‰ salinity and 18°C. Embryonic survival was determined at 2, 3, 4, 5, 6, 7, 8, 16, 24, 32, and 48 hours post fertilization (HPF), where the number of dead and alive eggs were counted and expressed as a percentage. Furthermore, cleavage abnormalities were determined at 4 HPF by counting the number of eggs with regular and irregular cell cleavages. Hatch success was expressed as the number of hatched larvae divided by the total number of eggs. Samples for gene expression included ovarian tissue after spawning, unfertilized eggs, as well as embryos at 2, 4, 8, 24, 32, and 48 HPF. RNA was then extracted using the NucleoSpinR RNAKit (Macherey-Nagel, Germany) and expression of genes was analyzed using the qPCR BiomarkTM HD system (Fluidigm). Data were analyzed by repeated measures ANOVA models using SAS statistical analysis software.

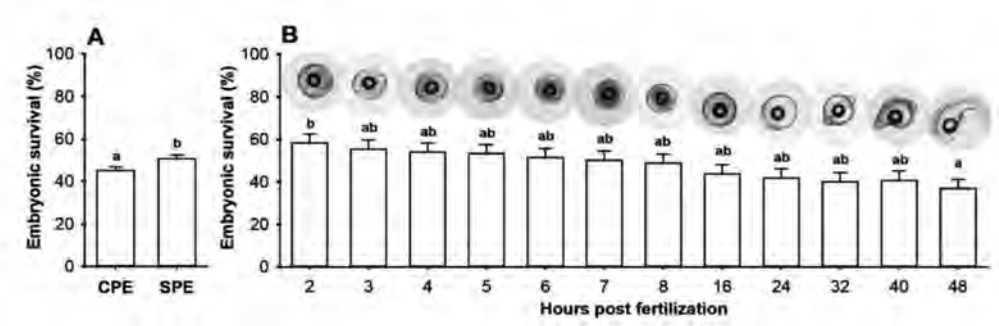

Fig. 1 Fertilization success and embryonic survival in European eel (*Anguilla anguilla*). Effects of hormonal treatment (A) and age (2 – 48 hours post fertilization, HPF; B) on fertilization success (2HPF) and embryonic survival. Bar plots represent means (± SEM) and lower-case letters significant statistical difference ($p < 0.05$).

(Continued on next page)

Results

Female responsiveness to CPE (96.4%) exceeded SPE (80.7%). However, the proportion of embryos obtained from SPE treated females and embryonic survival were significantly higher than for CPE females ($p = 0.029$, Fig. 1A). For treatments overall, the fertilization percent was 58.3%, while embryonic survival decreased gradually over time to 36.9% at 48 HPF ($p = 0.003$, Fig. 1B). Moreover, embryos obtained from CPE females showed significantly higher ratio of cleavage abnormalities at 4 HPF than those from SPE females ($p = 0.037$). In both treatment groups, a strong negative relationship was found between cleavage abnormalities and embryonic survival at 48 HPF (CPE: $Y = -1.31x + 87.83$; $R^2=0.64$, $p = 0.0003$; SPE: $Y = -0.66x + 52.80$; $R^2=0.76$, $p<0.0001$). The gene expression analyses underline differences between treatment and related maternal effects on embryonic developmental competence.

Discussion and conclusion

The study revealed enhanced offspring developmental competence from female European eel broodstock treated with SPE to induce ovarian development compared to those treated with CPE. The two hormonal product types are generally used as equal alternatives, although CPE is more frequently used for European eel, and SPE for the Japanese eel. However, this study reveals that while fertilization success is little affected, the PE origin has a profound impact on offspring quality. This may relate to genetic differences in hormone structure among species or the gonadotropin composition and content in the specific pituitaries. Data on the expression of developmental genes will be discusses in relation to possible causes for differences in developmental success and survival during early life history of captive bred eel offspring using assisted reproduction. Results of this study may be incorporated into future broodstock treatment improving offspring quality for future European eel breeding.

We thank the Lough Neagh Fishermen's Co-operative Society and Lake Vandet Eel Guild for donating silver eels. This study is supported financially by Innovation Fund Denmark through the projects: Eel Hatchery Technology for a Sustainable Aquaculture (EEL-HATCH; Grant no. 5184-00093B), and Improve Technology and Scale-up Production of Offspring for European eel aquaculture (ITS-EEL, Grant no.7076-00125B).

'Wherefore art thou Aquaponics – The herd of Elephants in the Room': FUTURE AQUAPONICS IN EUROPE TOWARDS SURVIVAL, GROWTH AND SUCCESS

Benz Kotzen

School of Design, University of Greenwich, Park Row, London SE10 9BD
b.kotzen@gre,.ac.uk

Introduction

Aquaponics in the EU has developed significantly over the last 5 years, since the initiation of the 4 year long COST (European Cooperation in Science and Technology) FA1305, 'EU Aquaponics Hub' by Benz Kotzen in 2014 and who was chair of the project for the duration. The Action brought together 90 members from 30 countries and initiated 6 international conferences attended by hundreds of people and numerous papers (over 30 review papers, journal special issues, books and monographs), a white paper, and 59 videos. It has been the catalyst for numerous another EU projects, including 'Aqu@teach' Erasmus+ Strategic Partnership in Higher Education, led by the University of Greenwich in partnership with institutions in Switzerland, Spain and Slovenia. The project concluded with a White Paper and as a final output an open access publication titled 'Aquaponics Food Production Systems' edited by Simon Goddek, Alyssa Joyce, Benz Kotzen and Gavin Burnell. This publication highlights the core of aquaponics and cutting edge aspects in many areas but the future of aquaponics not only lies in technical and scientific innovation but as importantly in the areas of policy, social acceptance and representation. For aquaponics to succeed, we need to deal with the *'herd of elephants in the room'*.

Discussion - Aquaponics the Present and the Future

The project was always envisaged to kick-start real growth in aquaponics research and entrepreneurship, and it did so, but what it did not envisage is the next steps and this is what this paper is about. The important areas for the future of EU Aquaponics was set out in the White Paper, highlighting 8 key areas:

1. The promotion of continued research in aquaponics;
2. The commercialisation and funding of aquaponics
3. Urban aquaponics – promotion of aquaponics as social enterprise
4. Developing world aquaponics and refugees
5. Aquaponics policy and legislation
6. Aquaponics and education
7. Aquaponics health and safety including fish welfar
8. Initiating the EU Aquaponics Association

This paper concentrates on the 3 connected areas of commercialisation / funding with regard to aquaponics policy and legislation and the initiation of the EU Aquaponics Association and discusses the placement of aquaponics in the global and European niches of production. Whilst this issue has been visited previously, it is one of the largest of the elephants in the room in terms of furthering aquaponics acceptance and thus commercialisation. Post the EU Aquaponics Hub, an EU Association was to be set up, but this has floundered for a number of reasons. The discussion in this paper concludes on how best we as an aquaponics community, both research and commercially based can best set up a group. For the purposes of this paper, we will call in the 'New EU Aquaponics Hub', whose aims will be to represent and assist the EU aquaponics community to fulfil its potential, by lobbying and representing aquaponics in terms of polic , law making, identity etc.

GASTRIC EVACUATION, STOMACH DIGESTA MOISTURE AND CARCASS PROXIMATE COMPOSITION OF MEAGRE, *Argyrosomus regius*, FED DIETS WITH DIFFERENT DIETARY LIPID LEVEL

Kounna Christiana*[,1], Fountoulaki Eleni[1], Miliou Helen[2], Chatzifotis Stavros[1]

*E-mail: ccounna@gmail.com

Introduction

Digestion characteristics are species-specific and are based, although not strictly, on fish size, diet formulation and composition, feed processing, feeding frequency and water temperature (Dos Santos and Jobling, 1991; Venou et al. 2009). Gastric evacuation (GE), the process of digesta leaving the stomach, has been greatly studied in wild populations as a means to define prey-predator interactions, adaptive seasonal physiological behaviour and quantify stock populations. In contrast, in aquaculture species fed pelleted diets, it has only been vaguely examined. GE can provide an indication of feeding rates and frequency, contributing to the optimization of feeding regimes, as well as on feed deprivation time before harvesting. Diet formulation, ex. dietary protein/lipid ratio, can influence nutrient transport and absorption in the organism. In meagre, a limited number of studies have investigated the effect of diet formulation on nutrient apparent digestibility coefficients (Kounna et al. 2012; Velazco-Vargas et al., 2014), but no available references exist yet on the effect of diet on GE. Hence, the present study investigated the effect of dietary lipid level on: gastric evacuation time and rate (GET, GER); digesta moisture content and carcass proximate composition of juvenile meagre for the first time

Materials and Methods

A 4-week feeding trial was conducted in an open flow-through experimental system. Three isonitrogenous (46% crude protein, dry weight), practical extruded diets -A1, A2, A3- with increasing lipid level (15, 18, 24% dry weight), were offered to the experimental fish in triplicate groups. Average fish weight was 114.5g ± 5.0 (± s.e.m) and fish density was 4.1kg/m^3. The fish were acclimatized to the system and diets for 19 days prior to the experiment. Feeding was performed by hand to apparent satiation, once a day. On the sampling day, fish were fed once to satiety (ca. 1% body mass) and then 5 fish treatment were sacrificed at 0.5, 2, 4, 6, 8, 10, 12 and 23 hours post feeding. Stomach contents were collected and their dry weight was determined and expressed as % of wet fish body weight. GET and GER were evaluated using regression analysis. GET was estimated as the time needed for the fish to empty 50% of its stomach content. At the end of the trial 3 fish/tank were collected for proximate carcass (no viscera) composition analysis. Water temperature during sampling was 25.5 – 26.2ºC; salinity was 37ppm and photoperiod 12L:12D.

Results

The exponential model best described the pattern of evacuation of the stomach of meagre in all 3 treatments. GET and GER were similar for diets A2 and A3 (3.61, 3.65h; 3.20, 3.17g/min x 10^{-3}, respectively), but statistically faster ($p<0.05$, t-test) for meagre feeding on diet A1 (2.41h, 4.80g/min x 10^{-3}). As a result, the group fed diet A1, had completely evacuated their stomachs close to 12h postprandial, whereas the other two groups a bit later. By 23h postprandial the stomachs of the fishes from all groups were empty.

Table I. Juvenile meagre carcass proximate composition (% wet weight) (mean ± std). No statistically significant difference between diets ($p > 0.05$)

Diet	Protein	Total lipids	Ash	Moisture
A1	18.03 ± 2.33	6.14 ± 0.77	4.05 ± 0.32	71.78 ± 0.78
A2	16.98 ± 0.19	6.06 ± 0.63	4.09 ± 0.19	72.91 ± 0.73
A3	17.99 ± 0.82	6.59 ± 0.18	4.02 ± 0.34	71.40 ± 1.04

(Continued on next page)

There was an effect of time on digesta moisture content but not of diet (at $p = 0.05$).
% digesta moisture at 0.5h ranged from 68.0% (A2) to 69.8% (A3). An increase (2-8%) was noted 2h postprandial in all treatments and a further statistically significant increase (6-18%) at 6h –diet A1, at 4h –diet A2 ($p<0.05$, Welch test, Games-Howell) and at 12h -diet A3 ($p<0.05$, Kruskal-Wallis). Finally, after 23h it had reached maximum, 96 - 98.5%, in all treatments.

Carcass proximate composition of meagre, Table I, was similar between the treatments ($p>0.05$, one-way ANOVA).

Discussion

There was an effect of diet on GET and GER but not on carcass proximate composition. The exponential model best described GET of meagre fed diets with different lipid level, as in seabream and seabass by Nikolopoulou et al. (2011). The model implies a quick stomach evacuation the first hours postprandial, which then slows down as the residual content in the stomach decreases. The group fed the lower dietary lipid content exhibited the highest GER, whereas the medium and high lipid inclusion levels produced similar results, indicating that the effect on GE does not change from 18 to 24% lipid content, but lower (15%), probably increases GER. Nevertheless, it appears that GET and GER were adequate in all treatments for sufficient nutrient digestion and absorption to occur, yielding fish with similar carcass proximate composition characteristics. This is further supported by the lipid and protein digestibility coefficients that were not affected by dietary lipid level in a previous study (Kounna et al. 2012). Under the specific conditions, meagre required less than 23h to empty its stomach contents.

The increase in digesta moisture content in all treatments after feeding, prompts to possible fluid secretions in the stomach of the fish to facilitate digestion. An increase in digesta moisture content after feeding was also observed in seabream by Venou et al. (2009) and Nikolopoulou et al. (2011). In these studies, stomach hydration level was also affected by feed processing method and diet composition. In the present study, there was no effect of diet formulation, perhaps because diet moisture level and composition were similar amongst the 3 diets.

This study was co-financed by the European Union (European Social Fund – ESF) and Greek national funds through the Operational Program Education and Lifelong Learning: "KRANIOS"

E-mail: Kovacs.Balazs@mkk.szie.hu

Introduction

The African catfish or sharp tooth catfish (*Clarias gariepinus*) is farmed in numerous African, Asian, and European countries. Moreover, during the last decades its production has grown significantly worldwide. Currently, following the carp, this species is produced in the second largest volume in Hungary. Despite its economic importance, the stocks have been maintained without genetic control or guided breeding. Molecular genetic data on bred populations or strains are very limited. Microsatellite markers are particularly suitable for numerous applications including population genetics, parentage analysis or marker assisted selection. In order to investigate the genetic structure of the stocks, 49 new microsatellite markers were characterized and tested on a Hungarian farmed stock. Based on the results an effective set of markers were identified for parentage analyses.

Materials and methods

Thirty-two African catfish individuals were sampled from closed bred population of Szarvas, Hungary. The genomic DNA was isolated using E.Z.N.A. DNA Tissue Kit (Omega BioTek). Repeat enriched DNA libraries were produced from pooled samples of male specimens following the protocol of Glenn and Schable 2005. Rsa I, Hae III, Alu I, and HpyCH4 V endonucleases and the Box I linker (F:Phos-ATGTCTGAAGGTACCA CTGCTGTCCGAAA; R:CGGACAGCAGTGGTACCTTCAGACAT) were used for librarie preparation. The insert size was 300-1000bp. The sequences of the inserts were determined by 3130 Genetic Analyser (Applied Biosystems). Primer3Plus software was used for primer design. Tail and tail specific fluorescent primers were used to reduce the costs of detection, as it was described by Shimizu et al. (2002). A 17 basipair long tail (ATTACCGCGGCTGCTGG-) were added to the forward primers' 5' ends to provide an attachment site for fluorescent dye labeled (FAM or VIC or NED or PET) tail-specific oligos. MICROSATELLITE TOOLKIT VER. 3.1.1 was used to estimate mean number of alleles and polymorphic information content. The Hardy-Weinberg equilibrium (HWE) were estimated by GENALEX VER. 6.5. The parentage and minimum set of markers which provides a high resolution of parentage allocation and the probability of exclusion in paternity were tested by PARFEX v1.0., while the inbreeding coefficient (Fis) was calculated by FS AT 2.9.3.

Results

In total, 127 selected clones were sequenced from four CA-repeat enriched genomic libraries. 55 microsatellite sequences were selected and primers were synthesized for later PCR analyses. Forty-nine of the selected markers were used to genotype 32 individuals. None of the 49 markers was monomorphic. The number of alleles per locus ranged from 2 to 11, with a mean of 4.818 (SE: 1,973) alleles. Twenty-seven loci were highly polymorphic (PIC > 0.5), 18 were moderately polymorphic (0.2 < PIC < 0.5), and four showed low polymorphism (PIC < 0.2) in our bred population. The expected heterozygosity (HE) among loci ranged from 0.147 to 0, whereas the observed heterozygosity (HO) ranged from 0.031 to 1.000. Thirty-one loci showed significant deviation from HWE, probably due to selection practice, artificial propagation, fluctuations in population size or stocking. No parental relationships were identified by the exclusion or the maximum likelihood methods. However, the maximum likelihood analyses of relatedness showed a high probability of full-sib or half-sib relationships between individuals. All the individuals showed relationship with at least two specimens, while three of them had ten probable relatives. Nevertheless, the high number of related individuals can lead to spurious associations in the estimation of random distribution. The overall FIS values were 0.063, while 29 markers had positive and 20 negative Fis values. The calculation of the minimum set of markers for parentage allocation or for identification over 99% probability resulted in a marker set containing 14 (Cg10, Cg175, Cg132, Cg370, Cg3, Cg341, Cg214, Cg661, Cg287, Cg299, MS647, Cg352, Cg639 and Cg294) markers.

(Continued on next page)

Discussion and conclusion

In conclusion, 49 newly isolated *C. gariepinus* microsatellites were tested and characterised. The genetic effects of long-term intensive breeding were also investigated on the examined Hungarian African catfish population by the markers. The expected and observed heterozygosity differed significantly from each other. The inbreeding coefficient also showed the presence of heterozygote surplus and deficiency in a wide range (from -0.709 to 0.899) at different markers. All these can be the consequence of intra-population genetic structures (non random mating) or small founder group with rare and unsystematic crossbreeding with other strains. The presence of intra-population genetic structures was confirmed by the maximum likelihood estimation of relatedness and the parentage allocation. However, none of these two methods identified parental relationships among the individuals, the maximum likelihood analyses highlighted the presence of a high number of half-sib and full-sib individuals in the analysed group. During the parentage analyses the most efficient set of markers were also calculated. The marker set contains 14 markers usable for parentage allocation or for identification of individuals over 99% probability in exclusion analyses.

EFFECT OF RATE OF FREEZING ON THE SPERM OF STURGEON

Aleksandra A. Krasilnikova

Southern Scientific Centre of the Russian Academy of Sciences
41 Chekhov Street, 344006, Rostov-on-Don, Russia
e-mail: alexandra.kras@yandex.ru

Introduction
Studies of cell structures and their organelles indicate that the effect of deep freezing can affect any of their components, which is an important obstacle to the preservation of the integrity of cells and tissues during cryopreservation.

The aim of this study was to establish optimal freezing rates during cryopreservation of sturgeon sperm, ensuring the preservation of the structural components of reproductive cells.

Materials and methods
Reproductive cells of Russian sturgeon (Acipenser gueldenstaedtii Brandt&Ratzeburg, 1833) and sterlet (Acipenser ruthenus Linnaeus, 1758) obtained at sturgeon hatcheries of the Astrakhan region during the spawning campaign served as material for research.

The following freezing rates were studied: 3°C/min, 10°C/min and step mode (6**°C/min for 6 minutes, 10°**C/min, for 4 minutes, then the samples were immersed in liquid nitrogen).

Thawing of sperm was carried out in a water bath at a temperature of 38-40°C.

Results
The best freezing speed for the sperm of Russian sturgeon was the speed of 3°C/min, both in activity and in life time of sperm after defrosting. Other modes of freezing showed results worse, however, it is noted that all three investigated speeds were not reduced frozen-thawed sperm quality below fish production parameters. Thus, all these freezing rates can be used for cryopreservation of sperm of Russian sturgeon, depending on certain conditions of conservation.

When working with sterlet sperm, less damage after freezing-thawing occurred at a freezing rate of 10 ° C/min, while under the same conditions and relatively high sperm quality for Russian sturgeon, the optimal speed was 3 ° C/min. the Speed of 3 ° C/min for sterlet sperm was slightly worse. Step freezing mode was much worse in both cases.

Discussion and conclusion
For sturgeon from the tested freezing rates the most acceptable are 3 ° C/min for Russian sturgeon and 10 ° C/min for sterlet.

The results indicate that the choice of the sperm freezing rate of sturgeon is species-specific.

Work is performed with the use of the Bioresource collection of rare and endangered species SSC RAS No. 73602 with the financial support of RFBR, research project No. 19-016-00208 (ice formation) and grant MK-68.2019.11 (the freezing rate).

FUTURE PROFITABILITY OF TYPICAL FINFISH FARMS IN EUROPE

Impacts of climate change on European marine and freshwater environments are already beginning to affect finfis production in Europe. Besides impacts on water quality and temperature that might influence growth performance, pathogen interactions, feed conversion ratio, and thereby the fish production itself, the aquaculture sector is also facing an uncertain future in terms of production costs and returns. Climate change, social and economic factors will determine future access to proteins and omega-3 fatty acids and thereby define the price of these crucial ingredients for fish feed. Another main expenditure within fish farming is attributed to energy, whose future price development is also dependent on various factors. Finally, the market price trends will have a major impact on future profitability within the aquaculture sector. This study analyses the future economic drivers of grow-out production of Atlantic salmon (*Salmo salar*), European seabass (*Dicentrarchus labrax*), Gilthead seabream (*Sparus aurata*) and Rainbow trout (*Oncorhynchus mykiss*) under four socio-political scenarios developed in the EU Horizon 2020 project CERES. Thereby, an established benchmarking approach was used to contrast today's economic performance of "typical farms" in selected European production regions with their future profitability under the different scenarios. The intra- and inter-species comparisons of different production systems for their future security is intended to create awareness among the aquaculture sector to prepare for the next decades.

THE EFFECT OF OZONE ON WATER QUALITY AND PIKEPERCH *Sander lucioperca* PERFORMANCE IN RECIRCULATING AQUACULTURE SYSTEM

Introduction

Aquaculture and recirculating aquaculture system (RAS) will be very important production system for future seafood production to supply the ever-expanding human population. However, RAS can provide problem with a latent disease and exposure of fish to pathogens, bacterial and fungal diseases. Ozone can effectively inactivate a viral, bacterial, fungal and protozoan fish pathogens in RAS. But the effectiveness of ozone treatment depends on ozone concentration, length of ozone exposure (contact time), pathogen loads and levels of organic matter (Gonçalves et al. 2011). The aim of this study was to compare ozone and/or nonozone water treatment for pikeperch ongrowing culture under RAS.

Material and methods

The experiment was carried out using triplicate groups of 500 fish for two tested groups presenting two different conditions: ozone treatment of water (ozone +) and control group without ozone (ozone –). In total, the 3000 juvenile pikeperch (9.2 ± 2g, 102.5 ± 8.1 mm) were used for this study. Water temperature and pH were kept under similar values for both groups. Group ozone + was supplied with 2.5g ozone per hour (60g ozone) per day. The duration of the experiment was 231 days. Water quality parameters (ammonia, nitrites, nitrates, total N and P, chemical oxygen demand, biological oxygen demand, suspended solids), fish mortality and feed intake were recorded daily. At the beginning of the experiment and then every three weeks until the end of the experiment, total length (TL), standard length and fish weight (FW) was measured in representative samples of fish from each tank, specific growth rate (SGR) and Fulton coefficient (FC) were compared. At the end of the experiment, the blood biochemical analysis: cortisol, albumin (ALB), alkaline phosphatase (ALP), alanine aminotransferase (ALT), total protein (TP), ammonia (NH_3), lactate dehydrogenase (LDH), lactate (LACT), Spleen Somatic Index (SSI), Hepato Somatic Index (HSI), Viscero Somatic Index (VSI) and fin erosion according Policar et al. (2016) were analyzed and compared between groups.

Results

At the end of the experiment, the average values of survival rate (ozone + and ozone –) were significantly different between groups ($P<0.05$). The group ozone + achieved higher survival rate 77 % in comparison with 67.2% in ozone –. No significant differences in FW, TL, SGR and FC were found (FW = 130.0 ± 26.2 g compared to 123.5 ± 21.3 g; TL = 258.0 ± 16.3 compared to 238.0 ± 15 mm; SGR = 1.15 ± 0.12 %.d^{-1} compared to 1.13 ± 0.1 %.d^{-1} and FC = 0.76 ± 0.05 compared to 0.91 ± 0.07 in ozone + and ozone – groups, respectively). The water quality parameters are shown in table 1.

Table 1. The average water chemical parameters in ozone – and ozone +. Values within column with different superscripts are significantly different ($P < 0.05$)

	NH_4^+- N(mg.l^{-1})	NO_3- N (mg.l^{-1})	NO_2- N (mg.l^{-1})	N-total (mg.l^{-1})
ozone –	0.37±0.1a	26.4±10.2a	0.09±0.03a	34.6±10,9a
ozone +	0.31±0.1a	23.6±9a	0.06±0.02a	29.4±8.9a
	P-total	COD_{Mn} (mg.l^{-1})	BOD_5 (mg.l^{-1})	suspended solids
ozone –	1.44±0.6a	10.7±1.6a	8.1±1.3a	8.17±6.2a
ozone +	1.22±0.6a	6.4±1.2b	5.32±1.8b	4.3±2.8b

Table 2. The blood biochemical profile in pikeperch.

	kortizol (ng/ml)	ALB (g/l)	ALP (µkat/l)	ALT (µkat/l)	AST (µkat/l)	TP (g/l)	NH_3 (µmol/l)	LDH (µkat/l)	LACT (mmol/l)
ozone–	124.5 ± 55.29	3.0 ± 1.10	1.4 ± 0.40	0.2 ± 0.07	3.0 ± 1.10	36.5 ± 4.32	931.0 ± 55.81	19.6 ± 2.07	3.5 ± 0,85
ozone+	151.8 ± 74.50	3.5 ± 1.38	1.3 ± 0.65	0.2 ± 0.14	3.9 ± 1.45	39.0 ± 2.61	872.5 ± 191.57	20.5 ± 1.55	4.0 ± 0.48

(Continued on next page)

The significant differences were detected in COD, BOD and suspended solids. Group ozone– was more organically loaded. The blood biochemical analysis is shown in Table 2. No significant differences in mentioned parameters were determined between tested groups.

In comparison SSI, HSI and VSI, the significant differences were observed in SSI and HSI. The bigger SSI 0.09 ± 0.03% was found in ozone + compared to 0.04 ± 0.05% in ozone–. The HSI 1.77 ± 0.2% was bigger in ozone– in comparison with ozone+ 1.34 ± 0.31%. Pikeperch from group ozone – were the mostly affected by fin erosion compared to group ozone +. The significa tly differences were observed in pectoral fin: 38-42% (degree 1) 8-10% (degree 2) compared to 55-65% (degree 1), 18 -20% (degree 2), in ozone + and ozone – respectively. Similar results were in first dorsal fin: 38% (degree 1) and 50% (degree 1) in ozone + and ozone –, respectively. The caudal fin was the most damaged fin in group ozone–. In this fin, the serious erosion 5% (degree 3) was detected. Degree 3 was not found in ozone + group. Degree 2 was 12 % and 27% and degree 1 was 76% and 67% in ozone + and ozone –, respectively. Other fins were not statistically different between groups.

Discussion

Ozone is a powerful oxidizing agent that can be put to numerous beneficial uses within RAS (Summerfelt and Hochheimer, 1997). In solids, the similar results achieved Davidson et al. (2011), who also demonstrated removing solids in water treated by ozone. Similar positive ozone treatment effect observed Powell et al. (2015) in turbot (*Psetta maxima*) and Davidson et al. (2011) in rainbow trout (*Oncorhynchus mykiss*). The present study showed better survival rate, quality of water and quality in fin erosion in ozone + compare to ozone– group. Furthermore, the biochemical parameters, growth rate, fitness condition were similar. In conclusion, we can recommend the using 2.5g per hour for on growing pikeperch fingerlings in RAS

Introduction

From a marine technology perspective, floating closed fish cages are novel structures with possible complex dynamic behaviour, where care should be exercised in the design process to reduce the risk of structural issues and failure. Floating closed fish cages have gained increasing attention and interest among fish farmers as a strategy to mitigate several challenges in sea-based farming of Atlantic salmon in open cages. Several new closed cage structures have been proposed by fish farmers, suppliers and others in development-permits applications to the Norwegian authorities. By enclosing the production volume the risk of sea-lice infections and need for medical treatment can be reduced, and deposits from the production collected. Further, the production efficiency can be improved by optimizing parameters such as water temperature, oxygen saturation, and acidity. The present work compiles results from previous and on-going research on floating closed fish cages to describe state-of-the-art in design of closed cages from a marine technology perspectiv

Design considerations of closed cages

In order to address the different structural and hydrodynamic properties of closed cage concepts, a categorization of closed cage structures based on their elastic properties was proposed in [1], where closed cages are defined as either rigid, elastic or fully flexible.

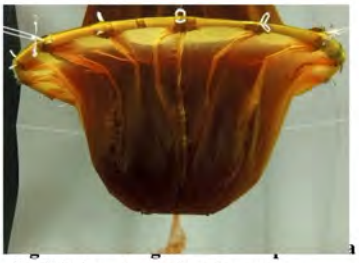
Stability: The free water surface inside the containment has a destabilizing effect on a floating closed cage, where the cage filling level is also a parameter. Furthermore, the hydrostatic restoring moment is typically small as the water-plane area of the structure is often limited to a narrow walk-way surrounding the cage. This can lead to stability related issues if it is not considered appropriately during design.

Water density: In fjord areas, where typically closed cages are installed, brackish surface water may cause density stratification in the upper part of the water column. Inlets of the water exchange system can be located at a distance below the surface, to reduce the risk of sea-lice contaminated water. If so, this can result in the contained water having a different water density compared to its immediate surroundings. The density difference combined with the internal filling level causes a hydrostatic pressure difference across the containment wall which can lead to discharge of contained water in damaged conditions. For flexible bag-type closed cages this can cause drainage and collapse if no countermeasures are taken (see e.g. in [2] and Fig. 1).

Sloshing: Closed cages are typically characterized with a large free surface that can be set into motion when the cage moves in response to waves. These induced motions of the internal water volume are known as sloshing and can have strong influence on the cage motions and structural loads. Particularly at resonant conditions when the cage is excited close to a natural period of sloshing (see e.g. in [1] and Fig. 2). From a design perspective, it is the first few highest natural periods that are of interest. They represent the most energetic conditions and may yield the largest structural loads. Hence, it is important to compare the expected exposure at the site in question to the estimated highest natural periods of sloshing for a given design. By modifying design dimensions and/or geometry the natural sloshing periods can be shifted away from the energic wave period, thereby reducing the risk of resonant conditions. Damping can also be used to limit the sloshing response. However, typical damping strategies for sloshing as used in ship tanks are considered less attractive for closed cages due to operational aspects. Whereas sloshing in rigid containers is well described (see e.g. in [3]), sloshing in elastic or flexible containers are still in the research front. Complex wave-structure interaction effects obtained from a 2D numerical model of a flexible type closed cage was presented in [4], where scaling issues of flexible bag models were also identified.

Parachute effect: Depending on the current conditions at the site, closed cages can be exposed to significant current-induced forces and moments. These can be static forces and moments, or dynamic loads e.g. due to flow separation from the structure. Current-induced loads on rigid type closed cages can be addressed by conventional design methods by the application of drag coefficients. However, for the flexible bag-type hydroelasticity matters, meaning that hydrodynamic loads and structural deformations are mutually dependent. For flexible bag-type closed cages in damaged condition with reduced filling ratio, bag deformation in steady current may cause a large increase of the current-induced drag compared to intact condition due to the so-called “parachute effect” [5].

(Continued on next page)



flexible bag-type closed cage.

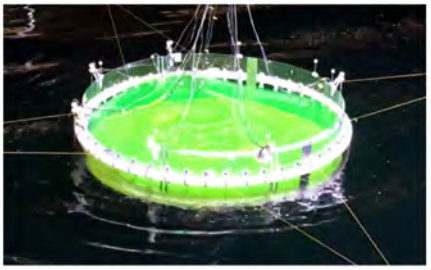


Fig. 2. Sloshing in an elastic closed cage.

Mooring analysis: Compared to traditional slender net cage structures, closed fish cages are large volume structures. Further, due to large displacement, closed cages with moorings represent a dynamic mass-spring system. This means that dynamic amplification of mooring forces due to excitation from slowly varying wave, wind and current forces should be considered as for conventional mooring analysis of large volume structures. First order wave induced motions of the cage, which are highly affected by sloshing, are also important. Due to small hydrostatic restoring moment, one should also be aware that unfavourable location of mooring line attachments may cause tilt moments that can result in static heel angles. Numerical modelling of wave response for moored closed cages in relevant sea-states is an on-going research activity.

Summary

Floating closed cages are novel structures with complex dynamic behaviour in a typical marine environment. In the present paper, important design considerations for floating closed fish cages resulting from recent experimental and numerical studies are presented. The importance of some of the design considerations depends on the category of the closed cage structure (rigid, elastic of flexible bag type). The main findings from these studies and relevant research activities are discussed.

For many years, symptoms of impaired lipid digestion, a lipid malabsorption syndrome (LMS), have been commonly observed in cultivated Atlantic salmon in Norway (Hanche-Olsen et al., 2013). Severe outbreaks are characterized by steatorrhea, visible in the environment as floating faeces accumulating on the water surface and on nearby seashores. In most cases, the symptoms are less pronounced and only visible upon opening of the abdominal cavity, macroscopically as foamy pyloric caeca, and histologically as hypervacuolation of the enterocytes. The occurrence of the symptoms appears to have increased as level of plant ingredients in the diets has increased, although the most severe symptoms have decreased in frequency. An ongoing survey will provide updated information on the situation in salmon farm sites along the Norwegian coast. The symptoms are accompanied by high content of lipid in the intestinal mucosa, indicating disturbance of lipid digestion, absorption and transport across the mucosa and/or delivery to the peripheral circulation. However, the mechanisms and structures involved in these processes in fish are not well described and clear differences, compared to mammals, exist (Bakke et al., 2010). Among the lipases responsible for lipid hydrolysis in the intestine, fish seem to lack pancreatic triacylglycerol lipase. This may affect the following micelle formation and lipid absorption including phospholipids, cholesterol, bile salts and other lipophilic compounds such as fat soluble vitamins. In the other end of the lipid absorption process, fish seem to differ from mammals by lacking a lymphatic system for conveying lipid to the peripheral circulation and tissues. The likely route of lipid transport from the intestine is, therefore, in the portal blood, as "portomicrons", to the liver, and onward in VLDL. However, this is not clearly documented. The same is the situation regarding the elements of lipid absorption into the enterocytes, lipoprotein assembly and export (Xiao et al., 2018). The core of lipoproteins formed in the enterocytes mainly contains triglycerides, esterified cholesterol as well as lipid soluble vitamins and other highly lipophilic compounds. The surface contains, besides a number of apolipoproteins, phosphatidylcholine and free cholesterol.

A series of feeding experiments has been conducted to find whether insufficient supply of compounds and metabolites involved in phospholipid and sterol metabolism might explain development of LMS. The figure below indicates relationships between the compounds in focus of these studies. The basal diets have been commercially relevant low fish meal, high plant and high lipid diets which have been supplemented with phospholipids, choline, cholesterol, bile salts and taurine. We have also investigated effects of supplementation with methionine and cysteine, involved in metabolism of methyl groups, which may be utilized in the synthesis of phosphatidylcholine from phosphatidylethanolamine (Schubert et al., 2003). The observed endpoints are growth, -nutrient digestibility, hypervacuolation as indicated by histology, expression of genes involved in nutrient digestion, cholesterol, bile salt and phospholipid metabolism, lipid transport, gut barrier functions as well as plasma metabolites.

Results from these studies will be presented under four titles:

1. Key components in intestinal lipid transport and metabolism. An overview. Å. Krogdahl
2. Report from an ongoing field survey of LMS in Atlantic salmon in Norway. E. Chikwati
3. Effects of dietary cholesterol and bile salts on intestinal lipid metabolism. T. M. Kortner

IMPLEMENTATION OF PROGRAMMABLE STRUCTURES FOR MODEL BASED ANALYSIS OF RECIRCULATING AQUACULTURE SYSTEMS

Balázs Kucska*, Béla Csukás, Mónika Varga

Kaposvár University, Department of Aquaculture and Institute of Methodology, 40 Guba S, 7400 Kaposvár (Hungary)

E-mail: kucska.balazs@ke.hu

Introduction

Recirculation Aquaculture Systems (RAS) became a commonly used solution to contribute food supply with the most productive utilization of limited land and water resources and, with the lowest possible load on environment. Regardless to the obvious advantages of RAS (e.g. Davidson et al., 2016), it is an almost closed technological system, involving livestock farming, (bio)technological and water treatment processes of high complexity in a recycle loop within a cyclically changing structure. Consequently, RAS is a typical example, where the design and operation of co-existing biological and technological processes require the application of dynamic simulation models and control engineering way of thinking.

Considering the challenges and the increasing importance of RAS, the modeling and control experts' attention has turned to this field for many years, and interesting works dealt with modeling and simulation supported design and operation. In line with the need to closing the loop, RAS modeling started intensively from the millennium. Several simulation and control models are introduced for RAS, e.g. (Wik and Lindén, 2004; Wik et al, 2009), (Schneider et al., 2007), (Barbu et al, 2016), (Yao, 2018), or for combined aquaponic systems (Karimanzira et al., 2016).

Materials and methods

In this work we investigated a pilot RAS, comprising 3x3 fish tanks with oxygen supply from an oxygen generator, a drum filte , and a biofilter for nitrification and COD removal from the recycling and emitted water. The investigate fish was *Cyprinus carpio*, fed with commercial carp feed (Aller Master –Aller Aqua Poland).

The applied non-conventional dynamic modeling methodology of Programmable Structure has developed by the process modelers of our team for the past years (Varga and Csukas, 2017a and 2017b; Varga et al, 2017). In this framework, process models can be automatically generated from one state and one transition meta-prototypes, as well as from the standardized description of the process network. The functionalities of the state and transition elements are declared by the local programs of the so-called prototype elements, which can also be derived from the general meta-prototypes. These prototype elements contain symbolic input, parameter and output variables, as well as an editable local program (e.g. equations, expressions, rules, constraints, etc.). The state and transition elements of the actual model can be parameterized and initialized concerning their case-specific prototypes. Next, the executable code of the model is automatically prepared and model is executed by a general purpose kernel program.

Results

First, we generated, parameterized and programmed the Programmable Structure based dynamic simulation model of the studied pilot RAS system. The model was prepared to follow the changing conditions. Accordingly, we utilized a mutual feedback between the pilot experiment and its model. Having compared the measured and calculated results we tuned the initially uncertain model parameters on the one hand, as well as we used the dynamic model for the prediction of the future behavior, supporting the defensive managerial control decisions in case of malfunctions (mainly caused by the applied drum filter). Regardless to the difficulties of simultaneous validation and model based control, this "predictor / corrector" like run tested the capabilities of the applied modeling methodology.

Based on the above experiences we prepared an improved model, and implemented it for the simulation-based analysis of a fictitious, but realistic system with typical parameters, adapted to the pilot unit (that helps to prepare the future experimentations). This model was applied for the simulation based sensitivity analysis of the investigated RAS process.

(Continued on next page)

Computational modeling supports building hypothetical models that help the effective problem solving with decreasing complexity. Actually, modeling of a single hypothetical fish tank with automatically increasing volume made possible to simulate the idealistic change of stocking density in preliminary design of a controlled multistage RAS process. The resulted change of volume may be derived from the simulated change of the volume. The Programmable Structures can easily be transformed into the State Space Model of control that helps the simulation based testing of various Multiple Input Multiple Output (MIMO) control strategies.

Discussion and conclusion

Considering the cost and time consumption of the experimental study of a realistic multistage RAS system, as well as the unavoidable malfunctions, dynamic simulation based analysis, design and control seems to be competitive and effective solution. In addition to the existing RAS simulation methods, the multiple time scales, the large complexity of the design space, as well as the highly interacting MIMO control are still challenging for the emerging non-conventional methodologies. Programmable Structures proved to be a possible candidate for model based analysis, design and operation of RAS. The structure, the data and the local programs can be reconfigured, conveniently. This flexibility supports also the utilization of the results, coming from non-ideal, erroneous experiments. Important issue is that the easily implementable, fictitious models can be used to simulate a single fish tank of hypothetically increasing volume with the prescribed change of stocking density. This make possible to reduce the complexity of design, because it supports to study the behavior and control of a multistage RAS in one single increasing volume. This supports also the simulation based testing of the various MIMO control strategies.

PIRAB^{VP} TOXIN MEDIATES *IN VIVO* PATHOGENICITY OF *Vibrio parahaemolyticus* AHPND STRAIN: ROLE OF NOVEL PLANT-BASED HSP70 INDUCING COMPOUND IN PROTECTION AGAINST AHPND STRAIN IN SHRIMP SPECIES

Vikash Kumar*, Kartik Baruah and Peter Bossier

Lab of Aquaculture & *Artemia* Reference Center
Department of Animal Sciences and Aquatic Ecology
Faculty of Bioscience Engineering, Ghent University, 9000 Ghent, Belgium
ICAR-Central Inland Fisheries Research Institute (CIFRI), Barrackpore, 700120, India
*Email: Vikash.kumar@ugent.be

The halophilic aquatic bacterium, *Vibrio parahaemolyticus* is an important aquatic pathogen, also capable of causing acute hepatopancreatic necrosis disease (AHPND) in shrimp resulting in significant economic losses. The *V. parahaemolyticus* encodes deadly toxins (VP_{AHPND} toxins) that are responsible for shrimp mortality during AHPND. Therefore, there is an urgent need to understand the toxicity mechanism of *V. parahaemolyticus* AHPND strain and VP_{AHPND} toxins and develop anti-infective strategies to control AHPND. The gnotobiotic brine shrimp (*Artemia franciscana*) and freshwater shrimp (*Macrobrachium rosenbergii*) model was used to determine the toxicity of AHPND strain and VP_{AHPND} toxins. In addition, the effective role of phenolic compound phloroglucinol was examined *in vivo* against the AHPND strain *V. parahaemolyticus*. It was found that toxicity of *V. parahaemolyticus* AHPND strains is mediated by VP_{AHPND} extracellular proteins (ECP) comprised of $PirA^{VP}$ and $PirB^{VP}$ (mostly). Moreover, $PirB^{VP}$ is more toxic to brine shrimp larvae as compared to $PirA^{VP}$. Furthermore, the survival of brine shrimp larvae challenged with a mixture of $PirA^{VP}$ and $PirB^{VP}$ toxins decreased ~2-fold as compared to $PirB^{VP}$ toxin and ~3-fold as compared to $PirA^{VP}$ toxin, as anticipated, as these 2 toxins seem to form an active complex.

We also found that pretreatment with phloroglucinol, at an optimum concentration (30 µM), protects axenic brine shrimp larvae against *V. parahaemolyticus* infection and induced Hsp70 production (2 folds or more) as compared with the control. We further demonstrated that the *Vibrio*-protective effect of phloroglucinol was caused by its prooxidant effect and is linked to the induction of Hsp70. In addition, RNAi confirms that phloroglucinol-induced Hsp70 mediates the survival of brine shrimp larvae against *V. parahaemolyticus* infection. The study was validated in xenic *Artemia* model and in a *Macrobrachium rosenbergii* system. Pretreatment of xenic brine shrimp larvae (30 µM) and *Macrobrachium* larvae (5 µM) with phloroglucinol increases the survival of xenic brine shrimp and *Macrobrachium* larvae against subsequent *V. parahaemolyticus* challenge. Taken together, our study provides substantial evidence that the prooxidant activity of phloroglucinol induces Hsp70 production protecting brine shrimp, *A. franciscana* and freshwater shrimp, *M. rosenbergii* against the AHPND *V. parahaemolyticus* strain. Probably phloroglucinol treatment might become part of a holistic strategy to control AHPND in shrimp.

HYDRAULIC IMPACT ON FISH MIGRATION IN SARIAKANDHI FISH PASS OF BANGLADESH

Bijoy Kumar Ghosh

Bijiy Kumar Ghosh, Institute of Water and Flood Management, Bangladesh University of Engineering and Technology, Dhaka, Bangladesh**,** Deputy Driector (Admin), Education Engineering Department, Ministry of Education, Bangladesh
E-mail: bkghoshbuet@yahoo.com

The importance of open water fish in our socio-economic regime has recently drawn the attention of the policy makers of the country. FCD/FCDI projects mainly serve the agricultural interests, but it interfere fish migration. This inevitably affects the open water fisheries sector as migratory routes. Nursing grounds of many species of fish are hampered and disturbed for these projects also. In order to permit fish migration in rivers, it is necessary to maintain conditions that help migrants reach their spawning grounds. To overcome obstacles, such as hydraulic structures, placed in the path of migrating fish, structures must be designed to assist the fish to pass them. The periodic and directed travel of fish mainly for feeding, breeding and over coming adverse climatic conditions is called migration. Fish passes are constructed to allow normal breeding migration and to ensure natural route of fish movement.

The concept of a fish passes is relatively new in Bangladesh. At present, two Fish passes and two fish friendly structures are constructed. These are Fish Pass in Jamuna to Bangali River at Sariakandi in Bogra, fish Pass in Kawadighi Haor of Monu river in Moulovibazar, fish friendly structure in Lohajong river of Tangail and fish friendly structure at Morichardanra in Chapainawabganj. Fish fry, spawning and hatchling movement from Jamuna to Bangali River was the main objective of Sariakandi Fish Pass Project. The Fish Pass Project of Sariakandi is necessary for the development of the dominant fishes like catfish and small fishes. The structures will also aid in efficient development of the carp fishes. Spawning migration, mainly in carp fish, in the study area was found to begin at the 2nd week of May and continue up to the 3rd week of July. Catfish migrations began at the last week of March and continue up to the nd week of June.

Fish fry and hatching movement from Jamuna to Bangali river was the main objective of Sariakandi fish pass project. The study also found that there were seven major category migratory species in the project area and the fish pass is contributing positively for growth of fishery resources in then study area. During the monsoon carp fish is the dominating migratory species. Carpfish migrates in a higher velocity, whereas, catfish migrates in a lower velocity. Some problems were found in the operation and management of fish pass.

COMBINING PHOSPHORUS REMOVAL BY ORGANIC FLOCCULANTS WITH WOODCHIP DENITRIFICATION IN RECIRCULATION AQUACULTURE SYSTEM (RAS)

K. Kujala[a], J.T. Pulkkinen[ab*] and J. Vielma[b]

[a]Department of Biological and Environmental Science, University of Jyväskylä, P.O. Box 35, 40014 Jyväskylä, Finland
[b]Natural Resources Institute Finland, Survontie 9A, 40500 Jyväskylä, Finland
* E-mail: jani.t.pulkkinen@luke.fi

Introduction

RAS farms use and discharge a fraction of the water volume compared to traditional flow-through aquaculture. Concentrated effluent enables use of conventional wastewater treatment technologies such as phosphorus (P) removal by chemical treatment followed by mechanical separation. In recent years, improved nitrogen (N) removal by denitrifying systems such as woodchip bioreactors has been increasingly studied and also constructed in commercial scale under fresh water conditions. The current study focused on combining P and N removal using organic flocculants and woodchip bioreactor in and outflows of freshwater and brackish (7 ppt) water RAS. We hypothesized that carbon from organic flocculants would stimulate N removal in woodchip denitrification

Material and methods

Laboratory scale RAS run at 500 liters of replacement water per kg feed delivered the P-rich sludge and N-rich discharge water for the experiments. In the first phase, both anionic and cationic flocculants based on potato starch (Chemigate Oy, Finland) were screened by jar tests. In brief, 24 hour sludge from 100 gram of feeding was collected and diluted to 10 L, i.e., 100 L/kg feed. Polyaluminum chloride dosing was 50 mg/L and flocculants were typically in the range 10-500 mg/L of sludge.

Based on screening, combination of anionic and cationic flocculants was selected for the combined P and N removal. Supernatant of the sludge flocculation was stored in containers and pumped with discharge water into duplicate woodchip denitrification bioreactors using silver birch (*Betula pendula*). The selected organic flocculant usage (200 mg/L sludge) increased the inflow soluble COD on an average from 38 mg/L to 315 mg/L. The EBCT (empty-bed-contact-time = hydraulic retention time without the woodchips) was set to 24 hours in the woodchip bioreactors. In the control, discharge water without sludge supernatant was used. The trial was run for 6 weeks.

Results and discussion

The N-removal efficiency was improved in the freshwater woodchip bioreactors from 20 % to 30 %, when effluent from chemical water treatment was used (Table I.) Much higher improvement was observed in the brackish water RAS, from 14 % to 43 %, respectively. However, in the freshwater bioreactors using supernatant, the nitrogen was mostly discharged as a nitrite-N, suggesting an incomplete denitrification. The results suggest that the organic flocculants provided an extra carbon for denitrificati n process, which improved the N-removal process. However, the N_2O and N_2 were not directly monitored, thus the total fate of nitrogen end-products was not confirmed

Table I. Average inflow and outflow of different nitrogen compounds from woodchip bioreactors running with outflows of RAS (control) and outflows combined with supernatant of chemical water treatment (treatment).

	Fresh (g N m^{-3} d^{-1})		Brackish, 7 ppt (g N m^{-3} d^{-1})

ADVANCES IN POLYCHAETE CULTIVATION TECHNOLOGY – AN INDOOR SPACE EFFICIENT CULTIVATION SYSTEM

B. Kvæstad[1]*, T. Solvang[1], A. Hagemann[1], H. Wang[1,2], K.I. Reitan[2], A. Handå[1], A. Malzahn[1]

[1] SINTEF Ocean, 7465 Trondheim, Norway. [2] Norwegian University of Science and Technology Department of Biology, 7491 Trondheim, Norway
Email: bjarne.kvaestad@sintef.no

Introduction

There is a growing interest in polychaetes, because of their superior biochemical composition and their role in maturation diets in shrimp cultivation. The annual trade of polychaetes is approximately 6000tons, of which ~5600tons are harvested from already depleted populations, whereas only ~400tons are cultivated in extensive systems in Holland, Wales and the USA (<4kg per m^2 pond area). Not all regions are suitable for pond culture due to available space, coast morphology or climate. Indoor cultivation might be a suitable alternative for extensive pond cultivation, allowing for full control of environmental parameters and year-round production. Moving cultivation indoors will inevitable increase production cost, therefore a need for space efficient and automated production arises to decrease cost and labou .

Materials & Methods

We designed a space efficient cultivation system which operates unattended over long periods of time, making the need of excessive manual monitoring obsolete. The system is comprised of shelf modules for polychaete cultivation units utilizing all three dimensions in order to increase space efficienc . The prototype accommodated 3 shelves (0.3 x 0.3m each) while the full-scale version is planned to be 1 x 1m with 10 shelves. Water was supplied in a recirculating manner and automatic feeding of suspended nutrients (e.g. salmon smolt sludge) was done using an actuated diaphragm valve controlled by the control unit. The control system was used to regulate water flow rates, light intensity and photoperiod. A concept sketch of the prototype is illustrated in Figure 1.

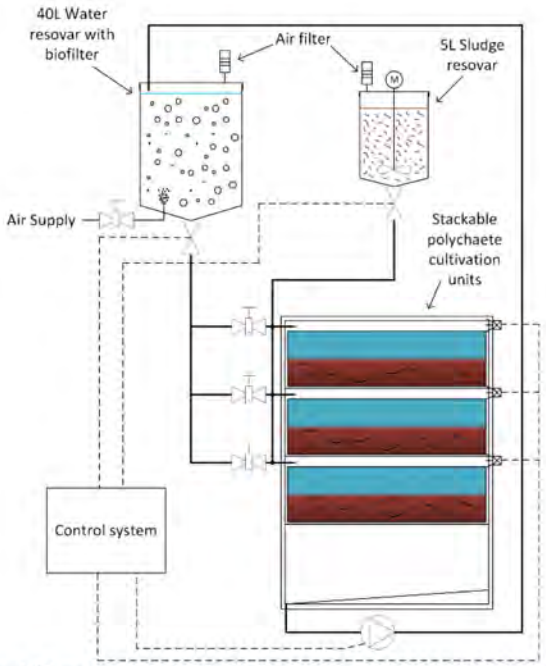

Figure 1 Conceptual outline of a production system designed for intensive cultivation of polychaetes

(Continued on next page)

Figure 2 Processed image of a polychaete where segments are marked with blue dots

A useful feature in this cultivation system is a machine vision-based system used for real-time monitoring of the worms coupled with automatic weight calculations based on L3-length. This feature allows for growth rate assessments without interfering with the worms in their burrows, monitoring worm densities and spatial distribution, and record mortality. We have experimented using state-of-art deep learning technology and computer imaging to automatically detect and count the number of segments in individual polychaetes, and the preliminary results look promising. Figure 2 shows an example of a processed image of a polychaete, where the blue dots indicate detected segments.

Future perspectives

The same technology used to detect segments is used to automatically measure L3 length (total length of prostomium, peristomium and first segment), a robust measure for worm size (Diaz-Jaramillo et al, 2011) when the worms come out of their burrows to feed, allowing to assess in situ growth rates in real time.

RAS SHRIMPS POTENTIAL ON THE POMERANIAN MARKET

H. Łądkowska*, B. Dmochowska, M. Normant-Saremba, and H. Kendzierska

Institute of Oceanography, University of Gdansk, Al. Marszalka Pilsudskiego 46, 81-378 Gdynia, Poland
hanna.ladkowska@ug.edu.pl

Introduction

With increasing global demand for seafood and the limited capacity for wild capture fisheries to meet our need, aquaculture will continue its growth and diversification. Recirculating aquaculture system (RAS) is an ideal solution which enables the production of food while sustaining natural resources. New RAS farms are emerging not only producing fish but also shrimps. Still, Poland plays no role in the sector. To change the current situation the team from the Institute of Oceanography, University of Gdańsk, has taken a challenge to develop the potential of shrimp aquaculture focusing on a combination of new species and technologies. In the course of InnoAquaTech project, the first demonstration facility for shrimps production in RAS system has been established at the University of Gdańsk. Two white leg shrimps' breeding experiments were carried out together with a series of outreach activities and consumer perception and awareness research.

Materials and methods

Shrimps *Litopenaeus vannamei* were grown in the small-scale laboratory RAS culture in two cycles. The cultivation trials were accompanied by outreach activities: Innovation aquaculture workshop (March 2017) and In the direction of crustacean farming: Innovative aquaculture – white shrimp – *Litopenaeus vannamei* summer school (September 2018). Feedbacks from the stakeholders of both events were crucial for further studies. The events were directed to aquaculture entrepreneurs, potential investors and specialists interested in recirculation technology and crustacean farming. In total, over sixty participants took part in the events. Furthermore, questionnaires were directed to consumers (first trial April 2018, 180 consumers questioned, 6 different questionnaires directed to 30 respondents each). The second trial of questionnaires (composed after verification of the first trial questionnaires) will be carried out in May 2019. Questionnaires directed to restaurants (April 2019, 104 restaurants questioned) were carried out in the Pomeranian region on public perception and market analysis of shrimps on the Polish market.

Results

Market conditions for the domestic production of warm-water shrimps seem to be very promising according to the presented research and discussions among stakeholders of the InnoAquaTech outreach events. Results of the so far carried out questionnaires show consumers recognize crustacean species available on the market very well. Still, restaurants representatives are very often not aware of the species the restaurant offers. Around 60% of the respondents (inhabitants of the Pomerania region) consume shrimps. And shrimps are the most popular crustaceans of all available on the market in the Pomerania region. However, the shrimps are consumed very rarely, the most frequent answer is once a month. Shrimps are mostly bought in the supermarkets, and the most important factor determining their purchase is the price. Still, all asked restaurants have shrimps in their menu. Also, restaurants consider price as the most determining factor in the shrimps purchase. Respondents who do not consume shrimp indicate other dietary preferences most frequently as the main factor for their decision. Most consumers are not aware either of the country of origin or the cultivation/capture method, having no awareness if the shrimps were caught or farmed. The same applies to restaurants, which the majority is not aware of the area of origin of the delivered shrimps nor the way of capture/cultivation. Most of the restaurants have no awareness in the area of RAS production, however, when explained, they are very willing to try the product and consider locally produced shrimp as a very promising option, regardless on the price. The results of consumers perspective and product awareness will be verified by the second trial questionnaires (May 2019)

(Continued on next page)

Discussion and conclusion

Public awareness of the RAS shrimp production is still poor in the Pomerania region. More educational campaigns and trainings are needed as the outreach activities together with the results of the questionnaires carried out showed. More research is required to change customer perspective and raise awareness of the RAS farmed products. So far obtained results in the pilot trial shrimps are characterized by a similar nutritional value as the same species imported to the Polish market, still contained higher levels of polyunsaturated fatty acids. Since the facility is established at the University of Gdańsk and has been well tested, it is planned to be developed and used for further demonstrations within the coming international projects, for both the experimental and the educational purpose. It is worth engaging restaurant sector into the promotion of new products such as RAS shrimps. Innovative aquaculture based on recirculating systems as well as the introduction of new species, such as shrimp *Litopenaeus vannamei* may give a high potential for investors and market in Pomerania but requires broad educational activities among stakeholders.

DIGITIZATION OF AQUACULTURE: REAL-TIME MONITORING AND PREDICTION FOR A SUSTAINABLE FUTURE

Maxime Lafont*, Ambre Vallauri, Samuel Dupont, Charlotte Dupont

BIOCEANOR SAS, 535, route des lucioles, 06560 Valbonne, France
maxime.lafont@bioceanor.com

Introduction

Aquaculture is a booming market since several decades and has surpassed fisheries worldwide (FAO, 2018). Like agriculture did, aquaculture needs to take the technological turn to be more simple, profitable and sustainable. The advancement of IoT will permits to answer to the digitization. In aquaculture, water quality is at the heart and its mastery is the key to success. Different parameters, biotic or not, such as pollutants, microbiological contamination, physico-chemical changes, coming to aquaculture can influence the quality of the breeding. These parameters can be disastrous for the farm and have dramatic consequences in the environment (Svobodová *et al*., 1993). The monitoring of water parameters is often long, expensive and gives a partial picture of the situation. The integration of sensors that we present in this paper, allow to measure water quality in real-time of a wide range of measurable parameters enabling a 3-dimensional view of the farm in real-time. To go further in this approach for aquaculture 4.0, it is now necessary to anticipate parameter changes that can influence the farms and more broadly the environment. The generation of large data sets coupled with big data analysis and machine learning now make it possible to anticipate the evolution of water parameters as the classical meteorology can do. The use and the control of the data leads to an improvement of the breeding techniques to anticipate risks from and to the farm. This transition to a connected aquaculture 4.0 will then allow to automate various processes towards a more profitable, sustainable and simplified management. This study was carried out to develop predictive algorithms to anticipate the evolution of dissolved oxygen in aquaculture farms.

Material and methods

The water parameters data were obtained by the Bioceanor products in an oyster farm in the Thau lagoon (Hérault, France), in an open environment. The water parameters were collected, using an autonomous energy measuring system coupled with a long-range radio wave transmission system (Aquabox, Bioceanor). This system allows the collection of water parameter data, processing and real-time visualization (less than 6s) on a computer interface (Aquareal, Bioceanor). The real-time analysis of the data enables to alert (by e-mail, sms) in case of exceeding of a critical threshold but also to store the data to access the history of measurements and for deeper analysis. Dissolved oxygen was managed every 20min during 21d, with 20d as training data and the 21th day as the test data. Data were aggregated to hourly level by arithmetic mean and imported in R Console for a 24h-ahead forecasting of dissolved oxygen (DO). The predictive model is based on an analysis of the DO signal by Complete Ensemble Empirical Mode Decomposition (CEEMD) proposed by Torres *et al.* in 2011. The resulting components were reduced into 4 components as recommended by Li *et al.* in 2018 and forecasted by Support Vector Regression (SVR) and Autoregressive Neural Network (ARNN). The 4 components were summed up to obtain the prediction of the DO signal.

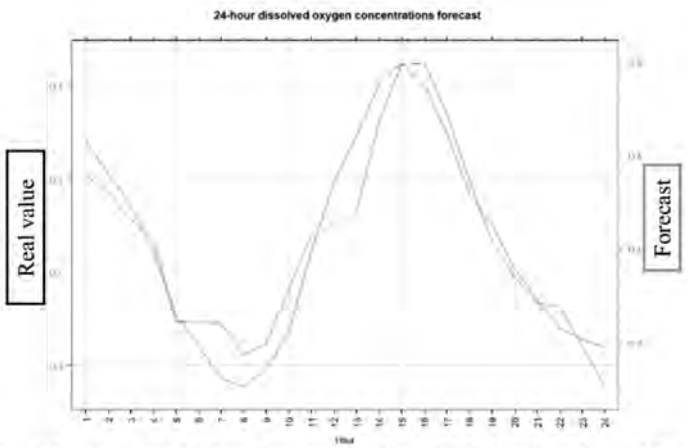

Fig. 1: 24h-ahead forecasting of DO concentrations (mg/L) with the CEEMD-SVR/ARNN model.

(Continued on next page)

Results

The results show an effective forecast of dissolved oxygen over a minimum of 24h. Based on the criteria of Mean Absolute Error equal to 3%, the predictive model tracked well the dynamics of DO, as shown in figure 1, overlapping the predicted (blue line) and the real (grey line) DO concentrations for 24h after 20d of data collection.

Discussion and conclusion

The complex model required a high computational cost, but it was able to predict the DO concentrations over 24h. Subsequently, the model can be used but with a lower stability. While all types of aquaculture are different and subject to several environmental impacts, the management and anticipation of input and output parameters are necessary for sustainable management. Therefore, integrating these parameters will greatly assist in improving the forecasts. Recently, the Convolution Neural Networks have proved successful (Ta and Wei, 2018). Theses algorithms thus provide an adaptability to various environments (such as fish/shrimp farms, open or closed like Recirculating Aquaculture Systems - RAS), and a global anticipation of the breeding. It will also make it possible to forecast parameters impossible to measure in real time, such as the bacterial microflora, reducing the need of long and expensive analyses. Correlative analysis coupled with forecasting algorithms could foretell risks of bacterial contamination of for example *Escherichia col*i or *Vibrio spp* in the field. Combining real-time measurements and forecasting systems in the aquacultures leads to a transition to aquaculture 4.0. Indeed, the opportunities of monitoring in real time providing a 3-dimensional view of farms coupled with prediction systems on the evolution of water parameters should revolutionize the management of aquaculture of tomorrow. These new systems assisted by the development of artificial intelligence will make it possible to automate many processes in aquaculture, for example aerator actuator in case of oxygen drop, the treatment or displacement of animals in case of risks contaminations, adjust the parameters of the water before they are harmful or even feeder actuator.

IN-DEPTH GENOMIC CHARACTERIZATION OF A UNIQUE COLLECTION OF RAINBOW TROUT ISOGENIC LINES

D. Lallias*, M. Boussaha, M. Bernard, A. Peigné, C. Ciobotaru, N. Dechamp, M. Dupont-Nivet and E. Quillet

GABI, INRA, AgroParisTech, Université Paris-Saclay, 78350 Jouy-en-Josas (France)
E-mail: delphine.lallias@inra.fr

Introduction

A unique collection of 19 isogenic homozygous rainbow trout lines has been established and maintained in INRA fish experimental facilities. These lines have been characterized for a variety of traits and proved to be a relevant resource to investigate the molecular bases of complex traits at different biological scales (cell, tissue, organism). Genomic characterization of the lines is pivotal to realize the whole benefit of this resource in integrative approaches aimed at dissecting complex traits and understanding the "genome to phenome" mechanisms. Having access to the genomic variability among lines is essential in functional or QTL studies in order to identify polymorphism(s) responsible for the phenotypes of interest and their variation. The objective of this study was to carry out in-depth genomic characterization of the trout isogenic lines, by investigating both small genomic variations (SNPs and InDels) and structural variants (SVs). SVs are defined as genomic alterations that affect large DNA segments ≥ 50 nucleotides, thereby causing modifications in either DNA quantity (insertions, deletions and duplications) or DNA structure (inversions). Although SVs have received increasing interest in many species and were shown to be associated with several diseases and phenotypes, they are poorly documented in fish

Material and methods

All isogenic lines (one or two individuals per line) have been resequenced at a depth of coverage ranging from 10X to 32X, on an Illumina HiSeq X-Ten platform, in paired-end 2x150 bp configuration. Analysis of small genomic variants was performed according to the GATK Best Practices. The identification and characterization of SVs was done by using 3 different tools corresponding to two distinct but complementary approaches: i) Pindel and Delly (split-read approach); ii) BreakDancer (paired-end approach).

Results

Search for small genomic variations with GATK Haplotype Caller software resulted in the identification of 15 064 416 SNPs and 3 173 673 InDels. A total of 17 037 putative SVs were identified, corresponding to 13 271 deletions, 3 386 tandem duplications and 380 inversions. Analysis of the length distribution revealed that most deletions (98.3%) were less than 10Kb (27.8% between 51bp and 1Kb), whereas the vast majority of tandem duplications (95.1%) were larger than 1Kb. Analysis of chromosomal distribution was also performed (Figure 1). Annotation of the SVs revealed a total of 8 326 regions which contain either entire genes or parts of genes, among them 5 967 deletions, 2 091 tandem duplications and 268 inversions.

Discussion

The fine characterization of rainbow trout homozygous isogenic lines will allow not only production of the information necessary for a full exploitation of the ongoing and future studies taking advantage of the contrasted phenotypes and/or of the original genomic features of the lines, but also add to the overall knowledge on rainbow trout genomic structure and polymorphisms and provide a description of broad interest of the structural and functional organization of its genome.

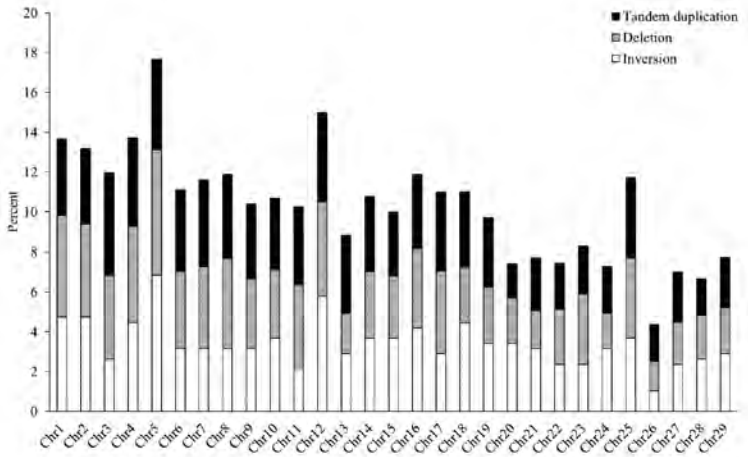

Fig. 1 Chromosomal distribution of SVs within the trout chromosomes.

ANALYSIS OF GENOMEWIDE PATTERNS OF DNA METHYLATION IN RESPONSE TO AN EARLY TEMPERATURE STRESS IN RAINBOW TROUT

D. Lallias*, E. Quillet, M. Bernard, C. Ciobotaru, N. Dechamp, J.-M. Le Calvez, M. Bideau, L. Goardon, L. Labbé and M. Dupont-Nivet

GABI, INRA, AgroParisTech, Université Paris-Saclay, 78350 Jouy-en-Josas (France)
PEIMA, INRA, 29450 Sizun (France)
E-mail: delphine.lallias@inra.fr

Introduction

We aim to investigate the potential role of epigenetic marks in the expression of phenotypes and their variability in fish, in particular to study whether the epigenetic marks established in response to an environmental stress depend on the genetic background. The environmental stress chosen here is temperature, a known induction factor of epigenetic marks in fish. In this context, rainbow trout isogenic lines are the material of choice. Within each line, all fish have the same genome i.e. there is no genetic variability. This allows the comparison of epigenetic marks among several individuals with the same genotype. The objective of this study was to test whether temperature regime experienced during early development leads to epigenetic modifications within and between lines

Material and methods

Six rainbow trout isogenic lines were chosen. For each line, half of the eggs were incubated at standard temperature (12°C) and the other half at high temperature (16°C), from eyed-stage to hatching. At eyed-stage just before hatching, analysis of HSP47 gene expression was performed by qPCR on 3 pools of 5 eggs per line and per incubation temperature. Also, genomewide patterns of DNA methylation were analysed by EpiRADseq on the same biological material. EpiRADseq is a reduced-representation library-based approach that has been recently developed and tested on a single clone of water fleas. The protocol was here modified to account for genetic variability and allow both within and between-lines comparisons

Results

An overexpression of HSP47 gene in the 16°C batches confirmed that the early temperature stress was successful. In total, 284 825 EpiRAD loci were defined, among which 102 354 were present in only one sample. In order to compare the lines, preliminary analysis was restricted to 57 129 loci that were common to the 6 lines. Globally, 325 loci spread across the genome (3 to 18 loci per chromosome) were differentially methylated between the two incubation temperatures, 169 loci being less methylated at 16°C compared to 12°C and 156 loci more methylated. This number differed between lines, ranging from 14 to 143 depending on the line (Fig. 1).

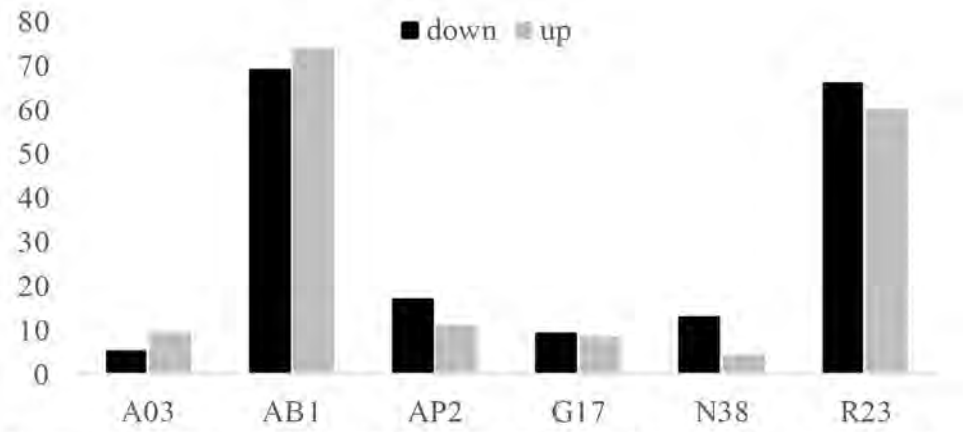

Figure 1. Number of differentially methylated loci between the two incubation temperatures (12°C vs. 16°C) for 6 rainbow trout isogenic lines. Down: less methylated at 16°C compared to 12°C; up: more methylated at 16°C compared to 12°C.

(Continued on next page)

Discussion

Rainbow trout isogenic lines are a unique biological model to study the interactions between genetics, epigenetics and environment. This study contributes to the understanding of the ability of organisms to cope with changing environmental conditions. Overall, the great majority of observed changes in methylation in response to an early temperature stress seem to be dependent on the genetic background. However, further studies are required. Preliminary analyses should be deepened by investigating the function of the genes located near differentially methylated loci. Analysis of expression of DNMT genes (DNA methyltransferase, involved in DNA methylation) could help to understand the establishment of differential methylation profiles during an early temperature stress. In the future, the impact of a longer exposure to high temperatures during early development could also be tested.

REPLACEMENT OF FISH MEAL USING ALTERNATIVE PROTEIN SOURCE IN FEEDS FOR PIKEPERCH *Sander lucioperca* (LINNAEUS 1758) DURING GROW OUT PHASE

S. Langi*[1], E. Panana[2], W. Meeus[3]

Email: Sandra.Langi@Ugent.be

Introduction

With the increase in the interest and culture of pikeperch *Sander lucioperca* (Linnaeus 1758) in RAS, one of the most critical issues still has to do with feeding. Pikeperch is a carnivorous fish and therefore has a high protein requirement. Currently, few companies produce commercial diets for pikeperch with fish meal as the main protein source. Finding alternatives to fish meal as the main protein source in fish feeds is critical especially as we strive towards more sustainable aquaculture production. There are limited studies investigating alternative protein sources in feeds for pikeperch in the grow out phase. No study has investigated a combination of feather meal with poultry meat and bone meal as a potential substitute.

Materials and methods

To demonstrate the effect of the different levels of fish meal replacement on growth of pikeperch, an eight-week feeding trial is on -going at INAGRO aquaculture research facility (Rumbeke, Belgium). Pike perch of an initial average body weight of 115g are being fed iso-caloric and isonitrogenous diets containing four different replacement levels of fish meal using a combination of feather meal with poultry meat and bone meal (Treatment A, B, C and D). The experiment is carried out in triplicate in recirculating aquaculture systems (RAS) in a randomized block design. Fish are sampled fortnightly and water quality parameters monitored. At the end of the feeding trial, fish will be bulk weighed and returned to their respective tanks for collection of feces for apparent digestibility analysis. Feed, feces and fish samples will be analyzed for dry matter, crude protein, ash, moisture, crude lipid and phosphorous. Visceral somatic index (VSI) and Hepatosomatic Index (HIS) will also be determined. Results will be statistically analyzed.

Results

Preliminary results after the first four weeks indicated that the fish accepted all the experimental diets. In the case of feed performance specific growth rate (SGR) was 1.65 ± 0.07% in treatment A, 1.65 ± 0.08% in treatment B, 1.60 ± 0.10% in treatment C and 1.44 ± 0.03% in treatment D. Feed conversion ratio (FCR) was 0.79 ± 0.01, 0.80 ± 0.03, 0.81 ± 0.01, 0.97 ± 0.04 (increasing alphabetically from treatment A to D). Results of proximate analysis, apparent digestibility coefficient, VSI, HSI and whole-body analysis are not yet available.

Discussion and Conclusion

These preliminary results show that a combination of feather meal and poultry meat and bone meal may have the potential to replace fish meal to some extent without have severe negative impacts on pikeperch during grow out phase. It is expected that the results on proximate analysis and apparent digestibility coefficient will provide a clear evidence of this. Concrete discussion and conclusion will be provided at the end of the feeding trial.

REPLACEMENT OF FISHMEAL USING ALTERNATIVE PROTEIN SOURCES IN FEEDS FOR PIKE PERCH *Sander lucioperca* (LINNAEUS 1758)

Introduction

Pike perch, *Sander lucioperca* (Linnaeus, 1758) is an emerging aquaculture species popular for its nutritional benefits, excellent flesh quality, good market value and as a sport fish. Pike perch is carnivorous and therefore has a high protein requirement usually met by fishmeal in commercial diets when cultured in recirculating aquaculture systems (RAS). The continued use of fishmeal is environmentally and economically unsustainable therefore, finding fishmeal alternatives is a priority. No study has assessed the potential of a poultry-based protein core comprising of poultry feather meal and poultry meat and bone meal as a fishmeal substitute in diets of pike perch.

Materials and methods

A 60-day growth trial was carried out to at Inagro aquaculture research facility (Rumbeke, Belgium). Four experimental diets were formulated in partnership with Odisee and Empro Europe (Dendermonde, Belgium). The positive control diet FM100 contained 55% of fishmeal as main protein source. In the 3 following diets i.e. FM80, FM60 and FM40, the percentage of fishmeal was gradually replaced by the poultry-based protein core. FM80, FM60 and FM40 contained 80%, 60% and 40% fishmeal compared to the FM100%, respectively. A total of 3000 fish with initial body weight (IBW) 113.09 ± 8.98 g were stocked in a total of 12 identical 1.8 m^3 circular RAS tanks in a randomized block design. A 12L:12D photo period was followed. The cut off biweekly feeding rates were 1.7, 1.5, 1.2 and 1.2% of total tank biomass. At the end of the feeding trial, feces were collected by dissection for apparent digestibility coefficient of protein (ADC) analysis. Proximate analysis of feed and whole fish carcass were carried out. Visceral somatic index (VSI) and Hepatosomatic index (HSI) were also determined.

Results

At the end of the study there were no statistically significant differences in feed intake between treatments. Feed conversion ratio (FCR) was significantly higher while final body weight (FBW), weight gain, final body length, protein efficiency ratio (PER) were significantly lower in fish in treatment FM40 in comparison to the other treatments ($p < 0.05$). There were no significant differences between treatments in condition factor (k), hepatosomatic index (HSI) and visceral somatic index (VSI). The ADC of protein decreased with increasing fishmeal replacement. The carcass of fish in FM40 had significantly higher ash content ($p < 0.05$) in comparison to the other treatments.

Discussion and Conclusion

The performance indicators observed in this study suggest that 40% of the dietary fishmeal could be replaced using a combination of poultry feather meal and poultry meat and bone meal in diets for pike perch without significantly affecting the growth and feed utilization.

Rhodomonas salina PRODUCTION: GOING FROM LAB TO SEMI-COMERCIAL SCALE

C. Latsos*, P. C. Oostlander, G.P. Verbeeke, M. Barbosa, R. Wijffels & J. van Houcke

HZ University of Applied Sciences, P.O. Box 364, 4380 AJ Vlissingen, The Netherlands
Email: christos.latsos@hz.nl

Introduction

The microalgae species *Rhodomonas salina* is known to be an excellent diet for all kinds of aquaculture species. The species has been successfully used in the production of live feed organisms such as copepods and rotifers (Zhang et al. 2013), as a larval diet for all kinds of shellfish (Seixas et al. 2009) and as a specialty diet in the refinement of oysters (Van Houcke et al., 2016). *Rhodomonas* species however, have been reported to be difficult to cultivate (Bougaran et al. 2010, Peltomaa et. al., 2017). Renaud et al. (2002) and Guevara et al. (2016) reported low growth rates (0.35 d^{-1} and 0.6 d^{-1}). Furthermore it has been reported that *Rhodomonas* cultures are prone to contamination with other algal species and that is therefore hard to keep *Rhodomonas* in stable cultures (Wang et al. 2013). These above mentioned problems have resulted in the lack of adoption of Rhodomonas cultivation in many aquaculture companies.

The aim of our research was to show successful *Rhodomonas salina* cultivation on a (semi-) commercial scale.

Methodology

In several experiments the effect of cultivation media, temperature and light intensity on the growth rate, volumetric productivity and yield on light of *Rhodomonas salina* have been investigated. Experiments were done in Algaemist-S lab-scale photo bioreactors (400 ml). Media evaluated in the experiments were NHN, L1 and GB. The temperature range evaluated was 10-30˚C while the light intensity evaluated ranged from 200-1500 µmol $m^{-2}s^{-1}$.

Validation of these lab-scale experiments was done using three commercial 200l tubular photo bioreactors (L-Gem, the Netherlands). Results from the lab-scale experiments (medium and temperature) were used as settings in the 200 l trails. As the 200 l reactors are placed in a greenhouse at the HZ University of Applied Sciences (Vlissingen, the Netherlands) light intensity and photoperiod were variable during the trails. Growth rate, volumetric productivity and yield on light were recorded during the trails.

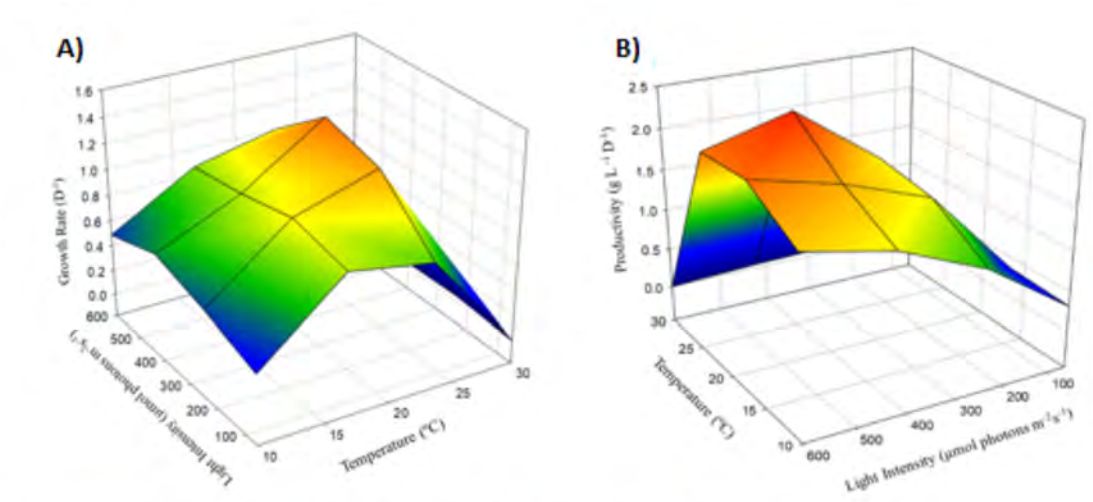

Figure 1: Optimization of Rhodomonas salina in lab scale experiments. Growth rate (A) and biomass productivity (B) for Rhodomonas salina. as a function of the supplied light intensity (µmol m-2s-1) and cultivation temperature (°C).

(Continued on next page)

Preliminary results and conclusion

The highest growth rate measured in lab scale experiments was 1.3 d^{-1} and maximum productivity was found to be 2.0 g l^{-1} d^{-1} with concentrated L1 medium. Optimal light intensity was 330 µmol $m^{-2}s^{-1}$ while optimal temperature was found to be 22-23˚C (Fig 1).

The commercial scale reactors were run in chemostat mode with a dilution rate of 0.35 d^{-1} and a biomass concentration varying from 2 to 5 million cells ml^{-1} depended on the natural light conditions.
The growth rate measured in the lab scale experiments is about twice the growth rate (1.3 d^{-1}) mentioned in literature. Growth rate was lower in the commercial scale trails, however this was due to a shorter photoperiod.

Introduction

Enhancing bivalve nursery technology is important for bivalve aquaculture, as deploying larger spat for on-growing has a significant effect on their survival (Cigarría and Fernández, 2000). However, spat have high nutritional requirements, in the order of 40% of live wet weight of the spat as diet dry weight (Helm and Bourne, 2004). Therefore, research efforts have been directed to develop cost-efficient and suitable diets for bivalve juveniles, including live or preserved microalgae, spray-dried microalgae, algae paste, artificial supplementation and single cell detritus (Hidalgo et al., 1994, Langdon and Onal, 1999, Caers et al., 2000, Nevejan et al., 2007, Carboni et al., 2016). Lipids represent the main energy reserve molecule in young spat (Holland and Hannant, 1974). To date, information available on bivalve lipid metabolism have been obtained through fatty acid or lipid class analyses. The application of these techniques has shown the importance of the essential fatty acid content in the diet for successful bivalve hatchery operations. However, such techniques can only target fractions or specific components of the lipidome (e.g. the totality of biological lipids). Recently, advancements in analytical platforms allow more holistic approaches, defined as untargeted lipidomics, to sample vast portions of the lipidome, providing detailed essential physiological information on organisms' biology and nutrition with minimal sample preparation work (Laudicella et al., 2019).

In this study, the effects of five diet are evaluated on growth performances (growth rate –GR and live weight increase – LWI) and the lipidome of recently settled *Mytilus edulis* (L.) spat. Four treatments included live single microalgae strains (*Cylindrotheca fusiformis* – CYL, *Isochrysis galbana* – ISO, *Monodopsis subterranean* – MONO and *Nannochloropsis oceanica* – NANNO), whilst the fifth being a commercial algae paste (InstantAlgae1800 – SP). The growth performances of lab-reared spat were compared with natural growth in outdoor deployed spats (OUT).

Materials and Methods

Recently settled Blue mussel (*M. edulis*) spat (shell length <5 mm) were placed in 10l tanks (static system, 20µm filtered seawater, aeration, 18^{0}C, 18:8 L:D). Diet was provided in a weekly ration of 0.4mgDW$_{diet}$ mgLW$_{spats}^{-1}$. Each treatment was replicated in three independent tanks with 30 spats per tank. The trial lasted for 4 weeks, at the end of which spats were measured and weighted before being snap frozen and stored (-80^{0}C). Diet fatty acid composition was analysed according to AOCS (2007). Untargeted lipidomics analyses were performed with a high-resolution LC-MS platform (Exactive, ThermoScientific) both in positive and negative ionisation modes. Acquired raw spectra data were processed with Progenesis QI (Nonlinear Diagnostics) and then analysed through the R package 'MetaboAnalystR' (Xia and Chong, 2018). Partial Least Square Discriminant Analysis (PLS-DA) was employed to identify the principal lipid responsible for groups clustering through variable of importance in projection (VIP) scores. These lipids were correlated (Spearman rank correlation) versus the spats' GR and LWI.

Results and Discussion

OUT deployed spat showed the best growth performances for GR and LWI. After OUT, the ranking order for GR and LWI in the lab reared spat sample groups was the following: ISO>NANNO/CYL>SP>MONO. All groups, apart MONO, resulted in significant increase in GR and LWI ($p<0.05$). PLS-DA analysis of untargeted lipidomics data evidenced the effect of diets on triacylglycerol (TG) accumulation in the spats, as poor performing groups (SP, MONO) resulted lower TG content ($p<0.05$). Furthermore, effects of the diet PUFA composition on spat phospholipids is also observed, with predominance of PC(38:6) in DHA rich diet (ISO), PC(36:5) in EPA rich diet (NANNO and CYL) and PC(36:4) in arachidonic acid (AA) rich diet (CYL). Several TG resulted positively correlated with GR and LWI across the different treatments (Spearman rank $R^2>0.91$ fdr-adj-$p<0.05$), suggesting their possible utilization as markers for spats growth performances. The results

(Continued on next page)

of this study show that ISO is a suitable diet for mussel spat, resulting in good GR and LWI. The elevate content of DHA in this diet is possibly one of the reasons for the good growth performances of spat fed with ISO. Diets lacking of DHA, but rich in other essential PUFAs (as EPA and AA), as CYL and NANNO, sustained spats growth, although with lower growth performances. SP, although balanced in the PUFA composition, resulted in minor growth, suggesting the use as partial substitutive for live algae. Fast growing spats are characterised by several TG species, thus lipidomics could represent a useful tool for identification of markers for mussel juvenile condition.

PROOF-OF-CONCEPT APPLICATION OF THE BENTHIC BOUNDARY LAYER TRANSPORT (BBLT) MODEL TO SALMON AQUACULTURE WASTE DISPERSAL

Brent A. Law*, Paul S. Hill, Adam Drozdowski, Fred Page

Bedford Institute of Oceanography
Fisheries and Oceans Canada
Dartmouth, N.S., Canada, B2Y 4A2
Brent.Law@dfo-mpo.gc.ca

Dispersal from a fin-fis aquaculture facility in Jordan Bay, N.S., Canada was simulated using the Benthic Boundary Layer Transport model (BBLT). The currents and waves were measured during the fall of 2014 and along with calculated bottom shear stress were used as model inputs. Four waste classes were considered: fines, flocs, feca waste and feed pellets, each with distinct settling velocities and critical erosion shear stresses. BBLT was used to simulate a 46-day continuous release scenario. The resulting concentration of each class within the cage site varied by approximately 5 orders of magnitude. The four classes mean concentration in bottom 10 cm under the cage were 0.003, 0.082, 122.4 and 234.6 g/m^3 respectively. Spatial patterns reveal the concentration of the fines to be relatively uniform inside and within a few hundred meters of the cage, and to fall by 1/10 a few kilometers away. Floc concentrations fall to 1/10 within a 100 m of the cage and by 1/1000 within a few kilometers. For fecal waste, concentrations fall by 1/10 directly outside the cage and may be undetectable a few kilometers away. Feed Pellet removal is somewhat more complicated due to the episodic deposition and advection of the sediment patch. However, just like for the fecal waste the concentration drops by at least an order of magnitude directly outside the cage and by as much as 1/1000 within a few hundred meters. The general direction of travel is to the south. The higher concentrations of fines and flocs in the far field as compared to fecal material and pellets represent a transport mechanism for constituents such as trace metals, pesticides and organics which have an affinity for the large surface areas of fine-grain sediments

Introduction

Aquaculture is one of the fastest growing food-producing sector. It represents the farming of aquatic species like fish, crustaceans, molluscs, aquatic plants and micro-algae. Recently, the fish demand is increasing, being twice as fast as the population growth since the 1960's [1]. To meet the demand, aquaculture is exponentially growing all over the world.

In order to contribute to the food security and safety in an overpopulated, aquaculture needs to be sustainable and with the lowest impact on environment as possible. IMTA is a form of multi-species production that provides the by products including waste, from one aquatic species as inputs to another The equilibrium of this kind of aquaculture production is complex to reach, and a lot of parameters, including water quality, needs to be finely managed

For instance, monitoring the water quality in the farms is one of the crucial steps in the commercial aquaculture process. It consists mainly of controlling, physical, chemical and biological parameters, such as: oxygen, temperature and pH in water, on an on-going basis in order to maintain precise conditions and avoid undesirable situations that may lead to issues for the aquaculture environment. Currently, aquaculturists are depending on manual testing due to the lack of integration of smart connected devices in aquaculture farms.

Integrating IoT technologies in aquaculture farms will lead to a new era of connected, responsible and efficient aquaculture. This compels the development of new IoT oriented applications in order to collect and control data from heterogeneous sources, and organise it in an inter-operable way for rapid and autonomous decision-making processes.

Technologies, such as semantic Web [2] and AI [3] are proposing new capabilities to promote data interoperability and to develop around it new smart and autonomous applications. Integrating such technologies through IoT based solutions in aquaculture will improve the decision-making, production control and management for all fish aquaculture systems. In this context, we exploit in this paper the existing vocabularies and semantic Web technologies in order to develop an interoperable semantic model that covers the core concepts required for aquaculture management used for organizing and managing data in aquafarms and exploited by smart and AI services automatically.

Vocabularies and Standards Requirement for Designing an IMTA Model

The aquaculture domain cover several fields. The principle in data modelling is not to develop a new model from scratch but to summarise required topics and relevant standardised vocabularies. Requirements for modelling aquaculture data are categorised in four main parts detailed below with one example of existing vocabulary for each one.

- Fisheries and Marine Environments:

The Food and Agriculture Organization (FAO) of the United Nations[1] maintains the AGROVOC vocabulary, which contains terms for over 36k concepts covering all areas of the FAO's interest, in food, nutrition, agriculture, fisheries forestry developed by experts around the world. Parterres of the project are initiated contacts with AGROVOC community in order to add new terms.

- Physical, Chemical and Biological Parameters

Physical, chemical and biological parameters are widely covered in terms of data standards, but, being a highly diverse set of concepts, not necessarily in single vocabularies. Individual standards for parameters relevant to aquaculture include WaterML[2].

(Continued on next page)

• Sensors and Measurements

Sensors and measurements are useful in an extremely wide range of fields and there have been a number of approaches to the sharing of sensor readings. Several standardised ontologies for IoT are proposed: SAREF[3], WOT[4], SOSA/SSN[5]… They present efficient ways for modelling Io data.

• **General Purpose Concepts**

Individuals and organizations present in aquafarms are also modelled and thus we have to refer to the foaf ontology[6]. Other filed such as date, time… have to be also referenced

Conclusion and Discussion

The work in modelling data of the aquaculture is in progress. The presented Reference Data Model has is developed using the Simple Knowledge Organization System, SKOS[7] ontology. SKOS is designed as framework for modelling relationships between vocabularies and facilitates the relating data models. SKOS is expressed in RDF[8] – every valid SKOS document is a valid RDF document, and is interoperable with the full Semantic Web technology stack. The actual step, is about identifying all possible terms according to project uses cases. Then, all these terms are referenced and aligned with the presented vocabularies. The future work includes adopting a standardised API for a standardised data accessing enabling smart services such as machine learning exploiting data. The research leading to these results has been supported by the iFishIENCi project, which receives funding from the European Union's Horizon 2020 Research and Innovation Program under grant agreement No. 818036.

Introduction

Aquaculture continues to develop rapidly, especially through its growth in Asia. In marine farms, the inputs are juvenile fish, fish feed, medicines, disinfectants and anti-foulants, and the outputs (losses) are harvested fish, escaped fish, uneaten feed, faeces, excreted metabolic wastes, and effluent chemical species e.g. medicines (Mente et al., 2006). The accumulation of effluents released, without being filtered, from the cages cultures in aquaculture may cause a changes in the benthos communities, eutrophication, which affects the natural ecosystem (Mente et al., 2006; McKindsey et al., 2011; Vidović et al., 2014; Lee et al., 2016ab). The objective of this study is to define the effect of biodeposits discharged from fish farms which converted from red laver farm on geochemistry of sediment and benthic foraminiferal assemblages in the shallow sea.

Materials and methods

Hwatedo is located at the entrance area of Gamak Bay which lies midway of the south coast in Korea with type of Ria. A sediment core sample collected from the fish farm located closely at landward analyzed the geochemical elements, ^{210}Pb dating measurements and benthic foraminiferal assemblage. Sediment core sampling also carried out at control plot far away from fish farms to understand the spreading and e fect of biodeposits.

Results

The sediment is composed mainly of fine-grained mud facies with average silt and clay contents of 47.03% and 52.65%, respectively, and a mean size of 8.45Ø. The contents of total organic carbon with average 1.29%, total nitrogen with average 0.17% and total phosphate with average 0.18% are shown gradually increasing profile from 23 cm of core depth, respectively. The concentration of Cu with average 34.03mg/kg increased gradually from 25 cm of depth to uppermost layer. This increase pattern in concentration of Cu are also shown at Zn (average 92.7mg kg^{-1}), Cr (average 44.87mg kg^{-1}), As (average 3.51mg kg^{-1}) and Cd (average 0.18mg kg^{-1}). Seven benthic foraminiferal assemblages with the dominant species of *Cribroelphidium excavatum* composed of *C. excavatum-Epistominella naraensis-Elphidium advenum-Ammonia beccarii* (Ce-En-Ea-Ab), *C. excavatum-A. beccarii-C. subarcticum-E.naraensis* (Ce-Ab-Cs-En), *C. excavatum-A. beccarii-E.naraensis-C. subarcticum* (Ce-Ab-En-Cs), *C. subarcticum-A. beccarii-C. excavatum-E. tamana* (Cs-Ab-Ce-Et), *C. excavatum-A. beccarii-C. subarcticum-A. ketienziensis* (Ce-Ab-Cs-Ak), *C. excavatum-A. beccarii-A. ketienziensis-C. subarcticum* (Ce-Ab-Ak-Cs), *C. excavatum-C. subarcticum-A. ketienziensis-E. naraensis* (Ce-Cs-Ak-En) are characterized by high similarity index of 88.1%.

Discussion and conclusion

Geochemical effect of fish farming on sediment is pronounced in increase of silt content and sedimentation fluxes in Zn_{EX}, Cu_{EX}, As_{EX} and TP_{EX} contents after red laver farming. However, seven benthic foraminiferal assemblages with the dominant species of *C. excavatum* was not shown the remarkable variation of assemblage and sustained the very low abundance frequency indicating bad habitat condition. *C. excavatum-A. beccarii-A. ketienziensis-C. subarcticum* assemblage of fish farming distributed from 21cm of depth to uppermost layer, among assemblages, is characterized by increase of *A. beccarii*. These are caused by the accumulation of organic matter discharged consistently from fish farm after red laver farm. *A. beccarii* is thought to the tolerant species to fish farming. Effect of fish farming on sediment geochemistry at control plot about 160m from fish far may be caused by tidal current.

Introduction

The rainbow trout (*Oncorhynchus mykiss*) is one of the major freshwater aquaculture fish species widely consumed because it has excellent taste and growth and is highly nutritious. Until recently, researchers have been doing experiments on the seawater adaptation of the rainbow trout in an attempt to enlarge its body size and improve its taste. Gills and skin are the organs that are directly exposed to the external environment and are known to control the concentration of ions and molecules to overcome the high osmotic pressure of the water. There have been many studies on various aspects of seawater adaptation and osmotic control capacity of Salmonidae fish so far (Kim et al., 2016; Richards et al., 2003). However, such an analysis has rarely been reported that the expression patterns of various osmoregulation proteins in skin tissues including the lateral line are analyzed at one point using transcriptome RNA-seq. Therefore, this study aims to analyze the expression patterns of membrane protein genes in skin ionocytes including the lateral line while the rainbow trout are exposed to brackish water.

Materials and methods

Rainbow trout (average weight is 99g) were transferred from the Pyeongchang fish farm (South Korea) to the laboratory and stabilized at a temperature of 16 ± 0.5°C and a dissolved oxygen level of 8.0 ± 0.5mg/ l. Brackish water (50% seawater) was used after filtration, and the individuals acclimatized in freshwater were transferred to the brackish water for the 3-week-adaptation. Then, some of them were randomly sampled. Skin tissues including the lateral line were extracted for a total RNA purification, and an RNA-seq library was constructed. After obtaining the sequencing, the researchers mapped the raw data to the rainbow trout genome assembly. The expression patterns were analyzed using BLAST2GO, gene ontology (GO; level 5), InterPro, GO-Slin and EggNog.

Results

About 82 to 83 percent of the raw data obtained by RNA-seq were mapped to the rainbow trout genome assembly (Table I). The Go (level 5) analysis performed for functional annotation indicates that in biological process (BP), genes in charge of the cellular protein metabolic process account for the highest portion. Meanwhile, in molecular function (MF), genes related to DNA binding takes up the highest. As for the cellular component, genes concerning nucleus are expressed the most. In order to validate the expression patterns of RNA-seq, qRT-PCR was performed on membrane protein genes for osmoregulation (Table II). The result was similar to the expression patterns of RNA-seq.

Discussion and conclusion

The osmoregulation capability of various membrane proteins in skin ionocytes including the lateral line of rainbow trout was studied. When transferred from fresh water to brackish water, the rainbow trout showed various gene expression patterns including sodium/potassium-transporting ATPase subunit alpha-1 (ATP1A1), sodium/potassium-transporting ATPase subunit alpha-2 (ATP1A2), sodium/potassium-transporting ATPase subunit alpha-3 (ATP1A3), sodium/hydrogen exchanger 1 (NHE1), sodium/hydrogen exchanger 1 (NHE2), sodium/hydrogen exchanger 6 (NHE6) and aquaporin (AQP3) which are found in other Salmonidae fish (Choi et al., 2013; McCormick et al., 2009). Also, faced with stress, the rainbow trout expressed various genes to maintain homeostasis.

This study observed gene expression patterns of rainbow trout both in the fresh water environment and in the brackish water, and then categorized the osmoregulation membrane genes according to their functions. The findings of this study are expected to be the basis for future research on the osmoregulation capacity of other Salmonidae fish and their ability to maintain homeostasis.

Bacillus spp. was found to have great potentials as supplemental probiotics in diets for shrimps. A control was made without the probiotic supplementation and four other diets were prepared by inclusions of *B. subtilis* (*BS*) alone and a mixture of *BS* and *B. pumilus* (*BP*) at different levels (0.1 x 10^{10} *BS*, 0.2 x 10^{10} *BS*, 0.1 x 10^{10} *BS*/*BP*, 0.2 x 10^{10} *BS*/*BP* diets for control, *BS*0.1, *BS*0.2, *BS*/*BP*0.1 and *BS*/*BP*0.2, respectively). Quadruplicate groups of shrimp (average body weight, 0.14 g) per each diet were hand-fed the diets for 8 weeks. Shrimps fed *BS* containing diets showed significantly higher apparent digestibility coefficient of dry matter and protein than shrimp fed the control diet. Phagocytic activity of shrimp fed the probiotic diets except for *BS*0.1 was significantly increaed than shrimp fed the control diet. Shrimp fed the probiotic diets showed significantly increased phenoloxidase activity compared to the control diet. *BS*0.2 shrimp group showed significantly higher antiprotease activity than the control group. Glutathione peroxidase activity was significantly improved in shrimps fed the probiotic diets except for *BS/BP*0.2 diet. The growth was significantly improved in shrimp fed *BS*0.2 and *BS*/*BP*0.2 diets compared to that of shrimp fed the control diet. Significantly lower feed conversion ratio was obtained from shrimp fed the probiotic diets except for *BS*/*BP* 0.1 than that of shrimp fed the control diet. In a zero water exchange test, shrimp fed the probiotic diets resulted in lower total ammonia concentration than shrimp fed the control diet (Fig. 1). In conclusions, the tested *Bacillus* spp. can positively affect digestibility, innate immunity, water quality, growth performance and feed utilization efficiency of *L. vannamei*.

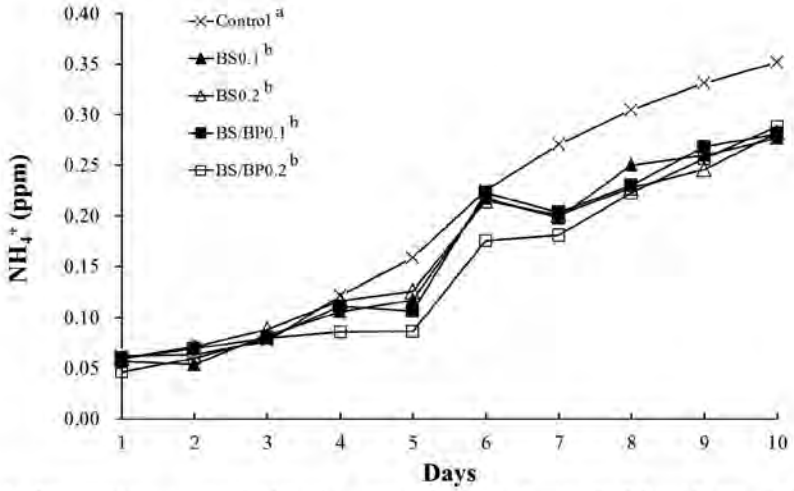

Figure 1. Ammonium concentration in a zero water exchange test for 10 days. Triplicate groups of shrimp were hand-fed with one of the test diets four times a day during the period.

ANIMAL WELLFARE AND HIGH YIELDS ARE NOT CONTRADICTORY

Introduction

High stocking densities and poor water quality are stressors for fish in aquaculture causing decreasing growth performance, depressing immune system functions and leaving fish even more vulnerable to infections (Bly *et al.* 1997, Tort 2011). Environmental and human health concerns have resulted in a ban of most chemical control agents inside the EU (EG1272 2008).

"Functional Feeds" that increase natural defense mechanisms have been studied as alternative treatments (Hoseinifar *et al.* 2015, Azimirad *et al.* 2016); however, feed competition prevents equal distribution between all fish. Because of their large surface area, gills are often portal of entry for pathogens, but at the same time are prone to xenobiotics in the water. We therefore hypothesized that immunostimulation can be achieved by supplementing the water with additives.

Humic substances are natural products, used as feed supplements in agriculture because of their growth-enhancing, immune-stimulatory and stress-reducing properties (Steinberg 2003, Islam *et al.* 2005). Up to 95% of dissolved organic matter in aquatic ecosystems is humic substances (mainly fulvic acid), giving them a great potential to be used in aquaculture.

Material and Methods

Juvenile rainbow trout (*Oncorhynchus mykiss)* were exposed for 4 weeks in a flow through system to 5 and 50 mg C/L of a fulvic acid. After first sampling, remaining fish were captured and exposed to air for 30s. Ninety minutes post-stress, blood was sampled again in order to determine stress response and recovery. Remaining fish were sampled two days post-stress for effects of stress on immune parameters.

Morphometric parameters were measured prior and after exposure. Head kidney cells were isolated to measure phagocytosis with heat inactivated yeast cells and respiratory burst activity by nitro blue tetrazolium reduction (Crampe *et al.* 1998). Plasma samples were taken to determine stress and immune response; Cortisol was measured with an ELISA, lysozyme activity as reduction of absorbance of a *Micrococcus lysodeikticus* suspension (Sitjà-Bobadilla *et al.* 2008) and protein content following Bradford (1976). Furthermore, immune response of gills was determined by same methods in supernatant of gill homogenates.

Results

Relative growth rate was significantly increased in the 50mgC/L group (20% in length and 57% in weight) compared to the control group (15% in length and +47% in weight). A similar trend was also apparent in the 5mgC/L group. Feed conversion ratio was decreased from 1.04 to 0.79 in groups exposed to the high concentration of fulvic acid. Lysozyme activity in the gills of the fish exposed to 50mgC/L was significantly higher compared to the control fish (238U/mL and 190U/mL, respectively); however serum lysozyme activity was not affected. Phagocytosis rate of head kidney cells increased from 31.5% to 57.6% and 70.7% after exposure to 5 and 50mgC/L, respectively. Phagocytosis index increased from 1.8 to 2.2 and 2.3 ingested particles/phagocyte after exposure.

Discussion and Conclusion

Fulvic acid is a natural product that occurs in aquatic ecosystems. Our results show that fulvic acid can be used as additive in order to improve growth of juvenile rainbow trout and to stimulate the immune response. Growth was significantly improved after 4 weeks of exposure. In addition immune parameters were increased, especcially in the gills, which are an important portal of entry for pathogens. Furthermore, we showed that in general immunostimulation can be acchieved by addition of stimulatnts to the water body. Up to our knowledge, this is the first time increased gill-associated immunity was determined after exposure to a water additive. Although more research on the application of fulvic acid is needed, such as application to different life stages of fish and under facility conditions, it is evident, that it improves growth and stimulates the immune system and has the potential to reduce mortality by infections in aquaculture.

DIETARY SUPPLEMENTATIONS OF *Bacillus* spp. IMPROVES INNATE IMMUNITY, GROWTH PERFORMANCE AND DISEASE RESISTANCE OF PACIFIC WHITE SHRIMP (*Litopenaeus vannamei*) AGAINST WHITE SPOT SYNDROME VIRUS AND ACUTE HEPATOPANCREATIC NECROSIS DISEASE

Chorong Lee[1], Ji Eun Kim[2], Hayun Jo[2], Sung Hun Kim[2], Jae Won Kim[2], Jong Su Eun[2] and Kyeong-Jun Lee[1*]

[1]Department of Marine Life Sciences, Jeju National University, South Korea

Under the field conditions, multiple infections by more than one pathogen can cause much greater losses in shrimp culture than any single infection. White spot syndrome virus (WSSV) and acute hepatopancreatic necrosis disease (AHPND) infects shrimps and spread rapidly causing a serious loss of the shrimp production in the world. However, there is limited information available on the multiple disease infections. A control was prepared without probiotic supplementation and four other diets were prepared by inclusions of *B. subtilis* (BS) alone, and a mixture of *BS*, *B. pumilus* (BP) and *B. licheniformis*(BL) at different levels (0.2 x 10^9 BS, 0.2 x 10^{10} BS, 0.2 x 10^9 BS/BP/BL, 0.2 x 10^{10} BS/BP/BL diets for the control, $BS10^9$, $BS10^{10}$, $BS/BP/BL10^9$, $BS/BP/BL10^{10}$, respectively). Quadruplicate groups of shrimp (average body weight, 0.15 g) per diet were hand-fed the diets for 51 days. Shrimp fed the $BS/BP/BL10^9$ diet had significantly higher phagocytic activity than shrimp fed the control diet. Growth performance and feed utilization efficiency were not affected by the probiotics. After the feeding trial, the shrimp were challenged with WSSV and *V. parahaemolyticus* through an immersion method for 187h. Survival was numerically higher in shrimp fed the probiotic diets (except for $BS10^9$) than in shrimp fed the control diet (Fig. 1). The findings indicate that innate immune response and disease resistance of *L. vannamei* against WSSV and AHPND can be improved when they are fed the tested *Bacillus* spp.

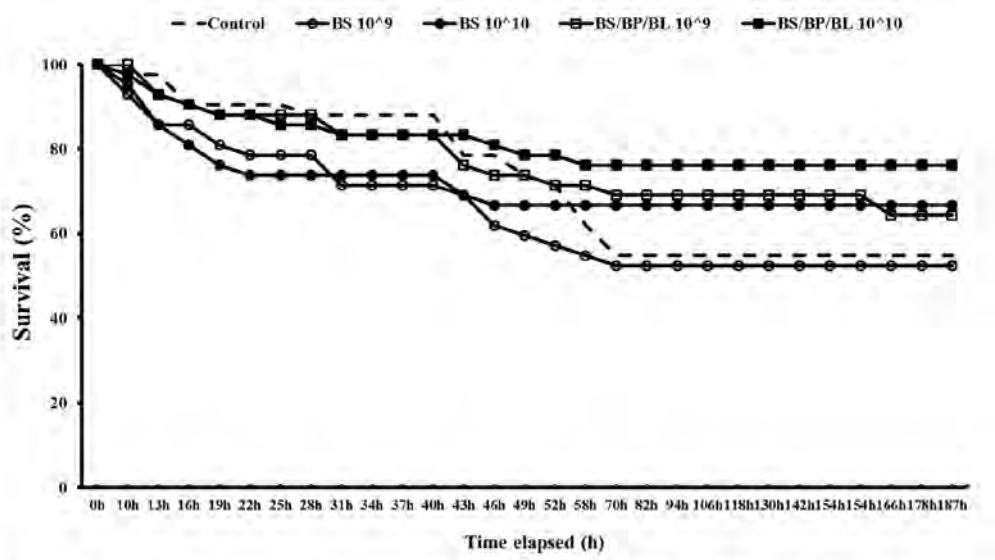

Figure 1. Survival rate of *L. vannamei* after challenged against WSSV and *V. parahaemolyticus*. Quadruplicate groups of shrimp were hand-fed with one of the test diets two times a day during the challenge period.

MOLECULAR CLONING, CHARACTERIZATION AND EXPRESSION OF OPSIN1 SUBFAMILY GENES FROM MUD LOACH (*Misgurnus mizolepis*)

S.Y. Lee[a*] and H.J. Lee[b]

aThe East Coast Research Institute of Life Science, Gangneung-Wonju National University, Gangneung 25457, South Korea

E-mail: lsy0423@gwnu.ac.kr

Introduction

The Mud loach (*Misgurnus mizolepis*) is a species that lives mainly in fresh water environment with shallow depths or changes in water level such as ponds, rice fields and waterways. They prefer dark places over bright ones and bury their bodies in the dirt. Mud loach can be found throughout Korea, but the number is gradually decreasing due to environmental changes, and much of it is supplied through aquaculture. In addition, mud loach farming systems have been conducted in a similar manner for a long time, and studies on growth, immunity, and induction of sexual maturation through various environmental conditions are less than those of other farmed fish. To date, various fish species have been studied for growth and immunity through food or administration, such as feed development research and functional peptide development. Recently, research has been published that improves the environmental conditions of fish as well as providing nutrition, resulting in increased growth and immunity. In particular, research has shown that it is possible to improve fish productivity by adjusting the type, intensity and exposure time of light sources. Therefore, the aim of this study was to identify the types of opsin protein genes that detect and absorb various light sources in retina tissues in mud loach eyes and to investigate their structure and expression characteristics.

Materials and methods

In-vivo experiments were conducted to investigate the effects of loach on light sources for each wavelength. The control group was set to two groups of natural light and non-light, and the experimental group was tested by exposing the respective wavelengths of LEDs (blue, green, red) to each tank. The eye and brain tissues were extracted and used for expression analysis of opsin genes. To identify mRNA structures of opsin genes, 3 ‘and 5’-RACE libraries were constructed and the genes were isolated using PCR amplification. In addition, opsin genes and amino acid structure comparison and phylogenetic analysis of other fish species were performed. We carried out qRT-PCR to investigate the effect of LEDs stimulation on the opsin genes in eye and brain tissues, and the expression of growth hormone and sex maturation genes.

Results and Discussion

As a result, opsin1 gene in mud loach retina was found to have short-wave-sensitive, long-wave-sensitive, and medium-wave-sensitive protein genes like other fish. Also within each opsin1 gene, various genes existed on the chromosome in the form of sub-isoforms. As a result of gene expression, various expression patterns were observed according to the LEDs stimulation of each wavelength in the eyes and brain, and the expression of growth hormone gene and sex maturation gene was also different according to the LEDs stimulation. The results of this study will be used as basic data for the study of protein in the fish eye and induction of growth and maturit .

Introduction

To meet the global food security needs of an expanding population, aquaculture production has grown rapidly Godfray et al. (2010). Atlantic Salmon *Salmo salar* are one of the most intensively farmed species in Europe and have a high dietary protein requirement. Traditionally, fish meal and plant proteins have been used to meet this dietary need, but the scale of aquaculture growth, negative environmental impacts and rising cost of sourcing large protein quantities hves driven a search for new protein sources Naylor et al. (2009). Single cell proteins, such as the protein-rich yeast, *Candida utilis*, represent a promising source of new material for future aquafeeds. It can be produced in industrial bioreactors using substrates derived from sustainable low-value feedstocks such as wood residues and has an amino acid profile appropriate for salmonid diets. Yeasts have historically been used in animal feeds as an additive to improve health, but cost and low protein content of standard production has limited applicability to *Salmo salar* diets Øverland et al. (2013). The juvenile stage of *Salmo salar* is a period of highest protein demand and fast growth and gut development, making it ideal to assess the potential of new protein sources NRC (2011).

Altering dietary protein can significantly change the gut microbiome of fish. This is important since the gut microbiome is linked to immune development, nutrient uptake and growth performance Ringø et al. (2016). The gut microbiome of juvenile salmonids is under studied and recently published literature highlights the challenging nature of characterizing the gut community Michl et al. (2019).

Candida utilis will be assessed in the diet of juvenile salmonids and this study aimed to investigate both the effect of increasing replacement of fish meal and plant protein blends meal on growth performance and the composition of the gut microbiome to inform the optimal development of future sustainable aquafeeds.

Materials and methods

Juvenile *Salmo salar*, of an average start weight of 1.14g were fed in quadruplicate tanks on 5 diets that increasingly replaced fish meal with *Candida utilis* at levels of 0%, 5%, 10%, 15%, and 20% and another 5 diets that increasingly replaced a plant protein blend with *Candida utilis* at levels of 0%, 5%, 10%, 15% and 20%. The *Candida utilis* cell biomass was produced in a 50-litre bioreactor using a hardwood carbohydrate hydrolysate as substrate and had a higher protein content than a standard industrial product at 52%. Growth performance of each diet was assessed by weighing all individuals before and after a 35-day feeding trial at 9.0±5°C in freshwater and statistically comparing results between feed

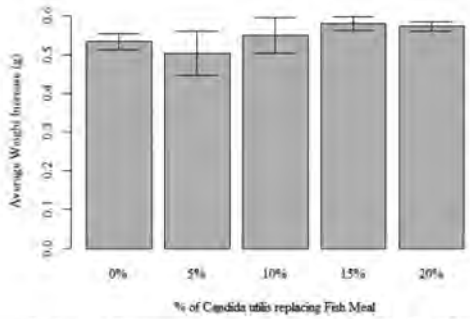

Fig. 1. Increase in weight (g) of *S.salar* fed diets where *C.utilis* replaced fish

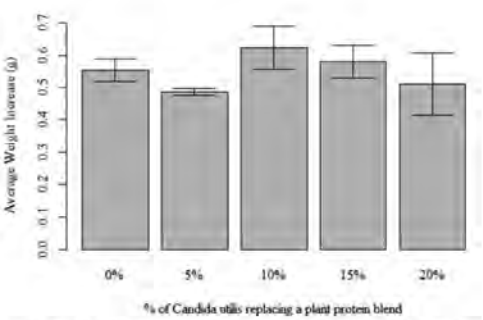

Fig. 2. Increase in weight (g) of *S.salar* fed diets where *C.utilis* replaced a plant protein blend.

(Continued on next page)

treatments. After a further 14-day feeding period 9 fish from each feed treatment were sampled for gut microbiome analysis of the mid and hind gut. Whole guts were processed using a novel DNA extraction protocol adapted from the QIAamp power fecal Pro kit by Qiagen with selective enrichment for prokaryotic DNA. Samples were then sequenced using the MiSeq Illumina platform to provide information about the bacterial community present for each feed treatment. Diversity indices and presence absence measures were statistically compared between feed treatments.

Results

Weight (g) of fish fed different feed treatments showed not significant difference after a 35-day growth period when either only fish meal was replaced at levels of (0%, 5%, 10%,15% or 20%) (figure 1), or when a plant protein blend replaced at levels of (0%, 5%, 10%,15% or 20%) (figure 2) by *Candida utilis*. The MiSeq Illumina sequence data from the gut microbiome of fish from different feed treatments will be presented at the European Aquaculture Symposium 2019 along with the statistical results from a comparative analysis of diversity indices of the gut communities.

Discussion and conclusion

Growth performance results suggest that the yeast *Candida utilis* can successfully replace both pure fish meal and a plant protein blend in the diets of juvenile *Salmo salar,* up to 20%, despite the high crude protein requirement of this growth stage NRC (2011). This result supports existing aquafeed research that suggests that many single cell proteins have comparable amino acid profile to fish meal, making them a promising replacement. The results from this study support the continued development of *Candida utilis* in salmonid diets and the results from sequencing will provide in-depth examination of how this protein alters the gut microbial community, which may have far reaching consequences.

THE ROLE OF INTERNET OF THINGS FOR HEALTHY FISH AND ENVIRONMENT IN THE EUROPEAN AQUACULTURE

Giuseppe Lembo*, Pierluigi Carbonara, Sebastien Alfonso, Walter Zupa, Maria Teresa Spedicato

COISPA Tecnologia & Ricerca, Via Dei Trulli 18, 70126 Bari, Italy
E-mail: lembo@coispa.it

Introduction

The overall objective of the project FutureEUAqua is to promote sustainable growth of environmental friendly organic and conventional aquaculture to meet future challenges of the growing consumer demand for high quality, nutritious and responsibly produced food. In WP5 of the FutureEUAqua project we are committed to develop and test a multiplatform tracking system for simultaneously monitoring the activity and physiology of fish, as well as the main parameters of the environment where they are farmed, by using a wireless communication system. The study of aquatic animals (e.g. fish behaviour, condition, physiology) and the farming environment presents unique challenges to scientists because of the physical characteristics of water. However, scientific studies and efforts have increasingly turned to the use of electronic sensors, which have enhanced our knowledge on the performances of the farmed fish and the impacts on the surrounding aquatic system. In their most basic form, electronic sensors and tags may include radio or acoustic beacons transmitting signals, which can bring specific codes to identify animals, and allow them to be tracked using receivers that detect the transmitted signals (Hazen et al. 2012). Basic archival tags must be, instead, physically recovered in order to obtain the data. Because the strength of radio signals rapidly attenuate in seawater, acoustic transmissions is preferred for fish tracking in marine environment (Lembo et al., 2002), while radio transmission is commonly used in freshwater environment. More advanced tags incorporate sensors that measure and record a suite of environmental and/or biological parameters of fish (Cooke et al. 2016). Simple biomass estimators and logging stations, installed on the feeding barge and/or on the cages, can give full control over all water parameters and provide the information required to monitor/expand the production. Flexible sensors systems are conceived to log oxygen, temperature, salinity, sea current, pH, wind and CO2. In addition, sensor and camera systems may provide also information for estimating the biomass in the cages and developing reliable fish feeding strategies. Indeed, electronic sensors are significantly improving our understanding of fish behaviour and are emerging as key sources of information for improving aquaculture management practices. The wireless communication system to monitor the large scale demonstration activities foreseen in the project FutureEUAqua will both facilitate effective study design and replication, increasing the accuracy of data standardization, processing and interpretation (e.g., Huveneers et al. 2016), providing industry with the information needed to facilitate health/welfare and optimal management practices.

State of the art

A first step activity carried out in WP5 was the review of the state of the art and future needs in terms of technologies for fish tracking, environmental monitoring and biomass assessing. The most relevant technologies and methodologies are described below. Accelerometer pressure tags transmit 3D acceleration of fish as they move within the receiver array and also transmit depth data. This acceleration value can be used as a measure of activity of a free ranging animal in nature or captivity. Applications may include measuring swimming speed via tail beat acceleration, feeding events, spawning activity, nocturnal/diurnal activity and responses to changing oxygen, salinity and temperature in the environment. Electromyogram (EMG) transmitters measure muscle activity using probes inserted into the musculature of the fish. They provide a powerful quantitative estimate of the energetic costs associated with physical activity of fish. EMG values can be calibrated in terms of fish oxygen consumptions measured over periods of spontaneous activity or over the same times in swims of selected speeds and durations, by using a swimming chamber. This in turn allows to obtain quantitative estimates of the metabolic costs of activity of farmed fish. The bioenergetics of the target species (muscular activity patterns) can be modelled, based on fish mass and swimming speed, to predict the mass-specific standard metabolic rate (SMR), the active metabolic rate (AMR) and the scope for activity (SFA). The difference between AMR and SMR indicates the energetic expenditure available to support all locomotor and physiological activities (SFA). The oxygen consumption rate (MO2) can be measured during exhaustive swimming trials (U_{crit}), carried out in swimming chambers, to estimate the energetic expenditure linked to the different swimming velocities. MO2 can be further calibrated with the signals transmitted by the tailbeat accelerometer tags, as well as with the EMGs signal received via two pairs of wire electrodes surgically implanted in both the red and white muscle (Zupa et al., 2015). The calibration gives the possibility to correlate each single swimming level of the fish to the oxygen consumption rate (e.g. Carbonara et al., 2014). In this way, the activity based energetic expenditure can be assessed (i.e. the fish physiological status), as well as the relative cost of living for fish in their environment. Fish detection and size measurement using acoustic signals has been used in research to measure fish

(Continued on next page)

size of farmed fish, although with severe limitation due to how inaccurate these measurements inherently are. Also infrared (IR) beam technology has been utilized in aquaculture to detect the presence of fish and biomass estimation. The concept utilizes an IR emitter on one side and an IR receiver on the opposite side. When the fish pass between the two then the beam is interrupted and the receiver will register the appropriate event. Moreover, mention should be made of underwater stereo-video systems, which are capable of making accurate, non-invasive measurements of fish length by analysing the pair of simultaneously captured images.

A real-time wireless communication system and sensor network

A real time wireless communication system and sensor network will be tested during the large scale demonstration activities. The system architecture includes a family of compact, submersible environmental sensors (e.g. dissolved oxygen, temperature, salinity, turbidity, tilt, etc.) with underwater and in air wireless communications. A cloud-based platform will allows to view and analyse data from the aquaculture sites in real time. The core of the system will be based on a hub supporting many telemetry protocols for cloud communications, including Cellular, Wi-Fi and Iridium. The wireless hub will supports also third-party sensors (e.g. accelerometer pressure tags, biomass monitoring systems, etc.) via its auxiliary sensor port. This technology will enable data-driven ocean farming where knowledge drives better decisions.

In a continuous sustainability improvement process, the aquaculture sector has been interested for many years in various alternatives available in terms of marine products substitution. Innovative raw materials such as algae, microorganisms or insect meal are becoming more and more popular.

Following July 2017's authorization of insect meal in the fish and shellfish diet, Le Gouessant Aquaculture, a major player in aquaculture nutrition in France, has set up two comparative trials under experimental conditions and three trials on fish farms.

The target of those studies conducted between October 2018 and March 2019 was to evaluate black soldier fly meal (BSF, hermetia illucens) as a partial or total alternative to fishmeal. This insect meal influence on the rainbow trout (Oncorhynchus mykiss) zootechnical performances was observed during the fish growing stage with weights ranging from 120 g to 700 g.

In the first test set up in an experimental station, three diets were tested, containing respectively: 25% of fishmeal, 12.5% of fishmeal and 12.5% of BSF meal, meaning a 50% substitution, and a last one with 100% substitution by BSF meal. This test was conducted in 2 phases. In the second test, a control feed containing 23% fishmeal was compared to a feed where 50% of the marine protein was replaced by BSF meal, meaning 12.5% because the BSF meal is less protein-rich than fishmeal.

During these trials, two different suppliers of BSF meal were solicited. In the first trial, the two insect-containing feeds showed similar performance on the first part of the test, and then slightly lower than those of the control on the 2nd phase ($P < 0.001$). However, during the second test, the feed with insect meal induced a better growth than the control feed ($P < 0.001$). Tests conducted in fish farms showed trends equivalent to those obtained in experimental structures. Fish nutritional composition and organoleptic analyses were performed, but no differences in the measured parameters were statistically significant.

Overall, the results confirmed the interest of this innovative ingredient. In fact, it is conceivable to substitute partially or totally fish meal with insect meal in a rainbow trout diet. Those conclusions encourage the study of future promising leads: interests in other aquaculture species, or livestock health.

THYROID HORMONE RECEPTORS A NEW PLAYER IN LARVAL METAMORPHOSIS OF THE HARD-SHELLED MUSSEL

Yi-Feng Li*, Xiao Liang, You-Ting Zhu, João C. R Cardoso, Deborah M. Power, Jin-Long Yang

College of Fisheries and Life Science, Shanghai Ocean University, Shanghai (China)
E-mail: yifengli@shou.edu.cn

Introduction

Many marine invertebrate larvae undergo a dramatic morphological and physiological transition from a planktonic larva to a benthic juvenile. Settlement occurs when larvae acquire "competence" and can respond to specific cues, that trigger a rapid metamorphosis and fixation to the substrate (Heyland et al., 2005). Metamorphosis in bivalves is correlated with morphological and physiological changes that include dramatic resorption and remodelling of larval and juvenile tissues. The regulation of this metamorphosis in bivalves remains enigmatic. The recent identification in bivalves of a thyroid hormone receptor (TR) gene raises the possibility that as occurs in vertebrate metamorphosis, TRs regulate this developmental process.

Materials and methods

Adult mussels were collected from Gouqi Island, (30↑72↑ N; 122↑77↑ E), Zhoushan, Zhejiang Province, China, in March 2017. Spawning and larval rearing followed the methods described by Yang et al. (2014). Swimming straight-hinge veliger larvae developed two days after fertilization and was maintained in 2 L glass beakers until they reached the pediveliger stage when siRNA transfection and metamorphosis assays were performed.

Results

An evolutionary study of TR receptors revealed they are ubiquitous in the molluscs. a single McTR gene was isolated from *M. coruscus*. An aa sequence alignment with vertebrate and invertebrate TR orthologues confirmed that McTR is a TR homologue. The BI tree showed that the TRs from invertebrates clustered separately from the deuterostomes and that McTR grouped closely with the other mussel TRs and they formed a specific cluster apart from the oysters TRs. Two TR genes (TRα and TRβ) were found in vertebrates but only a single TR gene was identified in invertebrates indicating that TR gene duplication occurred after the divergence of the vertebrates. Knock-down of the TR gene in the hard-shelled mussel, *Mytilus coruscus (Mc)*, using electroporation of siRNA significantly ($P < 0.01$) reduced TR gene expression. TR gene knock-down decreased pediveliger larval metamorphosis by 54% and was associated with a significant ($P < 0.01$) reduction in viability compared to control larvae.

Conclusions

TRs are ubiquitous across the bivalves. In the hard-shelled mussel TRs are essential regulatory factors for successful metamorphosis of the pediveliger larvae to a juvenile. The involvement of TRs during metamorphosis of bivalves suggests this function emerged early during evolution. It is revealed that electroporation is a practical approach for gene knock-down in minute marine invertebrate larvae.

EFFECT OF ARTIFICIAL LIGHT ON THE GROWTH AND SERUM CORTISOL LEVEL OF JUVENILE CHINESE SOFT-SHELLED TURTLES (*Pelodiscus sinensis)*

Haijun Li*, Songming Zhu, Zhangying Ye

College of Bio-systems Engineering and Food Science, Zhejiang University, Hangzhou, 310058, PR China
E-mail: lhjahau@zju.edu.cn

Introduction

It is well known that all living things depend on the sun for their growth. Therefore, light is essential to us and other animals and plants. Actually, light has been widely used in the aquaculture and plays an important role in larval(Suzer et al., 2006) and juvenile culture(Trippel and Neil, 2003), such as growth performance, survival, stress response. However, the influence of light on growth performance of fish differed among species. The Chinese soft-shelled turtle is an aquaculture species with a high nutritional and medicinal value which has been widely cultured in China and Southeast Asia. Juvenile soft-shelled turtles were usually cultured in the greenhouse without light for a year in order to increase the survival rate. However, it not only deprived the soft-shelled turtles the welfare of basking in the sun when cultured in the pond but also increased the aberration rates. The purpose of present study was to bring the sunlight into the greenhouse to improve the welfare of soft-turtles, meanwhile to investigate the effect of artificial light on the growth and serum cortisol level of juvenile soft-shelled turtles.

Materials and methods

Juvenile soft-shelled turtles (mean weight 3.0±0.1g) were cultured in an aquarium (1000*2000*300mm) which placed in a large concrete pond to keep the water temperature at about 30°C. There were a basking area, feeding table and water area in the aquarium. The stocking density was 60 individuals a square meter. There were two treatments in the study. One was without artificial light (WOL), and the other was with artificial light in the basking area (WL). Each treatment was with three replicates. The light source was from a sunlamp which contained UVB light, UVA light, visible light and some heat. The UVB light intensity was $0.25W \cdot m^{-2}$. The photoperiod was 12 h light and 12 h dark. The concentrations of ammonia nitrogen and nitrite nitrogen were maintained at a safe range. The concentration of dissolved oxygen was kept higher than 2mg/l.

Results

The parameters of growth performance and serum cortisol level were showed in table 1. The parameters of final weight and weight gain rate of soft-shelled turtles in the treatment with artificial light were higher than that without light. The serum cortisol level of turtles cultured in artificial light was lower than that in the treatment without light

Discussion and conclusion

The studies of light improving the growth of fish have been observed in various species. According to the results, the artificial light in the basking area increased the growth performance of juvenile soft-shelled turtles and decreased the level of the serum cortisol which was a parameter of stress response(Rtcsano J. SrneNcs and Scsnncx., 1978). It was possible that the components of artificial light were similar with sunlight which may comfort the juvenile soft-shelled turtles and improve the welfare for them as they had the preference of basking in the sun. Meanwhile, the UVB light could promote the skin to synthesis the vitamin D which can promote the absorption of blood calcium which may also enhance the growth performance of them.

In conclusion, the soft-shelled turtles cultured in greenhouse should be provided a basking area as it not only improved the welfare of soft-shelled turtles, but also increase the growth performance.

Table 1

Influence of artificial light on the growth performance and serum cortisol level of juvenile Chinese soft-shelled turtles at the end of the experiment (123 days). The data were presented by means ±S.D. (n=9).

Parameters	WOL	WL
Initial weight (g)	3.11±0.03	3.07±0.05
Final weight (g)	61.33±2.47	61.99±4.35
Weight gain rate (%)	1871.83±94.51	1921.10±168.61
Serum cortisol level ($ng.ml^{-1}$)	31.31±4.70	29.74±1.16

Introduction

In salmon aquaculture, the limited availability of sustainable feed ingredients is a major obstacle. Insects, being part of the natural diet of salmonids, may become a sustainable resource and expand the raw material repertoire. In the "AquaFly" project, the potential of black soldier fly (*Hermetia illucens*) grown on low-quality organic matter as a source of sustainable feed ingredients for Atlantic salmon (*Salmo salar*) was assessed in one freshwater and one seawater feeding trial. Herein, we summarize data from the 16-week seawater feeding trial with salmon (initial body weight, 1.4kg) fed either a reference diet (REF) with a combination of fish meal, soy protein concentrate, pea protein concentrate, corn gluten and wheat gluten as protein source, or a test diet (IM) wherein all the fish meal and most of the pea protein concentrate were replaced by black soldier fly larvae meal

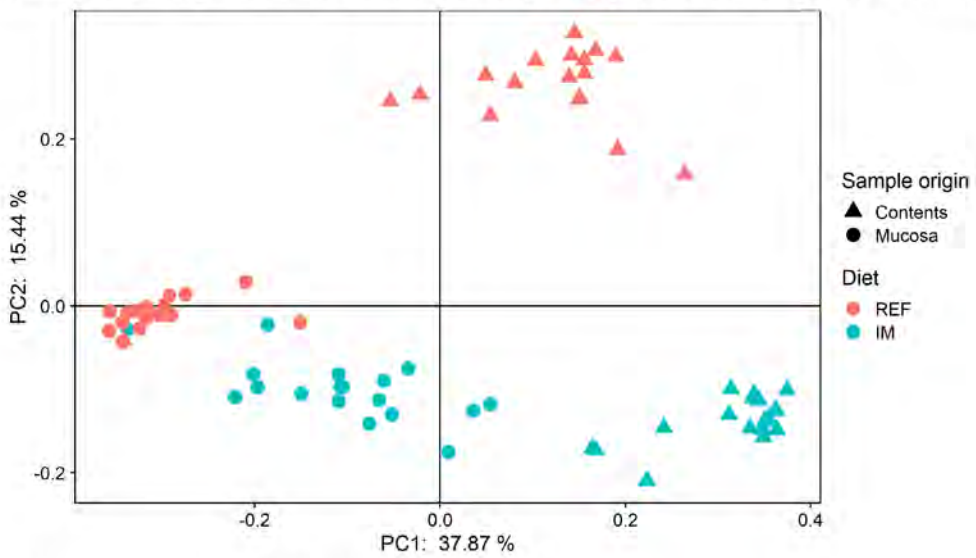
Materials and methods

The gut health of fish was evaluated using endpoints including organ and tissue indices, digestive enzyme activity, histopathological parameters and gene expression. In total, 36 genes under different functional categories were profiled via qPCR, including those indicative of lipid metabolism, immune responses, barrier functions and detoxification/stress responses. Microbiota in the distal intestine, both gut contents and mucosa associated, was analyzed via 16S rRNA gene sequencing.

Results

1. Histology. Hypervacuolization of enterocytes, suggestive of lipid accumulation, was observed in the proximal and mid intestine in both diet groups. It was, however, less severe in the proximal intestine of fish fed the insect meal diet ($p < 0.05$). Typical signs of enteritis commonly observed in salmonid intestine fed soybean meal diets were present in all the intestinal segments in both diet groups. A higher degree of submucosa cellularity was observed in the proximal intestine of fish fed the insect meal diet ($p < 0.05$).

Fig.1. Beta-diversity of distal intestine microbiota visualized by principle coordinate analysis (PCoA) of unweighted UniFrac distance. Each point represents one sample. The closer the points, the more similar their microbial communities are.



(Continued on next page)

2. Gene expression. Of the 36 genes profiled in the proximal and distal intestine, a few genes showed differential expressions. The only genes showing differential expressions were *mmp13* (matrix metalloproteinase 13) and *chk* (choline kinase), whose expression level was significantly lower in the proximal and distal intestine, respectively, in fish fed the insect meal diet ($p < 0.05$).

3. Gut microbiota. Both diet and sample origin (gut contents vs mucosa) affected microbiota in the distal intestine. All the measured alpha-diversity indices, including observed OTUs, Shannon index, Pielou's evenness and Faith's phylogenetic distance, showed higher values in samples exposed to insect meal diet or originated from gut contents ($p < 0.05$). For the beta-diversity, samples formed 4 distinctive clusters in the PCoA plot separated by the diet and sample origin (Fig.1), confirmed by permutational multivariate analysis of variance (*PERMANOVA*, $p < 0.05$). The diet showed a more profound effect on the samples originated from gut contents than those from mucosa.

Discussion and conclusion

In the present study, total replacement of fish meal with black soldier fly larvae meal showed no appreciable negative effects on the gut health and function of Atlantic salmon. In line with what we reported in the freshwater trial (Li et al., 2019), insect meal inclusion was associated with a lower degree of enterocyte hypervacuolization in the proximal intestine, which is suggestive of lower lipid accumulation. In the context of frequent occurrence of steatosis found in the proximal intestine of farmed salmon in field surveys (Chikwati et al., 2018), the potential beneficial effect of insect meal inclusion on reducing lipid deposition in the gut deserves further attention. In contrast to the previous finding in the freshwater trial that insect meal diet increased the expression of *foxp3* (Li et al., 2019), a transcription factor for the differentiation of naïve CD4 T-cells into regulatory T cells, no such effect was observed in the seawater trial. On the other hand, the present study showed increased submucosa cellularity in the proximal intestine. The effect of insect meal inclusion on the gut immune response is also worth of attention in future studies.

Introduction

The production of good quality fish eggs is influenced by environmental factors and aquaculture practices and development of biomarkers to assess egg viability is crucial (Migaud, Bell et al. 2013). Lysozymes (LYZ) are a group of non-specific innate immune enzymes. In vertebrates two main types exists C-type (LYZC) and G-type (LYZG) and they protect against bacterial invasion (Irwin, Biegel et al. 2011). In fish, where innate immunity prevails, LYZ studies are scarce. Multiple forms of LYZ exist in fish and they have been identified in the gills and skin (that are in direct contact with environment) but their role in fish immunity is surprisingly little understood (Saurabh and Sahoo 2008)Fish Hlth Management Div, Bhubaneswar 751002, Orissa, India</auth-address><titles><title>Lysozyme: an important defence molecule of fish innate immune system</title><secondary-title>Aquaculture Research</secondary-title><alt-title>Aquac Res</alt-title></titles><periodical><full-title>Aquaculture Research</full-title><abbr-1>Aquac Res</abbr-1></periodical><alt-periodical><full-title>Aquaculture Research</full-title><abbr-1>Aquac Res</abbr-1></alt-periodical><pages>223-239</pages><volume>39</volume><number>3</number><keywords><keyword>lysozyme</keyword><keyword>innate immunity</keyword><keyword>fish</keyword><keyword>immunostimulants</keyword><keyword>disease resistance</keyword><keyword>trout oncorhynchus-mykiss</keyword><keyword>carp cyprinus-carpio</keyword><keyword>goose-type lysozyme</keyword><keyword>indian major carp</keyword><keyword>dietary vitamin-c</keyword><keyword>flounder paralichthys-olivaceus</keyword><keyword>salmon salmo-salar</keyword><keyword>aeromonas-hydrophila infection</keyword><keyword>plaice pleuronectes-platessa</keyword><keyword>catfish clarias-batrachus</keyword></keywords><dates><year>2008</year><pub-dates><date>Feb 14</date></pub-dates></dates><isbn>1355-557x</isbn><accession-num>WOS:000252707800001</accession-num><urls><related-urls><url><Go to ISI>://WOS:000252707800001</url></related-urls></urls><electronic-resource-num>10.1111/j.1365-2109.2007.01883.x</electronic-resource-num><language>English</language></record></Cite></EndNote>. In this study we characterized LYZ gene evolution and function in fish. To assess the functional importance of LYZ in early developmental stages we determined enzyme activity and expression in important Mediterranean aquaculture species.

Materials and methods

In silico analysis: Homologues of human LYZG (LYZG1, ENSG00000144214: LYZG2, ENSG00000185674) and LYZC (ENSG00000090382) were retrieved from available fish databases (www.ensembl.org and https://www.ncbi.nlm.nih.gov/). Amino acid sequences were aligned and phylogenetic trees constructed using the BI (Bayesian Inference) method. *Functional studies*: Total RNA (tRNA) from sea bream (*Sparus aurata*) eggs (n=10 pools, Greece) was extracted and cDNA synthesized from 500ng genomic DNA-free tRNA and qRT-PCR reactions performed with the SsoFast EvaGreen Supermix (Bio-Rad, Portugal). LYZ activity was measured in egg protein extracts from: sea bream, sargo (*Diplodus sargus*) and meagre (*Argyrosomus regius*) (IPMA, Portugal). Total protein was extracted from 10 mg egg mixture (at least n=5 samples) from before hatch, hatch and after hatch with PBS pH 6.2 (0.25 mg of tissue $\cdot ul^{1}$ PBS). Assays were performed in duplicate using 20 µl of the protein extract diluted 1:2 in 0.05M PB, pH 6.2. Statistical analysis was performed using SPSS 25.0 two-way ANOVA.

Results

In fish LYZ gene members are variable and multiple members of the same family are present in some teleost species (Figure 1).

Phylogeny revealed that fish LYZ shared common ancestry with tetrapods but they evolved differently and species-specific gene duplicates exist suggesting functional divergence may have occurred. Only LYZG was detected in sea bream eggs by qRT-PCR. The overall LYZ enzyme activity was similar across the different egg stages but significant differences ($P < 0.05$) were found between the sea bream, sargo and meagre) (Table 1).

(Continued on next page)

	Human	Spotted gar	Zebrafish	Stickleback	Sea bass	Sea bream
LYZC	1	1	2	1	2	1
LYZG	2	ni	3	1	3	4

Fig 1. LYZ members in ray finned fishes and human. ni: not identified.

pTable 1. Lysozyme activity (U/mg) during fish early development.

	Before hatch	Hatch	After hatch
Sargo[ab]	0.11±0.04	0.18±0.08	0.13±0.07
Meagre[c]	0.23±0.11	0.29±0.18	0.26±0.12
Sea bream[ac]	0.19±0.08	0.15±0.08	0.10±0.09

Discussion and conclusion

A diversity of LYZs members exist and gene mapping revealed that evolution was complex and resulted from lineage-specific and species-specific tandem gene duplications. In different stages of hatching LYZ gene expression varied. Egg LYZ activity differed between sea bream, sargo and meagre and overall our data appears to suggest that the functional importance of this enzyme complex is species-specific and may have been shaped by their habitat. The importance of egg lysozyme for egg quality is currently under investigation.

Introduction

White spot syndrome virus (WSSV) is among the most damaging diseases in global shrimp aquaculture regarding production and economic losses (Sánchez-Paz, 2010). Resistance to WSSV in *L. vannamei* has previously been reported to have low but significant heritability in adult shrimp (Gitterle et al., 2006; Caballero-Zamora et al., 2015) and moderate heritability in juveniles (Trang et al, 2019). Selective breeding is therefore one method that is being used to increase WSSV resistance (Cock et al., 2015). Genomic selection has been predicted to be a powerful and accurate way of selecting among non-infected candidates based on challenge test results from relatives and estimated genomic relationships.

Two shrimp populations were used in this study, one line, "Tumaco", which had been exposed to WSSV infections for several generations and hence naturally selected for survival against WSSV, and a second line, "Cartagena", which had been kept in a pathogen free environment for generations and not exposed to or selected for WSSV resistance in the last 10 generations. The aim of this study was to compare purebred shrimp from the line already selected for resistance with crossbreds between the two lines, with regard to resistance and to estimate genetic parameters for WSSV resistance using genomic relationships.

Materials and Methods

A challenge test was performed with 751 pure Tumaco (T) and 696 crossbred Tumaco-Cartagene (TxC) shrimp randomly divided in two 4 ton tanks, using artificial seawater at 30 ppt salinity and 26^{o}C temperature. Juvenile shrimp of average weight 3g were infected with WSSV in a challenge initiated April 18th 2018, using minced infected tissue at 3 % biomass. Mortalities were recorded daily until May 10th. 12 days post infection, the shrimp were pooled into one single tank to avoid loss of infection pressure due to reduced shrimp density. Infection was confirmed by histopathology and PCR. All the shrimp in the study were genotyped for 18,643 SNPs. Based on the genotypes, a genomic relationship matrix between all the animals was estimated. Genetic parameters were estimated for survival, measured as a binary dead or alive trait during the trial and as days of survival. For the latter, all survivors were assumed to die the day after the trial ended. Genomic breeding values were estimated for both traits and a 10-fold random cross validation was used to estimate the accuracy of the genomic breeding values (correlation between estimated breeding values and phenotype divided by the square root of the heritability).

Results

The first mortality occurred April 19th, and peak mortality was observed from April 23rd through April 26th, approximately 5 days post challenge. Accumulated mortality for the whole experimental period was 888, corresponding to 61 % of the tested animals, 46 % of the purebreds and 76 % of the crossbreds.

Heritabilities of binary dead or alive and days survival traits were 0.30±0.05 and 0.55±0.05, respectively. Accuracy of genomic breeding values for the two traits were estimated to 0.69 and 0.64, respectively. The best linear unbiased estimated difference between the purebred T shrimp and the crossbred with regard to probability of surviving the test was 0.19, while the estimated advantage of purebred T in number of days until death was 2.71 days. Separate analysis of the purebred and crossbred animals did not reveal significant differences in genetic parameters between the purebred and the crossbred, and accuracy of selection decreased, probably because of the reduced size of the reference population when dividing the data in two.

Discussion and Conclusion

The heritability of WSSV resistance using genomic relationship data was shown to be moderate to high and genomic selection would therefore facilitate selective breeding for resistance. This holds regardless of whether resistance was measured as days survival or as a binary dead or alive trait. Accuracy of selection was high in both cases, indicating that the

(Continued on next page)

reference population, which consisted of 90 % of the animals in the cross validation test, was of sufficient size to estimate genomic breeding values for these traits. Selection of candidates based on information from challenge tested full sibs and genomic information is therefore expected to give genetic gain, dependent on selection intensity. The highest gain is expected if selection is based on days survival, because of the higher heritability of this trait.

The higher heritability found in this study as compared to other comparable studies (Gitterle et al., 2005; Trang et al., 2019) could be due to population characteristics or due to test characteristics. Mortality rate was lower and happened slower than in many other WSSV challenge test studies (Gitterle et al., 2006). This could be due to high WSSV resistance in this combined population, introduced by the Tumaco line. It could also be due to lower virulence or lower pathogen load in the present test as compared to the earlier trials.

The estimated difference in resistance between the purebred Tumaco line and the Tumaco x Cartagena crossbreds was significant, but relatively small, as compared to what should be expected based on the selection history of the respective lines and the heritability of resistance. This may suggest that the resistant genotype is partially dominant, causing crossbred animals to show a resistant phenotype. Alternatively, it could be that historical links between the populations has caused the resistant genotype to exist also in the Cartagena line, even without a selective advantage within this population or a heterosis effect from crossing the two populations. The similar genetic parameters obtained when analyzing purebred and crossbred animals separately (results not shown) indicates, however, that genetic variation for resistance has been maintained also in the purebred Tumaco line, despite a selection history with strong natural selection for increased WSSV resistance.

FITNESS EFFECTS OF INTROGRESSION OF ESCAPED FARMED SALMON INTO WILD POPULATIONS

M. Lillehammer[1*]

[1] Nofima AS, Postboks 210, NO-1431 Ås, Norway
E-mail: marie.lillehammer@nofima.n

Introduction

Every year, thousands of farmed salmon escape from Norwegian Aquaculture sites into the wild. These have been shown to have low spawning success and poor survival (Fleming et al., 1996), but still, extensive documentation exists that a fraction of the escaped salmon manages to interbreed with wild relatives and cause introgression of domesticated material into wild populations (Glover et al., 2013). Phenotypic changes due to introgression has been documented (Bolstad et al., 2017), which is likely to have negative impact on fitness and viability of the wild populations.

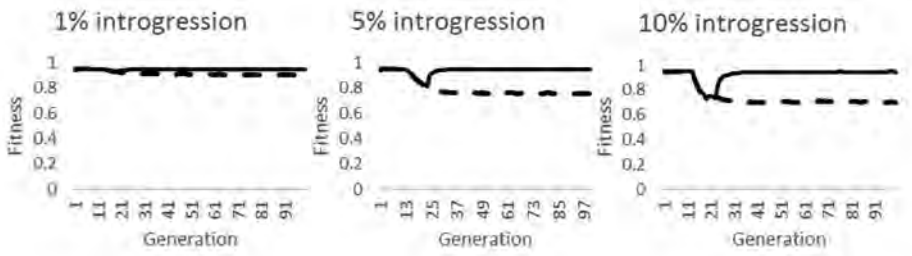
The aim of this study was to quantify the fitness consequences of introgression of farmed salmon into wild populations using stochastic simulations.

Materials and Methods

The software Nemo was used for stochastic simulations of individuals and their genomes. Fitness was modeled as a Gaussian function of one quantitative trait, which was controlled by 80 independent genes with Mendelian inheritance. A simple life cycle, consisting of mating and offspring generation, viability selection, straying and reduction to patch capacity was simulated for 2000 generations to obtain mutation-drift-selection balance. The wild population consisted of five subpopulations with 100-800 parents per generation in each subpopulation, 5% random straying between the subpopulations and slightly different environments between the subpopulations. Strength of natural selection was estimated based on the decline in wild survival for domesticated salmonids found in Araki et al. (2007). In addition, two levels of relaxed strength of selection were applied, to account for possible estimation errors due to confoundance between genetic and environmental effects and to test the sensitivity of the model for this parameter. Founders of the farmed population were sampled from all of the 5 subpopulations over two generations and domestication mimicked by running natural selection towards an extreme optimum. After 10 generations of domestication in the farmed population, farmed fish was migrated into the wild sub-populations to mimic escapees. Three levels of introgression, 1%, 5% and 10%, were tested, which corresponds to rivers with approximately 5%, 20% or 50% farmed salmon present. Introgression was then either kept constant for 85 generations, to study the long term effects of introgression that happens systematically over many generations or it was stopped after 10 generations to study the ability of natural selection to restore fitness in natural populations when introgression is stopped.

Results

Figure 1 shows the development in fitness assuming the strong natural selection as estimated from Araki et al (2007), and continuous introgression of 1%, 5% or 10%, respectively. The figure shows fitness for a river with 800 parents every generation, and results were very similar for smaller river sizes and different phenotypic optimum. Introgression started in generation 13 and lasted until generation 23 (solid line) or for ever (dotted line). The latter resulted in 5%, 20% or 30% loss of fitness in the wild populations, dependent on level of introgression (Fig 1). When introgression stopped after 10 generations, rapid recovery repaired 90% of the damage after 2 generations, but around 20 generations were needed for full recovery of all rivers. With relaxed natural selection (results not shown), rate of reduction in fitness was smaller but the asymptotic loss of fitness was higher (5%, 30% and 50%, respectively for the three levels of introgression). Rate of recovery was also slower with relaxed selection.



(Continued on next page)

Discussion and Conclusion

The results from the simulations support that systematic introgression over time reduces the fitness of the wild populations, and that the changes are reversible when introgression stops. The model used was not sensitive to river population size, fecundity or straying rate, including straying rates from 1% to 5% (results not shown).

The simulated life cycle was simple, with only one round of viability selection per generation. Density dependent or life stage specific selection, as well as non-genetic effects of farmed escapees were ignored. These limitation may cause under estimation of the damage caused by farmed escapees.

Regardless of strength of natural selection, 1% introgression per generation was shown to be negligible, but higher levels of introgression caused significantly reduced fitness. This is in concordance with findings from Castellani et al. (2015) who modeled a more complex life cycle using a different fitness and genetic model. However, Castellani et al. (2015) found that stronger natural selection, i.e. lower survival of escapees, led to a higher loss of fitness, which is opposite from other study, probably due to differences in model assumptions.

AMINO ACIDS AS FEEDING STIMULANT IN THE DEVELOPMENT OF SOYBEAN-BASED DIET FOR JUVENILE GROUPER (*Epinephelus fuscoguttatus*)

Leong-Seng LIM*, Rossita SHAPAWI, and Gunzo KAWAMURA

Borneo Marine Research Institute, Universiti Malaysia Sabah, Jalan UMS, 88400, Kota Kinabalu Sabah, Malaysia
Email: leongsen@ums.edu.my

Introduction

Groupers are carnivorous species and require high dietary protein for optimum growth. Thus, the expensive fish meal (FM) based-compounded feeds have been commonly used to farm groupers. From previous studies, soybean meal (SBM) protein has been proven practical to partially replace the FM protein in juvenile groupers diets. However, high dietary SBM protein inclusion levels can reduce the diets palatability and causes poor intake and fish growth (Lim *et al*., 2014). Dietary supplementation of feeding stimulants (FS) can solve this problem but information on the suitable FS for groupers is limited. Amino acids are common FS for fish but fish taste preference for amino acids is species-specific (Kasumyan and Døving, 2003). Therefore, the present study was aimed to identify the amino acids which are preferable by the juvenile grouper *Epinephelus fuscoguttatus* through behavioral assays (video recording), and a feeding trial was conducted to evaluate the potential of the selected amino acids as FS for the fish.

Materials and methods

In behavioral assays, agar gel pellet was used as the medium to deliver 19 amino acids to the fish (BW 22.9 g). The pure agar gel (PAG) and feed extract (FE) pellets were used as the negative- and positive-control, respectively. From the recorded videos, two parameters were observed: (I) the pellet was consumed or rejected [A] – if consumed, recorded 1; if rejected, recorded 0, and (II) frequency of the pellet been captured before it was consumed or rejected and ignored [B], and the preference index was calculated through [A] /[B] (Lim *et al*., 2016). The amino acids with high preference index were then supplemented (1.0%) into the SBM diet to evaluate its potential as FS through an 8-week feeding trial. In this feeding trial, one hundred eighty three *E. fuscoguttatus* (BW 15.6 ± 0.2 g) were distributed evenly into 15 floating cylinder cages (12 individuals per cage) placed randomly in 2 fibe glass tanks (3 tonnes each) that were provided with constant flow-through sea water and aeration. Three dietary treatments were prepared, namely the Control (FM protein-based), SBM40 (40% FM protein replaced with SBM protein) and AAM10 (SBM40 supplemented with 1% selected amino acids mixture), and each diet was hand-fed to triplicate cages of fish twice daily (approximately 0800 and 1400) until apparent satiation level. The uneaten feed was counted and mortality was recorded daily. After 8-week, all fish were anesthetized and measured individually for their total length and body weight. The fish body weight gain (WG), survival rate (SR), and feed intake (FI), were calculated using the following formula: WG (%) = (Final – Initial fish weight)/ Initial fish weight ×100; SR (%) = (Final fish number/ Initial fish number) × 100; FI (g/ fish) = (Total given feed – Total uneaten feed)/ Fish number.

Results

In the behavioural assays, the PAG pellet was totally rejected by the fish (index's value = 0). Among the 18 amino acids tested, only 6 amino acids were found acceptable to fish (index's value ranged from 0.07 to 1.00, see Fig. 1). From the feeding trial, the FI of AAM10 was found significantly higher ($P < 0.05$) than that of SBM40 (Fig. 2a). Fish fed AAM10 diet also attained the higher WG and SR than SBM40 but no significant difference ($P > 0.05$) was noticed. However, the FI, WG and SR of fish fed AAM10 were not comparable to those fed with the Control diet.

Discussion and conclusion

The amino acid spectrum that suited the taste preference of the grouper was considered narrow as only 6 out of the 19 amino acids were accepted, and only 1 was fully ingested by them. In the previous study by Kasumyan and Døving (2003), brown trout (*Salmo trutta caspius*) accepted 6, tench (*Tinca tinca*) can accept 12, while chub (*Leuciscus cephalus*) rejected all of the 21 amino acids tested. Apparently, present study results were in agreement with the finding by Kasumyan and Døving (2003) that fish taste preference for amino acids is species-specific. From the feeding trial in the present study, although the FI, WG and SR of fish fed AAM10 were not comparable to those fed with the Control diet, the positive effective of the AAM as FS for the grouper was confirmed as AAM dietary supplementation has significantly improved the fish intake of SBM diet. In conclusion, amino acids are FS for the grouper and the selected one can be used to improve their feed intake of SBM diet. Further study should be conducted to analyze the cost of AAM supplementation in the diets for grouper juveniles.

CULTIVATION OF A GREEN MICROALGA *Tetraselmis sp.* IN THE OCEAN USING FLOATING PONDS WITH SEMI-PERMEABLE MATERIALS

Hanwool Park, Sang-Min Lim*, and Choul-Gyun Lee

National Marine Bioenergy R&D Consortium & Department of Marine Science & Biological Engineering, Inha University, 100 Inha-Ro, Michuhol-Gu, Incheon 22212, Korea

Introduction

Phosphorus, an essential element for microalgal biomass production, is a non-renewable, finite resource produced from underground reserves. For sustainable large-scale cultivation of microalgae, phosphorus should be provided from sustainable sources (Park and Lee, 2016). The ocean has a very large reserve of phosphorus along with other nutrients needed for microalgae. However, their concentrations are too low to use as a culture medium. We implemented semi-permeable materials (SPMs) that are permeable to nutrients in seawater but not to microalgae cells to enable microalgal cultivation utilizing nutrients in seawater. In the SPM culture systems, phosphorus supply rate was the major limiting factor for the biomass productivity (Kim et al., 2016a). In this study, we developed SPM culture systems with higher phosphorus supply rate to enhance microalgal biomass productivity.

Materials and methods

A green microalga, *Tetraselmis* sp. MBEyh01L, used in this study was locally isolated from the offshore ocean test-bed of Marine Bioenergy R&D Consortium located in the nearshore of Younghueng Island, Incheon, Korea. Various SPMs were designed and customized by the authors and constructed by local manufacturers. Lab-scale floating ponds could hold up to 12 L of algal culture, and ocean-scale floating ponds could hold up to 12 kL of algal culture volume with 16 m^2 of culture area. Lab-scale experiments were performed in raceway ponds containing 8 kL of seawater in a greenhouse, located on the land adjacent to the ocean test-bed. Ocean experiments were conducted in the ocean test-bed, consisted of cube-shaped pontoons for human access.

Results and Discussion

Properties of SPMs, cell and ion permeabilities, greatly varied by configurations of SPMs. By optimizing weaving pattern and configurations of SPMs, ion permeability was increased by 727%. The actual biomass productivities from SPM-equipped floating ponds were similar with the theoretical biomass productivity calculated using the phosphorus supply rate and average phosphorus content of *Tetraselmis* sp., indicating that phosphorus supply rate was still the productivity limiting factor (Fig. 1).

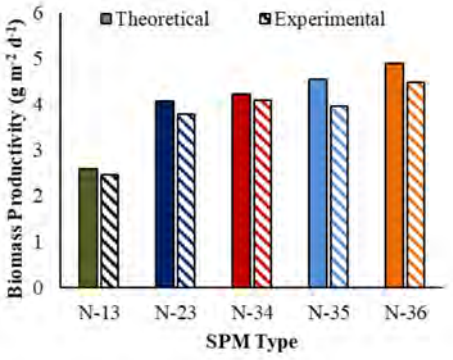

Fig. 1. Theoretical and Experimental Biomass Productivities by SPM Type

(Continued on next page)

Biomass productivity in the floating ponds equipped with the latest SPMs was improved by 971% compared with the early SPM culture systems used in the previous study (Kim et al., 2016b). In order to increase biomass productivity further from the level by passive diffusion, forced convection was implemented to the SPM culture systems, which could increase biomass productivity to 5.5-fold compared with the culture depended on diffusion. In the laboratory scale, up to 18.6 g m^{-2} d^{-1} of biomass productivity was achieved by supplying nutrients in the seawater to SPM Ponds. In the ocean scale, using floating SPMs ponds with forced convection, the SPMs ponds showed the similar level of biomass productivity to the cultures with concentrated nutrients, achieving up to 13.5 g m^{-2} d^{-1} of biomass productivity.

Conclusions

This study demonstrated that microalgal biomass could be produced using nutrients in seawater with SPM ponds. With enhancements in other aspects of microalgal cultivation, such as culture mixing by natural energy, pond design, operating parameters, *etc*. SPM culture technology would contribute to realization of sustainable mass production of microalgal biomass.

Introduction

In a conventional recirculating aquaculture system (RAS), the external water exchange is adjusted based on the concentration of nitrate in the system (Martins 2010). To reach a smaller inlet water requirement, the amount of nitrate must be reduced to acceptable level by denitrification. Denitrification is the process transforming nitrite and nitrate to reduced elemental nitrogen gas, but requires an external carbon source. Wood-based material is readily available as carbon source for denitrificati n (Schipper et al. 2010). As the water flows passively through the woodchip reactor, oxygen is removed due to bacterial metabolism, leading to anoxic environment suitable for denitrification (Warneke et al. 2011). However, woodchips can contain various compounds toxic to raised fish species (Billiard et al. 1999; Oikari et al. 2002). This study aims at evaluating a passive denitrification process in RAS, and developing analytical methods to quantify possibly toxic compounds towards the raised species.

Materials and methods

A new process design of a passive water treatment system was connected to a RAS. A more detailed description of the experimental RAS facility has been reported by Pulkkinen et al. (2018). In brief, the experimental RAS consisted of a 500 l fish tank, separate water treatment and water quality control systems. Two similar systems and side-loops with passive water treatment (small loop 25 l d^{-1}, large loop 40 l d^{-1}) included both a woodchip reactor filled with silver birch (*Betula pendula*) woodchips (< 5 cm), aiming at 95% denitrification efficiency with a 1.5 day delay, and a sand filter with an effective porosity of 0.35, 80% saturation, and delay of 3.5 days. Rainbow trout *Oncorhynchus mykiss* was fed at 0.1 kg d^{-1}, increasing in weight from 13g to 44g during the experiment. Denitrification was monitored by following nitrate levels after the side-loop reactors by a spectrophotometer (Nessler procedure 8038, DS 3900, Hach).

New analytical methods were developed and validated to study the fatty acid concentrations released from the woodchip reactor and to evaluate if they posed toxic effects towards the raised species. Fatty acids were extracted by liquid-liquid extraction (LLE) with MTBE, derivatized, and analyzed with GC-FID (Shimadzu GC-2010/FID). The analytes were identified by an Agilent 6890 series/5973 N GC/MSD under EI (70 eV) with [NIST] mass spectral library. For the elemental analyses, a microwave acidic digestion of the circulating water was performed according to US EPA 2008, method 3015. The analyses were conducted with a Perkin-Elmer (Optima 8300, Norwalk, CT, USA) ICPOES. Optimal analytical wavelengths were measured at (nm): Ca (315.887), K (766.490), Mg (279.077), and P (177.50).

Results

In the beginning of the experiment, denitrification rates ranged up to 85 %, but decreased later down to 40 %. This suggests that nitrogen load was excessive for the denitrification system and requires improved dimensioning. Certain fatty acids were detected in the circulating water, somewhat higher in the system with the large side-loop (Fig. 1). In the beginning, up to 2mg L^{-1} concentrations were found, but decreased rapidly to below 0.5mg L^{-1} levels. Similarly, increased levels of selected macro elements were found originating from the birch wood, especially potassium (Fig. 2). However, the concentrations settled rapidly to below 20mg L^{-1} for K and below 10mg L^{-1} for K, Mg, and P.

Discussion and conclusions

The results show that birch woodchips act as a carbon source for the denitrification. Overall, the concentrations of compounds accumulating into the system were low. Additionally, the developed analytical methods were shown suitable for analyses of the selected compounds or elements in aqueous matrices.

In brief, the experimental RAS consisted of a 500 l fish tank, separate water treatment and water quality control systems. Two similar systems and side-loops with passive water treatment (small loop 25 l d^{-1}, large loop 40 l d^{-1}) included both a woodchip reactor filled with silver birch (*Betula pendula*) woodchips (< 5 cm), aiming at 95% denitrification efficiency with a 1.5 day delay, and a sand filter with an effective porosity of 0.35, 80% saturation, and delay of 3.5 days. Rainbow trout *Oncorhynchus mykiss* was fed at 0.1 kg d^{-1}, increasing in weight from 13g to 44g during the experiment. Denitrification was monitored by following nitrate levels after the side-loop reactors by a spectrophotometer (Nessler procedure 8038, DS 3900, Hach).

New analytical methods were developed and validated to study the fatty acid concentrations released from the woodchip reactor and to evaluate if they posed toxic effects towards the raised species. Fatty acids were extracted by liquid-liquid extraction (LLE) with MTBE, derivatized, and analyzed with GC-FID (Shimadzu GC-2010/FID). The analytes were identified by an Agilent 6890 series/5973 N GC/MSD under EI (70 eV) with [NIST] mass spectral library. For the elemental analyses, a microwave acidic digestion of the circulating water was performed according to US EPA 2008, method 3015. The analyses were conducted with a Perkin-Elmer (Optima 8300, Norwalk, CT, USA) ICPOES. Optimal analytical wavelengths were measured at (nm): Ca (315.887), K (766.490), Mg (279.077), and P (177.50).

Results

In the beginning of the experiment, denitrification rates ranged up to 85 %, but decreased later down to 40 %. This suggests that nitrogen load was excessive for the denitrification system and requires improved dimensioning. Certain fatty acids were detected in the circulating water, somewhat higher in the system with the large side-loop (Fig. 1). In the beginning, up to 2mg L^{-1} concentrations were found, but decreased rapidly to below 0.5mg L^{-1} levels. Similarly, increased levels of selected macro elements were found originating from the birch wood, especially potassium (Fig. 2). However, the concentrations settled rapidly to below 20mg L^{-1} for K and below 10mg L^{-1} for K, Mg, and P.

Discussion and conclusions

The results show that birch woodchips act as a carbon source for the denitrification. Overall, the concentrations of compounds accumulating into the system were low. Additionally, the developed analytical methods were shown suitable for analyses of the selected compounds or elements in aqueous matrices.

TOXICITY OF PERACETIC ACID (PAA) PRODUCTS: IMPACT OF WATER QUALITY, PRODUCT COMPOSITION AND FISH SPECIES

D. Liu*, T. Meinelt, D.L. Straus and P. Bartschat

Department of Ecophysiology and Aquaculture, Leibniz-Institute of Freshwater Ecology and Inland Fisheries (IGB), Mueggelseedamm 301, 12587 Berlin, Germany
liu@igb-berlin.de

Background

Prophylaxis with peracetic acid (PAA) in aquaculture is a promising sustainable alternative. However, successful prophylaxis needs to consider composition of PAA products (ratio of PAA to hydrogen peroxide [H_2O_2]), fish production conditions (water parameters, culture system and management), cultured species and development stage of the fish. These parameters simultaneously determine an appropriate PAA product and PAA concentration to avoid harming the fish and to ensure prophylaxis success. The presentation will summarize three of our early-stage studies to address: 1) how water parameters affect the degradation of PAA, 2) how composition of PAA products affects their toxicity to aquatic animals and 3) how fish species di fer in their sensitivity to PAA.

Results

In study 1 we investigated the impacts of salinity, water hardness and dissolved organic carbon (DOC) on the degradation of 1 mg/L of three commercial Wofasteril® PAA products: E400, E250 and Lspez. The results showed that salinity and DOC stimulated PAA degradation, while water hardness had only minor impact.

In study 2 we performed 24-h toxicity tests using *Daphnia magna* with the aforementioned PAA formulations. Toxicity to *Daphnia* was greatest for Lspez (high total peroxide/PAA ratio), intermediate for E250 (intermediate total peroxide/PAA ratio), and lowest for E400 (total peroxide/PAA ratio) (Figure 1). An E400 + H_2O_2 mixture, which possessed a composition theoretically identical to the E250 formulation, had toxic effects and 24-h LC50 values similar to those of the E250 product. The results indicate that the toxicity of PAA formulations to *Daphnia* is due to the combined effect of both PAA and H_2O_2, namely the total peroxide.

In study 3 twelve species of fingerling fish that are important to aquaculture were exposed to PAA for 24-h static toxicity bioassays. Median lethal concentration (LC_{50}) values were estimated. The mean 24-h LC_{50} values were species dependent and ranged from 2.8 to 9.3 mg/L PAA. More importantly, the 24-h no-observed-effect concentration (NOEC) ranged from 1.9 to 5.8 mg/L PAA. PAA was more toxic in water with lower alkalinity and hardness, while a small increase of dissolved organic content had no effect on PAA toxicity.

Conclusion

Our early studies confirmed the complex influences of several biotic and abiotic factors on the toxicity of PAA. For this reason, strategies for successful prophylaxis with PAA in aquaculture facilities should be customized according to the onsite situation. In future studies we aim to quantify the impacts of these factors with a mathematic model and establish an easy-to-use tool for the customized use of PAA for prophylaxis in aquaculture systems.

Introduction

Syndecans are the earliest family of transmembrane receptor proteoglycans. They can be found in the extracellular matrix, cell surface, tissue compartment, and nucleus. Proteoglycans essential for development and function of the immune system, central nervous system skeleton of vertebrates. Syndecans contain six domains; ectodomain, co-receptor binding domain, a transmembrane domain, conserved (C1 domain, C2 domain), and variable (V) domain. The soluble syndecan ectodomains are involved in inhibiting growth factor, enhance proteinase activities, inhibit cell proliferation, wound healing and inhibit mast cell migration in teleost syndecans.

Big-belly seahorse (*Hippocampus abdominalis*) is an essential seahorse species, and they were used in oriental medicine, ornamental purposes and as food. Hence studying of seahorse immunity upon various immune stimulants provide a better understanding of teleost immunity.

Materials and methods

Here we characterized syndecan-2 (HaSDC2) from seahorse transcriptomic database and analyzed the tissue-specific expression and temporal transcription in against poly I:C, Lipopolysaccharides, and *Edwardsiella tarda* and *Streptococcus iniae*.

Results and discussion

The coding sequence of HaSDC2 is 798 bp long and encode a protein sequence with 265 amino acids. HaSDC2 protein consisted of 28.9 kDa molecular weight and 4.13 theoretical isoelectric point. Further, HaSDC2 showed the highest identity with *Hippocampus comes* (94.34%). According to the tissue-specific expression, HaSDC2 highly expressed in the liver (Fig1) due to Syndecan-2 is one of the most important proteoglycans in the liver, and it normally expressed on the surface of hepatocytes. Further, blood HaSDC2 showed significant transcriptional modulation towards all the immune stimulants (Fig2). Because due to the Syndecan ectodomain released to the extracellular matrix to protect the cells by regulating growth factor binding (Chen et al., 2004), cell proliferation (Park et al., 2002) and wound healing (Worapamorn et al., 2002) growth factors and a variety of other effector molecules. Accordingly, these molecules play a central role in various aspects of cell-cell and cell-matrix interactions. To investigate the expression and distribution of the cell surface proteoglycans, syndecan-1 and -2, during periodontal wound healing, immunohistochemical analyses were carried out using monoclonal antibodies against syndecan-1, or -2 core proteins. Both syndecan-1 and -2 were expressed and distributed differentially at various stages of early inflam atory cell infiltration, granulation tissue formation, and tissue remodeling in periodontal wound healing. Expression of syndecan-1 was noted in inflam atory cells within and around the fibrin clots during the earliest stages of inflammatory cells infiltration. During granulation tissue formation it was noted in fibroblast-like cells and newly formed blood vessels. Syndecan-1 was not seen in newly formed bone or cementum matrix at any of the time periods studied. Syndecan-1 expression was generally less during the late stages of wound healing but was markedly expressed in cells that were close to the repairing junctional epithelium. In contrast, syndecan-2 expression and distribution was not evident at the early stages of inflammatory cell infiltration. During the formation of granulation tissue and subsequent tissue remodeling, syndecan-2 was expressed extracellularly in the newly formed fibrils which were oriented toward the root surface. Syndecan-2 was found to be significantly expressed on cells that were close to the root surface and within the matrix of repaired cementum covering root dentin as well as at the alveolar bone edge. These findings indicate that syndecan-1 and -2 may have distinctive functions during wound healing of the periodontium. The appearance of syndecan-1 may involve both cell-cell and cell-matrix interactions, while syndecan-2 showed a predilection to associate with cell-matrix interactions during hard tissue formation.”,”author”:[{“dropping-particle”:””,”family”:”Worapamorn”,”given”:” W”,”non-dropping-particle”:””,”parse-names”:false,”suffix :””},{“dropping-particle”:””,”family”:”Xiao”,”given”:”Y” ,”non-dropping-particle”:””,”parse-names”:false,”suffix :””},{“dropping-particle”:””,”family”:”Li”,”given”:”H”,”non-dropping-particle”:””,”parse-names”:false,”suffix”:””},{“dropping-particle”:””,”family”:” oung”,”given”:”W G”,”non-dropping-particle”:””,”parse-names”:false,”suffix”:””},{“dropping-particle”:””,”family”:”Bartold”,”given”:” M”,”non-

THE EFFECT OF DIFFERENT HORMONAL INDUCTION STRATEGIES ON PIKEPERCH (*Sander lucioperca* L.) GAMETE QUALITY OBTAINED AFTER OUT-OF-SEASON ARTIFICIAL REPRODUCTION

U. Ljubobratović*, F. Demény, G. Peter, O. Malinovskyi, M. Kwiatkowski, A. Rónyai and Á. Horváth

NAIK Research Institute for Fisheries and Aquaculture, Anna-liget 35, 5540 Szarvas, Hungary

E-mail: u.ljubobratovic@gmail.com

Introduction

Seasonal artifici l reproduction is well documented in pikeperch and to date published protocols are applicable in hatchery practice all over the Europe (Zakęś and Demska-Zakęś 2009; Żarski et al. 2012). Nevertheless, hormonal induction in individuals which were induced to spawn in fully controlled conditions is still of unpredictable outcome. Therefore, the present study aimed to evaluate the effect of different hormonal preparations (gonadotropin vs. gonadoliberin) at different temperatures (5 °C vs 9 °C) on the spawning performance in males. Likewise, the effect of gonadoliberin dosage (5 µg vs. 50 µg) on the egg quality was additionally assessed.

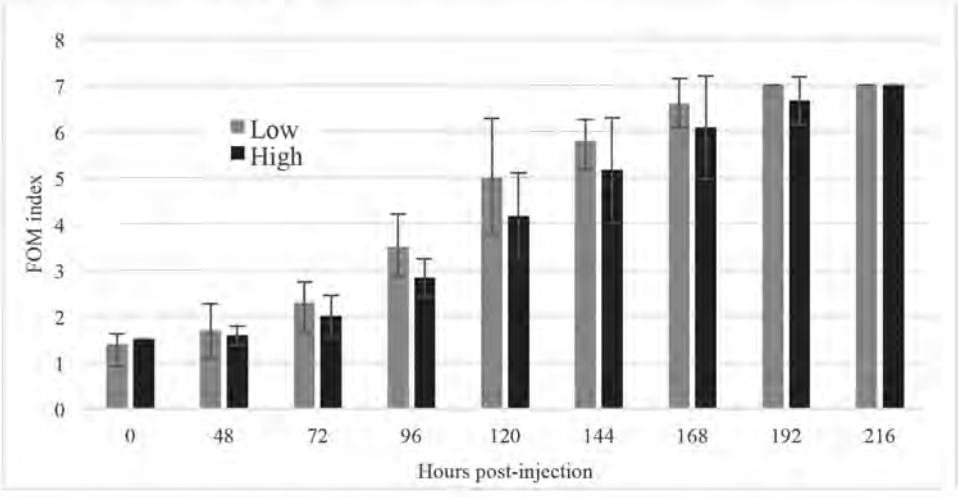
Materials and Methods

Following artificial reproduction, three-year-old-breeders were subjected to 5 months of grow-out, 4 months of cooling and 2 months of chilling and finally warmed in a week for one degree per day. At the start of warming week at 5 °C, two groups of males were injected with different hormonal preparations and at the end of warming week at 9 °C two additional groups of males were injected with same preparations as well as the control group which was injected with saline solution. A day after the second group of males two groups of females were hormonally treated at 10 °C. Each treatment group consisted of five individuals. Following the injection of females, water temperature was gradually increased to 12 °C in a week. Further artificial reproduction was performed as explained by Ljubobratović et al. (2018). Samples of sperm were taken 48 day-degrees following injection and their quality parameters were evaluated using a CASA system. Eggs of each female were fertilized with milt of two males and stocked into separate 2 L Zug jars for further evaluation of embryo survival, hatching and length of newly hatched larvae.

Results

Although no significant difference was found in males' reproductive performance, all evaluated parameters were highest in the group treated with gonadoliberin at higher temperature. In case of egg quality, significantly higher embryo survival (50.3 ± 7.3 % vs. 17.4 ± 29.1 %, $p = 0.048$) and hatching index (44.3 ± 0.5 % vs. 12.2 ± 20.4 %, $p = 0.031$) were found in females treated with higher dosage of salmon gonadoliberin analog. A more rapid progress of final oocyte maturation was observed in females treated with a lower dosage of salmon gonadoliberin analog (Figure 1).

Fig. 1. Final oocyte maturation (FOM) progress upon different dosage of hormonal injection (5 and 50 µg kg^{-1})



(Continued on next page)

Discussion and Conclusion

Salmon gonadoliberin administered at the higher temperature led to the highest spermiation response where 4 out of 5 injected males spermiated. In case of sperm quality parameters, these did not differ significantly among the groups, although all were in favor of the previously mentioned treatment. It appears that although some progress can be made in terms of sperm quality with different induction strategies, it remains rather tolerant to different preparation and temperatures of application. Unlike sperm, eggs seem to be rather vulnerable to hormonal application, namely the dosages. A previous study dedicated to the same issue (Żarski et al. 2019) found no such effect. However, using marginal dosages, the present study found the specific dose-dependent response of final oocyte maturation to the hormonal induction with salmon gonadoliberin. Application of salmon gonadoliberin at 9 °C can be suggested suitable to obtain high quality sperm in out-of-season pikeperch reproduction. Egg quality improvement can be foreseen with different hormonal strategies and the effect of temperature of application is to be considered for future studies.

GROWTH RATE AND SURVIVAL IN JUVENILES OF GREY MULLET *MUGIL CEPHALUS* REARED UNDER THREE SALINITY LEVELS

Barbara Loi*, Francesca Leggieri, Gemma Giménez Papiol, Dario Vallainc

IMC International Marine Centre, loc. Sa Mardini, Torregrande, 09170 Oristano, Italy

E-mail: b.loi@fondazioneimc.it

Introduction

Flathead grey mullet *Mugil cephalus* commonly inhabits tropical and temperate estuaries, where plays an important ecological role and supports fisheries, due to the high quality fish fillet, but also fish roe ("bottarga" in Italian). Mullets are highly euryhaline and tolerate a wide range of salinities (Whitfield et al., 2012), in fact they can be reared in brackish coastal lagoons or even raised in commercial freshwater ponds to improve yield (Cardona, 2000). Thanks to their euryhalinity, mullets have recently become a species of interest for worldwide aquaculture production. The influence of salinity on growth rate must be considered when developing its culture, in order to produce fish of the best quality at the most economical cost.

The growth of euryhaline species is often affected by salinity because the energy used for osmoregulation processes is not available for growth (Cardona, 2000). Therefore, they have an optimum salinity level at which growth rate is higher and osmoregulation cost is lower, which may affect fish distribution in the wild (Blaber, 1997). A study carried out in several inland estuaries of the Balearic Islands (Western Mediterranean) has shown that *M. cephalus* juveniles actively avoid polyhaline and euhaline waters, preferring freshwater and oligohaline waters (Cardona, 2000), even if laboratory experiences taking into account salinity and growth rate are often contradictory (De Silva and Perera, 1976; Rodriguez et al., 1993; Cardona, 2000). In the present work, the effect of three salinities on mullet growth and survival has been tested during the juvenile stage.

Materials and methods

The experiment was conducted in three separated recirculating aquaculture systems, each one composed by three circular, truncated, cone-shaped tanks (300 l volume each), equipped by biologic and mechanical filter and continuous aeration. Five-month old juveniles (N=540, 25±1mm length and 0.19±0.02g weight, mean±s.e.), from the same batch of eggs and reared in intensive conditions, were used in the experiment, 60 individuals per experimental replica. They were transferred into the rearing system containing seawater at 36ppt, and salinity was modified to the experimental salinity levels for one month before the onset of the experiment. The three salinity levels were 0ppt (freshwater, F), 18ppt (brackish water, B) and 35ppt (saltwater, S).

Water parameters such as salinity, dissolved oxygen, temperature were monitored daily. Ammonia, nitrite and nitrate were monitored once per week and 30% water exchange was performed when necessary. Fishes were fed *ad libitum* with artificial dry feed (Skretting).

Survival was monitored at the end of the experiment. Growth was assessed considering mean total length (TL, mm), mean body wet weight (BW, g), Growth Rate (GR, g day-

1), Specific Growth Rate (SGR, % day-1) and Condition Index (CI) for each treatment. Measurements were taken at the start and at the end of the experiment.

Results

Significant differences in terms of survival rate were observed among treatments, with similar survival in F (71±12%, mean±s.e.) and S (69±6%), higher than in B (33±3%). Therefore, F and S showed similar final fish densities. Both TL and BW were higher than the initial values, with no difference among treatments. GR for total length was similar among treatments. Samples from F and S showed similar GR for body weight (0.01±0.00g day-1) and SGR for total length (0.66±0.03 and 0.74±0.02% day-1) but were statistically different in terms of SGR for body weight (1.86±0.08 and 2.28±0.06% day-1). Final CI ranged from 2.95±0.07 in fishes reared in F to 2.55±0.13 in those reared in S.

Discussion

Fresh- and saltwater resulted the most suitable for juvenile survival. Both treatments showed similar growth (except for SGR for body weight). However, the Condition Index was slightly higher in juveniles reared in freshwater, suggesting that a longer trial period could result in a better growth than at higher salinity levels (i.e. marine waters).

Our results disagree with De Silva and Perera (1976), that observed maximum growth efficiency of wild *M. cephalus* juveniles (about 0.1g mean initial BW) at a salinity of 20ppt, and Rodriguez et al. (1993), that observed maximum survival and growth rate in wild juveniles (75-85mm mean initial TL) reared under salinities higher than 8ppt. Contrarily, the results we obtained are more in agreement with Cardona (2000), that described growth performance of wild juveniles (50mm mean initial TL) as negatively affected by salinity levels higher than 5ppt. Nevertheless, it should be considered that the mullet juveniles used in our experiment were born and reared in captivity, and tested during a different life stage compared to the specimens in previous studies.

Survival, growth and CI obtained at the salinity of 0ppt indicate that the rearing of mullet juveniles in freshwater is feasible. The rearing in freshwater could increase the number of suitable spaces available for mullet aquaculture, and could give a considerable boost to the development of mullet aquaculture techniques.

Introduction

Seaweeds are a renewable and non-traditional raw material that can be used as a feed ingredient to face some of the sustainability challenges in aquaculture production. Seaweeds are rich in nutrients and contain various bioactive compounds, which may have health-promoting effects in both humans and animals. Zebrafish (*Danio rerio*) is an attractive animal model for the investigation of immune and other health-related functions in animals, including fish as well as humans. The tools available for studying the biology of this model are numerous allowing thorough investigations of basic mechanisms. The intestinal wall morphology of zebrafish resembles that of other fish and mammals (Wallace et al. 2005), and most of the main immune cells have been described (Renshaw and Trede 2012). Feeding studies in zebrafish have however up until now mostly been performed in larvae or young individuals, which do not comprise a fully developed immune system and intestinal funtion. As part of a large collaborate project, PROMAC, adult zebrafish was used as animal model to evaluate possible health-promoting effects of two seaweeds: *Saccharina latissima* and *Palmaria palmata*.

Material and methods

Adult zebrafish were fed diets including seaweed products, and evaluated with regards to growth rates, intestinal immune stimulating effects and bacterial microbiota. Both whole products and protein concentrates of the seaweeds were applied and different inclusion levels of seaweed products were tested. As a dietary challenge, diet formulation also included high levels of soybean and purified soy saponin to induce an intestinal inflammatory response. In Atlantic salmon, anti-nutrients of soybean meal is known to induce a pronounced intestinal enteritis (van den Ingh et al. 1991; Krogdahl et al. 2015) and similar responses have also been reported in zebrafish larvae (Hedrera et al. 2013; Coronado et al. 2019). After four weeks of feeding, all fish were additionally challenged with a high cholesterol diet to trigger an inflammatory response based on previous experiment in rats and zebrafish (Progatzky et al. 2014; Arias-Jayo et al. 2018). Transcript levels of immune- and stress-related genes, enteritis markers and sterol metabolism genes were evaluated. Gut morphology was histologically evaluated and bacterial microbiome profile based on 16s rRNA amplicon sequencing was characterized. Possible effects of the seaweeds on tail fin regeneration were additionally approached with a fin clipping challenge. Fin regrowth lengths and regeneration stage was evaluated by macroscopic pictures and histology (Figure 1).

Results and conclusions

With this project, a model for feeding studies in adult zebrafish was established. Both soybean meal and cholesterol ingestion showed a significant effect on the expression of sterol metabolism genes in the intestine comparable to the lipid disorder observed in Atlantic salmon fed diets with high levels of soybean (Kortner et al. 2013). Interestingly, we could not demonstrate a pronounced intestinal inflammatory response after feeding with either soybean meal or cholesterol based on gene expression and histology evaluation. However, gene expression profiling demonstrated that both seaweed species were able to induce a mild modulation of stress and immune-related gene expression in the intestine. These findings suggest the presence of bioactive compounds in the seaweeds products evaluated. Preliminary results show no differences in intestinal microbiota profiles and tail fin regeneration between diet groups. Analyses are ongoing and more results will be presented at the conference.

MOLECULAR CHARACTERIZATION OF *Vibrio harveyi* STRAINS ASSOCIATED TO DISEASE IN REARED GREY MULLET (*Mugil cephalus*)

M. Lopez-Sanmartin, M Herrera, JR Lopez

IFAPA Agua del Pino, Ctra. El Rompido - Punta Umbría, km 3.8, 21459, Cartaya, Huelva (Spain)
Email: lasacias@yahoo.es

Introduction

Several types of pathogens, embracing parasites, virus or bacteria,have been described in *Mugil cephalus*. Inside species of bacteria that have been described stand out: *Edwardsiella tarda*, *Eubacterium tarantellae*, *Lactococcus garvieae*, *Nocardia seriolae*, *Streptococcus agalactiae* and *Photobacterium damselae* (both subspecies). *Vibrio harveyi* is member of the common microbiota of many marine species, also known as opportunistic pathogen in marine invertebrates (specially inshrimp) and fish, including species of *Mugil* gender. In fact, *V. harvehi* has been described causing haemorrhagic septicaemia in *M. curema* (White mullet) (Alvarez et al. 1998). However, to our knowlegde, *V. harveyi* has not been previously described in *M. cephalus*. A disease outbreak with 20% mortality was observed in *Mugil cephalus* reared in IFAPA Centre Agua del Pino between May and October 2013. This study characterizes *V. harveyi* strains recovered from this disease outbreak.

Material and methods

Microbiological analyses were performed from ulcers, haemorrhagic sky and mouth, and kidney. A *V. harveyi* specific PCR protocol was carried out according Pang et al. (2006). Phylogenetic analyses were computed with MEGA6 software (Tamura et al. 2013) using partial sequences of 16S, *gyr*B, *rpo*D y *rpo*A genes. Fingerprinting of *V. harveyi* isolates was performed with enterobacteria repetitive intergenic consensus (ERIC) PCR and repetitive extragenic palindromic (REP) PCR methods (Rodríguez et al. 2006), including the type species of *V. harveyi*.

Results

Three isolates were recovered from grey mullet samples, namely isolate a385 (from external ulcer), a636 (haemorrhagic mouth) and a661 (kidney), these two last obtained in pure culture. Isolates were recovered in different moments during the outbreak (May, September and October 2013).

The result of the molecular diagnosis described by Pang et al. (2006) showed the expected band for the isolates a385, a636 and a661 and type strain of *V. harveyi*. The phylogenetic trees carried out with the four genes analysed locate the three mullet isolates clearly associated with *V. harveyi*. Multilocus sequence analysis (MLSA) using 16S, *gyr*B, *rpo*A and *rpo*D gene sequences (3701 bp) confirmed these results. Mullet isolates showed 99.48% similarity with *V. harveyi* type strain and 99.42-99.48% between them, but these values were bellow 98% with the type strains of other related *Vibrio* spp (*V. campbellii* 97.39%, *V. owensii* 96%, *V. hyugaensis* 94.92%, *V. rotiferianus*94.16%).

Molecular fingerprinting of the grey mullet isolatesshowed that they share quite similar profiles, but not identical (Dice coefficients were of 0.75-0.88 for REP-PCR and 0.71-0.76for ERIC-PCR). The profiles were also quite similar to that of *V. harveyi* type strain (0.72-0.88 REP-PCR and 0.66-0.90 ERIC-PCR).

Conclusion

In conclusion, this study present three isolates, a385, a 636 and a 661, identified as strains of *V. harveyi*, as the cause of a mortality outbreak in reared *Mugil cephalus*.

Introduction

Shrimp farming has grown constantly in past years and Biofloc Technology (BFT) contribute with the intensification of Pacific white shrimp using minimum or zero water exchange, reducing the area and water resources use (Samocha et al., 2012). IMTA (integrated multitrophic aquaculture) is an aquaculture model which integrates different trophic levels in the same environmental system, resulting in a conversion of the culture residues of the main species into food, or fertilization, for the other species (Chopin et al., 2001).

This study aimed to evaluate the performance of an integrated multitrophic aquaculture (IMTA) system applied to shrimp rearing in biofloc technology (BFT).

Materials and methods

The IMTA system consisted of shrimp (*Litopenaeus vannamei*) in a rearing tank (800 L), a tilapia (*Oreochromis niloticus*) rearing tank (90 L), and a hydroponic bench with 0.33 m2 of planting space for *Sarcocornia ambigua* culture. A submerged pump constantly pumped water from the shrimp tank to the tilapia tank. Then, by gravity, water flowed through the sarcocornia hydroponic bench and returned to the shrimp tank. The hydroponic bench had enough capacity for 32 plants. Shrimp, tilapia and sarcocornia stock densities were 312 shrimp m-3 (250 shrimps per 800 L tank), 445 tilapia m-3 (40 tilapias per 90 L tank), and 97 sarcocornia plants m-2 (32 plant per system), respectively. The same experimental units were used in the control system which only differed by the absence of sarcocornia. The initial weight was 4.09±0.025 g, 1.16±0.02 g and 1.17±0.175 g for shrimp, fish and sarcocornia, respectively. Shrimps were fed according to the feed table, and the fishes were fed with 1% of fish biomass, stimulating tilapia to use biofloc as a food sourc

Table I: Total sludge produced, total suspendend solids (TSS), volatile suspended solids (VSS) and fixed suspended solids (FSS) for *Litopenaeus vannamei*, *Oreochromis niloticus* and *Sarcocornia ambigua* performance in an integrated biofloc culture system for 57 days.

	IMTA	Control	*p* t-test
Total sludge production (kg tank $^{-1}$)	0.18±0.02	0.35±0.055	0.039*
Total sludge removed by settling chamber (kg tank $^{-1}$)	120.27±11.04	194.18±14.13	0.028*
TSS (mg L^{-1})	437.9±5.7	484.4±7.35	0.002*
VSS (%)	50.9±0.5	51.1±0.5	0.227
FSS (%)	49.1±0.45	48.9±0.7	0.657

Data presented as mean ± standard error. * indicate statistical differences by the t-test ($p < 0.05$).

(Continued on next page)

Results

Results show no difference between shrimp and tilapia performance in either treatment. Only IMTA total yield (4.83±0.19 kg m-3) was significantly higher than that in the control system (3.99±0.045 kg m-3). Nitrate was higher in the control system (12.28±1.27 mg L-1) compared to the IMTA system (9.38±1.09 mg L-1). The total sludge production and the total suspended solids were reduced in the IMTA group compared with control group (table I).

Disscussion and conclusion

The IMTA system improves the total yield up to 21.5% by multitrophic integration of *L. vannamei*, *O. niloticus* and *S. ambigua* in a biofloc system. The increasing the sarcocornia area and/or tilapia stock density could improve this yield; however, this must be evaluated in future studies. Nitrate concentrations were lower in IMTA group probably by the preference absorption by halophytes plants for this N-source (Ventura and Sagi, 2013). The amount of sludge produced and consequently removed by the settling chambers, lower in IMTA group, could be related to a phytoremediation with microorganisms participation resulting in an organic suspended solids consume (Ansari et al., 2017) whit decrease of TSS and consequently sludge production. Experimental IMTA system with *L. vannamei*, *S. ambigua* and *O. niloticus* increased the total yield, reducing the nitrate levels, SST and sludge production that represents a significant ecological gain apart from the economic gain.

Introduction
The gut barrier has several significant biological functions and in addition to the primary function of absorbing nutrients, it is also an essential barrier between the fish and the external environment, controlling loss of nutrients and preventing uptake of noxious substances. Furthermore, it also harbors an extensive microbiota that can aid in nutrient utilization and protect against pathogen agents. However, several factors can interfere with gut functionality, with serious implications for the health and welfare or the organism (Peterson and Artis 2014, Butt and Volkoff 2019). Combinations of stressors throughout an animal's life, especially in agriculture and aquaculture settings may affect the regular operativity of this organ with negative consequences for animal welfare (Jiminez et al. 2015, Niklasson et al. 2011, Rolf Erik Olsen et al. 2005, 2002, Segner et al. 2012, Sundh et al. 2010). In the current study we report the effects of a 3 week unpredictable chronic stress (UCS) period on the intestinal morphology and transcriptome response of Atlantic salmon *(Salmo salar)* parr, midgut and hindgut.

Material and methods
The experimental design is described in Madaro et al. 2015. Atlantic salmon parr in six different tanks were divided into two groups (n=3 replicates), of which one received a set of random stressors (unpredictable chronic stress (UCS)) while the other was left undisturbed (control group). The UCS group was stressed three times per day (08:30 h, 13:00 h and 17:00 h) using a total of eight types of stressors given in random and unpredictable order. On day 23, 2 fish were sampled from each tank subjected to UCS (n=6) and compared with 2 fish from each tank from the unstressed control group (n=6). Midgut and hindgut from both control and UCS fish were collected for histology and RNA-seq analysis to identify respective changes in the membrane structures and putative genes and pathways responding to UCS.

Results
Histological analysis did not show any significant effect on morphometric parameters. In the midgut, 1030 genes were differentially expressed following UCS, resulting in 279 genes which were involved in 13 metabolic pathways, including tissue repair pathways such as cell cycle, DNA replication, mismatch repair, nucleotide excision repair, base excision repair, ribosome and ribosome biogenesis, RNA transport, spliceosome, pyrimidine metabolism, proteasome, homologous recombination and oxidative phosphorylation. In the hindgut, following UCS, 591 differentially expressed genes were detected with 426 downregulated and 165 upregulated. A total of 53 genes were related to 3 pathways. Downregulated genes include cellular senescence pathways, p53 signaling and cytokine-cytokine receptor pathways.

Discussion and conclusion
The overall results corroborate that salmon parr were at least partly habituating to the UCS treatment, activating adaptive mechanism to ensure essential functions relating to cell/tissue integrity while the fish immunity decreased. In fact, in midgut, the main upregulation was related to cell growth and repair, while in the hindgut there were indications of activated apoptotic pathway, reduced cell repair, and inhibited immune /anti-inflammatory capacity. This may be the trade-off between habituating to UCS and health resilience. This study provides new insight into the understanding the integrated genetic regulatory mechanisms of Atlantic salmon parr to cope with UCS in a farmed environment.

GENETIC EVALUATION FOR BODY WEIGHT USING SINGLE-STEP GENOMIC BEST LINEAR PREDICTION IN *Macrobrachium rosenbergii*

S. Luan[1*], J. Liu[1], J. Kone[1], G. Yang[2]

[1]Yellow Sea Fisheries Research Institute, Chinese Academy of Fishery Sciences, Qingdao, China
[2]Huzhou University, Huzhou 313000, China
E-mail: luansheng@ysfri.ac.cn

Introduction

Unclear relationship inter- and intra-founder populations is a very tricky problem when constructing the based population in a selective breeding program. Moreover, there are often pedigree errors because of the lose of individual tag, the drift of visual implant elastomer fluorescent tag and incorrect records. The errors could lead to biased estimates of genetic parameters and predicted genetic gain using the conventional best linear unbiased prediction method with pedigree (pBLUP). The accuracy of estimated breeding value (EBV) can be improved through correcting the pedigree using high-throughput molecular markers. The single-step genomic BLUP (ssGBLUP) method has been proposed (Aguilar et al, 2010), which replaces the traditional additive genetic relationship matrix A with a more accurate relationship matrix H combining pedigree and genomic relatedness (Lourenco et al, 2014). The objective of this study was to estimate genetic parameters and predicted response to two-generation selection for body weight of the giant freshwater prawn *Macrobrachium rosenbergii* using ssGBLUP.

Materials and methods

The dataset for body weight included three generations and 50271 individuals which originated from four founder populations in *M. rosenbergii*. Variance components and EBVs for body weight were estimated by fitting the animal model which used the relationship matrix A (only pedigree) or matrix H (pedigree combined with genomic information of 215 genotyped parents with 41,960 SNP loci). The accuracy of prediction was calculated through the 10-fold cross validation in which each of the ten subpopulations was used exactly once as the validation population and then repeated 30 times.

Results

Correlation coefficient between lower triangular relationship matrix A and H of the 215 genotyped parents was 0.56, which implies that there might have been inacurrate estimates of kinship in the selection population. Heritabilities based on relationship matrix A and H were 0.18±0.03 and 0.21±0.03, respectively. Accuracies of EBV estimated by pBLUP and ssGBLUP were 0.65 and 0.67, respectively, with an increase of 3.1%when matrix H was used. The genetic gains after two-generation selections for body weight were 5.09g and 6.09g based on pBLUP and ssGBLUP, respectively (Table 1).

Discussion and conclusion

In this study, a higher prediction accuracy of EBVs was obtained through ssGBLUP compared to pBLUP although the number of genotyped parents is limited. Variance components and genetic gain obtained from relationship matrix A were biased compared to relationship matrix H. Desirable response to selection for body weight was obtained in this selective breeding program compared to other programs (Luan et al., 2012). Prediction accuracy of EBVs may be further improved with increase of the number of genotyped parents and the number of SNP loci in the next generations.

Table 1. Predicted genetic gain for body weight in *Macrobrachium rosenbergii*

Method	Generation	No. of Families	No. of individauls	Breeding Value (g)	Genetic gain (g)
pBLUP	G0	78	8361	0.12	-
	G1	120	15394	2.53	2.41
	G2	129	25059	5.21	5.09
ssGBLUP	G0	78	8361	0.36	-
	G1	120	15394	3.62	3.26
	G2	129	25059	6.45	6.09

FISH WELFARE INDICATORS: LESSONS LEARNED FROM WELFARE STANDARDS IN TERRESTRIAL ANIMALS

Vincent Lugert*[1], Dieter Steinhagen[2], Verena Jung-Schroers[2], Mikolaj Adamek[2], Stefan Reiser[1]

[1] Johann Heinrich von Thünen Institute, Institute of Fisheries Ecology, Herwigstraße 31, D-27572 Bremerhaven, Germany

Introduction

There is substantial scientific evidence, that most animals, including fish, are sentient beings (Dawkins 1990; Manfrin et al., 2018). Accordingly, animal welfare has become an established scientific discipline with massive social support. The mass collection and analysis of data has led to a number of valid and reliable indicator to assess the status of animal welfare of almost every kind of terrestrial farm animal. However, the situation is somewhat more difficult in aquatic animals such as fish. The list of measurable parameters related to fish health and welfare easily exceeds several hundred items and largely varies between species, life-stage (Martins et al., 2012), and production system (van de Vis et al., 2012). As fish welfare is a comparatively novel discipline (Manfrin et al., 2018) and being confronted with this great number of measurable parameters it seems obvious to look into the development and application of terrestrial animal welfare indicators. This approach can help in order to develop appropriate strategies for the assessment of fish welfare and to avoid the repetition of errors.

Materials and methods

Today, a frequent corporate self-check of the state of welfare is required from every fish farmer. However, until now there is no universal set of indicators available to comprehensively implement this in an equivalent way. We reviewed the current guidelines for the assessment of welfare in terrestrial farm animals as well as the methodology used to develop these, in order to adapt a strategy for fish welfare indicators

Results

We found, that of a large number of measurable parameters only very few fulfill the necessary conditions in terms of reliability, objectivity, validity, and practicability (Figure 01). Additionally, such indicators need to be widely accepted by all, society, operators and farmers and need to be integrable into everyday routine work.

Figure 01: Two possible relationships between number of available parameters and practicability as welfare indicator

Discussion and Conclusion

Animal welfare is an ethical decision of society. Today more then ever, we have the understanding, knowledge, and evidence, that animals have the ability to suffer and experience distress. However, when compared to terrestrial animals, the evaluation of valid, reliable, and practicable indicators, to assess the state of welfare in farmed fish is yet at the beginning.

Introduction

In aquaculture operations, feed may represent more than 50% of the total cost of operations (Rana et al. 2009). As the industry is expanding rapidly, the rise in global demand has led to an increased price for fishmeal of almost 300% since 2005 (Roberts et al., 2015). Similarly, the cost of major oils used in the aquafeed industry has increased by 250 percent (Rana et al. 2009). This global trend in major feed ingredient has increased the average prices for aquafeeds by 20-90%, depending on region and target species. Accordingly, there is a steady demand to reduce feed production price by finding novel and alternative feed ingredients and formulations, while maintaining feed efficiency and growth performance of the reared organisms at the same time.

Currently, it is common practice to test new ingredients and formulations in laboratory trials, mostly on juvenile fish. However, there is evidence, that results obtained in such trails cannot be transferred across different life stages (Lugert et al., 2019), and therefore contain little information regarding rearing time and harvest size.

Mathematical modeling is an important tool to describe the growth process of an animal across life stages, from juvenile to maturity. The method also allows to predict and evaluate the goals of trait specific breeding programs (Lugert et al., 2019). In the current study, we have successfully tested the possibilities, to model the long-term effects of different feed formulations on cultured rainbow trout.

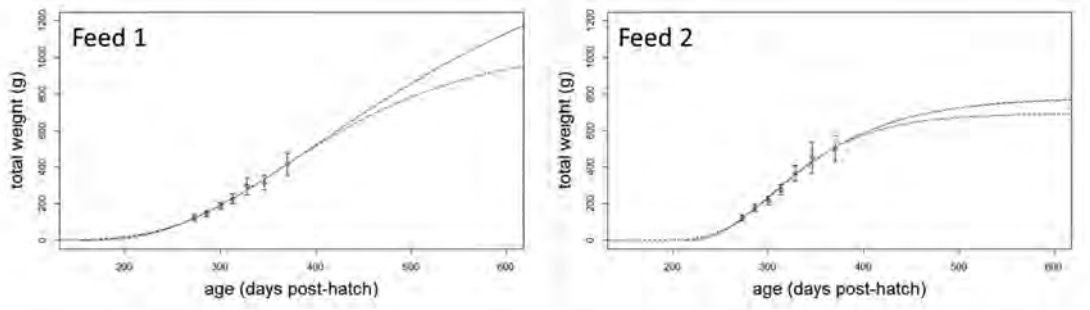

Figure 01: Simulation of long-term effects on growth trajectories, as a result of different feed formulations displayed by the same two models. Dotted line = model 1, dashed line= model 2.

(Continued on next page)

Materials and methods

The experiment was performed at a commercial farm. Fish (n=900) were acquired from the farms-own breeding program and were distributed randomly into nine tanks. Fish were fed with three different extruded pellets of different experimental formulations in triplicate groups. Rations were offered twice a day until apparent saturation. Several models of different complexity were tested against the data. The most suitable model was evaluated by a variety of statistical tests combined in a multi-criteria analisis.

Results

Despite the massive influence of the feed formulation on fish performance, the statistical analysis revealed the same mathematical relationships related to the growth process. This means, that different growth trajectories, triggered by different feed formulations and/or feed ingredients, can be described in the same manner and by the same function within the same species. This allows evaluation of a specific model and accordingly the prediction of the influence of specific feed formulations by a mathematical equation.

Discussion and Conclusion

The mathematical parameters estimated for the target species are in line with those from a variety of aquaculture studies. Accordingly, fish have grown in accordance with their biological attributes. This is important to justify the predictive capacities of the model. We could show, that it is possible to model the impact and long-term influences of varies feed formulations and ingredients on growth and rearing time in fish.

Introduction

Microalgae has been tested widely as potential microorganisms to phycoremediate wastewater from different sources (WW), including aquaculture wastewater (AWW) (Ansari et al., 2017; Guldhe et al., 2017). The results are promising, as they proved that microalgae can remove even more than 90% of the pollutants from the WW; however, most of the experiments have been performed in lab scale (Guldhe et al., 2017). By growing microalgae in AWW the economic and environmental factors of aquaculture can be improved considerably, as the AWW is used to grow algae and produce valuable biomass. The algae products can be used as fish feed ingredients or other valuable compounds. Additionally, after harvesting the algae the water can be reused in the aquaculture system (Guldhe et al., 2017). Thus, given the great potential of using the nutrients from AWW for algae production and the lack of experiments in pilot or commercial scale, pilot experiments were carried out to phycoremediate AWW and optimize the biomass production of *Chlorella sorokiniana*.

Materials and methods

Nile tilapia (*Oreochromis niloticus*) was the fish grown in the aquaculture system. The effluent water from the aquaculture system was deposited in 50L photobioreactors (model: HXDYKZ-12) and used as growth media for the microalgae. The photobioreactors had external light-emitting diodes with a proportion of 3:1 of red and blue, and an input of air of 0.4vvm enriched with 0.1% of CO_2. The growth rate and biomass production of *C. sorokiniana* (CCAP 211/8K) were tested in batch cultures using filtered AWW and AWW with additional N and P. The growth rate and biomass production from this experiment were compared to the properties of *C. sorokiniana* when it is grown in synthetic growth media with the same content of nitrogen and phosphorous as the AWW experiements.

On the other hand, in order to evaluate the efficiency of *C. sorokiniana* to remediate AWW, the quality of the water before depositing it on the photobioreactors and after harvesting the microalgae was measured. Parameters such as pH, total nitrogen, total phosphorous, dissolved oxygen and chemical oxygen demand were used as indicators of the water quality (Mennaa et al., 2015).

Results

The microalgae *C. sorokiniana* was able to grow well in AWW. The cells grown in AWW were not phenotypically different compared to the cells grown in synthetic media, which indicates that the cells were not under stress conditions.

Regarding the analysis of the quality of the water, results revealed that the microalgae was able to lower considerably the nutrient content in the water. As well, the CO_2 concentration decreased considerably in the water, and the dissolved oxygen increased.

Discussion and conclusion

As the nutrient content of the AWW was lower than in the synthetic growth media normally used for algae production, the experiment was also conducted with additional nutrients to the AWW. The lower concentration of nutrients in AWW is related to water quality required in the aquaculture system in order to keep the fish in good conditions and have greater productivity. The limited quantity of nutrients affects directly the microalgae biomass productivity (Bohutskyi et al., 2017). Thus, the four tests included AWW with and without additional nutrients and two synthetic growth media for comparison with the same amount of N and P.

Ansari, et al. (2017) were able to reach a higher biomass productivity by adding nitrogen to the AWW. Moreover, the sludge contained in the AWW can lower the light scatter and penetration, resulting in a lower photosynthetic activity (Guldhe et al., 2017).

The use of AWW for algae production still require further improvements, but results indicate positive results and could provide an additional income for aquaculture companies as well as lower the ecological impacts generated by aquaculture.

Introduction

European eel (*Anguilla anguilla*) is considered to be an economically important fish species. Overfishing, together with other anthropogenic factors and diseases suppress the revitalization of this species. Reproductive limitations in natural conditions are hindering the population regenerationand consequently, this species has been listed as a critically endangered species on the IUCN red list. Reproduction in captivity is considered as a possible solution to overcoming these problems. Although protocols for hormonal stimulation and *in vitro* fertilization are developed, there is still a serious problem in larval survival after hatching. Therefore, there is a need for new conservation strategies for genetic resources. Cryopreservation is a method that allows the preservation and storage of biological materials in liquid nitrogen for an indefinite time. Ovarian tissue banking is a novel strategy for the preservation of valuable female genetic resources (Lujić et al., 2017) and, accompanying with other methods, presents a promising method in overcoming reproductive difficulties in many fish species. The first step which can contribute to the development of new alternative conservation strategies for this species is the cryopreservation of early-stage germ cells such as oogonia. Further usage of obtained preserved cells might serve for subsequent manipulation, such as *in vitro* culture or germ cell transplantation.

Material and Methods

Fish were held in controlled conditions in a recirculating system of the Department of Aquaculture at Szent Istvan Univeristy in Hungary at a constant temperature of 16±1 °C without feeding. Individuals were euthanized, ovarian tissue was excised and immediately transferred into phosphate buffered saline (PBS) with 100 U/mL penicillin and 0.1 mg/ml streptomycin and placed on ice until further use. Tissue was cut in pieces which were subsequently used for cryopreservation. Fresh tissue was used as a control for assessment of OSC (oogonial stem cells) viability after thawing. Six sequential experiments were performed during optimization of the cryomedia and freezing protocol. Firstly, the effects of six cryoprotectants (dimethyl sulfoxide - Me_2SO, propylene glycol – PG, ethylene glycol – EG, glycerol – GLY, methanol – MeOH, 2-methoxyethanol – 2ME) on OSC viability were assessed. Then, different concentrations of the three best cryoprotectants from the firs experiment were tested followed by testing of sugar (glucose, sucrose and trehalose) and protein (bovine serum albumin – BSA and fetal bovine serum – FBS) supplementations. With the most suitable cryomedia, we proceed with testing the effects of different tissue pieces weight (25, 50 and 75 mg) and equilibration time (5, 15 and 30 min) in cryomenia prior to freezing to OSC viability. Then, six cooling rates (-0.5, -1, -5, -10, -20 and -40 °C/min) were examined using three thawing approaches (thawing in a 10 °C water bath, as well as at a controlled and reciprocal rate to the cooling rate). Lastly, three different plunging temperatures were assessed by cooling ovarian tissue pieces at -1 °C/min up to -40, -60 and -80 °C before the tissue was plunged into liquid nitrogen (lN_2).

In order to assess oogonia viability, all tissue pieces were weighed and dissociated in the solution of L-15, 2 mg/ml collagenase, 1.5 mg/ml trypsin and 60 µg/ml DNase I for one hour and terminated with adding the same volume of 10% Fetal bovine serum (FBS). The suspension was filtered, centrifuged and the supernatant was carefully removed since the pellet was resuspended by adding 50 µl of L-15. Verification of oogonia viability was conducted using the trypan blue exclusion test, where the viability was calculated as the proportion of the total number of obtained cells from cryopreserved tissue compared to the total number of cells obtained from the fresh dissociated tissue. Viability test was done using a Bürker-Türk hemocytometer.

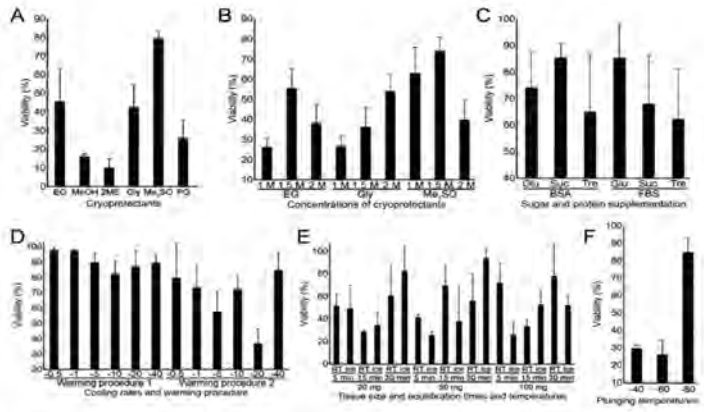

Figure 1. Optimisation of European eel ovarian tissue cryopreservation. Viability of oogonia after cryopreservation with A. 1.5 M of ethylene glycol (EG), methanol (MeOH), 2-metoxy ethanol (2ME), glycerol (Gly), dimethyl sulfoxide (Me_2SO) and propylene glycol (PG). B. 1, 1.5 and 2 M of EG, Gly and Me_2SO. C. different sugar (glucose (Glu), sucrose (Suc) and trehalose (Tre)) and protein (bovine serum albumin (BSA) and fetal bovine serum (FBS)) supplementations. D. different cooling rates (-0.5, -1, -5, -10, -20, -40 □/min) and warming procedures (warming procedure 1 (10 □ water bath), warming procedure 2 (reciprocal to the cooling rates)). E. tissue sizes (20, 50 and 100 mg), equilibration time (5, 15 and 30 min) and equilibration temperature (RT - 23 □ and on ice). F. plunging temperatures (-40, -60 and -80 □). All values are presented as mean ± SD. Different letters above the SD lines indicate statistical significance (Tukey's HSD, $p < 0.05$), while the lack of such letters indicates the lack of statistical significance.

Results and discussion

The first experiment (Fig 1.) displayed the superiority of three cryoprotectants: Me_2SO, EG and GLY. In the subsequent experiments, these three cryoprotectants were used in different molar concentrations (1 M, 1.5 M, and 2 M) and similar results were obtained where the highest OSC viability rates were observed when utilizing 1.5 M Me_2SO. Varying sugar and protein supplementation did not display significant differences, therefore 1.5 M Me_2SO supplemented with 0.1 M glucose and 1.5% BSA contributed to the best post-thawing survival rate. According to these results, the developed protocol was used to examine the influence of different tissue sizes, equilibration times and plunging temperatures. When comparing the effects of different tissue sizes, and equilibration techniques, equilibration of 50 mg tissue pieces for 30 min on ice resulted in the highest viability (93.8±5.8%). No significant differences were observed between the tested cooling rates when thawing in a 10 °C water bath, while reciprocal thawing rates yielded slightly lower viability rates. Lastly, the plunging temperature of -80 °C was superior to the other plunging rates.

Techniques developed in this study present the onset of the germline stem cell manipulation technologies in the European eel which will contribute to the development of new and improved conservation and management strategies for this species.

Introduction

Sea urchin gonads (roe) are a prize product and broadly recognized as a delicacy for human consumption. Due to the increasing demand for this product by Asian and European countries, overfishing is causing a sharp decline in the wild stocks of *Paracentotus lividus*. During the last decade a significant increase in efforts to develop cost-effective methods to culture sea urchins has been observed including research aiming to optimize the reproduction and juvenile production. The development and survival of larval planktonic stages is still one of the bottlenecks for the echinoculture development. This communication presents several trials aimed at improving existing hatchery methodologies and consolidate the early life stage culture of *P. lividus*.

Material and Methods

For this study, *P. lividus* adults, with test size superior of 35 mm, were collected from intertidal rock pools in the southern coast of Madeira island, Portugal. The rearing system consisted of four 200 L tanks at 22.05 ± 0.707 ºC and a 90 L/h of water renovation. Feeding was established at 5% weight.day^{-1} of macroalgae collected in the sampling site. The maturation stage of the population was analyzed *a priori* by determining the gonadal index (GI) and by histological analysis of the gonads of a subsample of 20 sea urchins. Following an initial evaluation of different spawning methods, the KCl 0.5M was chosen to induce spawning and to perform the artificial fertilization of sea urchin eggs. The viable echinopluteus were then fed with diets of different microalgae (*Dunaliella tertiolecta* and *Rhodomonas marina*) comparing larvae growth and survival, when competence for settlement was achieved. The larval experimental design consisted of three triplicated treatments, in 7 L cylindroconical incubators at 21 ºC. The microalgae rationing was established at 4000, 8000 and 16000 cells.ml^{-1} in treatment 1, 2 and 3, respectively for larvae (echinopluteus) with two pairs of arms. The microalgae concentration was doubled in all treatments with the increment of the 3rd and 4th pair of arms during the development of the echinopluteus.

Results

The first larval development experiments using a *R. marina* diet showed that the echinopluteus attain the settlement phase within 21 days. Higher survival rate in the treatment of lower microalgae concentration. Using *D. tertiolecta*, the echinopluteus attain the settlement phase within 15 days. Based on these initial results, further experiments are undergoing to allow for improvements in the larvae methods for *P. lividus*.

Introduction

In the last decades, aquaculture has become the fastest growing food production sector with an average annual growth rate of 5.4% (Valenti et al., 2018). This growth has been achieved due to the technification and intensification of aquaculture production systems. However, the increase in stocking densities, excessive handling, suddenly changes in temperature, poor water quality, and nutritional deficiencies generate stress and weaken the immune system of organisms (Reverter et al., 2014). All these conditions favor the outbreak of infectious diseases such as the acute hepatopancreatic necrotizing disease (AHPND) caused by *Vibrio parahaemolyticus* in shrimp.

Materials and methods

To determine the protective effect of bacilli inoculated into the water in small shrimp, a bioassay was conducted during 15 days with healthy shrimp weighing 213.4 ± 5.0 mg. Bacteria was inoculated in water (1 x 10^6 CFU/L) every 3 d and added to commercial feed (1 x 10^6 CFU/g). The mean lethal concentration of *Vibrio* put in the water was previously determined (LC_{50}= 77,000 CFU/mL). Uneaten food and waste material were removed every 3 d until day 12. The determination of physicochemical parameters (dissolved oxygen, pH and salinity) were determined daily. Six shrimps were taken per treatment and each one was stored in 1 mL of RNALater. The relative expression of immune-related genes was determined by qRT-PCR before bacterial challenge at day 12. Reference genes were β-actin, 40S-S24 and EF1α. ANOVA and Tukey test were performed. Data are mean ± SE. Different letters indicate significant di ferences ($p < 0.05$).

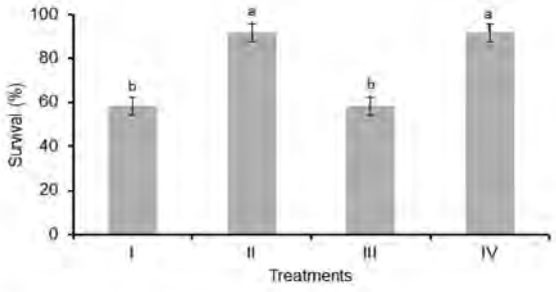

Figure 1. Survival of *L. vannamei o parahaemolyticus*. Treatments: **I)** Positive control, *Vibrio*; **II)** Bacilli (1 x 10^6 CFU/L) + *Vibrio*; **III)** Bacilli in feed (1 x 10^6 CFU/g) + *Vibrio*; **IV)** Bacilli (1 x 10^6 CFU/L, 1 x 10^6 CFU/g) + *Vibrio*.

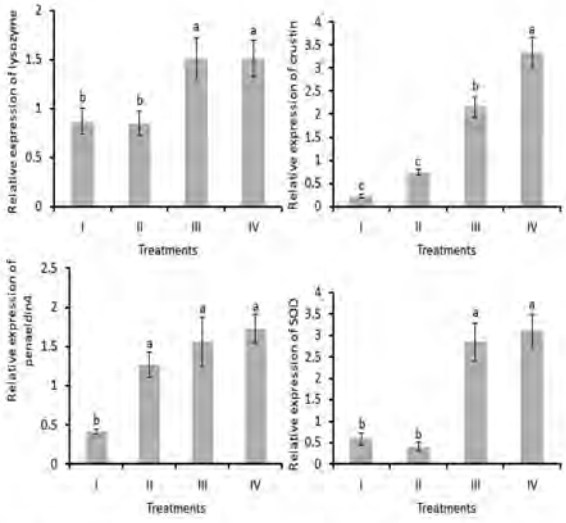

Figure 2. Gene expression in *L. vannamei*. Treatments: **I)** Positive control, *Vibrio*; **II)** Bacilli (1 x 10^6 CFU/L) + *Vibrio*; **III)** Bacilli in feed (1 x 10^6 CFU/g) + *Vibrio*; **IV)** Bacilli (1 x 10^6 CFU/L, 1 x 10^6 CFU/g) + *Vibrio*.

(Continued on next page)

Results

Survival was significantly higher ($p<0.05$) in the treatments with bacillus in the water as compared with the positive control and bacillus in the feed (Fig. 1). The expression of lysozyme, crustin, penaeidin4, and superoxide dismutase (SOD) genes was significantl up-regulated with bacillus in feed as compared with positive control and bacillus in water ($p<0.05$) (Fig. 2). *B. licheniformis* BCR4-3 in feed and water protects the white shrimp against AHPND and increases its immune response.

Discussion and conclusion

Bacillus licheniformis shown a positive overall effect when it was put in water during 15 d, efficiently increasing shrimp resistance to *V. parahaemolyticus* infection. Conversely, Zokaeifar et al. (2012) found that whiteleg shrimp treated with two strains (L10 and G1) of *B. subtilis*, added to feed during 8 weeks, improved disease resistance through an enhanced immune response. With respect to the immune system, the expression of the four immune-related genes studied was significantly up-regulated in treatments with bacilli in feed as compared with control group and shrimp of the treatment with bacilli in the water.

B. licheniformis BCR4-3 in feed and water protects the white shrimp against AHPND and increases its immune response.

Introduction

Blue Mussels (*Mytilus edulis*) have for decades been recognized as a potential mitigation tool to remove nutrients (Holmer et al. 2015, Petersen et al. 2019) while at the same time being a source of fatty acids and marine protein. Blue Biomass is a Danish company situated in the highly eutrophicated Limfjord in the Northwestern part of Denmark, aiming at producing 50,000 tons of blue mussels per year between 2020-2025. The farm now has 360 tube-net units (Smartfarm) with a total carrying capacity of 9000 - 12600 tons (25-35 tons/unit). The mussels are harvested twice a year and processed into animal feed and food for human consumption. Blue Biomass is the first large scale mussel farm in Denmark that through partnership with the feeds industry, has managed to open up for full scale production and processing of mitigation mussels. This study follows the biomass production and the effects from the farm on water transparency. Furthermore, the ecosystem service of nutrient removal provided by harvest is estimated.

Materials and Methods

The Blue Biomass mussel farm is situated in the western part of the Limfjord, in Northwest Denmark (56°34,266N, 8°34,372E). The mussel biomass, meat content, condition index (CI), and size distribution were monitored in diagonals from Southeast to Northwest in each farm area from 2018 - 2019. A one-way ANOVA was used to test for differences in CI of mussels between East, West and middle of farm areas. Additionally, profiles of fluorescence, salinity, temperature and oxygen (SeaBird, SBE19) was measured together with continuous surface fluorescence measurements, using a Turner Cyclops 7. In situ fluorescence was calibrated into in vivo chlorophyll from water samples using Turner designs (r^2 = 0.91). Mussel biomass was estimated from triplicate samples of areas of 25 x 25 cm from each unit (three units per area) and scaled up to full size (120 m long, three meters deep). Size distribution and meat content was measured on 100 mussels randomly selected from each sample. The CI was carried out on 10 mussels per sample and calculated as CI = dry $weight_{meat}$/$length^3$ according to standard methods. The monitoring was started with baseline measurements in May 2018.

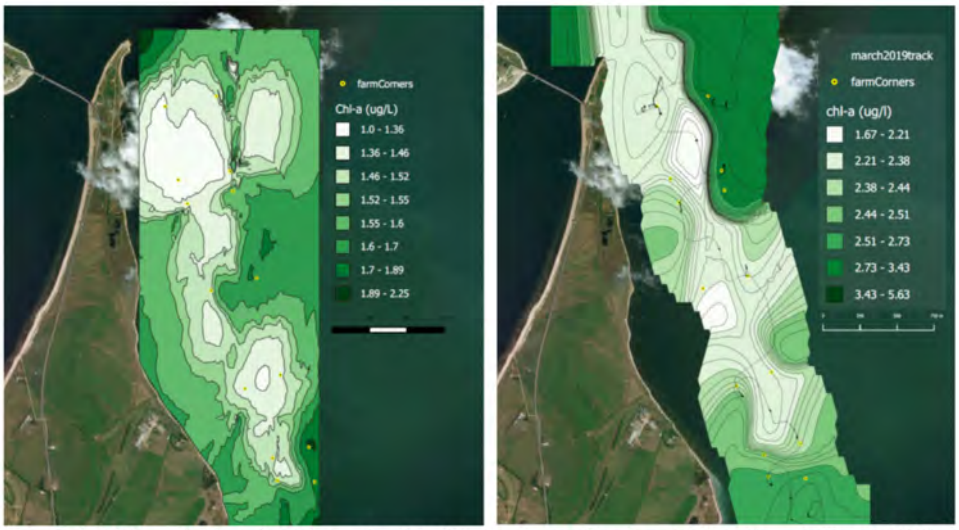

Figure 1. Chlorophyll (ug/l) at 2,5m depth in Limfjorden in October 2018 (left) and March 2019 (right). Farm corners are indicated with yellow dots. Current direction was NW on both days.

(Continued on next page)

Results

The settling of mussel larvae occurred in late May/early June and grew into an average biomass range from 6 – 34 tons per Smartfarm unit in December with an average value of 12.6 ± 7.7 tons, which was half of the estimated production capacity of the units due to loss of mussels caused by the extreme temperatures during the summer 2018. The average size of the mussels was from 39.2 ± 8.7 mm (sample size of 1200 mussels) in December. A complete harvest of the standing stock of mussels in December 2018 would remove 45.2 – 67.8 tons N and 2.2 – 3.1 tons P assuming the N- content of the mussels were from 1 – 1.5% and the P-content 0.05 - 0.07% (Petersen et al. 2014). Complete harvest of the full production capacity of 9000 - 12600 tons (25 - 35 tons per unit) would remove up to 189 tons of N and 8.8 tons of P per year from an area of 75 ha. The units reduced the phytoplankton concentration within the production area and downstream of the area, by more than 50 % (Figure 1). The middle of three out of four farm areas had the lowest average CI, and the Eastern part showed significantly higher CI than the middle and Western parts (one-way ANOVA, $p < 0.05$) indicating food depletion in the middle of the farm areas and a higher food availability in the eastern part of the farm areas. This indicates a maximum of carrying capacity for mussel density with regards to growth in the area.

Conclusion

The large-scale Blue Biomass mussel farm in Limfjorden, Denmark produces large amounts of marine protein and increases the visibility of the water. Measurements of growth parameters of the mussels from the middle, Eastern and Western part of the farm areas indicates food depletion despite the highly eutrophicated waters. A complete harvest of the standing stock of mussels in December 2018 would remove up to 67.8 tons of N which is equivalent to 3.2 % of the environmental reduction target of 2122.1 tons N yr^{-1} for the water body 156, as demanded by the EU water framework directive 1915-2021. The anticipated goal of 50,000 tons blue mussels per year harvested by Blue Biomass would cover 35.3 % of the reduction target and supply society with feed and food.

Introduction

Eutrophication of coastal water bodies by massive anthropogenic nutrient inputs is a serious global challenge. Suspended mitigation cultures of blue mussels have been suggested as a tool to remove nutrients through harvesting from eutrophic systems like the Western Baltic Sea (Petersen et al. 2014). The general idea of mitigation mussel farming is that the mussels remove nutrients contained in particles (mainly phytoplankton) directly from the water through their feeding activity and incorporate them into animal tissue during growth. Site-selection for marine mitigation aquaculture can be an important part of sustainable marine spatial planning considering both farm production, as well as environmental and socio-economic goals and interests. In the present study, mussel farm production potential was estimated for the Western Baltic Sea, which can provide input to a multi-criteria site selection tool in relation to marine spatial planning.

Materials and methods

We integrated data from field experiments and national monitoring programs within a sequence of numerical, statistical, and spatial models. Mussel individual growth was estimated by a dynamic Energy Budget (DEB) model (Maar et al. 2015) calibrated against observations from mussel long-lines and the environmental conditions. The DEB model was then applied to 59 monitoring sites with sufficient data and the results were used to make a more simple statistical model of mussel growth versus monthly data of temperature, salinity and chlorophyll-a (Chl *a*) concentrations. A spatial model estimated long-term (2008-2017) monthly means of environmental variables on 1km^2 scale based on monitoring data from Denmark, Sweden and Germany. The statistical growth model was imposed on the spatial environmental data and up-scaled to farm production taking bathymetry (depth of farm) and mussel densities within a standard farm into account.

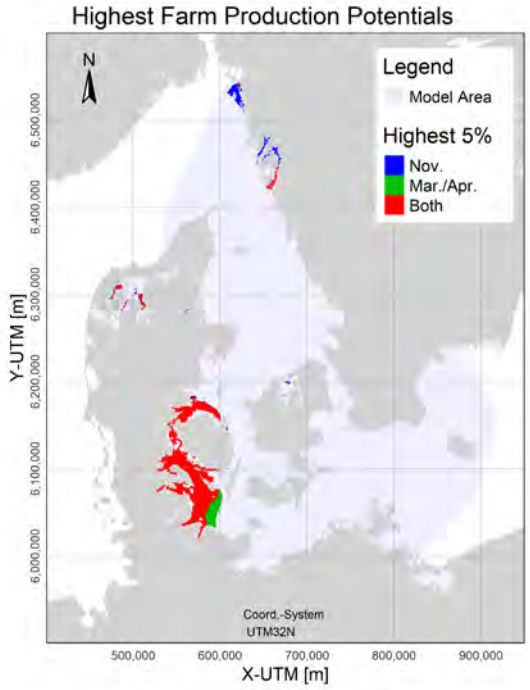

Fig. 1. Spatial model results of 5% highest farm production potentials in the W Baltic Sea indicated for harvest in November, March/April or both periods.

(Continued on next page)

Results and Discussion

We investigated model results for two growth seasons both starting in July and with harvest times in November or March/April. The modelled (long-term average) maximum biomass of individual mussels was 0.76g-DW and 1.7g-DW at harvest in November and March/April, respectively. Similarly, corresponding maximum farm production potential was 201t-DW and 302t-DW per standard farm. Water depths <4m was defined unsuitable for mussel farms. The smaller increase of maximum farm harvest compared to biomass of individual mussels is attributed to a functional decrease of mussel density on farm collector substrate with increasing mussel size. When selecting the 5% of sites with highest farm production potentials at harvest in November (163-201t-DW), Limfjord, Mariager Fjord, Isefjord, the whole area from the little Belt south to the Kieler Förde, and the north-west coast of Sweden are part of the selection (Fig. 1). The same selection at harvest in March/April (242-302t-DW) results in similar areas, except for the Isefjord. The impacts of different environmental variables on local farm harvest potentials are both of spatial and temporal nature. The typical temperature pattern is a major driver of seasonal dynamics of modelled mussel growth. Salinity expresses two major gradients: (1) There is a large-scale decrease of salinity from the Skagerrak area into the Western Baltic Sea; (2) numerous of the inner fjords show lower salinities. In our model, growth limitation by low salinity plays a major role south-east of the Danish islands Zealand, Falster, and Lolland between April and November. Chl-*a* expresses a strong seasonal pattern with a major peak in March, however, strong spatial heterogeneity is also observed throughout the year. Higher Chl-*a* concentrations are typically met within fjords and in near-coastal areas and especially along the northeast-coast of Germany. Low Chl-*a* concentrations limits mussel growth mainly in the open waters, as well as in the Sound and around the south-coast of Sweden. For the whole study area, water quality affects the growth of individual mussels in the following order of impact: salinity > Chl-*a* > temperature. Effects of bathymetry are super-imposed on the resulting growth of individual mussels, while upscaling to farm production potential. Within the applied spatial model, bathymetry limits the depth extent of mussel mitigation farms; therefore, shallow areas with depths <10m generally result in less farm production potential.

Conclusion and Outlook

Production potentials of mussel mitigation farms have been spatially modelled by integrating different modelling approaches. Results show that there are areas with likely good performance of this mitigation concept in the coastal waters of all three countries involved. In further steps, the results will be (1) validated against available independent mussel growth data from the study area, (2) evaluated with regard to model uncertainty and expected variability of mussel growth, and (3) overlayed with available spatial datasets relevant for marine spatial planning. Finally, a multi-criteria tool for optimal site selection of mussel farming will be developed to support sustainable marine spatial planning in the Western Baltic Sea.

IMPACT OF NSP LEVEL AND ENZYMES (PHYTASE AND XYLANSE) ON NUTRIENT UTILIZATION, GROWTH PERFORMANCE IN NILE TILAPIA (*Oreochromis niloticus*)

Introduction

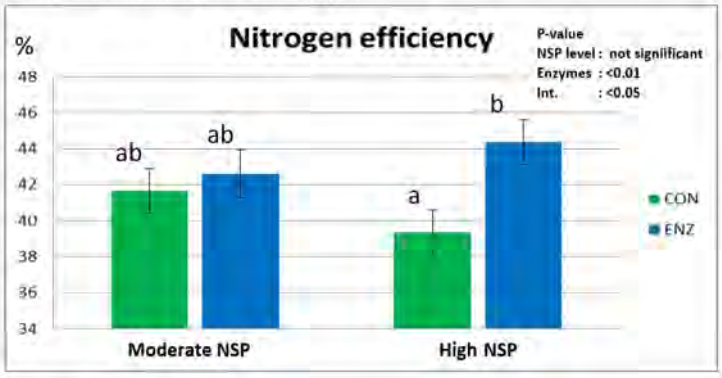
The expected future growth of the aquaculture sector increases the pressure of using more sustainable and novel feed ingredients in aqua feeds (Tacon & Metian 2015). However, with the inclusion of plant ingredients such as soybean and rapeseed meal, the content of non-starch polysaccharides (NSP) as well as phytate will increase in the fish feed. Both NSP and phytate are undesired in feed formulation due to their anti-nutritional properties. The NSP fraction generally remains undigested, as the enzymes to hydrolyse the glycosidic bonds are scarce or non-existing (Choct 1997; Francis *et al.* 2001; Sihna *et al.* 2011). Recently, the use of exogenous carbohydrase enzymes and phytase in aqua feeds is getting more attention. Studies showed that exogenous carbohydrase enzyme and phytase supplementation improved feed intake, growth rate and nutrient digestibility in fish (Castillo & Gatlin 2015; Goda *et al.* 2012).

The working hypothesis is that when NSP is degraded into less polymerised compounds enzymes, they can be further fermented by the gut microbiota into volatile fatty acids (VFA). By adding exogenous enzymes it is expected that the breakdown of NSP is increased and thus the production of VFA, thereby increasing the NSP digestibility. Differences in potential substrate (both composition and level) for gut fermentation is likely to influence the production of VFA. With an increasing breakdown of NSP, shift in microbiota can be expected as fermentation is through microbial anaerobic glycolysis. The main objective is to assess the impact of dietary NSP level and exogenous enzyme supplementation on the growth performance, nutrient utilization, gut microbiota and VFA production in Nile tilapia. This was tested using enzyme supplementation (yes vs. no) and two dietary NSP, to quantify the individual effects and the interaction between NSP level and enzyme supplementation.

Materials & Methods

Four experimental diets were formulated according to a 2 x 2 factorial arrangement, using enzymes (phytase and xylanase) and NSP level (moderate and high) as factor. For the enzymes a mix of phytase (from *Buttiauxella* at 1000 FTU/kg) and xylanase (from *Trichoderma ressei* at 5000 U/kg, both enzymes are provided by DuPont Animal Nutrition) was used (ENZ) versus no supplementation of enzymes (CON). A contrast in NSP level (moderate vs. high) was created by incorporating different levels of NSP rich ingredients into the diets. The first diet was formulated to have a NSP content of around 120 g/kg DM diet and is referred to as Moderate NSP diet (MOD), the second diet is formulated to have a NSP content of around 300 g/kg DM and is referred to as High NSP diet (HIGH). This resulted in a moderate NSP control diet (MOD-CON), moderate NSP enzyme diet (MOD-ENZ), high NSP control diet (HIGH-CON) and a high NSP enzyme diet (HIGH-ENZ). A recirculating aquaculture system was used, with common water supply and ensuring the same water quality for the inflow of each tank. In total 16 tanks (4 replicates/treatment) were used with 35 tilapia/tank and a mean

Figure 1. Effect of NSP level and enzyme supplementation on the nitrogen Efficiency in Nile tilapia.



(Continued on next page)

initial body weight of 33 g. Fish were restrictively fed (80% of expected satiation) twice daily with the experimental diets for 42 days. Growth rate, body composition, digestibility and the energy, nitrogen and phosphorus balances were measured. In addition, digesta in 4 different gut segments (stomach, proximal, middle and distal section) were taken and will be analysed for VFA concentration and composition and gut microbiota.

Results

The enzymes improved ($P<0.05$) the growth of the fish fed both diets. The interaction effect between enzymes and diet was present for FCR ($P<0.05$), with an improvement from 1.23 to 1.16 for the moderate NSP diet and from 1.33 to 1.19 for the high NSP diet (Figure 1). The enzymes improved the digestibility of the dry matter, carbohydrates, NSP, ash and the minerals P, Ca and Mg ($P<0.05$). In terms of growth (FCR and absolute) the diet high in NSP with enzymes was compatible with the moderate NSP diet without enzymes. The digestibility is not explanatory for the high growth of the fish fed the HIGH-ENZ diet (no interaction effects, $P<0.05$), with an ADC of 69.7% and 74.1% for energy and DM versus 80.7% and 84.4% for the MOD-CON diet. The nitrogen balance shows interaction effects ($P<0.05$) for the nitrogen retention, branchial nitrogen losses and nitrogen efficiency (Figure 1), with the highest nitrogen efficiency and retention for the HIGH-ENZ diet. Data on VFA production and gut microbiome are being analysed.

Conclusion

Supplementation of enzymes (*Buttiauxella* phytase and *Trichoderma* xylanase) showed to be an effective tool to improve nutrient digestibility and enhance growth in Nile tilapia at both dietary NSP levels. The improvement in growth was greater for the high NSP diet, with an interaction effect on the FCR. The higher improvement in growth for the high NSP diet can be explained by the higher nitrogen retention and efficienc . The data indicated that with the addition of the phytase and xylanase combination, diets can be formulated with increased level of high NSP by-products and maintaining the performance in tilapia.

SOLVING THE PROBLEM OF SALT ACCUMULATION IN RECYCLED BREWERY EFFLUENT THROUGH THE INTEGRATION OF WATER TREATMENT, AGRICULTURE AND AQUACULTURE

Nyiko C. Mabasa[1]*, Clifford L.W. Jones[1] and Mark Laing[2]

[1] Department of Ichthyology and Fisheries Science, Rhodes University (South Africa)

E-mail: charity.mabasa@gmail.com

Introduction

Water scarcity in South Africa, and many other parts of the world, presents challenges for industries that depend on this natural resource (Arnell 2004). This makes it important to have responsible waster use, such as recycling and reusing water from food processing industries for example. Breweries are one of the major consumers of freshwater and produce nutrient rich wastewater which can be released to the environment or reused for downstream purposes aquaculture (Jones *et al*., 2014; Power and Jones 2015; Taylor *et al*., 2018). The Ibhayi Brewery (SAB Ltd) currently employs a combination of alternative, sustainable treatment processes such as anaerobic digestion, primary facultative ponds, high rate algal ponds and constructed wetlands to treat brewery effluent on an experimental-scale, and this treated effluent has been shown to have potential use in agriculture and aquaculture. However, salt in brewery effluent is a constraint for its downstream uses, because cleaning agents used at source contain salts that accumulate in the system as water evaporates during the recycle process, which makes it less suitable for reuse or downstream use in agriculture and aquaculture.

The objective of this study was therefore, to determine the salt removal efficiency of halophytes (*Salicornia*, *Atriplex*, *Sorghum bicolor*, *Spinacia oleracea*) by looking at (1) brewery effluent irrigation, (2) crop rotation and (3) soil amendment on soil structure and its effect on selected agricultural crop production and (4) the suitability of this treated effluent for use in downstream aquaculture.

Table I: Soil and leaf sodium level in various crops irrigated with brewery effluent.

	Salicornia	*Atriplex*	*Sorghum bicolor*	*Spinacia oleracea*
Soil sodium level (mg/L)	2 596.3	2 983.6	2 985.0	2 135.0
Leaf sodium level (mg/L)	105 800	64 790	147	76 050

Table II: Survival, specific growth rate (SGR) and feed conversion ratio (FCR) of fish grown in brewery effluent treated in an agricultural-wetland (Experimental) or from a conventional water source (Control).

	Clarias gariepinus (Experimental)	*Clarias gariepinus* (Control)	*Oreochromis mossambicus* (Experimental)	*Oreochromis mossambicus* (Control)
Survival rate (%)	70	100	20	100
SGR (% g/day)	0.84	1.53	-0.96	0.69
FCR	2.05	1.11	-0.22	3.80

(Continued on next page)

Materials and methods

Glasswort *Salicornia*, saltbush *Atriplex*, sweet sorghum *Sorghum bicolor*, and spinach *Spinacia oleracea* were grown in raised beds for four months and irrigated with treated brewery effluent. Soil samples were taken monthly for laboratory analysis and plant biomass was recorded. *Spinacia oleracea* was also grown in an artificial wetland to treat the brewery effluent, and the treated effluent from this wetland was used to culture the African catfish *Clarias gariepinus* and Mozambique tilapia *Oreochromis mossambicus*. The experimental treatments were compared to a fresh water source, as a control.

Results and discussion

Spinacia oleracea had the best growth rate and biomass production. Salicornia had the highest accumulation of sodium in the leaf, while *Sorghum bicolor* accumulated the least (ANOVA, $F_{3,16} = 3.23$, $p<0.001$; Table I). Crop rotation had no significant e fect on plant growth. Soil amendment had a positive effect on soil structure and crop production.

There were significant differences in survival and growth of *Clarias gariepinus* and *Oreochromis mossambicus* cultured in different water treatments. The highest mean survival rates were observed in the control groups for both fish (Table II). *Oreochromis mossambicus* showed low growth rates and below optimum feed utilization while *C. gariepinus* showed higher higher growth rates and better feed utilization (Table II).

Treated brewery effluent may be suitable for irrigation of salt tolerant plants. It may also be suitable for the culture of hardy fish species such as *C. gariepinus* but may not be suitable for tilapia culture. The application of these data in the development of methods to determine the risk of using treated effluent in agriculture and aquaculture will be discussed.

EFFECT OF VARIANT OVARIAN FLUID ON SPERM PERFORMANCE AND EGG FERTILIZATION RATES OF ARCTIC CHARR (*Salvelinus alpinus L.)*

Lwabanya Mabo

Swedish University of Agricultural Sciences (SLU), Dept. of Wildlife, Fish and Enivironmental Studies
Umeå, Sweden

Successful *in vitro* fertilization in aquaculture is highly dependent on the method used to handle or treat the eggs and milt. As such it is of paramount importance that timely evaluation of the methods is conducted to enhance hatchery productivity and reduce the cost of production. In this study, three methods of handling eggs of Arctic charr in Sweden were evaluated, with the objective of ascertaining the importance of retaining the ovarian fluid in the egg batch. Further, activation of fish sperms with a commercial activator, ActiFish^{TM}, was tested to compare the fertilization rates, in a bid to overcome the current low egg fertilization and hatching rates among farmed Arctic charr. Variation of the volumetric amount of the ovarian fluid did not yield dissimilar fertilization rates. As such, tempering with the volume of the ovarian fluid under the current study did not affect the performance of the sperms and consequent fertilization rates. Further, no differential fertilization rates were recorded for the sperm extender and freshwater. However, positive relationships were recorded for fertilization rate and sperm velocity (VCL). The study contends that high and successful fertilization rates are likely to be obtained with or without the ovarian fluids under *in-vitro* fertilization of Arctic charr eggs.

MANIPULATING MACRONUTRIENT CONCENTRATION (N, P, FE) TO ENSURE VEGETATIVE CULTIVATION OF KELP GAMETOPHYTES (*Saccharina latissima)* FOR THE AQUACULTURE INDUSTRY

Maryam MacCorquodale*, Adam D Hughes, Philip D Kerrison

Scottish Association for Marine Science (SAMS), Oban, Argyll, UK PA37 1QA
Email: Maryam.maccorquodale@sams.ac.uk

Introduction

European seaweed aquaculture requires reliable methods to produce high-volumes of kelp gametophytes as a seedstock. These can be maintained vegetatively in seedbanks for year-round access, negating the need for natural spore collection (Westermeier et al. 2006). Additionally, since kelps are a source of valuable bioactive compounds, these vegetative gametophyte could be an alternative source, reducing harvesting of natural beds.

A number of abiotic factors influence growth and gametogenesis of gametophytes. Commonly, red light is used to maintain their vegetative growth. Yet, their growth rate is not optimal under red light and faster growth can be achieved under white light, but this also stimulates reproduction. The aim of this study was to identify the conditions that inhibits gametogenesis and maintains vegetative growth under white light.

Material and Method

Oogenesis was studied through factorial experimental on the female gametophyte of *Saccharina latissima.* Cultures were maintained under either red or white light (at 10 , and 12:12 L:D photo period. The effect of concentration of phosphate and nitrate in culture media and the ratio (N:P range: 4.5:1 – 60:1) was investigated over 35 days. In a separate experiment the iron concentration in artific al seawater (GP2) was manipulated (range 0 -0.0117 mM) and availability of this iron modulated using the chelator EDTA.

Results

All cultures remained vegetative under red light. Under white light cultures with Nitrate at concentrations above remained vegetative, while increases in phosphate reduced oogenesis. The culture remained vegetative when iron was excluded from the culture medium. Additionally increases in concentration of the chelator EDTA reduced the oogenesis.

Discussion

The manipulation of macronutrient concentrations is an effective method to allow vegetative cultivation of gametophytes under white light. Alteration of the N:P ratio did not fully inhibit oogonia formation, yet high nitrate concentrations did; possibly due to toxicity.

Iron appears to be essential for gametogenesis, with similar results reported for other species of kelps (Lewis et al. 2013). Depleting the medium iron concentration may be an effective method to maintain vegetative gametophyte cultures as a seedstock for seaweed aquaculture.

ADVANCING EUROPEAN AQUACULTURE BY GENOME FUNCTIONAL ANNOTATION: 'AQUA-FAANG'

D. J. Macqueen[1*], S. Lien[2], AQUA-FAANG consortium

[1] The Roslin Institute and Royal (Dick) School of Veterinary Studies, The University of Edinburgh Midlothian, EH25 9RG, UK

Email: daniel.macqueen@roslin.ed.ac.uk

Introduction

Recent developments in genomics have greatly advanced research and commercial innovation in European aquaculture. In particular, the creation of reference quality genome sequences for all the major farmed finfis species has enabled the development of robust genotyping tools, allowing the identificati n of numerous QTL of commercial importance, alongside the routine application of genomic selection in many species. Despite this progress, our understanding of the functional genomic basis for commercially important phenotypic variation (i.e. growth rate, disease resistance, etc.) remains limited, limiting our ability to exploit the predictive ability of genetic information.

Our project, "AQUA-FAANG", funded by the European Commission H2020 program, is tackling this knowledge gap, and aims to deliver a step improvement in understanding of genome function and the exploitation of genotype-to-phenotype prediction in the six most important European farmed fish species, Atlantic salmon (*Salmo salar*), rainbow trout (*Oncorhynchus mykiss*), European seabass (*Dicentrarchus labrax*), gilthead seabream (*Sparus aurata*), turbot (*Scophthalmus maximus*) and common carp (*Cyprinus carpio*), which together account for >90% commercial finfis production in Europe.

The AQUA-FAANG project

Our poster communicates the aims, deliverables and progress of AQUA-FAANG, funded at €6-million over 48 months (start date: 1st May 2019). The consortium comprises an interdisciplinary team of academics and industry partners from eight European countries: Norway, the United Kingdom, France, the Netherlands, Spain, Italy, Greece and Poland. AQUA-FAANG is one of three projects funded under the same H2020 Research and Innovation Action, with the others focussed on livestock. All three projects will coordinate to ensure the outcomes align with the objectives and principles of the international 'Functional Annotation of Animal Genomes' (FAANG) initiative (Andersson et al. 2015; Giuffra et al. 2019). AQUA-FAANG will also coordinate with other international actions to promote knowledge exchange and standardization of functional annotation datasets, including DANIO-CODE (Tan et al. 2016) and FAASG (Macqueen et al. 2017).

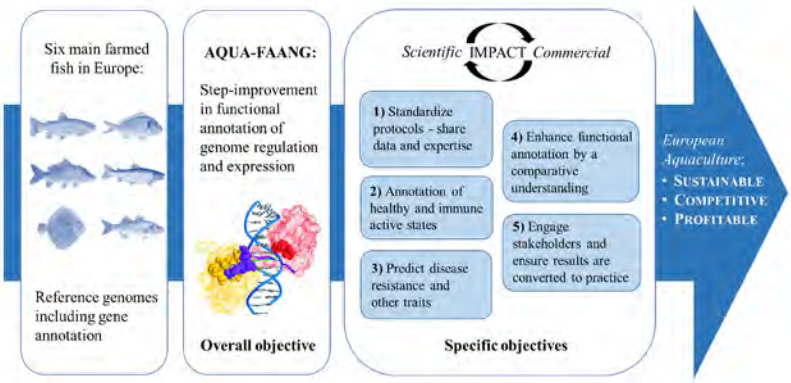

Fig. 1. Overall concept of the AQUA-FAANG project

(Continued on next page)

The AQUA-FAANG project (Fig. 1) will functionally annotate the genomes of the six targeted species, employing standardized assays and pipelines defined by FAANG. The goal is to document genome-wide functional and regulatory features under distinct biological conditions, including chromatin accessibility (by ATAC-Seq), enhancer and promoter activity (by ChIP-Seq), and protein and non-coding gene expression (by RNA-Seq). This will be done across distinct tissues and development stages in healthy animals, in addition to immune-activated and disease-challenged states, addressing the need to tackle the huge threat posed to aquaculture by infectious disease.

In total, ~28,000,000,000,000 basepairs of new sequencing data will be generated, which will be shared and managed through a dedicated centre (Harrison et al. 2018), and made publically available in an easy-to-visualize format via the Ensembl genome browser. Comparative analyses of the target species will enhance the quality of functional annotation by identifying conserved and lineage-specific features of genome functional regulation, which will provide transferable findings to other species and improve our understanding of genome functional evolution in fishes

The project includes applied research activities that aim to establish functional mechanisms underpinning resistance to infectious disease, and enhance the accuracy of genomic prediction of disease resistance. For example, marker panels enriched for prioritized causative genetic variants and novel statistical methods will be developed to improve the accuracy of genomic selection using functional annotation data.

To summarize, AQUA-FAANG is aimed at enhancing precision breeding, scientific innovation, and competitiveness within the aquaculture sector.

Introduction
The increasing fish oil substitution by vegetable oils in aquafeeds decreased dietary input of n-3 LC-PUFA. Marine carnivorous fish have limited capacity to produce LC-PUFA from C18-PUFA due to low enzymatic activity of fatty acid desaturases and elongases. Thus, dietary supply of arachidonic acid (ARA; 20:4n-6), eicosapentaenoic acid (EPA; 20:5n-3) and docosahexaenoic acid (DHA; 20:6n-3) are needed to fulfil animal's requirement for these essential fatty acids. A well-balanced dietary n-3/n-6 fatty acid ratio is also required to modulate fish health and welfare. The aim of this study was to evaluate different dietary ARA/EPA/DHA ratios on several oxidative stress indicators and microbial community of gilthead seabream juveniles.

Materials and methods
A feeding trial was performed with triplicate groups of gilthead seabream (IBW=15g), for 56 days at 23 °C. Four isoproteic (47%CP) and isolipidic (18%CL) plant-based diets (including 17.5% fish meal) were formulated containing a vegetable oil blend (20% rapeseed, 50% linseed, 30% palm) as main lipid source. Diets were supplemented with purified sources of fatty acids to obtain the following n3/n6 LC-PUFA levels: Diet A (2%ARA: 0.2%EPA: 0.1%DHA); Diet B (1.0%ARA: 0.4%EPA: 0.4%DHA); Diet C (0%ARA: 0.6%EPA: 0.6%DHA); Diet D (0%ARA: 0.3%EPA: 1.5%DHA).

Results
Diet composition did not affect growth performance of gilthead seabream. Total glutathione (tGSH), oxidized glutathione (GSSG), reduced glutathione (GSH), and oxidative stress index (OSI) in liver and intestine were not affected by dietary treatment (Table I). However, LPO was higher in fish fed diets C and D than diets A and B. GSSG, OSI, and LPO levels were higher in the intestine than in the liver, while GSH was higher in the liver (Table I). Glutathione reductase (GR) activity was higher in fish fed diet A than diets C and D. Catalase (CAT), glucose-6-phosphate dehydrogenase (G6PDH), superoxide dismutase (SOD), and glutathione peroxidase (GPX) activities were unaffected by dietary treatments (Table II). G6PDH and GPX activities were higher in the liver than in the intestine, while the opposite was true for CAT, GR, and SOD activities (Table II). In intestine mucosa, Bray-Curtis dendrogram showed that diets with and without ARA supplementation clustered separately (Fig.1). The pathogenic species *Edwardsiella tarda* was only isolated in the intestinal mucosa of fish fed diets with lower n-3 LC-PU A levels (diets A and B; Table III).

Conclusions
Overall, results indicate that diets with high EPA and DHA levels slightly increased lipid peroxidation but seemed to promote a healthier gut microbiota.

Introduction

Glycerol is a readily available and inexpensive source of dietary energy proposed as a feed component to replace other ingredients currently included in animal feeds. Glycerol inclusion in feeds for terrestrial livestock has been investigated to some extent, although studies evaluating its potential use in fish feeds are scarce.

Rainbow trout is considered to be one of the most commonly exploited species in freshwater aquaculture worldwide. The provision of dietary energy in this carnivorous species derived from compounds other than from protein, such as glycerol, may reduce the use of dietary protein as an energy source through catabolism, decreasing the ammonia that is excreted to the environment by the fish

This study tested the effects of dietary glycerol inclusion on growth performance, nitrogen and energy balance, digestive capacity, as well as fillet quality in rainbow trout fed to apparent sa iation for 60 days.

Materials and methods

Rainbow trout were fed diets with 0 (control), 2.5, or 5 % glycerol inclusion (w/w, refined), all formulated to have an equal energy and protein content (21 kJ kg^{-1} and 49 % DM, respectively). The incorporation of cellulose at different levels in the formulation was used to create the dietary contrast for the addition of glycerol.

Table 1. Zootechnical and nitrogen balance parameters in rainbow trout fed diets with (2.5 and 5 %) or without (Control) glycerol inclusion.

	Control	2.5 %	5 %
IBW (g)	20.30 ± 0.06	20.14 ± 0.04	20.23 ± 0.07
FBW (g)	87.49 ± 2.09	85.27 ± 2.86	79.39 ± 1.39
SGR (% day^{-1})	2.43 ± 0.04	2.40 ± 0.05	2.28 ± 0.03
VFI (% BW day^{-1})	1.87 ± 0.04^{a}	1.87 ± 0.02^{a}	2.05 ± 0.03^{b}

(Continued on next page)

Juvenile rainbow trout were reared at the UTAD facilities in freshwater. Fish were divided into groups of 25 fishes between nine tanks (300 l) connected to an open circulation water system (15 ºC). Experimental diets were randomly assigned to each tank in triplicates, and fish were hand-fed ad libitum daily (9:00 and 17:00 h). Total feed consumption and mortality data were daily recorded. Feed, faeces and whole-body samples were analysed for dry matter, ash, crude protein content crude fat content and gross energy. Digestive enzyme activities (α-amylase, lipase, trypsin, and chymotrypsin) were measured in whole intestinal tract including pyloric caeca at 6 or 24 h after feeding (n=8). A separate trial was conducted to measure the apparent digestibility (ADC) adding 1 % of Cr_2O_3 in each diet. Dietary and faecal Cr_2O_3 concentrations were determined after perchloric acid digestion. One hour after feeding, 6 fish (BW 112.4 ± 5.6 g) from each tank were transferred to 30 l boxes (triplicates) containing well-aerated freshwater. Water samples were obtained from each tank to calculate total ammonia nitrogen excretion rate (TAN_{ER}). Parameters were analysed by one-way ANOVA and Tukey's post-hoc tests were applied ($P<0.05$).

Results & Discussion

Refined glycerol was well digested (>99.7 %) in rainbow trout fed diets supplemented this compound up to 5 %. Amylase, but not proteases and lipase, was altered by glycerol inclusion, as this digestive enzyme activity increased 6 h post-feeding in trout fed 2.5 and 5 % diets. Growth performance was not altered by glycerol inclusion, although dietary inclusion of this compound at 5% induced an increase in voluntary feed intake (Table 1). Opposite to what it was expected, dietary inclusion with glycerol had a negative effect on protein efficienc . Trout fed the 5 % diet displayed increased energy intake, which was not reflected in a reduction of the TAN_{ER}, indicating that glycerol at 5 % does not spare the use of proteins as a metabolic fuel in trout. No differences were detected between dietary treatments in the fillet colour characteristics investigated. Despite of this increased catabolism of proteins when refined glycerol is included at 5 %, the inclusion of this compound at 2.5 % does not appears to had negative effects on growth performance and the nitrogen excretion rate, which may indicate that the inclusion of this ingredient could be possible in rainbow trout diets. This suggests that dietary inclusion with glycerol at this level could be a convenient source of metabolically available energy in rainbow trout.

Introduction

Artificial spawning substrates are widely used for supporting reproduction of percids (Čech et al., 2012; Crane & Farrell, 2013; Lehtonen et al., 2006). Investigation of spawning substrate preference could help to support natural pikeperch populations. The aim of this study was to determine spawning substrate preferences of pikeperch broodstock and to clarify some aspects natural spawning behavior. The secondary objective was to assess the suitability of the preferred substrates for egg incubation, hatching and subsequent larvae production in RAS (recirculating aquaculture system).

Material and methods

Mature pikeperch males (n=6) and females (n=6) with oocytes in first and second stages (Zarski et al., 2012) were randomly placed into each of three similar sized earthen ponds 10 m x 5 m x 1 m. To observe a natural pattern of spawning kinetics, spawning was not hormone-induced. Water temperature at one meter depth was measured at hourly intervals with an auto-recording thermometer (Minikin Tie, EMS Brno Ltd. Czech Republic) throughout the trial. Three types of substrate were used to make circular (Ø = 890 mm) spawning nests: soft brush (bottle brushes) with fiber length 100 mm, artificial turf of 35 mm length and a smooth plastic sheet (Fig. 1). The following parameters were observed: time from fish stocking to male occupation of a nest; time from stocking to spawning; and time from male occupation of nest to spawning. After detection of spawning, nests with attached eggs were moved to controlled conditions of RAS for evaluation of incubation success (hatching rate %).

Results

Fourteen days after the beginning of the experiment, 17 of 18 pikeperch pairs had spawned, and spawning success accounted 94.4%. A significantl higher preference ($p < .05$) was found for brush (61.1±9.6%) than for artificial turf (33.3± 0%). Throughout the experiment, 65% of spawning events occurred between 0700 and 1100 hr and 18% spawned between 1900 and 0700 hr. Spawning during the day was 12% and 6% for the periods from 1100 to 1500 hr and 1500 to 1900 hr, respectively. The time from broodstock stocking to male occupation was 96.5±45.5 hrs in brush and 98.5±17.9 hrs in turf. Time between the first male occupation of a nest and spawning was 79.5±77.1 hrs in brush and 48.7±52.2 hrs in turf nests. Time from stocking to spawning was 167.4±72.8 hrs in the brush nests and 147.2±46.3 hrs in turf. The general linear model showed higher water temperature to be significantly associated with spawning occurrence ($F_{1, 24} = 32.27$; $p < .05$) but not substrate preference. The preference for brush substrate was consistent throughout the experiment and was not influenced by water temperature or nest availability ($p > .05$).

Discussion

Availability of suitable spawning grounds is crucial for sustainability of wild population (Lehtonen et al., 2006). In this study pikeperch exhibited preference to thick rigid structure of the brush nest over soft artificial turf fibers, while smooth plastic has not been selected at all. Results confirmed opportunistic strategy of pikeperch spawning and emphasized the importance of suitable spawning sites to be available during reproduction period. Temperature was the only factor affecting spawning substrate selection. Fish was tending to select the most suitable type of spawning substrate even when number of available nest was decreasing. Despite the fact that significant difference in incubation success between two spawning substrate types was absent, there was a tendency to higher larvae production from brush nest compare to artificial turf. In the nature, pikeperch spawn on dense structures such as plant roots and branches (Lappalainen et al., 2003). Gravel or sand is used rarely, and according to current study could indicate lack of the suitable spawning grounds. Obtained data could be used for indication and supporting of spawning sites in natural water bodies and will help to increase the natural production of pikeperch populations. Adding of artificial substrate to shallow areas of open waters has been found supportive for several percid species (Crane & Farrell, 2013). In the same way, spawning opportunities for pikeperch in natural conditions could be increased by providing of artificial spawning substrates

Introduction

The potential of macroalgal biomass as feedstock for biorefinery is being are increasingly recognized worldwide (Bikker et al., 2016). Seaweed components have been shown to possess interesting properties for applications in functional feeds, for instance in aquaculture (Fernández-Díaz et al., 2017), and in the cosmeceutical and nutraceutical industries. However, to be able to guarantee constant quality and production, essential for the development of for instance human functional products, development of low-cost, high-efficient on-land cultivation systems is essential (Hafting et al., 2012)

Phytoplankton indoor cultivation is commonly carried out in photobioreactors (PBRs). Especially since the definite breakthrough of LED lightning, drastically decreasing energy costs of cultivation, this process has rapidly gained importance. First studies with *Ulva* sp. in PBRs under controlled climate conditions and fluorescent light (Rodríguez et al., 2012) and various seaweed species in outdoor PBRs aerated with CO_2-enriched air (Chemodanov et al., 2017) showed first potential of seaweed production using PBRs. In the framework of the European BIOSEA project, cost-effective cultivation technology of micro- and macroalgae is studied to obtain potentially valuable extracts through biorefinfer . Here, we explore the potential of PBRs under semi-controlled conditions for the year-round production of *Ulva* biomass.

Material and methods

The chlorophyte macroalga (*Ulva ohnoi*), isolated from a former salt evaporation pond in south Spain, was grown in 75 L polycarbonate photobioreactors (PBR) at room temperature and under constant aeration, receiving light from LED tubes (150 µmol photons.m^{-2}.s^{-1}, 16:8 L:D cycle). Nutrients (f/2 solution) were added following growth-dependent uptake predicted by a model. Temperature was recorded continuously. Trials were held in weeks with different temperatures to determine starting biomass for maximum yield. Seaweeds were restocked to starting biomass weekly, at which time yield and growth rate were calculated. Harvested algae were dried at room temperature for component extraction, analysis of proximate composition, and detailed analysis of amino acids, fatty acids and sugar composition. Cultivation periods were November 2017 – September 2018 and November 2018 until now.

Results

The algae generally grew well in the cylinders. Highest growth rates and yield were obtained between March and the end of July, with temperatures ranging from 16-17 to 24°C. Growth rates averaged 10% d^{-1} during this period (average yield 104g FW.PBR^{-1}). Optimum biomass yield could be obtained at an initial density of 60 – 70 g FW biomass per PBR. Growth was mainly determined by room temperature, which was limiting in the coldest months of the year, whereas continuously high temperatures (> 26 °C day and night) throughout summer caused collapse of the cultures by the end of September.

Preliminary results of proximate composition of samples taken at 2 month intervals indicate fairly constant carbohydrate, lipid and protein levels in the seaweeds. *U. Ohnoi* was rich in sugars with the polysaccharide ulvan and rhamnose, glucose and xylose as most dominant monosaccharides. Interestingly, lipid contents were consistently high (≥ 5% DW) compared to the literature median of 2.3% DW.

Discussion and conclusions

The results of this study show that it is possible to grow *Ulva* in indoor PBRs in the south of Spain during large part of the year with low energy consumption (LED light and aeration) and hence costs. The bottleneck for year-long growth under these circumstances is temperature. During winter months, growth is reduced but does not cease altogether. The collapse of the cultures in early autumn is most likely related to continuously high temperatures, especially at night. *U. Ohnoi* in the field from the same location have been shown to have highest growth rates in July, with water temperatures averaging ≥ 30°C, however, night temperatures always decreased below 25°C (Coste et al., 2018). This suggests that a better control of room temperature during the night (for instance through improved ventilation) might prevent collapse of the culture.

(Continued on next page)

Earlier studies have showed promising results of cultivation in PBRs for other smaller seaweed species, such as the red alga *Gracilaria gracilis* (Malta and Sánchez, 2012) and *Cladophora* sp., *Ulva compressa* and *U. rigida* (Chemodanov et al. 2017). As the method is entirely modular, it can be easily upscaled to larger surfaces, for instance in greenhouses. It is concluded that the PBR method combined with LED lighting shows great potential for the continuous production of seaweed biomass with a constant quality for production of valuable compounds through biorefiner .

Introduction

Integrated Multitrophic Aquaculture (IMTA) refers to the associated cultivation of aquatic species belonging to different trophic levels, in which only one level is externally fed. The other levels use the waste (debris from uneaten food and excreta) produced by the former, potentially increasing production efficiency and decreasing waste. IMTA is recognized worldwide as one of the models of sustainable aquaculture (Neori et al., 2004). The concept of IMTA has a long history of successful commercial applications in Asia, in particular. In Europe however, only few companies implement this system, while facing socio-economic, administrative and legal bottlenecks hindering the development of IMTA to its full potential (Kleitou et al. 2018). The European Project Integrate, funded by the ERDF through the Interreg Atlantic Area Programme, and running since 2017, is working on taking down these barriers in order to foster cooperation for industrial transition towards IMTA in the European Atlantic Area (Dove and Agraso, 2018). To identify the knowns and unknowns of IMTA, three pilot actions are being carried out within the project across the European Atlantic Area, representing forms of aquaculture in the participating countries.

Earthen pond IMTA pilot action

This pilot action intends to develop and consolidate a land-based IMTA standard model: fish (poly)culture-mollusks-invertebrates-salt tolerant plants or algae taking advantage of existing aquaculture earthen pond systems. Earthen pond aquaculture is commonly found in southern Spain and Portugal. The earthen ponds are salt evaporation ponds adapted for aquaculture production of fish, shrimps, bivalves and other species. These land-based production systems are ideal candidates for IMTA development due to the possibility of controlling the diversion of water through the different inputting and extracting compartments that comprise IMTA systems before final discharge (Cunha et al. 2019). However, there has been no major commercial development of pond IMTA due to the lack of clear standard models to enable upscaling.

Experimental pond IMTA systems have been set up for the Integrate project in an existing and operational fish/oyster farm (CTAQUA, Spain) and in a pilot scale experimental earthen pond system (EPPO-IPMA, Portugal) in which different cultures are grown simultaneously in the same water body. Cultures were started at the beginning of 2018 and have been ongoing throughout 2019. Different cultivation methodologies are being developed and tested and extensive sampling and monitoring of the different cultures is being carried out. For the biological compartments (fish, oysters, phytoplankton and seaweeds), this includes monitoring of growth and biomass development. Furthermore, the relevant water and environmental parameters are monitored.

In this poster, we present the first results of these pilot systems. Flow charts and conceptual models intend to trace the nutrient flows in the system and to show how and where these are interconnected. Data of the experimental systems, such as growth of the organisms, nutrient content of the water, the feed and the organisms form the basis of a numerical ecosystem model. The model is one way to determine the degree of interconnection of the cultures, alongside mixing models with stable nitrogen isotope levels. Results will be integrated in guidelines for good practice of a standard model for semi-extensive land-based IMTA.

Introduction

"*In a world with growing pressures on resources and the environment, the EU has no choice but to go for the transition to a resource-efficient and ultimately regenerative circular economy*" (EREP, 2014). Bio industries are especially well suited to spearhead circular principles, as biological processes *per se* rely on recycling and reuse of organic and inorganic compounds. Circular approaches can help making aquaculture operation greener, e.g. by producing high quality feed components rather than harvesting them. Polychaetes are a natural part of the diet of many aquatic animals and contains high levels of sought after biochemicals, such as omega-3-fatty acids and proteins. Further, they are detritivores, making them perfectly suited as recyclers of organic side streams. Sludge from RAS aquaculture is an obvious feed source for aquatic vermiculture, and has been shown to be promising (Bischoff, Fink, Waller, 2009; Pajand, Soltani, Bahmani, Kamali,

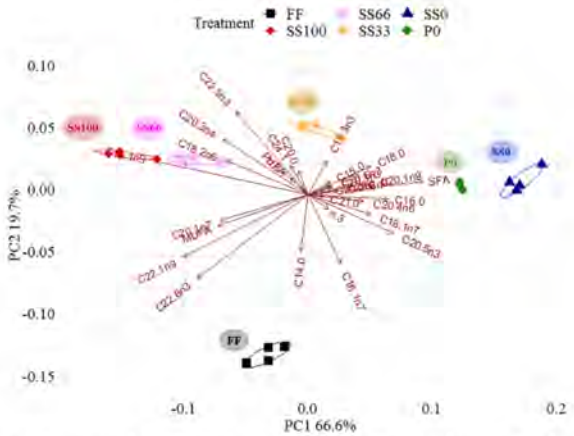

Figure 1: PCA of fatty acids (% of the total FA) of polychaete feeding with different feeds, the data was arcsine transformed, SFA, MUFA, PUFA, and TFA was included.

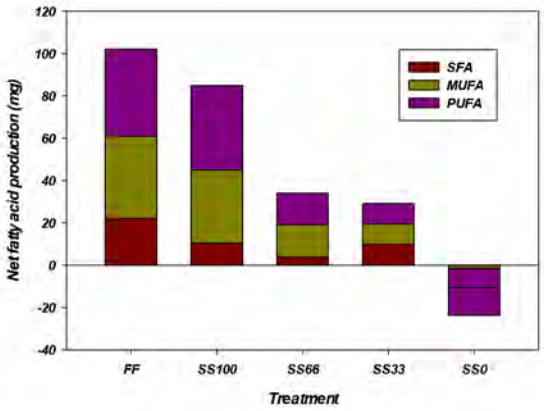

*Figure 2: Net production of different FA's (mg) in polychaetes (*H. diversicolor*) after 30 days of cultivation on fish feed (FF), solid biogas digestate (SS0), smolt sludge (SS100) or a 2:1 and 1:2 mixed ratio of smolt sludge and solid biogas digestate (SS66 and SS33, respectively).*

(Continued on next page)

2017). As an alternative, biogas production is on the rise, and the solid digestate after methanogenesis might also pose a promising substrate for worm faming.

Material & Methods

We reared the polychaete *Hediste diversicolor* along a gradient spanning from pure sludge from salmon smolt production to pure solid biogas digestate in 33% steps for 30 days. A group receiving fish feeds served as the positive control. Worms reared on these five different diets were analysed for growth, survival, (cf. part I of this study; Hagemann et al), and biochemical composition.

Results

The polychaetes accepted all diets and displayed positive growth. Their biochemical composition reflected their diets and the groups were clearly separated for considering fatty acids (Figure 1). Worms grown on fish feed showed the highest net fatty acid production, while there was a decrease along the gradient of solid biogas digestate addition (Figure 2).

Discussion & Conclusion

H. diversicolor is a promising candidate to produce high quality feed components from to-date-considered wastes. However, current regulations on an EU level do not allow to use animal products produced on aquaculture and biogas side streams as feed ingredients. Clearly, regulations have to be reviewed to unleash the full potential of circular approaches.

Introduction

Oxidative stress is the result of an imbalance between free radicals and antioxidants defenses. In aquaculture, this phenomenon can be induced by different factors, among which, the temperature, oxygen and salinity changes (Brinie-Gauvin *et al.*, 2017). To estimate the effect of treatments on the reduction of oxidative damage, red blood cells can be exposed to an artificial oxidative stress in order to activate the antioxidant defenses (Stocker *et al.*, 2003; Girard *et al.*, 2005; Lykkesfeldt *et al.*, 2007). Antioxidants from natural sources, especially grape polyphenols have been evidenced to reduce oxidative damage caused by free radicals (Bagchi *et al.*, 2000). The aim of this study was to evaluate the protective effect of standardized dry grape extract, as a source of antioxidants to protect red blood cells from hemolysis induce by osmotic stress in rainbow trout (*Oncorhynchus mykiss*).

Materials and methods

Red blood cells have been prepared from blood collected on rainbow trout at slaughter at the end of the production period then placed in heparin tubes. The blood samples were centrifuged at 3500 rpm for 12 minutes at room temperature. Supernatants were removed and the red blood cells were washed 3 times with a solution of NaCl (9mg/ml of distilled water). The solution of standardized dry grape extract (Nor-Grape® WS, Nor-Feed) were prepared at different concentrations, 2.5mg/ml, 5mg/ml and 7.5mg/ml in phosphate buffer saline (PBS, 1g/100ml of water, pH = 7.4).

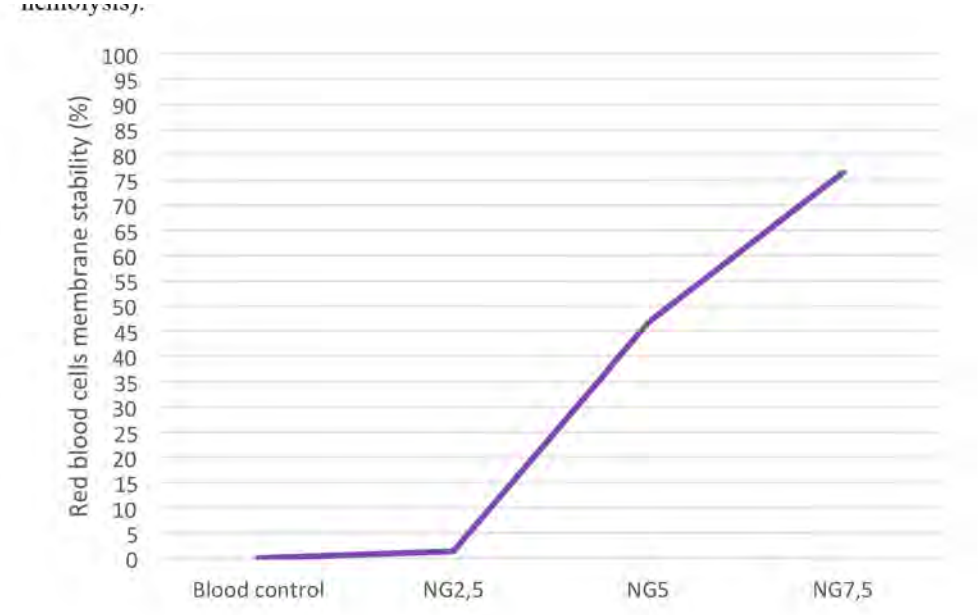

Figure 1. A standardized dry grape extract effect on red blood cells membrane stability

(Continued on next page)

The assay solutions (NG2.5 , NG5 and NG7.5) were composed of 1ml of PBS, 1ml of a solution of grape extract (2.5 mg/ml, 5 mg/ml or 7.5 mg/ml), 0.5ml of the red blood cell solution (RBCS) at 25% (v/v) and 2ml of NaCl solution at 2g/l in water, to induce an osmotic stress. In the blood control (BCTL), NG solutions were replaced by PBS while control solutions were also prepared (NGCTL), containing the NG solutions without RBCS (replaced by PBS). The solutions were incubated at 56°C for 30 minutes, to induce a hemolysis reaction and were then centrifuged at 5000 rpm for 10 minutes at room temperature. The released hemoglobin was measured by spectrophotometry at 560 nm. Stability of red blood cells was expressed as follow:

% stability = 100 – ((Abs assay solution – Abs NGCTL)/Abs BCTL) × 100
The absorbance value represented the mean of 3 consistent measures.

Result

Results evidenced that standardized dry grape extract at the two highest concentrations (5mg/ml and 7.5mg/ml) improved the membrane stability of red blood cells to 50% and 80% respectively (Figure 1.), compared to the lowest concentration (2.5mg/ml, 98% hemolysis).

Discussion and conclusion

This trial showed the positive impact of a standardized dry grape extract on the stability of red blood cells from rainbow trout. A dietary supplementation with a standardized dry grape extract in the fish diet could thus be an efficient solution to manage oxidative stress, induced by the fluctuation of salinity, in order to reduce oxidative damage fish cells. More research is required in order to evaluate the validity of this method on RBC from different situations.

Introduction

One of the most common parasites in production of shrimp is an endoparasite, gregarines from gender *Nematopsis sp*. and *Cephalolobus sp*. These parasites represent one of the principal infectious agents of anterior, medium and posterior digestive tract in shrimp (Jones *et al.*, 1994; Zanguee *et al.*, 2011). They stay in the gut, reduce feed absorption and may induce mortality of the hosts (Lightner, 1933). The aim of this trial is to evidence the effect of a standardized saponins-containing plant extract used in animal nutrition on the reduction of gregarines from gender *Nematopsis sp*. and *Cephalolobus sp*. in shrimp in Ecuador.

Materials and methods

The trial was conducted in two pools heavily infested with gregarines (Pool 1 and 2). In these pools, the supplementation of a standardized saponins-containing plant extract (Norponin® XO2, Nor-Feed) was done during 3 days, incorporated at 2g/kg in the complete feed of shrimp. The measured parameter, count of shrimp intestinal parasites (gregarines trophozoite and adult forms), was analyzed before providing standardized saponins-containing plant extract and after 3 days of treatment. In the two pools, 10 alive shrimps were randomly collected before the inclusion of standardized saponins-containing plant extract, and 10 animals after 3 days of supplementation. Analysis of the shrimp intestine was made directly after their collection. This analysis consisted to get a homogeneous and representative sample of intestinal content of shrimp. The entire intestine was taken out the animal, placed with 10ml of lugol and the mixture was placed in test tubes. After the homogenization, a sample of 1ml of this mixture was placed under the microscope to count the parasites (gregarines trophozoite and adult forms).

Figure 1. Effect of standardized saponins-containing plant extract on the reduction of the intestinal endoparasites infestation in shrimp.

(Continued on next page)

Result

Analysis of the shrimp intestinal content (Figure 1) evidenced the positive effect of standardized saponins-containing plant extract inclusion at 2g per kg of shrimp complete feed during 3 days on the reduction of gregarines infestation by 64% in the pool 1 and 73% in the second, compared to animals before the treatment.

Discussion and conclusion

This trial evidenced the positive effect of the standardized saponins-containing plant extract in shrimp production to reduce infestation of the intestine by endoparasites, especially gregarines (*Nematopsis sp*. and *Cephalolobus sp*.). This treatment has to be tested in new trials in shrimp production to better understand the mode of action of the standardized saponins-containing plant extract.

IMPACTS OF BOTTOM TRAWLING ON MARINE ECOSYSTEM

Introduction

Trawling is a fishing technique in which a boat pulls a net through the water to trap and catch all kind of fishes. The net can be pulled anywhere in the water column of the ocean, including the midwater or bottom sections. Bottom trawling is a type of fishing in which a net or other collection device is dragged over the seabed to catch demersal fish, crustaceans and shellfishes. It is also referred to as 'dragging'. When the net is towed along the sea floo , the technique is called bottom trawling. There are two types of bottom trawling. They are benthic and demersal bottom trawling. Benthic trawling involves towing a net at the very bottom of the ocean, while demersal trawling is the process of towing the net just above the benthic zone.

Impacts on marine ecosystem

Bottom trawling causes several negative impacts on marine ecosystem which are leads to overfishing, bycatch, affect the seabed, damage coral ecosystem, affects benthic habitat and benthic flora and fauna. Large numbers of fish are caught through bottom trawling which adversely affect the fish stocks. The catch other than the target species is called by bycatch. Bottom trawling is entrap the many fish species, marine invertebrates, marine mammals, reptiles and even seabirds are caught in bottom trawling. The seafloor is a very stable and calmest part of the sea, where currents, temperature, and other natural conditions remain relatively undisturbed. Bottom trawling across the sea floor to scoop up fish, stirs up the sediment lying on the seabed, displaces or harms some marine species, causes pollutants to mix into plankton and move into the food chain and creates harmful algal blooms or oxygen deficient dead zones, resulting in a destabilization of the seaflo .

Coral reef is a habitat to many species. But, bottom trawling can uproot and kill coral colonies. Destruction of such corals adversely affects the species dependent on them. Bottom trawling cause negative effects on benthic habitats such as sandbanks, reefs and biogenic structures with their characteristic ecological communities and sensitive species. Bottom trawling operations uproot and displace marine flora and fauna living on the ocean floo . Sea anemones, sea pens, sponges, urchins and other fragile bodied marine fauna are destroyed during the trawling process.

Fishery management tools can be used to mitigate the effects of bottom trawling on seafloor habitats. Fishery management tools include fishing effort reduction, modification of fishing gear design or gear type and establishment of areas closed to fishing. Effort reduction is the cornerstone of managing the effects of fishing, including, but not limited to, the effects on habitat. The success of fishing effort reduction depends on the resilience and recovery potential of the habitat. Gear modifications will be most useful for finfis species that can be caught with gear that does not rely on disturbing the bottom to catch the fish. Closed areas are necessary to protect a range of representative habitats. Closures are particularly used for protecting areas with emergent epifauna (e.g., corals, bryozoans, hydroids, sponges) that are vulnerable to even low levels of fishing effort. The ultimate aim is to develop the alternative gear against bottom trawl net and create awareness to the fishermen s regarding the impacts on marine ecosystem

1-MONOGLYCERIDES OF SHORT- AND MEDIUM-CHAIN FATTY ACIDS PROVED TO BE EFFECTIVE IN DECREASING THE MORTALITY CAUSED BY *Flavobacterium psychrophilum* AND IN REDUCING THE ANTIBIOTIC TREATMENTS IN RAINBOW TROUT (*Oncorhynchus mykiss*), WITH FAVORABLE ECONOMIC RETURN FOR THE FISH PRODUCERS

Manuela Parini*, Matteo Calligaris, Alessio Paoli

SILO International – Italy – Florence
e-mail: manuela.parini@silospa.com

Introduction

Visceral flavobacteriosis is the most frequent cause of mortality in trout fry and fingerlings, involving economic losses for the trout producers. Flavobacteriosis outbreaks can occur up-to 10g of fish size. The standard approach to contrast this infection is the use of florfenicol. Despite the efficacy of the antibiotic in controlling the disease, the production losses can be severe if the antibiotic is not given promptly: the mortality caused by flavobacteriosis ranges, in standard farming conditions, between 10% and 30% during the whole cycle; it can reach peaks of 20-25% during a single outbreak. Another negative consequence deriving from the antibiotic usage is the photo-sensibilisation that can occur when the fish is treated in outside ponds and that can cause severe mortality. A specific composition of 1-Monoglycerides of short and medium chain fatty acids from C3:0 to C12:0, available on the market under the commercial name SILOhealth 108, inhibited the *F. psychrophilum* growth *in vitro*, at pH 6-7 (pH of the fish gastro-intestinal tract) at the concentration of 0.01%. In a previous trial, the 1-Monoglycerides composition modulated the fish intestinal microbiota by increasing the number of beneficial lactic bacteria and reducing several pathogenic bacteria (Rimoldi et al., 2018). In the present study the composition was tested for three years in two trout Italian farms with different environmental conditions and proved to be able to prevent flavobacteriosis outbreaks, to reduce the mortality and the antibiotic treatments in the hatcheries phase, with favourable economic return for the feed producers.

Table I. Characteristics of the farms

	FARM 1	FARM 2
Water source	Spring-water (or pumped water in emergency cases)	River
Geological features	Plain	Mountain
Yearly trout production in 2018	750 tons	450 tons
Stocked eggs/year	3 000 000	2 000 000

Table II. Direct yearly costs without or with 1-Monoglycerides in the hatchery period in two trout farms

Direct costs	Without 1-Monogl.	With 1-Monogl.	Without 1-Monogl.	With 1-Monogl.
	Farm 1	Farm 1	Farm 2	Farm 2
Antibiotic	990€	712€	519€	73€
Dead fish (*)	11 724€	6 224€	9 512€	2 182€
1-Monogl.	==	551€	==	248€
Total of costs	12 714€	7 478€	10 031€	2 503€
Saved amount		5 227		7 528

(*) The costs for the dead fish include the cost of the eggs, the feed cost and the general production costs.

(Continued on next page)

Field observations related to the control of infections caused by *Flavobacterium psychrophilum* in the trout farming practice with 1-Monoglycerides

The impact of the 1-Monoglycerides composition on the visceral flavobacteriosis incidence in the hatchery phase was evaluated in two trout farms located in North Italy for three years, from 2016 to 2018. The characteristics of the farms are reported in the table I.

The production parameters, some direct and indirect costs generated in the farms during the observation period were compared with the historical average data recorded in the previous three years. In the Farm 1, before the introduction of the 1-Monoglycerides composition, the flavobacterios outbreaks used to occur at the fry sizes of 0.6-0.7g, 1.8-2.2g and, sometime, at 3.5-4g, with mortality rates of 15%, 8% and 6% respectively per cycle. In the Farm 2 the flavobacterios outbreaks were observed at fry sizes of 0.55-0.65g, 1.5-2.1g and 3.0-3.8g, with mortality rates of 16%, 9% and 6% respectively per cycle. During the three years of observation the 1-Monoglycerides composition was administered at a dosage of 1% of the feed in both farms during the whole hatchery period. In the Farm 1 the treatments with florfenicol were reduced by 72% compared to the standard treatment programs implemented in the previous cycles, and the mortality was reduced in average by 65.2%. In the Farm 2 the treatments with florfenicol were reduced by 66% and the mortality by 71.6%. The 1-Monoglycerides composition prevented flavobact riosis in the majority of fingerlings, and only some tanks were treated with the antibiotic. The economic benefit for the producers derived from the reduction of the antibiotic costs and from the significantly higher survival rate which reduced the costs related to the dead fingerlings. The calculation factors are reported in the Table II. The costs incurred by the producers for the dead fingerlings were calculated by considering the biomass during each single flavobacteriosis outbreak, the mortality rate, the cost of the eggs and of the feed, the general production costs.

The direct costs resulted to be reduced by 41.1% in the Farm 1 and by 75.1% in the Farm 2. Other indirect costs like those related to the reduction of the final biomass to be sold on the market due to the mortality in the hatchery period were also considered in the final costs/benefits evaluation. Higher mortality in the hatchery involves less revenues for the trout producer at the end of the production cycle and higher incidence of the general production costs. As previously indicated, the mortality caused by flavobacteriosis in the hatchery period was reduced by 65.2% in the Farm 1 and by 71.6% in the Farm 2. The production costs at the end of the production cycle were reduced by 7% in the Farm 1, that is from 2.60€ to 2.45€/kg of produced fish, and by 6%, from 2.72€ to 2.55€/kg of produced fish in the Farm

Conclusions

The 1-Monoglycerides composition proved to be effective in decreasing the mortality caused by *F. psychrophilum* and in reducing the antibiotic treatments in the trout hatchery phase, with positive economic return for the fish producers. It can be taken into consideration as a valid and promising alternative approach, complying with the EU and global policy for antimicrobial resistance reduction.

Introduction

Barramundi, or Asian sea bass (*Lates calcarifer*), is an emerging species for aquaculture worldwide (ABARES, 2013). The growing demand for barramundi fillets necessitates intensification of barramundi production. Breeding practices in barramundi farming have not evolved since the 1980s with the introduction of hormonal therapy to trigger group-spawning events. This group mating strategy often leads to highly skewed paternity among offspring, resulting in a loss of valuable genetic diversity (Frost et al., 2006; Loughnan et al., 2013). With few studies available on male fertility and a lack of technology to quantify sperm quality in barramundi, efforts to develop reproductive tools to obtain such knowledge for this species is warranted. Thus, the aim of this study was to develop high throughput techniques to evaluate barramundi sperm quality in order to provide preliminary information on basic sperm biology that allows future investigation of male fertility.

Materials and methods

Spermatozoa were collected by catheterization on multiple occasions from n=15 mature male broodstock maintained in breeding condition at 30°C in 28,000 l tanks, with salinity at 30ppt on a 16h light: 8h dark cycle. Samples were diluted in marine Ringer's solution, adjusted to 400mOsm to mimic osmolality of barramundi seminal plasma, then held on ice. Sperm morphology was measured by ImageJ on SpermBlue-stained smears, and this data was used to calibrate and validate automated sperm counting and motility assessment by computer-assisted sperm analysis (CASA; Androvision, Minitube). Factors such as optimal sample dilution, the minimum number of fields, and the effect of motility were examined to determine sperm detection accuracy compared to manual haemocytometer methods. A Hoechst/propidium iodide (PI) viability assay was validated using 70°C heat-treated controls and a 5-point intact:damaged dilution curve of 0:100, 25:75, 50:50, 75:25 and 100:0% spermatozoa assessed by flow cytometry (≥100 000 cells; FACS Canto II, BD Biosciences). Lastly, a FITC/PI TUNEL DNA fragmentation assay (In situ cell death detection kit - fluorescein, Roche) was validated using DNase-treated sperm controls assessed by flow cytometry (≥100 000 cells). Once validated, the optimised assays were used to characterise baseline barramundi sperm quality.

Results

Barramundi spermatozoon has a structure, consisting of an ovoid head (length 2.44 ± 0.03µm; width 2.23 ± 0.03µm; ratio 1.11 ± 0.01), and a single flagellum (length 30.99 ± 0.49µm) connected by a short midpiece. Based on these measurements, a detection profile was created on the Androvision CASA system to identify barramundi spermatozoa. Accuracy of the automated sperm count was highly correlated with the manual counting method (r = 0.99, P < 0.001). Sample dilution at 1:1000 (across 5 dilutions ranging from 1:250, 1:500; 1:1000, 1:2500 and 1:5000) gave the most accurate automated sperm concentration when compared to manual haemocytometer (r = 0.87, P = 0.001, ICC = 0.99). Automated sperm concentration determined using three or more CASA fields of view have similar or improved precision (coefficient of variation ≤ 8.7%) when compared to manual haemocytometer (coefficient of variation = 8.0%). Moreover, detection accuracy was not affected by sperm motility since automated sperm concentration was highly correlated when using motile or immotile cells (r= 0.99, P < 0.001). Approximately 99.9 ± 0.07% of heat-treated spermatozoa were detected as dead Hoechst+/PI+ cells by flow cytometry. Moreover, sperm viability detected by Hoechst/PI assay was highly correlated with predicted viability using the 5-point dilution curve of intact:damaged spermatozoa (r= 0.98, P < 0.001). Lastly, 71.9 ± 4.4% of DNase-treated spermatozoa were detected as DNA damaged FITC+/PI+ cells by flow cytometry. Based on the validated assays and optimized conditions above, male barramundi broodstock exhibited baseline sperm quality of 15.1 ± 3.6 x 10^9 sperm.ml.-1 concentration, 52.8 ± 9.6% total and 13.1 ± 4.2% progressive motility, 64.2 ± 3.5% live, and 43.5 ± 6.0% DNA damaged spermatozoa.

Discussion and conclusion

Through several technical trials, we have validated the use of CASA, Hoechst/PI staining, TUNEL and flow cytometry for reliably assessing the concentration, motility, viability and DNA integrity of barramundi spermatozoa. Importantly, these assays permitted a rapid and accurate assessment of up to 100 000 sperm per fish; providing a comprehensive assessment of barramundi semen characteristics. Preliminary sperm quality data obtained in this study exhibited levels of cellular damage similar to that of frozen-thawed spermatozoa of other species (Zilli et al., 2003*;* Pérez-Cerezales *et al.*, 2010). Further research is necessary to identify the cause of such damage to determine whether it was artificially induced by sperm handling procedures (e.g. sub-optimal extender, prolonged storage), or was the result of poor quality spermatozoa in some individuals that could potentially explain the underlying mechanism for highly skewed paternity previously observed in offspring from captive bred barramundi.

Introduction

African catfish *Clarias gariepinus* is widely distributed throughout Africa, and has been considered one of the most important farm fish on that continent. During the last few decades, this species has been introduced into Europe, Asia and Latin America. The suitability of this species for aquaculture comes from its high growth rate, relatively low requirements for water quality, resistance to handling stress, ability to tolerate high stocking densities and having a good meat quality. Gamete manipulation during artificial propagation of these species presents several problems with the main one being that these species are oligospermic with the volume of sperm collected generally very low, even after hormonal treatment. Therefore, sperm needs to be extracted from the testes themselves, however, during this procedure males are either killed, or the testicular pieces are obtained through biopsy. As *in vitro* germ cell culture through which spermatogenesis can be recovered from a number of seeded SSCs can overcome some of the hurdles present in the artificial propagation of catfish species, the aim of this study was to optimize the spermatogonia cryopreservation procedure as the first step in the germline cell manipulation techniques, as well as to initiate *in vitro* spermatogonia proliferation from frozen/thawed samples.

Material and methods

African catfish used in this study were kept in a recirculation system (Sentimento Kft., Hungary) at the Department of Aquaculture, Szent István University, Hungary. Fish were housed under a 12 hr light/12 hr dark cycle at 26 ± 0.2 °C. Fish were sacrificed with a 2-phenoxyethanol overdose and testes were aseptically excised as previously described. Testes were kept in PBS on ice until further work (maximum 1 h). Tissue was cut into small pieces (~ 30 mg) which were subsequently used for cryopreservation.

Protocol for freezing of both European and African catfish spermatogonia was optimized in a single trial in which we tested the effects of two extenders and three cryoprotectants in three concentrations (a total of 18 test groups). Two tested extenders were (1) PBS supplemented with 1.5% BSA, 0.1 M trehalose and 20 mM HEPES and (2) the extender developed by Yoshizaki group (100% extender: 55.27 mM HEPES, 375.48 mM NaCl, 7.28 mM KCl, 23.10 mM KH_2PO_4, 3.82 mM Na_2HPO_4, 3.64 mM sodium pyruvate, 2.6 mM $CaCl_2 \cdot 2H_2O$ and 1.4 mM $MgCl_2 \cdot 6H_2O$, pH 7.88) used in zebrafish and trout species. Cryoprotectants tested were MeOH, Me_2SO and EG in 1, 2 and 3 M concentrations. Each piece was equilibrated for 30 min in 1 ml of cryomedium in 1.8 ml cryotubes. Samples were then frozen in CoolCell boxes in a -80 °C freezer (enabling a cooling rate of ~1 °C/min), while the thawing was conducted in a 26 °C water bath.

Optimization of the vitrification protocol was conducted in a single trial in which we tested the effects of two equilibration solutions and two vitrification solutions, as well as by testing the exposure time to the vitrification solutions. ES and VS contained different concentrations of MeOH, EG and Me_2SO (ES1: 1.5 M MeOH + 1.5 M M Me_2SO; ES2: 1.5 M PG + 1.5 M Me_2SO; VS1: 1.5 M MeOH + 5.5 M M Me_2SO; VS2: 3 M PG + 3 M M Me_2SO). The exposure to the equilibration solutions was 15 min, while the exposure to the vitrification solutions was either 1, 1.5 or 2 min. The extender consisted of L-15 supplemented with 10% FBS, 25 mM HEPES and 0.5 M trehalose. The NIV procedure was done following the protocol described above with ~20 mg tissue pieces.

In order to verify the functionality of SSCs after cryopreservation, testicular cells isolated from mature frozen/thawed African catfish testes were seeded into a 6-well plate, and cultured for three weeks. The culture medium consisted of L-15 medium supplemented with 10% FBS, 1% common carp serum, 100 U/ml penicillin, 100 mg/ml streptomycin, 2.5 µg/ml amphotericin B, 800 µM $CaCl_2$, 20 mM HEPES, 0.1 mM β-mercaptoethanol, 20 µg/ml L-proline, 20% ddH2O, 10 IU/ml hCG, 100 ng/ml EGF, 50 ng/ml 11-KT and 10 ng/ml DHP (pH = 7.4). Approximately 3 million cells were seeded in each well containing 3 ml of the culture medium. Cells were cultured at 26 °C in air. Medium was changed every two to three days; as the cells were cultured in a suspension culture, prior to every medium exchange cells were centrifuged at 200 ×g for 10 min to allow cells to sediment.

(Continued on next page)

Results

Cryoprotectants and their concentrations had a significant effect on post-thaw viability (three-factor ANOVA; $p < 0.01$), while the extenders did not have a significant effect. The highest SSC viability was observed when using 3 M Me_2SO with Yoshizaki extender and 3 M EG with PBS (Tukey's HSD, $p < 0.05$). Therefore, cryomedium containing 35.2% Yoshizaki extender and 3 M Me2SO was determined as the optimal reaching SSC survival rates of approximately 75%.

During NIV, all tested parameters displayed a significant effect on SSC viability (three-factor ANOVA; $p < 0.01$), while the statistical differences among individual groups were difficult to delineate (Tukey's HSD, $p > 0.05$). As the highest average post-warming viability was below 20%, freezing of catfish testicular pieces was evidently superior to vitrificatio

Individual cells that were seeded at the start of the culture started to form small spherical aggregates of approximately 15-20 cells during the first day. As the culture period progressed, the size of aggregates became larger which was indicative of cell proliferation. The size of aggregates grew from 28.1±4.9 µm on day 1 to 60.4±20.6 µm on day 7. At day 7, tails of spermatozoa started to emerge at the edges of aggregates. As all spermatozoa initially seeded were washed away during the initial two washes, spermatozoa observed after the first week were most likely produced from the seeded early-stage germ cells.

Discussion and conclusions

This study is the first to demonstrate successful freezing of African catfish SSCs. In addition, *in vitro* germ cell culture was adapted for the first time for African catfish SSCs and thus displayed that the cryopreserved early-stage germ cells are functional and are able to proliferate, differentiate and produce spermatozoa in culture. Technology developed in this study has the potential to overcome several hurdles present in catfish spawning. The main ones are the small volume of sperm produced by these species even after hormonal treatment, and the necessity to extract testicular sperm which can be of a lesser quality. Additionally, the need for extraction of testicular sperm inevitably evokes the need to either sacrifice the fish, or to conduct biopsy. In both cases, sperm extraction is laborious, and can lead to a reduction of brood fish, however the extracted sperm will most likely be used for only one spawning. A step towards improving this practice came in sperm cryopreservation, where the unused spermatozoa could be saved and stored for the next spawning.

The technique developed in this study presents the logical progression in the spawning technology. Beside the spermatozoa obtained through testicular samples, one can also obtain early-stage germ cells, including SSCs. These cells can be then seeded into culture, and spermatozoa can be produced through in vitro spermatogenesis. Later, such sperm can be used for fertilization and the production of the next generation. In addition to these techniques, an in vitro culture of SSC which can induce their self-renewal will enable a continuous availability of germ cells which can be later used for in vitro spermatogenesis, spermatozoa production, and subsequently in vitro fertilization and creation of offspring.

AN OPTIMIZED PROCEDURE FOR NUCLEAR EXTRACT PURIFICATION FROM MARINE FISH AND APPLICATION TO HISTONE ACETYLTRANSFERASE AND DEACETYLASE ACTIVITY EVALUATION IN GILTHEAD SEABREAM (*Sparus aurata*) EGGS

Introduction

Gene expression regulation is an important mechanism to control the production of a given gene [Emerson and Li (2010)]. Changes in gene expression that does not involve alterations in the DNA sequence are, generally, designated by the term epigenetics and refers to the trait variations resulting from external or environmental factors that switch genes on and off [Moore (2015)].

Acetylation and deacetylation of lysine residues are common epigenetic modifications, mediated by histone acetyltransferases (HAT) and deacetylases (HDAC3), respectively.

In this work we aimed at the development and validation of an effective extraction method for an enriched nuclear protein fraction and evaluate how maintaining a viable portion of gilthead seabream Sparus aurata L. 1758 eggs in the sieve for a longer period of time (in this case 30 minutes) affects the histone acetyltransferase and deacetylase activities.

Material and methods

Gilthead seabream (*Sparus aurata*) eggs were obtained from the broodstock adapted to captivity, at the Aquaculture Research Station of the Portuguese Institute for the Sea and Atmosphere. Fish are kept in in a flow through water system with controlled temperature and constant aeration. Eggs were collected in triplicates at the beginning of the experiment (T0) and after were left exposed to air for 30min and new samples were collected. Protein extracts, enriched in the nuclear fraction were purified and used to determine the activity of histone acetytransferase and deacetilase using the Histone Acetyltransferase Activity Assay and Histone Deacetylase Activity Assay kits, respectively.

Results and discussion

Hereby, we describe a cost-effective methodology, which allows an enrichment of the protein extract in the histone-containing fraction and that have been successfully applied to marine species.

HAT and HDAC3 activities were measured and a significant decrease on the HAT activity (figure 1A) was observed, after the period of exposure (T30), suggesting a decrease on transcriptional activity [Bannister and Miska (2000)], fact that may have an important impact on the normal fish development. Early stages of vertebrate development are a critical period concerning epigenetic reprogramming with a consequent increase on the transcriptional activity and initial cellular differentiation [Bonnet-Garnier et al., (2018)].

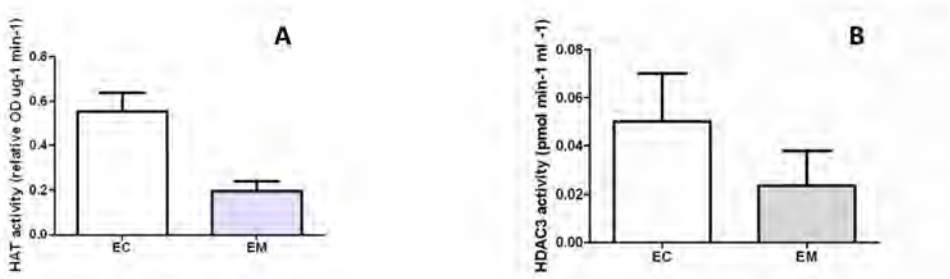

Fig. 1 Histone acetyltransferase (A) and deacetyltransferase (B) activities in control (EC) and manipulated (EM) situations. * indicate values significantly different (unpaired T-test; $P < 0.01$)

(Continued on next page)

Regarding the effect on deacetylase activity, it was not observed a significant change (figure 1B). The effect of histone acetylation is normally counterbalanced by histone deacetylases and gene knockout studies have shown that the four classes of histone deacetylases play important roles during vertebrate development [Haberland et al., (2009)]. Also, several studies suggest the use of deacetylase's-directed therapies for diabetes and cancer treatments, for example [Kawada et al., (2017)].

Since hatcheries daily routines could have a significant impact on organism's welfare and future development, handling procedures, should take these results into account in order to minimize as much as possible their negative effects on fish development.

Also, it would be interesting to use this methodology on the evaluation of the effect of other routine procedures (e.g. egg disinfection) and environmental changes (e.g. acidification) on HAT and HDAC3 activities and correlate the results with the level of expression of selected genes, to have some inference on the impact it may have on organism's welfare and development.

Introduction

Currently, natural spawns from Senegalese sole (*Solea senegalensis*) in culture are only obtained from wild individuals adapted to captivity (Angus and Cañavate, 2005) or mixed broodstocks of wild males and cultured females (Personal observation). Spawning of cultured broodstock (F1 generation) has failed as fecundity was low and eggs were unfertilized (Guzman et al., 2008). This has been correlated with dysfunctions detected in both sexes, male and female cultured breeders exhibited reduced sperm production and low fecundity compared to wild breeders. Therefore, *in vitro* fertilisation is a possible solution to overcome these problems (Rasines et al., 2012; 2013). The most important aspects of an in vitro fertilisation protocol are to obtain high quality sperm and eggs at the same time. A commonly used strategy to stimulate ovulation for *in vitro* fertilisation in fish is by means of an exogenous treatment with gonadotropin-releasing hormone agonists (GnRHa). In the present study, the timing of ovulation, stripping and egg quality was determined when Senegalese sole (*Solea senegalensis*) females were administrated GnRHa.

Material and methods

Prior to hormone induction the female maturity status was determined using three different methods, abdominal swelling, ratio between total and gonad length and oocytes diameter. In addition, sperm parameters sperm motility (28.59 ± 22.18%) and velocity average path (VAP) (216.80 ± 55 μm/s) were determined with computer assisted sperm analysis (CASA - ImageJ). Optimal time between ovulation and stripping of eggs was determined by stripping induced females every three hours starting from 35 hours after the injection of GnRHa (25 μg/ kg). Each batch of eggs was fertilized with pool of sperm. Lastly preliminary trials were completed to examine the sperm to egg ratio (pure sperm, 1:2; 1:4; 1:8; 1:16; 1:32; 1:64) required to obtain high rates of fertilisation.

Results

The optimal stripping time was from 40 to 44 hours following GnRHa injection at 16ºC. The GnRHa induction had successful rates of fertilization of 37.81 ± 44.43 %. The period of egg viability after ovulation until eggs lost viability was three hours after the stripping 44 hours post injection. The three different methods: abdominal swelling, ratio between total and gonad length and oocytes diameter were useful for determining maturation status and were positively correlated. Highest rates of fertilisation were obtained with females that had abdominal swelling index 3, ratio between total and gonad length of 0.55 and oocytes diameters of 580 μm. High fertilisation rates (76%) were obtained with a spermatozoa to egg ratio of 75:1, however, this result should be treated with caution until confirmed with repetition

Discussion and conclusions

When *Solea senegalensis* was induced with a single injection of 25 μg/kg body weight of GnRHa at 16°C, the time of ovulation into the ovarian cavity was between 41 and 44 hours post induction (Rasines et al., 2012; 2013). There was a positive correlation between the different determinations of maturity status. According to oocytes diameter, the ideal stage for high fertilisation was the post vitellogenic stage. When the oocytes were in a hydration phase fertilisation was poor and it appeared that ovulation was earlier and eggs became overripe indicating that possibly it was not necessary to induce. In the case of abdominal swelling, stage 3, gave the higher fertilization rate. Ratio between gonad and total length was the least useful method to predict egg quality after GnRHa application.

(Continued on next page)

Sperm quality (VAP and motility) decreased during the experimental period. The percentage of initial motility was as others reported for sole (30-40%) (Chauvigne et al., 2017), nevertheless, there was a large difference with previous studies in pelagic fish. However, the VAP (µm/s) observed in this study, average values were 216 µm/s, was low compared with values obtained in previous studies. On the other hand, the successful fertilisation of eggs (76%) with a sperm to egg ratio of 75:1 was surprising and very different to other studies. In contrast, the values that were found in other reports about other species showed higher ratio of spermatozoa per egg.

The use of GnRHa to induce females successfully accelerated the oocytes develop to obtain good quantity and quality of eggs released. There was a positive correlation amongst the three different methods that were used to observe the maturity status. When broodstock were injected with GnRHa at 16ºC, females should be examined at 41 hours post induction. Good egg quality was maintained for three hours, between 41 and 44 hours post injection. High fertilisation rates (76%) were obtained with a spermatozoa to egg ratio of 75:1, however, this ratio should be treated with caution until confirmed with repetition.

Introduction

Ciguatera poisoning is a food-borne illness mostly caused by consumption of fish contaminated with polyether toxins known as ciguatoxins (CTXs). Originally known as a tropical disease, Ciguatera is being increasingly reported from areas previously not considered endemic, namely in the North-Eastern Atlantic. The epi-benthic dinoflagellates *Gambierdiscus* and *Fukuyoa* are considered to be the causative agents of Ciguatera. Furthermore, these genera have recently been shown to have an increasing number of species, also discovered in areas where it had not been observed before, namely the Canary Islands. A total of 54 strains of the genus *Gambierdiscus* were recently isolated from field samples collected from the Macaronesian Region. The study presented here is part of the MIMAR project (MAC/4.6D/066) (2017-2020) aiming at the characterization of hitherto unidentified CTXs from the North-Eastern Atlantic Ocean.

Materials and methods

Two strains of *G. australes* (OCH85 and OCH141), one strain of *G. carolinianus* (OCH100) and two strains of *G. excentricus* (OCH45 and OCH92) originated from the Canary Islands were cultured using 150 mL of culture medium in 75 cm^2 culture flasks under the same culture conditions. Culture medium consisted of natural Atlantic seawater (salinity adjusted to 32), filtered at 0.2 µm and enriched with f/5 nutrients (Guillard and Ryther, 1962), with the addition of selenium and the exception of silica. Cultures were maintained in a thermostated incubator at 25 °C under full spectrum LED lights with an incident photon flux density of 60 µmol photons $^{-2}$ s^{-1} and a daily light-dark cycle of 12 h :12 h.

Culture experiments were conducted using a semi-continuous batch method to keep the cells into the log-phase growth, as previously described by Pisapia et al. (2017) and Litaker et al. (2017). Four different treatments of the bottom surface of the culture flasks (Corning®), i.e. Non-Treated (NT), TC-Treated (T), CellBind (CB) and Ultra-Low Attachment (ULA), were evaluated for their influence on the growth of *G. australes* strains. Cell concentration (cells mL^{-1}) was estimated once per week, using a 1 mL Sedgewick-Rafter counting chamber under a light microscope. Specific growth rate (µ, d^{-1}) was the slope calculated by the linear regression of the natural logarithm of the cell concentration versus time, after correcting for serial culture dilutions.

Gambierdiscus cells were harvested in the log-phase growth and toxins were extracted using MeOH (x2) and MeOH:H_2O (1:1, v/v) (x2). Crude extracts were adjusted to MeOH:H_2O (3:2, v/v) and partitioned twice with dichloromethane (DCM). The lipophilic CTXs were partitioned into the DCM soluble fraction (DSF). Triplicate DSF samples were used for screening their CTX-activity using the O/V neuro-2a (n2a) assay. The assay was carried out in 96-well flat-bottom plates with vacuum gas plasma

treatment for cell adhesion. Pacific ciguatoxin-1B (CTX1B) was provided by R. J. Lewis (Queensland University, Australia) and used as reference standard material. For each DSF sample, four 10-fold serial dilutions were tested in three separate experiments and three replicate wells for each dilution were run for each experiment.

Results

Specific growth rates (μ) of *G. australes* strains under ITC laboratory conditions ranged from 0.088 d^{-1} ± 9.2% (RSD) to 0.165 d^{-1} ± 3.3% (RSD). *G. australes* OCH141 exhibited slightly higher μ than *G. australes* OCH85 in all the conditions tested. Slight differences in μ were observed depending on the bottom surface tested. The fastest growth was observed when the cells were cultured in Corning® ULA flasks, and the slowest growth occurred in Corning® CB flasks. Estimation of μ of *G. carolinianus* and *G. excentricus* strains is currently ongoing.

A first screening of the neurotoxic activity of the strains revealed that *G. carolinianus* OCH100 and *G. australes* OCH141 showed no detectable CTX-activity at any of the concentrations tested. Some low CTX activity was observed in *G. australes* OCH85, at the highest concentration only. Both *G. excentricus* strains were clearly positive for the presence of CTXs.

Discussion and Conclusions

This study showed that *Gambierdiscus australes* strains behaved as slow growers under ITC laboratory conditions, with $\mu < 0.17$ d^{-1}, which appeared similarly low or somewhat lower than those reported in literature (Pisapia, 2017). All the different flasks employed for the culture experiments were suitable for cell growth, although some slight differences were observed in specific growth rates. Interestingly, the treatments for cell adhesion seem to disfavor *G. australes* growth. Still, statistical analyses are needed to determine whether the different substrates have an authentic impact on cell growth.

Preliminary results of the n2a assay suggest that *G. excentricus* species is likely to produce more CTXs than the others, in accordance with previous studies (Pisapia et al., 2017; Litaker et al., 2017). A serial dilution scheme with a narrower dilution factor is needed to trace sigmoidal dose-response curves, determine EC_{50} values and to quantify the amount of CTX1B eq per cell. For the other species, more concentrated samples are needed to clearly detect and quantify the low CTX amounts they are likely to produce – they are expected to produce CTXs in the range of fg $cell^{-1}$.

Further studies will focus on culture scale-up and bioguided fractionation of the most toxic strains in combination with high resolution mass spectrometry to pinpoint known and/or previously undescribed toxins.

Introduction

The replacement of fish oils (FO) with vegetable oils (VO) in aquafeeds is a viable alternative for the sustainability of the aquaculture industry. However, it compromises the nutritional value of the species by decreasing the supply of long chain polyunsaturated fatty acids (LC-PUFA), such as 20:5n-3 (EPA) and 22:6n-3 (DHA). The ability of fish to biosynthesise LC-PUFA can be influenced by the environmental conditions, food habits, and phylogeny (Castro *et al*., 2016). It is well known that *Solea senegalensis* (SS), displays *fads2* (Δ4) activity which is involved in the biosynthesis of DHA from EPA, and its gene expression responds to dietary modulation (Morais *et al*., 2012, 2015). However, the combined effect of dietary and salinity modulation on the lipid metabolism of SS remains unknown. The aim of the present study was to assess the capacity of SS to biosynthesise LC-PUFA with different sources of dietary lipids (FO *vs* VO) as well as under different environmental salinities (35ppt *vs* 20ppt), analysing the flesh fatty acid composition and the expression of *fads2* (Δ4 desaturase) and *elovl5* (C_{18} & C_{20} elongation) in liver and foregut.

Material and methods

24 fishes of 491.0 ± 75g (mean ± SD) initial body weight were distributed into 4 tanks and cultivated for 9 weeks. Two tanks were fed with a commercial SS diet (FO) while the other two received an experimental diet (25% commercial SS diet and 75% commercial tilapia diet; VO). For each dietary treatment, a control and a low salinity were assayed (35ppt and 20ppt, respectively). For all treatments, fish were reared under natural photoperiod, at an average water temperature of 18.5 ± 0.4 ºC and dissolved oxygen above 5ppt. At the end of the experiment, the individuals were slaughtered by a sharp blow to the head, individually measured and weighed. Samples of blood, muscle and several tissues were taken for further biochemical analysis. In addition, samples of liver and intestine were collected in RNAlater® to measure the expression of the *fads2* and *elovl5* genes by qPCR (Morais *et al*., 2012).

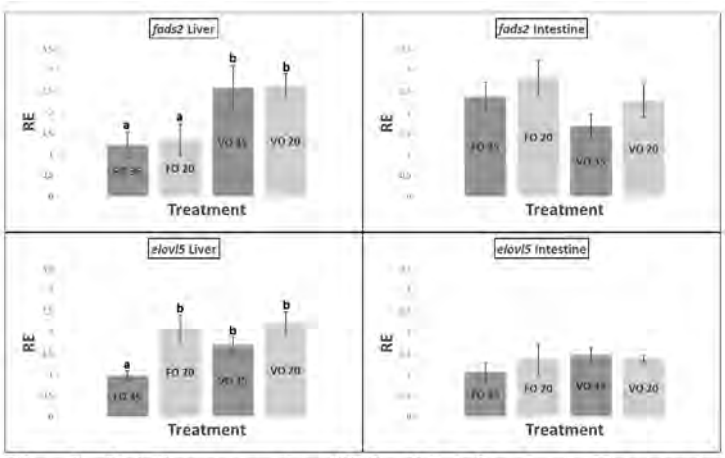

Fig. 1. Relative expression (RE) of *fads2* and *elovl5* genes in liver and intestine of *Solea senegalensis* (mean ± SE, n = 6). Different letters indicate significant differences (ANOVA, Duncan post-hoc test, P <0.05).

(Continued on next page)

Results

After 9 weeks of experiment, the greatest weight gain was registered in the FO-20 treatment (FO-20: 103g; FO-35: 54g; VO-20: 35g; VO-35: 33g). VO-based diets provided 43% less DHA and 42% less EPA than FO diets. Muscle of the FO-20 fish contained 18% less DH than that of FO-35.

The relative expression studies showed that liver *fads2* gene was upregulated in fish receiving the VO diet compared to FO-fed fish (Figure 1) whereas the *elovl5* gene was downregulated in fish fed the FO-35 treatment compared to the rest of treatments, indicating a trend for a higher expression at low salinity groups (FO-20 and VO-20). Intestinal *fasd2* and *elovl5* gene expression did not vary among treatments. However, for the same diet, *fads2* gene expression tend to be upregulated at lower salinity.

Discussion and conclusions

The greater growth of FO-20 fish could be associated with a lower energy expenditure for osmoregulation (lower salinity), in combination with a diet adapted to fulfill the nutritional requirements of *Solea senegalensis* (FO diet). On the other hand, although the VO diet provided less EPA and DHA, the composition of muscle fatty acids shows an important elongation and desaturation activity by converting significant amounts of E A into 22: 5n-3 and DHA, respectively.

The expression of *fads2* was upregulated in liver of fish fed the VO diet accordingly to Morais *et al.* (2015). This result confirms that lower dietary levels of ω-3 LC-PUFA, stimulates the capacity of biosynthesis in this species. Furthermore, Morais *et al.* (2012) observed that the enzymatic activity and the transcription of genes modulated by the diet were more evident in the liver than in the intestine, in agreement with our results. The liver has an important role in lipogenesis, showing more variable levels of gene expression than intestine. The partial substitution of FO by VO in combination with a decrease in salinity seems to be a more sustainable farming strategy in order to obtain SS specimens particularly rich in DHA.

Introduction

Tolerance to environmental warming and persistence in the natural environment depends on the limited capacity to acclimate to changing temperatures. Temperature plays a key role among these environmental factors due to its direct impact on all physiological processes. Temperature has a direct impact on all physiological processes including oxidative damage, showing enormous influence in the physiological adaptation to the aquatic environment. Rises of temperature can increase growth rates and food conversion efficienc . For profitable operation of aquaculture facilities, it is necessary to feed fish preferably with the optimum feeding rate. The appetite and thus the optimum feeding rate increase with temperature. The food consumption continues to rise even if the temperature exceeds this limit, but the food is no longer completely digested. Overfeeding and excessive temperatures generate unnecessary costs; also decreasing the water quality and finally the profit. Therefore, in the present study we test the combined effect of three different temperatures (23, 25 and 27ºC) and two different ration sizes in growth performance and the response of biomarkers of oxidative stress and antioxidant enzymes within the nervous, branquial, intestinal and hepatic tissues and blood of gilthead seabream juveniles.

Materials and methods

288 alevins born in captivity (average weight of 6.2±1.15g and size 7.1±0.3cm) were randomly divided into 18 homogeneous groups of 16 fish each. The groups were maintained at the Instituto Español de Oceanografía (Tenerife, Spain) facilities in fibe glass tanks (1m^3 cylindrical) with a constant water exchange and aeration, under natural conditions of photoperiod, water salinity (37.5psu), and oxygen saturation (92.4 ± 4.8%). Fish groups were maintained at a temperature of either 23, 25 and 27ºC. Fish were fed a commercial pellet for seabream (Skretting Ltd 1.5) at 50% or 100% of optimum feeding rate resulting in 6 treatments by triplicate. Feed was supplied daily (6 meals day-1). Feed left uneaten was recovered from the bottom of the tank 30 minutes after its administration to quantify the daily feed intake (FI). The samplings were carried out over a period of 0, 15, 30, 45, 60 days. Growth performance (specific growth rate, SGR; coefficient of variation for weight, CV; condition factor, CF), Hepatosomatic index (HSI), survival (S) and feed intake (FI) were determined.

Blood was collected from the caudal vessels using heparinized syringes. Plasma samples were separated after centrifugation and levels of glucose, lactate sodium and potassium, were determined by standard spectrophotometric assays (Spinreact, Spain). Also classical stress biomarkers: reactive oxygen species (ROS) and lipid peroxidation and blood indicators were analyzed.

Results

Results in growth performance showed that significant main effects of feed restriction and temperature on specific growth rate (SGR) were detected. Also, there was a significant interaction between temperature and feed restriction. Overall, exposure to 27°C significantly increased SGR and feed-restriction significantly decreased SGR. Warming did not affect body size variations of fish (P>0.05). In contrast, hepatosomatic index (HSI) was lower in feed restriction and with temperature increased (P<0.05).

The condition factor index (CF) was similar during the experiment irrespective of the temperature tested. However, at 23º and 25ºC the fish under feed restriction showed a significantly lower CF (P<0.05). Regarding intake, an increase in total intake (g) was observed with the increase in temperature but % Feed Intake (% of biomass per day) was not affected by the effect of food restriction or temperature.

In relation to stress biomarkers and specifically reactive oxygen species, catalase, superoxide dismutase (SOD), glutathione peroxidase (GST) and lipid peroxidation were determined. Results on catalase showed that there was no significant main effect of feed restriction or temperature on catalase levels in gills, liver, intestine and brain tissues, nor was there a significant interaction between temperature and feed restriction.

(Continued on next page)

Furthermore, there was no significant effect of temperature, feed restriction or an interaction between temperature and feed restriction on SOD levels in brain and liver tissue
Other blood indicators were also analyzed, and again no significant differences were observed in haematocrit, glucose, lactate and sodium after 60 days of trial. Only levels of chloride were decreased in fish exposed to a 27°C compared to 23ºC.

Conclusions
Preliminary conclusions showed that higher temperatures promoted increased SGR and total intake regardless of the food restriction. No mortality was observed during the experiment and no significant effect of temperature increased on coefficient of variation for weight and condition factor was observed. Stress biomarkers and blood indicators were not significantly affected by temperature increased. These results suggest that the degree of thermal stress endured by these fish was not severe

A modelling approach was developed to analyse the potential direct (temperature and food availability) and indirect (pathogen) effects of climate change on cultivated shellfish species of commercial interest

Four species-location pairs were considered: Pacific oysters and blue mussels in the North Sea (Netherlands), blue mussels in the North Sea (Denmark), and Mediterranean mussels in the SW Atlantic coast of Europe (Portugal). The focus was on biological effects on shellfish production (growth and mortality), together with changes in environmental externalities related to water quality, and resulting socio-economic consequences.

The modelling work was supported by (i) multi-stressor laboratory experiments (temperature x food concentration x oxygen saturation) designed to parameterize the direct effects of climate change on bivalve growth; (ii) future climate predictions under several IPCC scenarios generated from downscaled physical and biogeochemical models. These predictions were used to drive individual growth models for the three cultivated shellfish species, applied to selected geographical areas where those species are presently cultured. The physiological models were used to drive two different local-scale models which provided outputs at the population level. One of these models (FARM[1]) focused on direct effects of climate change, such as temperature-driven changes in production, and the other (ABC[2]) provided results on host-pathogen interactions in a changing climate.

The results obtained for present-day conditions were compared with scenarios for the mid-twenty-first century (2040-2060), and the end of the century (2080-2100). For each of those scenarios, two different IPCC projections were considered: (i) a moderate situation (IPCC RCP 4.5); and (ii) an extreme situation (IPCC RCP 8.5).

We completed the study with the analyses of future economic drivers for grow-out production of the four species-location pairs under four socio-political scenarios studied in the EU Horizon 2020 project CERES. An established benchmarking approach was used to compare present-day economic performance of 'typical farms' with their future profitability under different climate change scenarios.

The modelling tools presented herein aim to increase awareness in the aquaculture sector about the potential effects of climate change, and help the industry respond appropriately. The results obtained will be used to support shellfish farmers in the adaptation of their farming activities to underlying biophysical and economic changes; such adaptations include the development of early warning methods, new operating procedures, infrastructures, location choices, and commercial markets.

HOW WILL THE PRODUCTION OF AN ECONOMICALLY RELEVANT ALGA (*Gracilaria* SP.) VARY WITH TEMPERATURE RISE?

Introduction

Red seaweeds belonging to the genus *Gracilaria* are within the most cultivated and valuable marine macrophytes in the world (Rocha et al., 2019). Their applications range from the nutraceutical and pharmaceutical industries to other emergent uses, such as dietary ingredients for fish or dairy cattle (Valente et al., 2015; Lima et al., 2019). In addition, *Gracilaria* spp. are present at coastal areas worldwide, being relevant to the function of these ecosystems, where along with other marine macrophytes, they act as nutrient sinks and carbon sequestration mediators (Duarte et al., 2018). However, since temperature is the most important range limiting factor for many marine macrophytes, ocean warming is expected to have significant impacts on the productivity of some species (Díez et al., 2012). Baring this in mind, our aim is to develop a numerical model for the production of *Gracilaria* sp. that can be both applied to natural systems and aquaculture farms, and that will be used to predict variations on *Gracilaria* growth, standing stock and production under climate change scenarios, especially, temperature rise within the ranges estimated by the IPCC (2014). Multiple-stressor simulations (e.g. temperature, salinity, sea level rise) are also run to check for interactions between different stressors and their impact on algal growth.

Materials and methods

The model accounts for the processes that control *Gracilaria* biomass through time (GPP, NPP, reproduction, decomposition, grazing) and the regulation exerted by environmental factors (temperature, PFD, external concentration of N and P, salinity). Along with *Gracilaria* biomass, the algal internal concentration of N and P are also described as state variables, due to the algae's capacity to store nutrients. Field, experimental and literature data are used to parameterize and test the model. All relationships are expressed as numerical formulations written in STELLA (ISEE systems) and R (R project). A simple conceptual diagram of the model is shown in figure 1

Long-term stability, verification, calibration and validation are performed to assess the model's accuracy and performance. Regression analysis is used to compare observations with simulations. Once the fitting level is statistically significant, scenario simulations accounting for temperature variation according to RCP scenarios (IPCC, 2014) and multiple-stressor scenarios are run, to check for the effects on *Gracilaria* production.

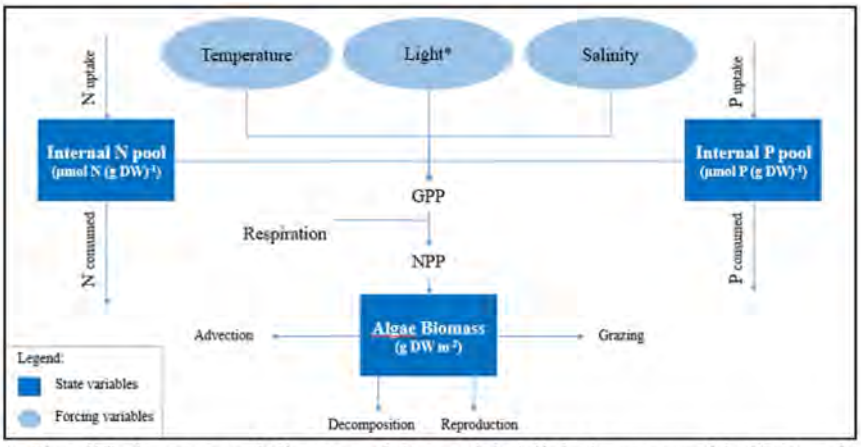

Fig. 1. Simplified conceptual diagram of the model. * light is measured in PFD – photon flux density (µmolE m^{-2} s^{-1}); GPP – Gross Primary Production (d^{-1}); NPP – Net Primary Production (d^{-1}); N – Nitrogen; P – Phosphorous

(Continued on next page)

Results

Results show that the model is able to reproduce the variation of *Gracilaria* sp. biomass and production through time accordingly to observations. Furthermore, while scenario simulations highlight the potential for a general enhancement of *Gracilaria* sp. biomass under temperature rise scenarios, multiple-stressor scenarios (e.g. temperature, sea level rise, DO) highlight the complexity inherent to stressors' interactions and the different responses of *Gracilaria* sp. to these.

Discussion and conclusion

The consistency found between the patterns of predicted and observed *Gracilaria* biomass variation validated the subsequent use of the model in checking the algal responses to single-stressor (temperature) and multiple-stressor scenarios (temperature, sea level rise, salinity). According to results, while temperature rise seems to benefit the production of *Gracilaria* sp., particularly in some parts of the growing season, the interactions between different climate stressors may be adverse to *Gracilaria* sp. production. This is in accordance with previous studies that show the existence of intrinsic interactions between the biological systems and climate change stressors, frequently resulting in synergistic or antagonistic interactions (Falkenberg et al. 2013). Thus, the present results should be acknowledged with caution. On the other hand, the model may be further improved e.g. by incorporating more accurate data. Nonetheless, the present model provides a comprehensive and supportive tool for sustainable management strategies, either aiming to harvest natural populations of *Gracilaria* sp or optimizing algae farming under a changing climate with therein improvements to the income of seaweed farmers.

STRESS HORMONES EVOKE CHARACTERISTIC EXPRESSION PROFILES IN SALMONID HEAD KIDNEY CELLS UNDER IMMUNE STIMULATION

Joan Martorell-Ribera*, Mareen Nipkow, Torsten Viergutz, Christian Plinski, Tom Goldammer, Ulrike Gimsa & Alexander Rebl

Leibniz Institute for Farm Animal Biology (FBN), Wilhelm-Stahl-Allee 2, 18196 Dummerstorf, Germany
E-mail: martorell-ribera@fbn-dummerstorf.de

Introduction

Under stressful conditions, the head kidney of teleosts plays a central role in the neuro-immune interactions. As an endocrine tissue, it releases cortisol and the catecholamines adrenaline and noradrenaline, but also fosters hematopoietic and lymph node functions (Wandelaar et al., 1997). Once released, cortisol and catecholamines will interfere with the immune response through the glucocorticoid and adrenergic receptors present on the different leukocyte populations (Cortés et al., 2013, Roy and Rai, 2008.). Using gene expression analysis and flow cytometry, we analysed the immune-cell lineages in the head kidney and their repertoire of glucocorticoid and adrenergic receptors. In the next step, we performed a series of in-vitro stimulations of head kidney leukocytes to study the expression of immune-relevant genes when stress hormones are present. This study aims at defining reliable markers for the stress-induced immune modulation, in order to evaluate the effects of stress on the immune system of maraena whitefish (*Coregonus maraena*), a 'newcomer species' in intensive aquaculture.

Materials and methods

First, a single-cell suspension obtained from *C.maraena* head kidney was analysed in the flow cytometer and sorted according to granularity and size. Subsequently, head kidney cells were cultured for defined periods between 1h and 48h and stimulated with adrenaline, noradrenaline or cortisol, either alone or in combination with pathogen-associated molecular patterns (PAMPs). A large set of specific primers was designed for reverse-transcription quantitative real-time PCR analyses, including marker genes for specific leukocyte populations, glucocorticoid and adrenergic receptors and markers for immune activation and stress response genes.

Results

Flow cytometry analysis of head kidney cells identified two groups with different cell characteristics. One group was less granular and of smaller size, located in the lower part of the forward and side scatter axis ($FS^{lo}SS^{lo}$). The other cell group showed higher granularity and bigger size, located in the higher part of the forward and side scatter axis ($FS^{hi}SS^{hi}$). $FS^{lo}SS^{lo}$ cells expressed a higher proportion of transcripts characteristic for lymphocytes, while $FS^{hi}SS^{hi}$ cells expressed higher levels of transcripts specific for the myeloid lineage. Gene markers for glucocorticoid and adrenergic receptors were equally expressed in both clusters. The in vitro experiments with primary cells stimulated with cortisol and PAMPs showed differential gene expression depending on incubation time, particularly with regard cytokine, acute phase and stress response genes. In essence, cortisol exerted a down-regulatory effect on immune-gene expression in the presence of PAMPs.

Discussion

The flow cytometry analysis together with cell-specific transcript markers corresponds to the known FS-SS distribution of myeloid and lymphocyte populations (Wilkerson, 2012). The even distribution of stress hormone receptors in both groups suggests potential stress-response targets, which might modulate leukocyte activity, updating the actual knowledge on adrenergic receptor gene expression in salmonid leukocytes (Flory et al., 1990). Our in-vitro experiment of stimulating head kidney cells with PAMPs and cortisol gave insights in the regulatory mechanisms behind the interaction of cortisol with activated leukocytes. On the one hand, our data indicates the constant upregulation of stress-related genes (HSP70) in the presence of either cortisol or PAMPs, confirming the interrelation of HSP70 with stress and immune system (Zhang et al., 2011a). On the other hand, we suggest a modulatory role for cortisol on cytokine gene expression, affecting their up-regulation when cells are confronted with PAMPs. This is in line with findings on the anti-inflammatory functions of a stress hormone (Barton et al., 1987).

Introduction

Formulating feed on a digestible nutrient basis is a key strategy on the success of profitable and environmental friendly farming. Several approaches have been taken in the past years to standardize methodology for determining nutrient digestibility of ingredients. In the digestibility study, test diets are normally produced by mixing a test ingredient with a reference diet at a ratio (weight basis) of 30:70 (test ingredient: reference diet) (NRC, 2011). Nutrient digestibility of reference and test diets are determined separately and used to calculate nutrient digestibility of ingredients. Recently, Carvalho et al. (2016) showed in shrimp that differences in the inclusion levels of a test ingredient in the reference diet affect the nutrient digestibility values of ingredients determined. This could be because certain ingredients at higher inclusion increases antinutritional factors and thus reduces the nutrient digestibility. On the other hand, at low inclusion of test ingredient, accuracy of nutrient ADC may be compromised. Another potential factor that can affect the measurement of nutrient ADC is feces collection method. Among different methods, Guelph system and its modified versions have been commonly adopted for several fish species. Although this system is known to produce reliable values, there is still an opportunity for nutrient leaching from feces. Another approach is called Choubert or INRA system where feces are continuously captured on a movable screen and then deposited in collection tray. With this approach, feces are removed from the tank almost immediately. However, this approach is not commonly practiced because of its practical difficult . The objective of this study was to evaluate the effect of feces collection methods (decantation vs. mechanical filtration) and the dietary inclusion level of test ingredients (10 and 30%) on the energy, fat, protein and amino acid digestibility of ingredients in Nile tilapia.

Material and Methods

The study was conducted at the experimental facilities of the University of Trás-os-Montes e Alto Douro (Vila Real, Portugal). Fish meal, meat and bone meal, soybean meal, rapeseed meal, and cotton seed meal were evaluated. A reference diet was formulated with fishmeal (15%) and several plant ingredients. None of the plant ingredient was included at more than 10% to avoid extreme levels when cumulated with the incorporation of the various test ingredients. Chromic oxide was added at 1% in the reference diet as an indigestible marker. All the diets were extruded at SPAROS Lda., Portugal.

Table 1: ADC of energy, protein and amino acids of various ingredients in Nile tilapia

Ingredients	Feces collection method	Energy	Protein	Lys	Met	Thr
Fish meal	Guelph	77.8	82.4	89.0	85.5	83.3
	INRA	78.9	84.6	89.7	85.7	83.8
Meat and bone meal	Guelph	73.8	75.3	72.3	61.4	69.7
	INRA	74.2	75.2	71.3	59.5	66.7
Soybean meal	Guelph	81.6	90.3	92.3	90.3	89.8
	INRA	81.7	91.3	92.6	90.1	89.7
Rapeseed meal	Guelph	63.5	80.2	83.1	84.8	81.2
	INRA	65.3	81.6	83.2	83.8	80.4
Cottonseed meal	Guelph	64.9	80.8	73.3	69.5	76.0
	INRA	65.7	81.5	76.5	72.2	78.7

(Continued on next page)

Ingredient inclusion level

Groups of 20 fish (body weight: 40-60 g) were stocked in 44 fibe glass tanks at a constant water temperature of 28 ± 1°C. Two sets of test diets for the five ingredients were prepared by mixing a test ingredient with the reference diet at a ratio of 10:90 or 30:70. Ten test diets and the reference diet were randomly allotted to the experimental tanks and all dietary treatments were tested in quadruplicate. Prior to initiation of feces collection, fish were subjected to a 12-day adaptation period to the rearing conditions and experimental feeds. Following this adaptation period, fish were fed once a day (9.00 h), by hand in slight excess. Upon a thorough cleaning of the tanks for any feed residues, feces were collected daily for 10-15 consecutive days in the feces decantation column (Guelph system). Feces were collected approximately 8 hours after the meal. After removal of excess water, daily feces were frozen at -20°C. Pooled feces from each group of fish were freeze-dried prior to subsequent analysis.

Feces collection method

Test diets for the five ingredients prepared at the ratio of 30:70 (test ingredient : reference diet) were used for evaluating the two feces collection methods. Data generated from the ingredient inclusion level (30:70) using the Guelph system were used for comparing the feces collection method. For the INRA system – outlet water filtration method, similar conditions were adopted as in the "Decantation method" except for the feces collection procedure. Feces were collected using a mechanical system by continuous filtration of feces in the outlet water (INR system).

Results and Discussion

Changes on the dietary incorporation level of the ingredient (10 or 30%) had little effects on the protein and amino acid ADC of fishmeal, and meat and bone meal. However, incorporation level of the test ingredient (10 or 30%) showed significant effect on the ADC of protein and amino acids for soybean meal, rapeseed meal and cottonseed meal. The ADC values for protein and most amino acids tended to be lower for the 10% ingredient inclusion relative those obtained for 30% inclusion level. In some ingredients, this reduction on ADC is quite marked and would require a further attention. However, inclusion of ingredients did not affect ADC of energy. Feces collection method (decantation vs. mechanical filtration of outlet water) had little effect on the nutrient and energy ADC of the various ingredients tested (Table 1). Results of this study have implications on determining digestibility values and formulating tilapia diets on digestible nutrient and energy basis.

Introduction

Photoinhibition is the light-induced reduction in the photosynthetic capacity of a photosynthetic organism which takes places when they are exposed to high irradiances that exceed its light energy requirement. Photinhibition includes photoprotection, to overcome the inefficiency in the utilization of light and photodamage, which takes place when light energy cannot be converted into chemical energy and cellular damage can appear.

Algae will be subjected to light conditions which can vary daily and also momentarily, either by the passage of clouds and the effect of waves in the open sea, or by the vertical movement of seaweeds when cultivated in aerated tanks. Effects on growth and photosynthesis have been attributed to both type of fluctuations: low frequency-fluctuations (photoperiod) (Fortes and Lüning 1980, Li et al. 2018) and high frequency-fluc uations (clouds, waves, and, in tanks, agitation) (Pang and Lüning 2004, Msuya and Neori 2008, Ben-Ari et al 2014).

In natural environments (under a sunlight regime) photosynthetic activity exhibits a symmetrical diurnal pattern, which inversely tracks instantaneous irradiance. A progressive decrease in the the effective quantum yield (ΔF/Fm') (which indicates that photoinhibition takes place) is observed from sunrise to midday and in the afternoon seaweed photosynthesis recovers and full recovery is reached during the night (Hanelt 1992). In seaweed cultured in tanks it has been observed that manage of densities and incident irradiance can aid to reduce the effects of photoinhibition.

The objective of this work was to study the photoinhibition of *Ulva ohnoi* submitted to sudden lighting in an IMTA-RAS system with artificial illumination. Experiments were made with four different photoperiods and with two stocking densities.

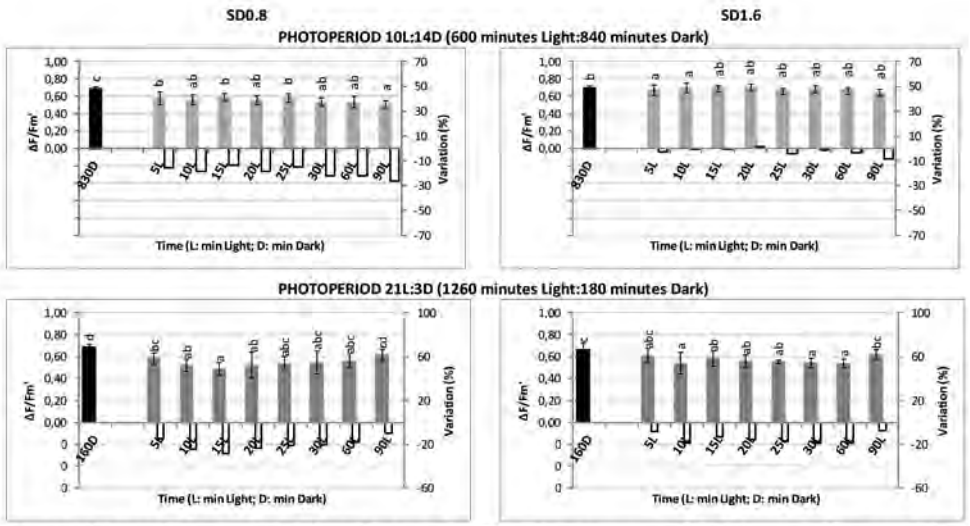

Figure 1: Evolution of ΔF/Fm' during the first 90 minutes of lighting in photoperiods 10L:14D (above) and 21L:3D (below) in SD0.8 and SD1.6 tanks (stocking density of 0.8 and 1.6 kg m^{-2}, respectively) Black bar: measurement in the dark period (10 min before lights on), Grey bars: measurements in the light period. Bars represent the average of five samples±SD. Different superscripts show significant differences (0.05 level, Fisher). White bars: difference in percentage respect the measurement in the dark period

(Continued on next page)

Material and methods

U. ohnoi tanks were integrated in a recirculating system (RAS) with one tank of sole (*Solea senegalensis*) and a nitrifying biofilte , and were cultured with bottom agitation at two stocking densities (0.8 and 1.6 kg m^{-2}, named SD0.8 and S1.6, respectively). Four photoperiods (10L:14D, 14L:10D, 18L:6D and 21L:3D) were tested; at each photoperiod after a complete cycle of light and darkness (24h) ΔF/Fm' was measured during the first 90 minutes of light (measurements were made at minutes 5, 10, 15, 20, 25, 30, 40, 50, 60 and 90 after the lights were on). Effective quantum yield of Photosystem II (ΔF/Fm', where ΔF=Fm'-Ft) was measured with a pulse-amplitude modulation fluorometer (PAM-2100, Walz, Germany).

Results

Photoinhibition, expressed as a decrease in ΔF/Fm', was observed in the first measurement made after lighting (after 5 minutes of light) and in general no changes were observed from then on (to 90 minutes) in all photoperiods (Figure 1). With 10 and 14 hours of light stocking density aids to reduce photoinhibition, but increasing lighting hours (photoperiods with 18 or 21 hours of light) photoinhibition effect was not different under the two stocking densities. Also this results confirm that under controlled photoperiod (artificial illumination) fluorescence parameters during light periods varied little (*U. rotundata*, Henley 1992) comparing with seaweeds submitted to sunlight.

These results together with the previous ones point out that photoprotection takes place in all photoperiods during the first minutes of lighting, and that photodamage appears from photoperiod of 18L:6D and persist even if after 18h of light, lighting hours were reduced to 14h (Masaló et al 2018).

Introduction

Among IMTA techniques, the integration of fish and seaweed cultures in recirculating systems (IMTA-RAS) is currently one of the most promising strategies, in order to achieve diversification and sustainability in aquaculture activities. Macroalgae of the genus *Ulva* (*Ulvales*, Chlorophyta) have shown to be especially suitable for use as biofilters in IMTA-RAS systems. Combining *Ulva* spp. with sole (*Solea senegalensis*) is based on the matching of ecophysiological requirements for both cultures, the simplicity of cultivation and the high growth rate of *Ulva*, as well as the commercial interest of sole, whose cultivation on an industrial level has been recently developed and mainly performed in inland facilities.

A crucial factor in the intensive cultivation of macroalgae is the light dose received by its thallus, which must be administered in the best possible way to obtain optimal growth, avoiding productive losses that could cause both light deficiencies and processes of photoinhibition. The determining factors to achieve this optimum growth are the incident light intensity, the photoperiod, the cultivation density and the rotational velocity of the thallus in the culture volume. The influence of culture conditions on the safety and nutritional quality of the obtained *Ulva* biomass is also a key factor for the viability of its commercialization. In this sense, the systems in recirculation can increase the nutritional quality of the algae and, in addition, eliminate the uncertainties due to possible microbiological contamination or heavy metals or other toxins that can occur in the crops of wild populations.

The main purpose of the **UlvaPro** coordinated project, funded by the Spanish government, is to find the most efficient design and the optimal management of the IMTA-RAS fish-macroalgae system, from the point of view of energy, quantity and quality of macroalgae production, biofiltration capacity and maximum probiotic effect of the epiphytic microbiota. Subproject 2 focuses on aspects related to the engineering of the IMTA-RAS fish-macroalga systems, emphasizing the adequate management of light in algae culture tanks to obtain the best macroalgae production, both from the quantitative and qualitative point of view, by managing the incident irradiance, the photoperiod, the cultivation densities and the rotating velocity of the algae. Here we show the main goals and activities of the project.

Material and methods

The optimization of *Ulva*'s culture conditions, emphasizing on the management of light, is approached from a multidisciplinary perspective, including different objectives and milestones (M):

Analyze the processes of photoinhibition and productivity in *Ulva* cultured in tanks according to the growing conditions: light intensity, stocking density, flow pattern and photoperiod

M: Establish the culture conditions (lirradiance, density and photoperiod) that optimize the growth of *Ulva* in an IMTA-RAS system of *Ulva-Solea senegalensis*

Determine the permanence of *Phaeobacter* in the IMTA-RAS system under the conditions selected

(Continued on next page)

M: Establish the most cost-effective combination of intensity and photoperiod for the optimization of *Ulva* growth and permanence of the *Phaeobacter* in the IMTA-RAS system

Analyze the influence f light intensity, stocking density and *Phaeobacter* colonization in the nutritional quality and food safety of *Ulva* grown in IMTA-RAS

M: Establish the nutritional quality and food safety of *Ulva* depending on the growing conditions in the IMTA-RAS system, as well as the influence of colonization with *Phaeobacter* on these parameters.

Results

The results of this subproject will help to identify the best algae management conditions for the most efficient use of light in order to maximize the productivity of the algae culture and, in turn, maintain a sufficient microbiota concentration to benefit of its probiotic effects. At the same time, the potential improvement of safety and nutritional quality of the algae produced in these systems will be evaluated.

Introduction

Insects have been widely studied as a fishmeal substitute, due to their balanced amino acid profile, even comparable to fishmeal, and their ability to consume organic waste while producing high-quality protein and contributing to nutrient recycling and circular economy.

In gilthead sea bream (*Sparus aurata*), it has been found that *Tenebrio molitor* meal can substitute up to 33% of dietary fishmeal, resulting in improved growth performance and feed conversion (Piccolo et al. 2017). So far, most studies regarding the inclusion of insect meals in fish feed focus on one insect species individually. This study aims to compare the use of *Tenebrio molitor*, *Hermetia illucens* and *Musca domestica* meals in experimental diets and to examine their effect on growth performance, feed conversion, somatic indexes, whole-body composition, nutrient utilization and digestibility of gilthead sea bream.

Materials and methods

A growth and a digestibility experiment were conducted with juvenile sea bream. For the growth experiment, 360 fish (with an average individual weight of 29.5±0.7g) were divided into 12 indoor open-circulation 500 l tanks. Fish were fed with formulated diets (Table I), in which 30% of fishmeal was substituted by 30% insect meal (*Tenebio molitor*, *Hermetia illucens* or *Musca domestica*) for three months. By the end of the experiment growth and somatic indexes, as well as whole-body proximate compositions and nutrient productive values were determined. For the digestibility experiment, 180 fish (with an average individual weight of 49.9±0.7g) were divided into 250 l digestibility tanks. Fish were fed with the growth diets with the addition of 1% celite® as an inert marker. Feed, whole-body and faeces proximate compositions were determined according to (AOAC, 1990). Crude protein content was adjusted for the nitrogen linked to acid detergent fibe .

Results and Discussion

The experimental diets, in which 30% of fishmeal was substituted with insect meals, were well accepted from the fish and were rather palatable, as shown by the daily feed intake (1.4-1.5% of body weight day^{-1}, $p>0.05$). Numerically, the best FCR was achieved when fish were fed with FM and MD diets (1.0), though without statistical significance Growth performance was similar between fish fed the insect diets and the FM diet (1.5-1.6% day^{-1}). However, fishmeal substitution with TM led to statistically lower growth compared to substitution with HI. Fishmeal substitution did not affect viscerosomatic, hepatosomatic and mesenteric fat indexes. Gut length can be affected by the source of protein used in the diet and the diet digestibility. Fish fed with plant proteins appear to have longer intestines (Odedeyi et al. 2014), however, in the present study, fishmeal substitution with insect meals did not affect gut length. Piccolo et al. (2017) found that 33% fishmeal substitution with TM, improved growth and feed conversion and increased somatic indexes. Growth improvement was attributed to the presence of chitin, which in small amounts acts as a prebiotic while the increase in somatic indexes was attributed to the lower digestibility of the TM diet.

Table I: Composition of the experimental diets

Ingredients (%)	FM	TM	HI	MD
Fishmeal	65	45.5	45.5	45.5
Insect meal	0	19.5	19.5	19.5
Fish oil	9	5	9.7	6.3
Wheat	17.2	16.6	14.8	16.8
Wheat gluten	6	9	6	8.5
Premix	2.5	2.5	2.5	2.5
Methionine	0.3	0.7	0.7	0
Lysine	0	1.2	1.3	0.9
Proximate composition (% of dry weight)				
Crude Protein	55	55	55	55
Crude Fat	15.2	15.2	15.2	15.2
Ash	13.3	10.5	11.1	11.1
Crude fiber	1.7	2.5	3.9	2.9
ADF	6.2	5.6	8.8	7.1
Gross energy (Mj kg^{-1})	21.8	21.9	22.2	22.2

The diets containing insect larvae did not affect the digestibility of protein, energy and ADF in gilthead sea bream (90-92%, 81-85% and 48-61% respectively). Dry matter digestibility did not differ between the insect diets and the FM diet (66.5-73%); nonetheless the TM diet dry matter digestibility was significantly lower than the HI diet. Fat digestibility was lower for the diets containing TM (73.6%) compared to the other three diets (78.9-83.2%). Some studies have shown that

(Continued on next page)

chitin can interfere with fat and protein digestibility (Köprücü and Özdemir 2005; Kroeckel et al. 2012). Under the present experimental conditions, the ADF content of the diet appeared to be positively correlated with the digestibility of dry matter and energy of sea bream.

Sea bream whole-body dry matter, protein and ash were not affected by the fishmeal substitution (32.4-33.3%, 53-55% and 10.1-11% respectively). In addition, body fat of fish fed with TM and HI diets was similar to fish fed FM diets (31.9-35.7%), while fish fed the MD diet exhibited significantly lower body fat compared to the FM group. Finally, whole-body energy of the HI and MD (30.4Mj kg^{-1}) groups were significantly lower than the FM group (31.6Mj kg^{-1}), while no differences were observed between the three insect-fed groups. Even though significance occurred, the differences were minor, and it can be said that overall, the whole-body composition was not affected by the fishmeal substitution. Regarding the nutrients' utilization, fishmeal substitution did not affect protein retention (29.3-31.3%). Furthermore, the diets TM and MD led to similar dry matter, fat and energy retention to each other and the FM diet (32.5-33.8%, 69.2-74.2% and 37-39.1% respectively). On the contrary, the inclusion of HI in the diet resulted in significantly lower dry matter and energy retention compared to the FM group and lower fat retention than the rest of the dietary treatments. Our results showed a negative correlation between dietary fiber and whole-body fat and fat retention. Thus, the lower body fat and fat retention of the HI-fed fish could be attributed to the higher crude fiber an ADF of the HI diet.

In conclusion, under the present experimental conditions, the inclusion of *T. molitor*, *H. illucens* and *M. domestica* larvae meals had no adverse effects on growth performance and digestibility of gilthead sea bream and dietary fishmeal can be successfully substituted by these insect meals in 30%.

Introduction

The sustainability of natural resources is a worldwide concerning issue, reflected in several production sectors such as aquaculture, where many efforts have being made. One of these efforts includes the substitution of fishmeal by proteins of vegetable origin in fish feeds. Grain and oilseed by-products are good sources of protein and energy for aquaculture feeds. However, high dietary inclusion levels of plant proteins generally reduce fish growth and feed efficienc . This poor growth performance commonly found in fish fed plant-protein rich diets is generally related to the lower biological value (essential amino acid imbalance, impaired phosphorus availability, presence of anti-nutritional factors, higher carbohydrate fraction) and lower palatability of the plant-protein sources, Gatlin III et al. (2007). Increasing evidence indicates that some marine fish have a conditional requirement for taurine, and its supplementation is often promoted in a fishmeal replacement scenario. Meagre is a very interesting species for aquaculture due to its fast growth rates and flesh quality. This fish species has high dietary protein requirement and a good tolerance to diets containing plant protein sources, Ribeiro et al. (2015). With this study, we intend to understand the mechanisms behind taurine and protein turnover in order to find an optimized vegetable fish diet formulation that reduces protein degradation and supports fish somatic growth

Materials and methods

Meagre juveniles (3.2±0.2g) were fed with a plant-based diet containing five different taurine concentrations (0%, 0.5%, 1.0%, 1.5% and 2.0%) for 38 days. The resulting growth parameters, protein expression and protein degradation levels in several tissues were analysed in order to evaluate the modulator potential of taurine in protein turnover of meagre fed with vegetable diets. Techniques like protein extraction, enzymatic activity and semi-quantitative protein expression were employed.

Results

Our results showed a significant correlation between the feed conversion ratio (FCR) of meagre and dietary taurine levels, indicating that as taurine concentration increases, juvenile meagre uses more efficiently feed to grow. Besides prompting significant growth rates, diet supplemented with 2.0% Taurine seems to induce the expression level of molecular chaperones and also to decrease protein degradation in several tissues, including muscle.

Discussion and conclusion

Somatic growth implies changes in protein turnover with slightly increase in protein synthesis over protein degradation. This phenomenon is a highly controlled process where several degradation systems assume their role, Seiliez et al. (2014). Because taurine deficiencies in fish fed with plant-based diets are often associated to depressed growth, Salze and Davis (2015), we hypothesized that this nutrient could be able to modulate protein turnover in meagre. In our study, meagre growth seems to be related to the increasing taurine concentration in plant-based feeds, which can be explained by an increase of protein turnover, Feidantsis et al. (2014) with a concomitant decrease of protein degradation in muscle.

The Astrakhan State Technical University, 16, Tatishchev Astrakhan, 414056, Astrakhan, Russia
e-mail: kafavb@mail.ru

In the Southern federal district (SFD), the most suitable natural and climatic conditions are noted, which allow the development of all types of fish farming. The most promising areas are: pasture aquaculture; pond; industrial fish farming; recreational aquaculture; mariculture.

The volume of aquaculture in the southern regions of the country in 2018 amounted to more than 78,0 thousand tons, in total in Russia reached 268,65 thousand tons, an increase of 8 % (http://www.fish.go .ru). Leaders in the production of aquaculture in the southern Federal district are the Rostov region, Krasnodar region and Astrakhan region, their total share in 2018 amounted to 92.8 % (figure 1)

For the southern regions of Russia, it is most advisable to use intensive cultivation technologies that allow producing 17-24 c/ha of fish planting material and commercial fish. The main objects of pond fish farming are carp and herbivorous fish. In recent years, we added fish the native fish fauna (pike, perch, pike, tench, common catfish, crucian carp, and perch) and earlier species (paddlefish, channel catfish, haard , buffalo).

Special attention should be paid to the development and improvement of technologies used in the cultivation of hydrobionts in controlled conditions of installations with a closed water supply cycle. Scientific organizations have created and successfully implemented a number of scientific and technical solutions, new biotechnologies in sturgeon breeding on fish farms in the South of Russia. In order to obtain ecologically clean fish products of sturgeon, a complex biotechnology has been developed in the SSC RAS, which allows eliminating climate risks. “Green” technologies are widely introduced, which provide for general environmental management, that is, the utilization of production waste, the production of energy from renewable sources (solar energy, biofuels), the reduction of harmful emissions into the atmosphere, the fight against water and air pollution.

The publication was prepared in the framework of the state assignment of the SSC RAS, № project 01201354245 using USI MIC SSC RAS and Bioresource collections of rare and endangered species, SSC RAS No. 73602.

Introduction
Poultry production for human consumption results in large amounts of by-products, which can be rendered to produce hydrolyzed feather meal (HF), poultry by-product meal (PBM) and poultry fat (PF). These ingredients can be good protein (HF and PBM) and lipid sources (PF) for aqua feeds, mainly due to their high availability and relatively low price, reducing the need for imported feedstuffs. This work assesses the environmental life cycle impacts of rendering poultry by-products into PF, PBM and HF, based on their valorization as ingredients for the aqua feed industry, promoting a circular economy system.

Materials and Methods
Information regarding PF, PBM and HF production chains was collected directly from two by-product rendering units in Portugal and the following impact categories were analyzed: global warming (GW), abiotic depletion (AD), acidification (AC) and eutrophication (EUT), within the system boundaries, using the CML 2 baseline 2000 Life Cycle impact assessment method. A sensitivity analysis was conducted for the allocation method and for the type of fuel (fuel oil vs wood pellets) used to generate heat for the rendering process, aiming at impact reduction.

Results and Discussion
The results obtained show that, in both production systems, the poultry production is the main contributor for the impacts in AC and EUT categories, while the rendering process of the by-products is the main responsible for the generation of GW and AD impacts (Fig 1 and 2). Using exclusively wood pellets would reduce impacts in all categories except eutrophication. The sensitivity analysis conducted on the allocation method applied to the poultry by-products showed that it has a huge impact on the results obtained, being much higher for all impact categories when mass allocation is used.

Conclusions
The present results show that the poultry production phase is the main responsible for the acidification and eutrophication potential factors in the poultry fat and poultry by-product meal production system and in the feather meal production system. On the other hand, global warming and abiotic depletion factors are mainly influenced by the rendering process of the by-products, in which the main responsible is the fuel mix used in the boilers. A sensitivity analysis showed that a scenario where wood pellets were used exclusively as heat source in the boilers could reduce all the impact categories considered except eutrophication. A sensitivity analysis on the allocation method applied to the poultry by-products was also conducted and showed that the impacts of the life cycles analyzed depend greatly on the allocation method, being much higher for all impact categories when mass allocation is used. Overall, the production of these ingredients from poultry by-products has relatively low impacts for the categories analyzed and they could therefore be used as environmentally sustainable ingredients in animal feeds.

THE MICROALGA *Isochrysis* AS AN ENRICHMENT DIET FOR ROTIFERS: EFFECTS OF HARVEST TIMING ON ROTIFER VITALITY AND FATTY ACID PROFILES

H. Matsui[1*], S. Kono[2], K. Okita[1] and T. Kotani[1]

Introduction

Enrichment of docosahexaenoic acid (DHA) in the polar lipids (PL) of rotifers is an essential process in the larval rearing of marine finfish The microalga *Isochrysis* has the potential to be used in an enrichment diet due to its inclusion of DHA. However, little is known about the effects of the timing of *Isochrysis* harvest on its PL-DHA content and that of the rotifers to which it is fed. Concurrently, rotifer vitality should also be considered as a factor that can reduce later larviculture performance. In this study, we aimed to determine the optimum harvest timing of *Isochrysis* as an enrichment diet for rotifers which are essential for marine finfish larva

Materials and methods

Isochrysis sp. Tahiti strain was cultured in Guillard-*f* medium under irradiance of 150μmol photons m^{-2} s^{-1}. Changes in the concentrations of phosphate (P) and nitrate-nitrogen (N) in the medium were colorimetrically assessed. These measurements were used to harvest cells in P/N-sufficient, P-deficient, and P/N-deficient phases, and these cells were used for fatty acid analysis and rotifer enrichment. *Brachionus plicatilis* sp. complex was pre-cultured using commercial *Chlorella vulgaris* and fed *Isochrysis* of each phase for 12h. The population dynamics and fatty acid profiles of non-polar lipids (NL) and PL after the enrichment were measured. Swimming speed of the rotifers was also measured as a metric of individual vitality.

Results

During *Isochrysis* cultivation, P was depleted from the medium, followed by N starvation. At the transition from an N/P-sufficient phase to a P-deficient phase, *Isochrysis* exhibited a remarkable increase in DHA in its PLs, whereas DHA levels dropped in the P/N-deficient phase. Rotifers that fed on the P-deficient phase cells produced the highest content of DHA in PL (Table I).

The other highly unsaturated fatty acids (HUFA), arachidonic acid (ArA), and eicosapentaenoic acid (EPA) in rotifers were also enhanced by feeding P-deficient cells. The growth rate and egg ratio of rotifers was also the highest when they were fed with P-deficient phase cells. The same trend was observed with swimming speed.

Table I. Fatty acid contents (mg g dw^{-1}) in rotifer PL after the enrichment.

Rotifers fed cells of each phase			
P/N-sufficient phase		P-deficient phase	P/N-deficient phase
ArA	0.05 ± 0.03	0.12 ± 0.02	0.02 ± 0.01
EPA	0.06 ± 0.04	0.24 ± 0.03	UD.
DHA	0.07 ± 0.06	0.33 ± 0.06	UD.

Table I. Fatty acid contents (mg g dw^{-1}) in rotifer PL after the enrichment.

	Rotifers fed cells of each phase		
	P/N-sufficient phase	P-deficient phase	P/N-deficient phase
ArA	0.05 ± 0.03	0.12 ± 0.02	0.02 ± 0.01
EPA	0.06 ± 0.04	0.24 ± 0.03	UD.
DHA	0.07 ± 0.06	0.33 ± 0.06	UD.

(Continued on next page)

Discussion and conclusion

Our results indicate that the harvest timing of *Isochrysis* is a crucial factor for enriching rotifers with PL-DHA. It has been reported that compared with microalgae with nutrient salt repletion, cells with nutrient salt deficiency showed lower proportion of HUFA in total lipids (Reitan et al., 1992). In this study, a similar trend was observed in PLs in the P/N-deficient phase, except for the phase with P deficiency alone. Accumulation of HUFAs in the PLs of microalgae under P starvation is possibly related to the dynamics of the betaine lipids (Iwai et al., 2015). From the perspective of fatty acid profiles and rotifer vitality, the recommended harvest timing for *Isochrysis* for later larviculture performance of marine finfish is the P-deficie phase.

Introduction

Determination of the basic nutritional requirements of a species and, in particular, the protein/lipid ratio with optimal inclusion of fish oil, is an essential prerequisite for a well-balanced diet (Fountoulaki et al., 2017). Amongst other fatty acids, EPA and DHA are very important for human consumption because it can affect human health (Jobling and Leknes, 2010). The aim of the study was to evaluate the fatty acid profile of the muscle tissue of meagre (*Argyrosomus regius*) fed diets containing different levels of fish oil.

Material and methods

The feeding trial was performed in three feeding groups: A (CP=52.0; CF =21.0; FO=15%), B (CP=56.0; CF=18.0; FO=10%), C (CP=48.0; CF =16.0; FO=7%) with two repetitions in marine net cages (V = 225 m³) in the Adriatic Sea (44°01'28.6" N 15°13'11.2" E) during 15 months. Fish muscle tissues from each feeding group were sampled and stored at -80°C until analysis. The fatty acid analysis was performed by gas chromatography. ANOVA was used for data analysis with Fisher's LSD test ($p < 0.05$).

Results

The results of fatty acid profile of muscle tissue of meagre fed diets containing different levels of fish oil showed the fish fed diet A had the highest amount of C20:5 (n-3) (EPA) and C22:6 (n-3) DHA with significantly higher ω-3/ ω-6 ratio compared to diets B and C. Other results are presented in Table I.

Discussion and conclusions

The proportions of the fatty acids measured in the present experiment partly correspond to Hernandez et al. (2009) who mentioned higher levels of SFA and lower levels of MUFA in the same fish species. PUFA was found in higher proportions in all 3 diets. Evidence of similar levels of fish flesh n-3 in Grigorakis (2011) and Poli et al. (2003) implies that meagre retains n-3 PUFA well. This is also a good indication that EPA transforms into other n-3 fatty acids in fish flesh. The n-3/n-6 fatty acid ratio recommended by the WHO is 1:1 or above (Simopoulos, 1991), which emphasizes the significantly higher results of n-3/n-6 fatty acid ratio in diet A. In comparison to B and C, fish fed diet A had the promising results of LC-PUFA profile and -3/n-6 fatty acid ratio in terms of promotion of human health.

Introduction

Chemical contamination and climate change constitute two of the greatest environmental problems related with the increase of anthropogenic activities. Despite both factors acting alone can have negative effects at different levels of biological organization, as well as in seafood safety, the underlying interactions between them are still poorly understood. In this context, this work presents an overview of the main findings obtained within the framework of the FP7 project ECsafeSEAFOOD, to assess the combined effects of seawater warming and/or acidification on the bioaccumulation of different emerging chemical contaminants (ECCs) and ecotoxicological responses of farmed marine species from two distinct taxonomic groups (fish and bivalves).

Materials and Methods

The effects of the following ECCs were assessed: toxic metals – methylmercury (MeHg) and inorganic arsenic (iAs); pharmaceuticals and personal care products: diclofenac (DCF), venlafaxine (VFX), triclosan (TCS); flame retardants: dechloranes (Decs) 602, 603 and 604, and tetrabromobisphenol A (TBBPA); perfluorinated compounds - perfluorooctanesulfonic acid (PFOS) and perfluorooctanoic acid (PFOA). Five marine species were used as biological models: European seabass (*Dicentrachus labrax*), meagre (*Argyrosomus regius*), white seabream (*Diplodus sargus*), Mediterranean mussel (*Mytilus galloprovincialis*) and Japanese carpet shell clam (*Ruditapes philippinarum*). Several *in vivo* trials were carried out between 2014 and 2018, simulating ECCs exposure, seawater warming (+5ºC) and acidification (-0.4 pH units; scenario RCP 8.5; IPCC, 2014). After a period of chronic exposure (minimum 20 days) to these three environmental stressors, marine organisms were sampled to determine ECCs' concentration (in different tissues), as well as the ecotoxicological responses at the behavioural (anxiety, activity, shoaling and lateralization), animal/organ condition (Fulton's condition, hepatossomatic and brain-to-body mass indexes), haematological (erythrocytes viability and nuclear abnormalities) and biochemical levels (antioxidant activity, protein repair and degradation, neurotoxicity and endocrine disruption; Maulvault et al., 2016, 2017, 2018abcd, 2019).

Results and Discussion

Warming promoted the bioaccumulation of lipophilic and persistent ECCs (e.g. MeHg, Decs and TBBPA), suggesting increased risks of human exposure to these compounds through the consumption of contaminated seafood in tomorrow's ocean (Maulvault et al., 2016, 2018a). On the other hand, warming and/or acidification elicited lower bioaccumulation of ionisable and/or less persistent compounds (e.g. iAs, VFX and TCS) (Maulvault et al., 2018ab, 2019a). Such trend may not necessarily represent lower human risks, as it may be associated with enhanced biotransformation of parental ECCs, potentially representing increased levels of metabolites for which the toxicological attributes (to both biota and humans) are still unknown. Within an ecotoxicological context, overall, the simultaneous exposure to ECCs, warming and acidification promoted more severe responses (at the biochemical, animal condition and behavioural levels) than those elicited when each stressor acted alone (Maulvault et al., 2018cd, 2019).

Conclusions

This work revealed that the exposure to ECCs within a climate change context will likely defy the resilience of marine organisms, particularly those farmed extensively and semi-intensively in coastal areas subjected to strong anthropogenic activities. Hence, climate change will greatly challenge the sustainability and management of aquaculture resources, thus, calling for urgent regulatory, mitigation and/or adaptive actions at a global scale.

Introduction

Insect meals have been emerging as a natural alternative to fishmeal replacement in fish nutrition, due to the fact that they are part of the fish diet in nature. In the last years, certain insect meal tests have been conducted in some Salmonidae species, such as *Hermetia illucens* in salmon (Belghit et al., 2019; Lock et al., 2015), and rainbow trout (Bruni et al., 2018) or *Tenebrio molitor* in rainbow trout (Belforti et al., 2015). Like the rest of Salmonidae species, brown trout (*Salmo trutta*) is a carnivore fish, and terrestrial and aquatic insects are part of their diet (Elliot, 1967). Considering these facts, the aim of this trial was to evaluate the growth performance and feed efficiency of brown trout fed with full-fat black soldier fly (*Hermetia illucens*) larvae.

Materials and methods

The test was done in the aquaculture laboratory, belonging to the Poznan University of Life Sciences. 225 brown trout fingerlings (*Salmo trutta*) of initial average weight of 48.88 ±2.19 g were fed with three diets: Control diet with 0% of BSF meal inclusion; 2nd diet with 5% of full-fat BSF meal; 3rd diet with 10% of full-fat BSF meal; and 4th diet with 20% of insect meal inclusion. Animals received their feed according to the size and water temperature. The fish were reared under the open-flow system. The trial lasted 58 days. During the experimental period, the water temperature was 14.7 ± 0.6°C, dissolved oxygen stayed constant at 7.5 ± 0.3 mg L^{-1} and the photoperiod was maintained at 16:8 (light: dark).

Results

At the end of the experimental period, there were no significant differences among treatments in the final growth performance as well as specific growth ratio (SGR) in fish fed with different levels of full-fat BSF meal inclusion. In the feed efficiency parameters, there were also no statistical differences among treatments.

In the case of survival rates during the experimental period, it was 100% in all the treatments.

Table I. feed efficiency and growth performance of brown trout fed different levels of full-fat BSF meal inclusion at the end of the experimental period.

	0%	5%	10%	20%	P-value
IBW (g)	49.34	47.51	47.71	48.79	0.6277
FBW (g)	111.30	100.82	99.40	102.14	0.1094
SGR	1.40	1.30	1.27	1.27	0.3236
FIR	1.85	2.03	2.07	2.10	0.2920
FCR	1.07	1.18	1.21	1.22	0.2813

Five replicates per treatments were used. Values in the same row having different superscript letters are significantly different at $P < 0.05$.
Specific growth rate (SGR) = [(ln final body weight (g) – ln initial body weight (g)) / number of days] × 100
Feed intake ratio (FIR) = [(feed intake (g) / total weight (g)) / number of days] × 100
Feed conversion ratio (FCR) = total feed supplied (g DM) / weight gain (g)
Protein efficiency ratio (PER) = [weight gain (g)] / total protein fed (g DM)

(Continued on next page)

Discussion and conclusion

Black soldier fly is one of the promising meals to replace fishmeal in farmed fish. In the case of juveniles brown trout, the inclusion up to 30% of BSF meal did not affect the growth and feed efficiency parameters, similar results were observed in total replacement of FM by BSF larva meal in salmon (Belghit et al., 2019). Also, Magalhães et al. (2017) did not find significant differences with the maximum inclusion of pre-pre-pupa BSF meal in seabass. Although, Dietz and Libert, (2018) found significant differences in SGR and feed efficiency parameters in Nila tilapia fed with the maximum level of inclusion in comparison to soybean concentrate. These differences in response could be due to the fish species habits due to sea trout, rainbow trout and salmon are carnivorous-insectivorous species, and in the case of Nile tilapia is an omnivorous species.

Introduction

The chemical EDTA, is widely used for conditioning seawater for larval rearing in shellfish hatcheries around the world (Adams et al., 2009; Gale et al., 2016; Helm, 2004; Utting and Helm, 1985). The effectiveness of EDTA is widely attributed to its capacity to chelate heavy metals that would otherwise interfere with larval development, however, this mode of operation has not been confirmed to our knowledge. Alarmingly, EDTA is not readily biodegradable and will accumulate in the environment, which could result in significant changes in environmental metal distribution, and potential ecological impacts (Oviedo and Rodriguez, 2003). The present study was undertaken to determine the role of EDTA and a potential biodegradable alternative (EDDS) (Pinto et al., 2014), in improving larval yields in shellfish hatcheries. This was achieved by measuring the concentrations of heavy metals and how they are changed with treatment with the addition of chelating agents EDDS and EDTA, whilst rearing the New Zealand green-lipped mussel (*Perna canaliculus*) larvae.

Materials and methods

Fertilised *P. canaliculus* ova were incubated for 48 h in UV and 5 µm filtered seawater with five different treatments; control (no chelating agent added), 3 µM EDTA, 12 µM EDTA, 3 µM EDDS, and 12 µM EDDS. Each treatment had ten replicates, to account for between tank variability (50 tanks total). At the end of incubation, D-veliger larval yields in each tank were estimated using counts of three 10 µL samples under a microscope, and comparing these to the initial counts of ova for each tank. The tanks were drained through 40 µm nylon mesh, and D-veliger larvae were collected for analysis of metal content. All mussel larvae samples were analysed for concentrations of chromium, iron, cobalt, nickel, copper, zinc, arsenic, cadmium, mercury and lead with Inductively Coupled Plasma Mass Spectrometry (ICPMS). These data were statistically tested for significant differences among treatments using ANOVA. Mussel larvae samples were further analysed with synchrotron X-ray Fluorescence Microscopy (XFM), providing internal distributions of calcium, copper, zinc, iron, mercury and arsenic in larvae.

Results

There was a marked improvement (37 – 64%) in the yields of D-veliger larvae, with the addition of both chelating agents (Table 1). The yields were improved further at the higher concentration of chelating agent, i.e., 12 versus 3 µM**)**.

ICPMS results show a significant reduction in the concentrations of chromium, copper, zinc, cadmium and lead in D-larvae grown with EDTA ($P>0.05$) (Figure 1). However, they also show a significant increase in the concentrations of cobalt, arsenic, and mercury with EDTA ($P>0.05$) (Figure 1). XFM images demonstrate the distribution of six of the metals of interest for the first time in mussel larvae to the best of our knowledge, and allow for distribution comparisons between treatments. For example, XFM results indicated a change in the distribution of zinc between larvae grown with and without EDTA (Figure 2), with zinc more evenly distributed throughout mussel larvae, rather than localised in areas of high shell content.

Discussion and Conclusion

The results prove that EDDS is as effective as EDTA for improving D-veliger larval yields, and should be considered as a biodegradable alternative for aquaculture application. The concentrations of metals within mussel larvae are significantly different with the presence of 3 µM EDTA in the incubation water. Further work using XFM methods will allow us to investigate the chemical state of metals and their distribution within mussel larvae. This will allow us to determine if chelating agent affects the proportions of chemical states for each metal. For example, we could determine if the presence of chelating agent changes the concentration of protein bound metals in the larvae.

(Continued on next page)

Table 1. Percentage yields of *P. canaliculus* D-veliger larvae

	D-veliger Larval Yield (±S.E.)
Control	37.4 ± 9.7%
EDTA 3 µM	84.1 ± 11.1%
EDTA 12 µM	89.6 ± 12.9%
EDDS 3 µM	64.6 ± 12.6%
EDDS 12 µM	90.2 ± 9.59%

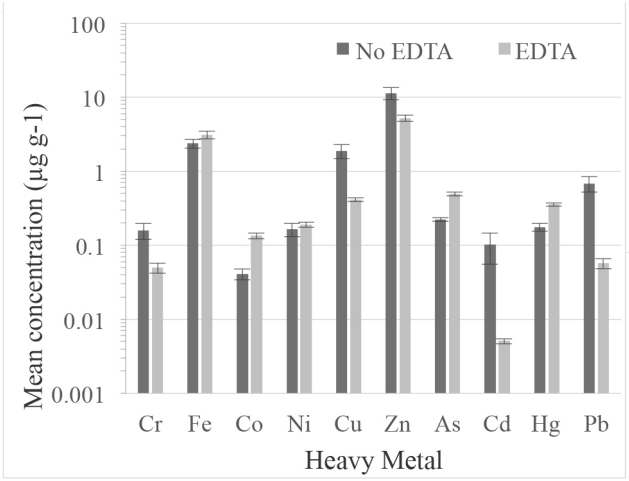

Figure 1. Mean concentrations (± S.E.) of heavy metals in control *P. canaliculus* larvae (reared in seawater without EDTA) and larvae reared in seawater with 3 µM EDTA added. Note: concentrations are on a log scale. Significant differences in the mean concentrations between larvae from control tanks and larvae from EDTA-treated tanks for Cr, Co, Cu, Zn, As, Cd, Hg and Pb ($P<0.05$), but no significant difference for Fe and Ni ($P>0.05$).

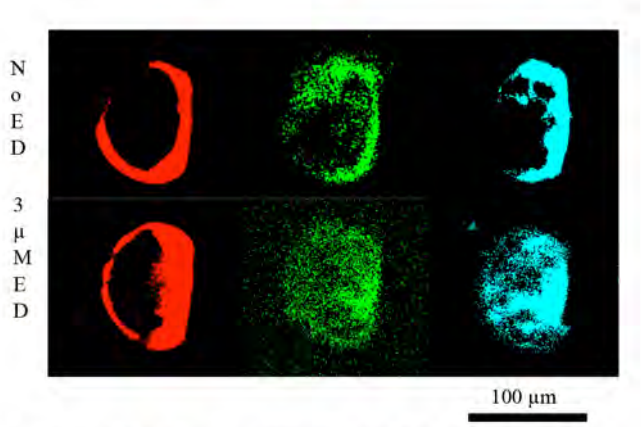

Figure 2. Distributions of calcium, copper and zinc within 2 day old *P. canaliculus* larvae raised with and without 3 µM EDTA added to incubation seawater. Pixels with the highest counts for the respective metal (10% of all counts) are displayed to visualize the distribution of metal concentrations without undue influence from measurement background.

THE SHELLFISH GROWERS CLIMATE COALITION: A BUSINESS PARTNERSHIP OF 100+ COMPANIES TAKING ACTION TO SECURE A LOW CARBON FUTURE FOR THE BENEFIT OF SHELLFISH AND THE ENVIRONMENTS THEY DEPEND ON

Sally McGee, The Nature Conservancy, 159 Waterman Street, Providence RI 02906, U.S.

www.nature.org/shellfish4climate
smcgee@tnc.org

The Shellfish Growers Climate Coalition is a partnership launched in April 2018 by business owners who grow, harvest, prepare, and serve shellfish, in collaboration with The Nature Conservancy. Member businesses recognize that climate change threatens their businesses and food production for a rapidly growing human population. As of April 2019, more than 100 shellfish growers, hatchery operators, wholesalers, retailers, and restaurants from twenty U.S. states and Canada have joined the Coalition. The Coalition is dedicated to engaging consumers and policy makers to secure a low carbon future for the benefit of shellfish and the environments they depend o

Members of the Coalition recognize that human impact on the Earth's climate system is well-documented and it's happening right now. Carbon dioxide emissions are absorbed by the oceans, changing the chemical composition of the seawater. A decade ago the Pacific northwest shellfish industry experienced a crisis as production of oyster larvae failed in two of the major hatcheries and in the wild. Ocean chemistry altered by dissolved carbon dioxide (ocean acidification) was identified as the culprit. Acidification also impacted at least one hatchery in the Northeast at about the same time. Today, satisfactory larval production in these hatcheries depends on monitoring water chemistry and buffering the incoming seawater to ensure that the proper conditions exist for shellfish larvae to grow their shells. Some growers have shifted hatchery capacity to less impacted locations to avoid the effects of ocean acidification

Other climate-related impacts on our industry include:

- Increasing global temperatures have been strongly linked to growth in Vibrio bacteria abundance, resulting in rising costs of control measures to ensure shellfish safety.
- Storm damage from heightened winds and flooding, and storm tides exacerbated by rising sea levels, have severely damaged hatcheries and nurseries and can disrupt the transportation and sale of our products. Scientists increasingly can quantitatively attribute increased storm intensity to global warming.
- Increased stormwater runoff can mean lower pH water and costly harvest closures to ensure shellfish safety.
- Fluctuation in salinity levels can result in excessive shellfish mortalit .

All these impacts on shellfish farms add up to the need to take action to address climate change. Therefore, members of the Coalition agree that:

- Human impact on the Earth's climate system is well documented, scientifically understood and profound
- Taking action to address climate change is imperative to secure the viability of our businesses, our communities, and the natural resources they depend upon.
- Improving people's understanding of climate change and its impact on our businesses represents an important way to promote and enact climate policies that guide the U.S. to a low carbon future.
- Enacting policies that reduce carbon emissions and encourage low-carbon choices are crucial to a low-carbon future.

Based in these climate change impacts and agreed upon principles, the Coalition has taken actions with consumers and public policy makers to achieve its goal. These actions include educational events at food festivals, industry and scientific conferences, and online, and actively supporting policy measures at the state and federal level to address climate change.

GENERATION OF THE TAPAS TOOLBOX AND SUSTAINABILITY DECISION SUPPORT SYSTEM

S. McLoughlin* & P. O'Donohoe

Marine Institute, Rinville, Oranmore, Galway, Ireland

In response to the increasing global population and the resulting growth in demand for protein, aquaculture has been one of the main focus' of the EU's Blue Growth strategy. In comparison to other nations, Europe is a "small fish" in terms of overall production, with development hindered by stagnated growth and European and country-specific "gold-plated" regulatory obligations. In order to facilitate sustainable growth of the sector, an EU Horizon 2020 funded project called TAPAS (http://tapas-h2020.eu/) was established with the aim of promoting sustainable expansion of European aquaculture and identifying and resolving key bottlenecks.

In order to alleviate these regulatory bottlenecks a comprehensive consultation process was conducted with stakeholders all over Europe. The consultation method, consisting of a questionnaire and direct stakeholder interviews, identified the inefficiencies, burdens and faults within the licencing and regulatory processes.

The results of the consultation process allowed identificati n of key areas which required modifications such as; clarification of the consenting process; communication; simplifi ation and harmonisation of legislation; impact assessment and balancing risk; and facilitation of aquaculture zonation within the environment.

This poster presentation details the work done by the TAPAS working groups in finding resolutions to current issues, by designing new, flexible approaches to licensing and monitoring work to common standards. Constant testing, consultation with stakeholder and refining of technologies and ideas was continued throughout the duration of the project to deliver tools to support best practice and efficienc .

These novel ideas and methods were developed into the TAPAS Sustainability Toolbox and the Aquaculture Sustainability Decision Support System, to the acceptability and utility of the stakeholders, to support the development and implementation of spatial planning, and enable less costly, more transparent and efficient licensing the development of sustainable European aquaculture.

Here, brief overviews of the initial problem, followed by the developed method, guideline or integrated tools are given, along with case studies or examples of best practice, to demonstrate the work of the TAPAS groups. Tools discussed include "E-Licensing System", "One-Stop-Shop", "Public Information Platform", "Aquaculture Zones Guidance" and "Environmental Monitoring Database", amongst the many generated TAPAS Tools.

MATE FINDING OF *Ceratothoa oestroides* IN FISH FARMING CONDITIONS

Introduction

An isopod, *Ceratothoa oestroides* (Risso, 1816) is a parasite in buccal cavity of farmed fish and is causing significant economic losses due to fish mortality and growth reduction (Šarušić, 1999, Horton and Okamura, 2001). Parasites live as a pair in fish buccal cavity and there is a challenge to find a mate in open sea conditions, where visual communication is very difficult. Males need to detect minor amounts of female pheromones and track down the female that usually remains stationary in fish host, while signaling (Phelan, 1997). Aim of the study was to evaluate the capacity of parasite to find a mate in farming condition.

Material and methods

The experiment was performed in two marine net cages (V = 225 m³) in Adriatic Sea near the island of Bisage (44° 01'28.6 "N 15° 13'11.2" E). The experiment was carried out from May 22 to July 4, 2018. The sea temperature during the experiment ranged from 19.7 to 24.0° C. Cage 1 represents infected fish, where female parasites were manually removed and male parasites were left in buccal cavity of fish. Cage 2 represents uninfected fish (i.e., control cage). At the end of the experiment visual control of all fish was carried out. *C. oestroides* were removed with tweezers. The total length (mm) was measured, sex, sexual maturity and fecundity of *C. oestroides* females was determined.

Results

At the end of the experiment, after 930 DD, 93.04% of fish in Cage 1 had a pair of parasites (both male and female). Conversely, in Cage 2 only 1.39% of fish had parasites in pairs. The results showed a statistically significant difference ($P < 0.05$) in the number of parasite pairs in fish between Cage 1 and 2 at the end of the experiment. There was no mature *C. oestroides* female found and therefore parasite fecundity was 0. In cage 1, average total lengths of female and male parasites were 1.89 ± 0.27 cm and 0.63 ± 0.22 cm, respectively.

Discussion and conclusions

Significantly higher number of parasite pairs in Cage 1 compared to the Cage 2 suggests that *C. oestroides* male turns into a female in the absence of females, and successfully found his male pair. Moreover, there were no mature female parasite found at 930 DD, which could indicate that maturity, and therefore fecundity of *C. oestroides* requires more degree days. Knowledge on *C. oestroides* mating behavior can be useful for future health management measures, especially in Mediterranean aquaculture.

Introduction

Due to the fact that global food demand increases, the scientific community is searching for new sources of protein such as insects, both for humans and farm animals (Olsen and Hasan, 2012; Wan et al, 2018). Diets based on the most commonly researched insects have a similar amino acid profile to that of other viable diets (Iaconisi et al, 2017; Magalhaes et al, 2017) and, as well, fairly similar amino acid profiles to fishmeal (Barroso et al, 2014). But on the other hand, it is well known that using insectmeal to feed fish tends to lower the levels of n-3 fatty acids (FA) in their nutritional profile of the fillet, since these insects have a low concentration of these components (Belforti et al, 2015), being EPA and DHA content their major limitations. Nevertheless, some researchers already started looking for a solution to this problem, and there has already been described the possibility of improving the n-3 FA profile of insects by feeding them with a high n-3 FA diet during the last days of their raising period (Barroso et al, 2017). By this way, the FA profile in the fillet could be improved with the use of this enriched insectmeal. With this in mind, our experimental protocol aimed to use one enriched insectmeal to feed rainbow trout in order to, as a whole, prove the theoretical possibility of using an alternative protein source for fish without lowering its n-3 FA profile

Material and Methods

Different levels of fishmeal were replaced with three insectmeals (T: *Tenebrio molitor;* H: *Hermetia illucens*; H*: enriched with n-3 *Hermetia illucens*), leading to the following combinations of fishmeal replacement: 0% (control diet, C), 30% (H30), and 50% (T50, H50 and H*50). All three insectmeals were analysed to specify their proximate composition, FA and amino acid profiles before formulation. The FA profile showed a clear increase in the content of EPA (2.87%) and DHA (1%) of H* respect to T and non-enriched H, where these FA were not detected. For the growth essay, five isoproteic (~43%) and isolipidic (~17.5%) diets were formulated, and 600 rainbow trouts (*Oncorhynchus mykiss*) with an initial body weight

Table I. Effect on growth performance and protein utilization

	C	H30	H50	H*50	T50	SEM
Initial body weight (g)	14.33	14.28	14.82	14.73	14.68	0.22
Final body weight (g)	76.39^{b}	73.35^{ab}	69.36^{a}	75^{ab}	81.92^{b}	2.74
Weight gain (%)	415.03^{ab}	400.03^{ab}	354.75^{a}	387.87^{ab}	438.84^{b}	15.86
SGR (% day^{-1})	2.17^{ab}	2.12^{ab}	2^{a}	2.11^{ab}	2.23^{b}	0.04
DFI (g100g $fish^{-1}$ day^{-1})	1.57	1.59	1.62	1.54	1.57	0.02
FCR	0.98	0.98	1.03	1.02	0.91	0.03
ADCprot (%)	92.58^{b}	84.49^{a}	81.01^{a}	84.8^{a}	91.17^{b}	1.13

*SGR: Specific growth rate; DFI: Daily feed intake; FCR: Feed conversion ratio; ADCprot: Apparent Digestibility Coefficient of protein; SEM: Standard error of the mean. C: control diet (0% insectmeal); H30 and H50: 30% and 50 % fishmeal replacement with H. illucens; H*50: 50% fishmeal replacement with enriched H. illucens. T50: 50 % fishmeal replacement with T. molitor. [a, b]Indicate significant differences (P<0.05) between diets.*

(Continued on next page)

of ~15g were distributed randomly in 20 tanks of 500 l in a RAS system in optimal and controlled conditions. The growth performance shown (Table I) correspond to a 77 days trial, where they reached a final body weight of ~72.2g. At the end of the growth trial, apparent digestibility of the protein (ADCprot) and FA content in the fillet were analysed

Results and discussion

For the growth parameters studied (Table I) there was only one significant difference between diets C and H50, revealing the latter a lower growth. The growth rate (Weight gain and SGR) was significantly higher ($P<0.05$) in trout fed with T50 than H50. There was also a significant difference in the ADCprot, between diets C and T50, and those diets with H, being the H diets that maintained the lowest results. As a whole, these results could be positive in the way that diets with T50 are viable for rainbow trout growth, as well as H30 and H*50, even though these two have a lower ADCprot.

Samples of rainbow trout fillet will be analysed to quantify their proximate and FA composition, to determine the effect of the replacement of fishmeal by insect meal and if it is possible to modify the FA profile with the use of enriched insectmeal.

Introduction

The wedge clam *Donax trunculus* constitutes an important fishing resource in several countries, such as Spain. However, this bivalve is in regression in some Spanish natural beds (e.g. in Galicia). In order to increase the production of this resource hatchery-produced seed could be used to repopulate natural beds. The aim of this study is to carry out parentage analysis that could help improve supplementation strategies used in *D. trunculus* stock enhancement programmes.

Materials and methods

A total of 364 individuals from a wild population in Northern Spain (Vilarrube – Galicia) were used as breeders in the hatchery of Centro de Cultivos Mariños de Ribadeo. The seed obtained was maintained in the hatchery until they were at least 1500 µm and, after that, transferred to a raft in the Arousa estuary. Seed was divided into four groups for analysis (Table I).

DNA was extracted using the Chelex-100 based method (Walsh et al., 1991) and 11 microsatellites were amplified (Nantón et al., 2014). In order to reduce the number of amplifications, the previously optimized multiplex PCRs were redesigned. Multiplex 1 was used as previously described and four loci (Dtr47, Dtr90, Dtr108 and Dtr117) were optimized in a new multiplex PCR (Multiplex 2'). Parentage assignment was carried out using Cervus v3.0.3 (Kalinowski et al., 2007). This programme uses simulation of parentage analysis to evaluate the confidence in parentage assignment to the most likely candidate parent. This analysis is performed with the simulated genotypes as it is with real genotypes, but in the simulation the identity of the true parent is known for each offspring. Cervus compares the distribution of LOD or Delta scores for tests in which the most likely candidate parent is the true parent with that for tests in which the most likely candidate parent is not the true parent. Ten thousand cycles of simulated assignments were performed. Finally, all the offspring were assigned to the most likely candidate parent pair in the real parentage assignment. Both analysis, simulation and real assignment, were carried out using two confidence levels, strict and relaxed, with 95% and 80% of confidence, respective .

Table I. Characteristics of seed groups

Seed group	Number of individuals	Size (µm)	Days in hatchery	Days in raft
T1	400	>1000	~75	-
T2	100	>1500	~105	-
T3	100	>1500	~150	-
T4	99	3900 – 5900	~75	~165

Table II. Contribution of males and females to reproduction.

	Confidence level	N (%)	Mean	Variance	Range
Mothers	Relaxed (80%)	78 (45.88%)	4.91	52.39	1 - 41
(N=170)	Strict (95%)	43 (25.29%)	5.14	39.36	1 - 29
Fathers	Relaxed (80%)	97 (50.00%)	3.08	23.84	1 - 35
(N=194)	Strict (95%)	57 (29.38%)	3.16	26.81	1 - 30
Families	Relaxed (80%)	417 (1.26%)	1.27	0.56	1 - 7
(N*=32980)	Strict (95%)	176 (0.53%)	1.32	0.52	1 - 5

*: Number of potential families

(Continued on next page)

Results and discussion

Parentage assignment was carried out using 10 out of the 11 microsatellite loci amplified, given that Dtr126 locus showed high frequency of null alleles and was excluded from the analysis. Parentage simulation showed an assignment percentage of 55% and 84% for strict and relaxed levels of confidence, respectively. In order to carry out the real parentage assignment, a total of 1063 individuals were genotyped, including 699 seed individuals, 170 candidate females and 194 candidate males. Individuals genotyped for less than five microsatellites were excluded (6 individuals of seed and one candidate mother). Values obtained in the parentage assignment (33% and 76% for strict and relaxed confidence levels, respectively) were lower than those observed in the previous simulation. With respect to the seed groups, expected percentages of assignment were 55% and 84% for all cases. However, the real parentage assignments for strict and relaxed levels of confidence were: 35% and 76% for T1 group; 27% and 79% for T2 group; 46% and 87% for T3 group; 21% and 61% for T4 group, respectively. The decrease in the percentages of parentage assignment could be related to different factors that affect the power of assignment techniques (marker variation, null alleles, dependent segregation of the loci, mutation events and genotyping mistakes) (Castro et al., 2004; Dakin and Avise, 2004; Vandeputte et al., 2011; Karaket and Poompuang, 2012).

Table II shows the contribution of males and females to reproduction. Percentage of males and females that contributed with, at least, one descendant was approximately 50% considering a strict level of confidence and about 30% when a relaxed level of confidence was considered. The mean and variance of number of descendants were slightly higher in females, but the range of descendants was similar in both sexes. Regarding families, only 176 and 417 families were detected for strict and relaxed confidence levels, respectivel . The mean, variance and range of descendants were similar for both levels.

Conclusion

The present study constitutes the first work that evaluates the process of obtaining seed of *D. trunculus* in hatchery through parentage assignment. Parentage assignment percentages were lower than those expected. Moreover, a reduction in the number of males and females that contribute to the next generation was observed. However, further studies are necessary to provide genetic information for seed production in hatcheries.

Introduction

The genetically improved farmed tilapia (GIFT) strain has been selected for increased body weight for 17 generations. The realized genetic gain in GIFT breeding program was between 10 to 15% per generation. The reported coefficient of variation (CV) for body weight in the GIFT strain ranges from 47 to 60% (Khaw et al. 2012, Ponzoni et al. 2005), which is relatively high compared to the CV reported for other Nile tilapia strains (18 to 34%; Gjerde et al. 2012, Omasaki et al. 2016). The GIFT strain has been selectively bred under optimal dissolved oxygen (DO) conditions, while most of the small-holder production still takes place in non-aerated ponds, where large diurnal DO fluctuations are apparent and DO levels can drop to almost zero during the night and early morning. Therefore, selecting for resilient fish for environments with large diurnal DO fluctuati ns is important. Berghof et al. (2019) defined resilience as the capacity of an animal to be minimally affected by disturbances or to rapidly return to the state pertained before exposure to a disturbance. Variance of deviations is one of the indicators of resilience. The objective of this study was to estimate heritability and genotype by environment interaction (GxE) between aerated (Ap) and non-aerated ponds (NAp) for resilience in Nile tilapia using the log-transformed variance of deviations (lnvar) of body weight measured five times during grow-out

Materials and methods

For this experiment, about 3000 fish were mass produced using 200 dams and 72 sires in four 30m^2 hapas. In each hapa 50 dams and 18 sires were stocked for 15 days. After 60 days of nursery period, the fingerlings were individually tagged using PIT tag. Next, the fingerlings were randomly divided between an Ap and NAp. The grow-out period was 218 days. Except for the use of aerator in one pond the feeding and pond management were the same in both ponds. Body weight was recorded five times: at stocking, at harvest and at three different times in between. Among 1500 stocked fish in each pond, 887 fish from the Ap and 799 fish from the NAp had body weight records for the five time points. The 1686 fish from both ponds with body weight records for the five time points were genotyped by sequencing (GBS). A genomic relationship matrix was built using 11,929 single nucleotide polymorphisms SNPs. To standardize the body weight deviations, first the mean body weight (WTg) and standard deviation (SDg) for fish belonging to the same nursery hapa, grow-out pond and sex were calculated. Subsequently, the standardized deviations of body weight were calculated by subtracting WTg from the body weight recorded and dividing by SDg. Finally, the variance of standardized deviations was calculated and log-transformed (lnvar) to estimate genetic and phenotypic parameters.

Results

Genetic parameters were estimated using a bivariate mixed animal model. The additive genetic and residual variances of lnvar for the Ap were 0.12±0.05 and 0.80±0.05, respectively, while for the NAp the values were 0.15±0.06 and 0.85±0.06. The h^2 for lnvar were 0.13±0.05 and 0.15±0.05 for the Ap and NAp, respectively, indicating substantial heritable variation for resilience. The r_g between the Ap and NAp for lnvar was 0.80±0.18. The r_g and r_p between lnvar and harvest weight were 0.42±0.30 and 0.11±0.04 in the Ap and 0.24±0.28 and 0.08±0.04 in the NAp.

Discussion

Variance of deviations is an indicator for resilience. Resilient fish are minimally affected by fluctuating DO and grow more uniformly. Uniformity in aquaculture is an important trait for various reasons. Resilient fish grow more uniformly, resulting in less feed loss and higher revenues. It allows harvesting the whole batch at the same time and avoids size grading, which means less stress for the fish and less labour cost. Finally, uniformly sized fish are easier to process. The additive genetic variances and residual variances of lnvar were higher for the NAp, likely indicating that genetic variation in resilience is more expressed due to greater fluctuations in DO. The estimated genetic variance for lnvar in the Ap and in the NAp were lower than in Marjanovic et al. (2016) and similar to Khaw et al. (2016). The heritability cannot be directly compared,

(Continued on next page)

because the heritability in Khaw et al. (2016) was defined at the group level and here at the individual level using five observations per fish. To the best of our knowledge, this is the first study on Nile tilapia resilience based on individual fish with repeated body weight measurements.

We found high positive r_g (0.80±0.18) between the Ap and the NAp pond for lnvar, indicating low GxE for resilience. This result shows that selecting for resilient fish in an aerated pond could also lead to a resilient fish in a non-aerated pond. The r_g between lnvar and harvest weight in both ponds were low, and come with high standard errors so caution is needed when interpreting these results. However, it seems that resilience and growth are different traits, and that both traits could be included in the breeding goal. In summary, our findings show the presence of substantial genetic variance in resilience and low or negligible GxE for resilience between the aerated and the non-aerated ponds.

Organic production is a system of farm management and food production that combines best environmental practices, a high level of biodiversity, the preservation of natural resources, the application of high animal welfare standards and a production method in line with the preference of certain consumers for products produced using natural substances and processes (Mente et al., 2019). Organic aquaculture reflects a specific production approach driven by the growing public interest in sustainable utilization of resources (Mente et al., 2011, 2012, 2019). When applying the principles of organic aquaculture production the following factors need to be addressed: production system design that assures ecosystem balance, biodiversity stewardship, and avoidance of environmental pollution; animal welfare and feeding requirements that respect the health of the organism, product quality, and the expectations of feeding requirements along the lines of similar organic systems; and certain challenges related to breeding (Lembo and Mente, 2019).

Organic fish feed is currently produced according to the EU regulations 834/2007, 889/2008 and 710/2009, 1358/2014, 673/2016, 848/2018. However, due to the limited options in available certified organic ingredients rich in essential nutrients needed to cover the dietary needs of farmed fish, it is challenging for the feed industry to achieve organic feeds of equal quality compared to the conventional ones. Thus, the farmers may experience reduced fish and feed performance leading to disproportionally higher costs in organic farming practices, both due to lower production volumes and to higher feed conversion ratios. Prolonged production cycles increase also the risk of losses due to diseases. Hence, replacing fishmeal and fish oil in high performing diets for organic fish farming is not straightforward. Another challenge related to organic aquaculture is maintaining in practice zero levels any undesirable compounds along the food chain, from ingredient to fork, as consumers often demand from organic products. Chemical antioxidants currently used in conventional aquaculture, in order to safeguard in particular marine ingredient quality, though some on the way out (such as ethoxyquin and its dimers), pesticides etc., find their way in the fish production line, and even if present in small amounts in the fillet, this may represent a risk for scandals and food scares (IFFO, 2015). However, the use of natural antioxidants is of great interest for organic aquaculture.

To safeguard biodiversity and sustainable exploitation of natural resources, the use of capture fisheries-based fish meal and fish oil needs to be limited in both organic and conventional fish feeds (Tacon and Metian, 2015; Lembo and Mente, 2019). However, fish performance, health status and final product quality (Kousoulaki et al., 2016) may be jeopardized when substituting dietary fishmeal by alternative ingredients of lower nutritional value. Thus, new fish aquafeeds and feeding strategies and the exploitation of the genetic potential of farmed fish by selective breeding in using and transforming more efficiently the dietary components to the necessary essential nutrients provides great potential and may allow safer larger steps in the progress of achieving sustainable and resilient fish farming practices

Moreover, though fish cannot synthesize several essential nutrients required for their metabolism and growth, and depend on the feed for their supply, certain animal groups can use nutrient-deficient diets, as they bear symbiotic microorganisms that can provide these compounds (Douglas, 2010). Thus, also aquatic animal's gut microbiota can in theory play critical role in obtaining sustainability in fish farming (Mente et al. 2016; Antonopoulou et al., 2019). Fish would obtain maximal benefits when the microbial supply of essential nutrients is scaled to its demand. Undersupply would limit fish growth while oversupply could be harmful due to allocation of resources to neutralise toxicity caused by non-required compounds. The extent to which the microbial function varies with fish demand and which are the underlying mechanisms are largely unknown.

(Continued on next page)

In terms of sustainable feed formulations, recent advances prove, among other low trophic level organisms the concept of the nutritional (Kousoulaki et al., 2017) and technical (Samuelsen et al., 2018) feasibility of substituting fish oil by heterotrophically produced microalgae in salmon feeds. Such organisms may be grown on byproducts and waste of other agricultural industrial practices. Nevertheless, achieving the desirable circular economy, which demands recycling of organic and inorganic nutrients, we unavoidably press the current set regulatory limits for undesirable compounds in raw materials and seafood products with potential risks for animal health, welfare, production performance and product safety for the consumers. Mapping occurrence and continuous monitoring and documentation on uptake and accumulation of contaminants on farmed animals in relation to the current levels in feed ingredients and diets is necessary to update and render regulations relevant.

The FutureEUAqua project through workpackage 2 will demonstrate sustainable and resilient nutritional solutions for highest possible fish performances, using common or specially selected fish population, in terms of growth, health, welfare and end product quality, progressing the current state of the art, already endorsed in laboratory or industrial relevant environments to operational environments. FutureEUAqua will design, produce and test commercially relevant, safe, of low ecological footprint, species specific nutritionally adequate or currently inadequate (for non-selected families) innovative feeds for organic aquaculture using feeding protocols, that match the natural feeding behaviour of farmed fish. Both already existing and new candidate ingredients will be documented. Pilot (tanks and cages) and large scale (tanks/ cages) fish performance results will be validated via innovative nutrient retention biomarkers (gut microbiome evaluated by 16S rRNA NGS), welfare indicators (e.g. mucosal mapping), quality indicators (nutritional value, taste and texture) and bioenergetics modelling. The ongoing positive growth trend of the aquaculture industry is expected to continue, reflecting the rising demand for healthy human food products. Hence, since 2000 there has been an increasing demand for seafood that has been farmed according to certified organic standards, notably in European countries. It follows, therefore, that like the terrestrial organic livestock production sector, the onus is on the aquatic nutritionist to formulate an organic feed close to the feed that each fish and shrimp species are consuming in their natural environment

Introduction

Phycotoxins are potent marine toxins produced by certain photo- or mixotrophic microalgae. Being accumulated and sometimes metabolized by shellfish these compounds find their way to human diet (Lewitus, et al., 2012). If contaminated seafood is consumed by humans, severe intoxications can occur (Hégaret and Shumway, 2009). Depending on their chemical structure phycotoxins are divided in hydrophilic (e.g. saxitoxin and analogues such as gonyautoxins (GTX), domoic acid (DA) etc.) and lipophilic toxins (e.g. diarrheic toxins, yessotoxin (YTX), pectenotoxin-2 (PTX-2) etc.)

Investigation on occurrence of phycotoxins in shellfish has become important since the Bulgarian coast developed into a spawning area for mussels.

The aim of this study was to compare seasonal phycotoxin profiles of cultivated mussels collected from the South Bulgarian coast.

Materials and Methods

Cultivated mussels were sampled at the main farming areas situated on the South Bulgarian coast. Sampling campaigns include harvesting seasons in 2017 and 2018.

Aliquots of mussel hepatopancreas homogenates were subjected to extraction with acetic acid and subsequently analyzed for paralytic shellfish toxin (PSP) analysis by ion pair chromatography coupled to post-column derivatization and fluorescence detection (Krock, Seguel and Cembella 2007). Extraction with methanol followed by LC-MS/MS analysis (Krock, et al. 2008) was performed for DA and lipophilic toxins.

Results

In total 41 farmed mussel samples collected in four harvesting seasons – spring 2017, summer-fall 2017 and winter-spring 2018 were studied for the presence of hydrophilic and lipophilic toxins.

Results showed significant variations in phycotoxin content between seasons. 60% of the samples from spring 2017 (N=15) were positive for DA. YTX was registered in 27% of the samples, PTX-2 in 13% and the PSP toxin - GTX-2 in 7% (one sample). Other lipophilic toxins were not detected. In the samples from summer-fall 2017 (N = 15) GTX-2 was again detected in only one sample. YTX was registered in 60% of the samples. Domoic acid and other lipophilic toxins were not detected. In the winter-spring 2018 samples (N=11) 64% were positive for PTX-2sa/ epi-PTX-2sa.

Table I. Concentration range of the detected toxins in investigated period (nd – not detected)

Harvesting season	Detected toxins, positive concentration range				
	GTX-2, $ng.g^{-1}$	DA, $ng.g^{-1}$	YTX, $ng.g^{-1}$	PTX-2, $ng.g^{-1}$	PTX-2sa/ epi-PTX-2sa, ng PTX-2 $eq.g^{-1}$
Spring 2017	nd-1.75	108.3 – 618.9	0.009 – 24.6	0.6- 1.8	nd
Summer-fall 2017	nd - 2.59	nd	2.2 – 14.8	nd	nd
Winter-spring 2018	nd	nd	nd	nd	3.1-7.1

(Continued on next page)

Abundances of the determined phycotoxins (Table I) showed that DA level increased up to six times and PTX-2 up to three times in spring 2017, approaching highest values in April 2017. YTX is reaching its highest value in May 2017. Detected GTX-2 levels in the two samples from spring and summer- fall 2017 were similar. PTX-2sa/ epi-PTX-2sa appeared in winter-spring 2018 when their abundances increased more than 2 times in this season.

Discussion and conclusion

Phycotoxins regulated in EU - DA, YTX, PTX-2 and GTX-2 as well as the non-regulated epimeric pair PTX-2sa/ epi-PTX-2sa were detected in the samples. Richest variety of marine toxins was estimated in spring samples from 2017 whereas DA, YTX, PTX-2 and GTX-2 were determined. Interestingly, DA and PTX-2 were determined in the samples until beginning of May, while YTX is detected throughout the whole season. DA being the predominant toxin in the phycotoxin profile, is the toxin that is achieving highest level (619 $ng.g^{-1}$) for the whole investigated period.

The phycotoxin profile of summer-fall 2017 is more uniform containing YTX and GTX-2. In general, the presence of GTX-2 in samples from both seasons is scarce. YTX appears in the samples from two subsequent seasons – spring and summer-fall 2017. Its positive concentration range in spring 2017 is much wider than in summer-fall 2017.

Surprisingly, in the third studied period- winter-spring 2018, none of the already registered phycotoxins were detected and a new toxin emerged in the samples - the epimeric pair PTX-2sa/ epi-PTX-2sa. As there is evidence of PTX-2 presence in plankton samples from other investigation seasons (Peteva, et al. 2018) and conversion of PTX-2 into PTX-2sa is well documented in the literature (Ciminiello, et al. 2010), it is reasonable to assume that PTX-2sa/ epi-PTX-2sa also result from PTX-2 through metabolic conversion in mussels.

Since the comparison of seasonal phycotoxin profiles showed the presence of DA, YTX, PTX-2, GTX-2 and PTX-2sa/ epi-PTX-2sa in farmed mussels at low but significantly varying levels in time, further surveillance on phycotoxins content in cultivated mussels is required in order to protect consumers ’health.

Introduction

The Mediterranean mussel (*Mytilus galloprovincialis*) is the most important marine aquaculture species in Bulgaria with high socio-economic value in the Black Sea region (Stoykov and Petrova, 2010). The aim of this study was to determine seasonal changes in proximate and lipid composition in market ready mussels from the northern part of the Bulgarian Black Sea coast.

Materials and methods

Proximate composition (carbohydrates, crude protein and total lipid) was determined using standard procedures. Lipids were extracted from mussel tissue by solvent extraction and purified by chromatographic techniques. Gas chromatography–mass spectrometry (GC-MS) was used for the analysis of sterols (St) and fatty acid (FA) composition of phospholipid and neutral lipid fractions. The non-saponifiable lipids were identified by high-performance liquid chromatography (HPLC) with ultraviolet (UV) and fluorescence (FL) detectors

Results and discussion

Highest protein (19.90g.100g^{-1}) and lipid (2.34g.100g^{-1}) contents were found in spring, carbohydrates in autumn (2.73g.100g^{-1}), whereas lowest values were detected in summer samples: protein (16.60g.100g^{-1}), carbohydrates (2.40g.100g^{-1}) and lipids (1.45g.100g^{-1}). Results for lipid classes and FA distribution are presented in Table I.

Although there were significant seasonal variations in lipid classes and fatty acids profiles of studied mussels, lipid classes followed the same pattern: PL > NL > St in all seasons. FA groups showed similar distribution in TL and PL (PUFA > SFA > MUFA) fractions, while in NL: PUFA ≈ SFA > MUFA in spring and summer seasons. NL classes presented notable annual variations (MUFA and SFA decreased from spring to autumn), since their FA composition reflects the dietary sources (Balzano et al., 2017). The sum of EPA (eicosopentaenoic acid, C20:5n-3) and DHA (docosahexaenoic acid, C22:6n-3) were higher in spring and autumn, despite 100 g edible portion (EP) provides more than 100% of RDI (EFSA, 2012). Well-balanced n-6/n-3 ratios were observed in all lipid fractions. The main sterols identified were cholesterol (43.4-52.0% of total sterol fraction) and brassicasterol (24.3-34.0%). Other minor sterols (<10%) were campesterol, β-sitosterol and Δ^5 – avenasterol. In this study, significant annual change in analyzed fat-soluble vitamins (A, D_3 and E) and carotenoids (β-carotene and astaxanthin) was observed. Highest vitamin A content (59.3μg.100g^{-1} EP) and vitamin E (5.9mg.100g^{-1} EP) were found in autumn samples. Studied Black Sea shellfish could be regarded as a good source of vitamin D_3 (from 5.53μg.100g^{-1} EP in summer to 14.7μg.100g^{-1} EP in spring). There was inverse correlation in the astaxanthin and β-carotene amounts in the studied seasons. Astaxanthin content was highest in summer (50μg.100g^{-1} EP) and lowest in spring and autumn (23.9 and 26.4μg.100g^{-1} EP, respectively), while β-carotene levels were lowest in spring (318μg.100g^{-1} EP) and increased to 950 and 760μg.100g^{-1} EP (in spring and autumn, respectively).

(Continued on next page)

Conclusions

There were significant seasonal variations in proximate and lipid composition of aquaculture *Mytilus galloprovincialis*. The present study characterized Black Sea mussels as high in proteins and low in carbohydrates and lipids, regardless of season. The tendency of decreasing levels of macronutrients, cholesterol and β-carotene in the summer season correlates with the reproductive cycle of the Black Sea mussels. Although low total lipid content, mussel meat showed appreciable amounts of long-chain PUFA. Beneficial levels of EPA+DHA (mean 0.71g.100g^{-1} EP) were found during the whole study period, supplying 142% of RDI for these FAs. In addition, more than 50% of these n-3 PUFA were bonded to PL, which increases their bioavailability.

Presented results illustrate well the high potential of Black Sea aquaculture mussels as healthy food, regardless of season. Although proximate and lipid composition of mussel meat are strongly dependent on biotic and abiotic environmental factors, we can summarize that their consumption could promote dietary recommendations for the consumption of low-saturated fat, high n-3 PUFA and vitamin D_3 food.

THE USE OF COMET ASSAY TO DETECT DNA DAMAGE IN *TILAPIA* ERYTHROCYTES TREATED WITH MALATHION

Hager Metwally

Alrazy Clinic Centre, Giza, Egypt
Email: hagermetwally1993@yahoo.com

Pollution of environmental waters is a serious problem all over the world. Fish accumulate pollutants directly from contaminated water and indirectly by ingestion of the contaminated organisms. Genotoxic pollutants induce DNA strand breaks and mutagenic lesions that proposed as genotoxicity biomarkers monitoring the fresh water environment.

These lesions are believed to induce chemical carcinogenesis. In the present communication, the alkaline single cell gel electrophoresis; comet assay which is a rapid ,simple and sensitive technique measuring DNA strand breaks in individual cells was used. The genotoxic potential of the widely used pesticide (Malathion) was evaluated in *tilapia* erythrocytes. The cells were exposed to three sub-lethal concentrations of malathion (0.04, 0.5 and1.0 µ g/ml).
Alkaline comet assay was performed on nucleated erythrocytes after 24,48 and 72hrs. The amount of DNA damage in cells was estimated from comet tail length as the extent of migration of the DNA damaged.

DNA damage was observed to be increased with the increase of the concentration compared to the control ($p<0.05$).
The comet tail showed a concentration – time relationship. The maximum tail length at highest concentration and longest time was (8.62µ m). The present study indicated that comet assay applied on fish erythrocytes is a useful tool in estimating genotoxicity of chemical pollutants, such as malathion .

OPTIMIZING OXIDATIVE STABILITY OF EXTRUDED FEED

Koen Meynen*

Kemin AquaScience™, Toekomstlaan 44, 2200 Herentals, Belgium | koen.meynen@kemin.com

Lipid autoxidation is a free radical-mediated chain reaction in which oxygen binds to unsaturated lipids under mild conditions. Fish meal, fish oil, and vegetable oils are rich sources of polyunsaturated lipids, making them highly susceptible to autoxidation. Lipid peroxides are the primary oxidation products and when these are decomposed, secondary oxidation products are formed that result in a rancid or fishy smell. Lipid oxidation products can be taken up in the body through the diet and affect cellular integrity by reacting with proteins, phospholipids and DNA. Fish have protection mechanisms against free radicals, including endogenous antioxidants like vitamins E and C, and endogenous enzymes such as superoxide dismutase, catalase, and glutathione peroxidase. Exogenous antioxidants can also be obtained through the diet. An imbalance between uptake of oxidation products and the animal's defense system has a negative impact on the health and the growth performance of the animal. This has been demonstrated in different species when oxidized lipids were used in test diets. In some but not all of these cases supplementation with vitamins E or C could reduce this negative impact. To ensure optimal health and growth, it is necessary that the feed is low in oxidation products. Application of antioxidants can be used to prevent oxidation of feed.

Extrusion is a continuous process that uses high shear and high temperature to cook and shape feed. During this process free radicals are generated. The oxidative quality of extruded feed is impacted by the quality of the raw materials, the formulation and processing of the feed. All sensitive ingredients should be of good quality and be treated with antioxidants as early as possible. Using antioxidant treated protein meal results in a more stable extruded feed compared to non-treated protein meals (Figure 1).

During extrusion and drying, high oxidative stress is put on the feed. Antioxidants are added to the dry mix to protect the sensitive raw materials during this process. At the end of the process, a significant part of the added antioxidants is sacrificed (Table I). The final feed is protected against oxidation by further coating the extrudate with a good quality oil containing enough antioxidants.

By applying a comprehensive program to control the quality of raw materials, protection of the feed during processing and optimizing the feed characteristics, oxidation can be limited. This reduces the potential production loss associated with the consumption of oxidized feed.

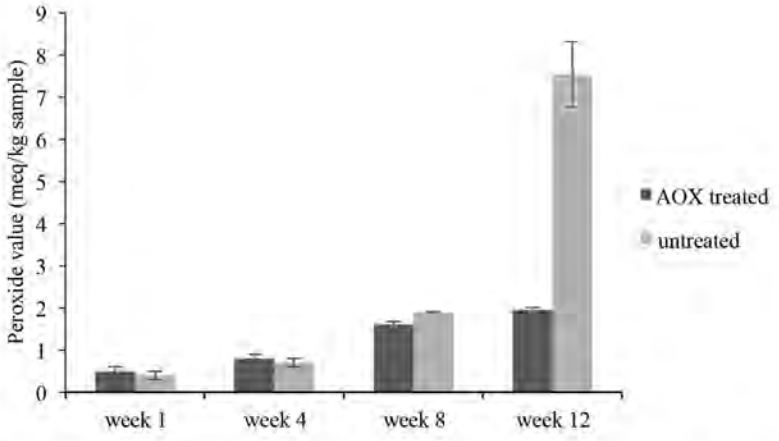

Figure 1. Using antioxidant (AOX) treated protein meals in extrusion improves stability of the extruded feed.

Table I : Antioxidant sacrificace due to impact of processing conditions

	Low	High
Extrusion	15%	35%
Drying	20%	45%
Total	32%	64%

SPAWNING KINETICS OF GREATER AMBERJACK *Seriola dumerili* IN RESPONSE TO DIFFERENT DOSES OF GnRHa IMPLANTS

Andrea Miccoli[1,2,4*], Ioannis Fakriadis[1,3], Irini Sigelaki[1], Anastasios Raftopoulos[2], and Constantinos C. Mylonas[1]

Introduction

The greater amberjack (*Seriola dumerili*) is a prominent species for aquaculture diversification due to its high growth rate, late reproductive maturation, excellent flesh quality and worldwide consumer acceptability. One of the main bottlenecks for its aquaculture production is the lack of reliable reproduction, which has been recently overcome using agonists of gonadotropin-releasing hormone (GnRHa). The use of implant-delivered GnRHa was proved to be more effective than injections (Fakriadis et al., 2018). In the present study two different doses of GnRHa were evaluated in terms of egg production and quality.

Materials and methods

Twenty wild-captured breeders (10 females mean weight ± SD, 23.0±2.2 kg and 10 males 18.4±1.9 kg, respectively) were kept at Argosaronikos Fishfarm S.A. in a 1000 m^3 cage throughout the year and were fed with a broodstock diet (Skretting, Vitalis Cal, 22 mm). The spawning trial was conducted between June 7 and July 5, 2017. Females were treated with an Ethylen-Vinyl Acetate copolymer (EVAc) GnRHa implant of either ~25 μg GnRHa kg^{-1} ("LOW") or ~75 μg GnRHa kg^{-1} ("HIGH") (Mylonas and Zohar, 2001). To enhance spermiation and ensure adequate sperm production, all males were treated on the first day with a GnRHa implant at a dose of 58.3±17.7 μg GnRHa kg^{-1}. After being implanted, fish were transferred to an inland facility into four 23-m^3 flow-through round tanks (n=2-3 females in each), in a 1:1 sex ratio. Females and males were given a second treatment of the same dose two weeks later. Tank overflow egg collectors were examined three times a day, and fecundity and fertilization success were estimated immediately after egg collection. Egg and larval quality parameters were estimated using the microtiter plate method (Panini et al., 2001) with some modifications

Results and discussion

In both treatment doses, spawning started one day after the 1st application as some females had oocytes in maturation stage at the time of treatment. Fish spawned for 7-9 times after the 1st treatment and only 5 times after the 2nd treatment. The highest egg production was observed in the LOW group with 33826 eggs kg^{-1} 2 days after the 1st treatment, while egg production in the HIGH was 30206 eggs kg^{-1} on the same day (Fig. 1).

Mean daily relative fecundity was not significantly different between the two groups. The LOW group produced 17801±4127 eggs $kg^{-1}day^{-1}$ and the HIGH group 14648±2285 eggs $kg^{-1}day^{-1}$ after the 1st treatment. After the 2nd treatment, the LOW group spawned 13,373±3,022 eggs $kg^{-1}day^{-1}$ and the HIGH group 8,484±3,228 eggs $kg^{-1}day^{-1}$. Fertilization success was significantly higher in LOW group after the 2nd treatment ($p=0.015$). No statistical differences were observed for the 24 h embryo survival, hatching and 5d larval survival between the different doses and treatment number.

Conclusions

As no significant differences were observed between the LOW and HIGH GnRHa doses, it is preferable to use the LOW dose due to its cost-effectiveness. It should be noted that in a different experiment where a MEDIUM GnRHa dose (50 μg kg^{-1}) and exactly the same setup were used (Fakriadis et al., 2018), the fecundity was higher compared to both LOW and HIGH doses.

(Continued on next page)

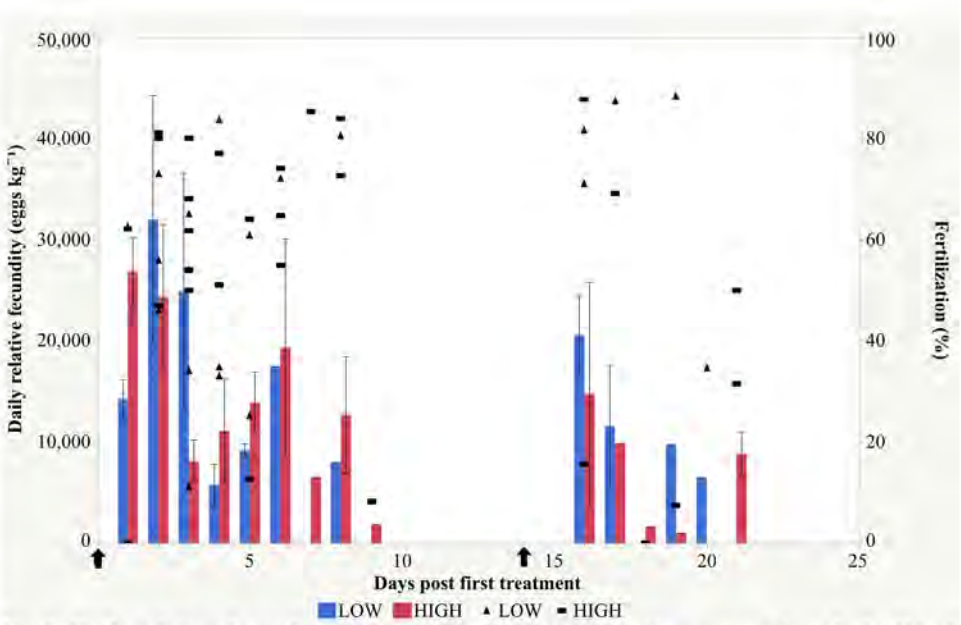

Fig.1. Daily relative fecundity (bars, eggs kg^{-1}) and fertilization success (symbols, %) of the LOW (blue bars) and HIGH (red bars) GnRHa groups of greater amberjack implanted with different doses of GnRHa. Arrows indicate the time of treatment. The first application was done on June 7, 2017.

TOWARDS AN INTELLIGENT MANAGEMENT SYSTEM FOR INTREGRATED MULTI-TROPHIC AQUACULTURE (IMPAQT)

Michalek K*,[1], Macleod A[1], Ditchfield A[1] and Stanley M S[1]

[1] Scottish Association for Marine Science (SAMS), PA37 1QA Oban, UK
Email: kati.michalek@sams.ac.uk

Aquaculture is growing rapidly in response to increasing protein demands and limited resources from wild fisheries. At the same time, the sector continues to intensify and diversify by modifying systems and practices in place as well as introducing new cultivated species.

Here, integrated multi-trophic aquaculture (IMTA; i.e. co-cultivation of fed species (finfish and extractive species such as seaweeds and/or shellfish), offers a promising approach to improving the sustainable development of the sector by providing environmental benefits, spatial optimisation and increased productivity for cultivation sites. The efficient development of the sector will thereby largely depend on improved monitoring and management practices offered to the producers, while paving the way to a more environmentally friendly, efficient and high-yielding industry in the future

The project IMPAQT (Intelligent Management Systems for Integrated Multi-Trophic Aquaculture) was funded under the EU H2020 call for 'Sustainable Food Security' to specifically address these needs, bringing together 21 partners from research, technology, and industry; all experts in their respective fields and businesses. Our mission is to develop and validate in-situ a *multi-purpose* (inland, coastal, offshore production), *multi-sensing* (heterogeneous sensors and new technologies) and *multi-functional* (advanced monitoring, modelling, analytics and decision making) management platform for sustainable aquaculture/IMTA production.

Using six pilot sites located inside and outside of Europe, which differ in farm scale, design and species cultured, IMPAQT adopts a holistic approach combining i) autonomous real-time data acquisition and communication, ii) an advanced IMTA model and iii) an integrated management system. IMPAQT outputs provide monitoring and management guidance to producers specificall , and inform and promote the eco-intensification of EU aquaculture in general.

SPECIES COMPOSITION, INTROGRESSION AND SHELL PLASTICITY IN FARMED MYTILUS SPP. ON THE WEST COAST OF SCOTLAND

Northern Hemisphere populations of mussels belonging to the *Mytilus edulis* species-complex (*M. edulis*, *M. galloprovincialis*, and *M. trossulus*) often occur in sympatry, facilitating allele introgression and the formation of hybridization zones. Mussel aquaculture practices can favour hybridisation and, depending on the species present, can lead to an increased occurrence of individuals with unviable traits for cultivation; e.g. weak-shelled and low meat-yielding mussels, as observed at several farm sites in Scotland.

We combined multi-dimensional genetic analyses (monolocus genotyping, developed SNP panel diagnostic for *M. trossulus*) and shell morphometric analyses (shell shape and shell strength) to assess the genetic and phenotypic variability in naturally occurring mixed-species stocks at Scottish mussel farms on a vertical scale - along the cultivation rope.

The genetic composition and shell morphology of the stock differed across culture depth. Although *M. edulis* was the predominant genotype, every sixth individual carried alleles of *M. trossulus*, but the level of introgression was overall low. However, highly-introgressed mussels (*M. trossulus* allele frequency $\geq$ 75%) presented distinct shell morphology with significantly lower shell strength and a more elongated shell shape, and originated predominantly from shallow culture depths. This phenotype distinguished them from their congeners and further allowed for their identification based on shell characters.

Our data highlight the variability as well as complex relationships between the environment of culture, and the genetic and morphological make-up of the stock. In addition, our findings suggest that a combination of shell strength and shape assessments provide a promising approach for the identification of *M. trossulus* mussels on site, which would support the prevention of a further spread of this commercially damaging species for Scotland.

ANTI-INFLAMMATORY EFFECTS OF BETA-1,3/1,6 GLUCAN SUPPLEMENTED FEED IN ATLANTIC SALMON (*Salmo salar*)

Paul J. Midtlyng

Norwegian University of Life Sciences, Faculty of Veterinary Medicine, Oslo, Norway

In two recent studies, evidence was found that orally administered ß-1,3/1,6 glucans possess anti-inflammatory effects in fish. In the first trial, groups of seawater adapted Atlantic salmon post-smolts were fed a commercial salmon diet without (control) or with supplementation of 0,1% of a beta-1,3/1,6 glucan derived from *Saccharomyces cervisiae* (Macrogard – MG diet) After 4 weeks of priming, the study groups were vaccinated intraperitoneally using a multivalent, oil adjuvanted salmon vaccine. This and similar vaccine formulations are known to induce intra-abdominal inflammatory reactions in the fish during the subsequent period

Periodically after immunisation, the lymphoid organs of both feed groups were sampled and the expression of inflammation associated cytokine genes was assessed. In head kidney and spleen there was a weak upregulation of IL-1β in both groups shortly after vaccination. However, at several time points thereafter, a clear down-regulation of the pro-inflammatory cytokines TNF-α and IL-17a in head kidney and spleen of the MG group compared to the control fish was observed. The consistency of the outcome patterns indicates that the effects were systemic.

To confirm these results, a second vaccination study of similar design was initiated, this time using salmon smolts reared in freshwater at higher temperature. Again, a downregulation in the expression of several inflammation-associated genes in the MG dietary group was observed during the post-vaccination period.

The strong and systemic effects seen in fish receiving the MG supplemented feed suggests that oral administration of beta-glucans may reduce inflammato y damage caused by viral infections of major relevance to salmonid farming. Examples of such clinical applications will be discussed.

NUCLEIC ACID VACCINES ARE EFFECTIVE FOR CONTROL OF VIRAL INFECTIONS AND DISEASE IN SALMONID AQUACULTURE

Paul J. Midtlyng

Norwegian University of Life Sciences, Faculty of Veterinary Medicine, PO Box 362 Sentrum, N-0102 Oslo, Norway

Inducing transient production of vaccine antigens in the recipient's own cells by delivery of naked DNA or RNA is one of the most recent developments in disease prophylaxis and therapy. DNA vaccines were first licensed for use in animals 2005, one of which conferred protection against infectious hematopoietic necrosis (IHN), a viral disease of wild salmonids of the Pacific regions of North America. The disease is currently also endemic in many parts of international salmonid culture including Europe. For humans, several DNA vaccines (the majority targeting HIV and influenza) are still in the clinical development phase, while the same technology is even more intensively employed for experimental immunotherapy against cancer.

The field experiences with use of the North American DNA vaccine against IHN have been remarkably positive, as the historic pattern of clinical disease outbreaks associated with the annual migration of wild carrier populations has discontinued since mass vaccination of smolts were implemented by the local salmonid farming industry.

Although over many years very successful research on DNA vaccination of rainbow trout against viral hemorrhagic septicemia (VHS) that is caused by another virus closely related to IHN virus has been carried out by European researchers, there has been no attempts for commercializing vaccine in Europe.

Then in 2017, the first nucleic acid vaccine for Europe was licensed for prophylaxis against Pancreas Disease (PD) in Norwegian salmon farming. The vaccine has been on the Norwegian market since mid-2018. PD is caused by several genotypes of salmonid alphavirus (SAV), and occurs in Norway, Scotland and both parts of Ireland. In European freshwater pond culture of rainbow trout, SAV genotype 2 causes Sleeping Disease (SD).

In controlled challenge trials, DNA vaccination was highly protective against PD clinical symptoms and tissue pathology for at least 12 months and allowed the challenged fish to experience a normal weight gain.

Recent further information and results emerging from the use of DNA vaccines against IHN, PD and other viral infections of salmonids in clinical trials and in the field will be summarized and discussed. All of the viral infections mentioned above are widely spread in European aquaculture, yet the transfer of highly successful research into vaccination practice is slow or non-existent. The reasons for and potential ways to remedy this situation will be discussed.

INFLUENCES OF ALTERNATIVE FEEDS BASED ON *Arthrospira platensis* AND *Hermetia illucens* ON INTESTINAL HEALTH OF RAINBOW TROUT (*Oncorhynchus mykiss*)

Introduction

Genetic adaptation to new environmental conditions, such as changing diets, has always played a key role in the evolution of animals. Due to the fishmeal intensified feeding of carnivorous fish species, not only sustainably managed and overfished fish stocks have to face a growing problem. This is one of the reasons why novel sources of protein substituted fish feeds are of increasing interest in aquaculture. However, plant-based protein sources in the diet of carnivorous fish, may lead to inferior feed conversion and hence poorer growth, as well as negative animal health and welfare effects. An inflammation of the small intestine as well as immune suppression due to various amounts of soybean supplementation within the ration was observed in a number of species, such as rainbow trout *(Oncorhynchus mykiss)*, carp (*Cyprinus carpio carpio*), zebrafish (*Danio rerio*) and salmon (*Salmo salar*) (Burrells et al., 1999; Hedrera et al., 2013; Krogdahl et al., 2003; Urán et al., 2008; Venold et al., 2012). Also, studies on red sea bream (*Pagrus major*) suggest that high levels of soybean meal can lead to increased stress and reduction of immunoglobulins (Khosravi et al., 2015). The cooperative project "Sustainalbe Trout Aquaculture Intensificati n – SusTAIn" aims at making use of the genetic variability of trout in order to gain new insights into the adaptability to innovative raw materials and thus to pave the way for a sustainable and intensified, as well as animal and environmentally friendly aquaculture.

Material and methods

Trout of a commercially available origin were compared to a regional trout strain under the influence of three different feeds that included a conventional fishmeal-based trout feed and two feeds in which the fish-meal was partly substituted with *Hermetia illucens* or *Arthrospira platensis*. Overall, the research included 54 almost one year old animals at a weight of 75-124g and a length of 18-22cm. Three animals per feeding group in three replicates (n=9) were sampled. All animals were examined macroscopically for fin and skin lesions and deviations from physiological traits were recorded. Sections of the anterior and the posterior intestine were prepared for histological examinations using HE and PAS staining. Histologically the total number, the color and the fill level of goblet cells were examined. Furthermore, the thickness of tunica muscularis, stratum granulosum and stratum compactum were measured. Inflammatory cell infiltration was analyzed on the basis of a predetermined score from 0 (absent) to 3 (high grade infiltration of inflammatory cells)

Results

Macroscopically, the muscles of the *Arthrospira platensis* fed groups showed a yellowish coloration. In addition, in some animals from this group, and in some fish fed with *Hermetia illucens*, a dull and whitish appearing foregut was noted. Almost 50% of the *Arthrospira platensis* fed group showed a dilatation of the stomach with injected blood vessels. Those alterations could not be observed in the control group. The lamina epithelialis was densely populated with goblet cells in trouts from all feeding groups. Per 100µm in the *Arthrospira* fed group 8.0 goblet cells, in the *Hermetia* fed group 8.6 goblet cells and in the control group 9.7 goblet cells were counted. The filling and color of the goblet cells turned out to be independent of genetic lineage and feeding. Initial results also indicate that in approximately 44% of the examined animals in the lamina epithelialis mucosae of the foregut, vacuoles occured in varying degrees, which overlaps predominantly with the macroscopically findings

(Continued on next page)

Discussion

In the current work we describe the histological changes of rainbow trout. As a part of the research on intestinal health and welfare, it can only be considered as such and provides a first impression of the animals studied. No clear inflammatory response could be detected in the small intestine of rainbow trout of different genetic origins and in relation to substitution of *Arthrospira platensis* or *Hermetia illucens* to the feed. This is in contrast to other studies (Hedrera et al., 2013). Our results might show that possibly an adaptation of the fish to the novel feed occurred. Subsequent gene expression of various inflammatory markers, anti-microbial peptides and transmembrane proteins on internal organs of the test animals should bring deeper insights. Noticeable however, was the formation of fat vacuoles in the foregut in 44% of the animals, which largely coincided with the slightly yellowish muscle and blunt consistency of the foregut in the feeding groups with *Arthrospira platensis* as well as in parts of the *Hermetia illucens* fed groups. These changes suggest a feeding-related influence, whose relevance for intestinal health and animal welfare requires further research

Conclusion

Initial results suggest that feeding based on substitution of fishmeal with *Arthrospira platensis* and *Hermetia illucens* does not result in increased inflamma ory infiltration of the intestines, which is an essential parameter in terms of gut health and animal welfare. Nevertheless, further investigations are needed, such as the gene expression of inflammatory markers and anti-microbial peptides.

GOOD ATTRIBUTES OF SUSTAINABLE AGRICULTURE DEVELOPMENT WITH FOCUS ON CAP REFORM AND WATER FRAMEWORK DIRECTIVE

Alda Miftari

PhD student at Department of Social Sciences and Economics at Sapienza University of Rome, Italy
e-mail: alda.miftari@uniroma1.it

This paper focuses the attention on contribution of the diversity of production of farms on the economy scale and the related social impact for the environment process. Farms in Italian regions are growing fast and are developing new paradigms on sustainable agriculture for development and eco-friendly products for the future of farming. On behalf of CAP reform 2020 and the Sustainable Development Goals, Agriculture is one of pointed sector and discussed for preservation of environment and the welfare of the future generations. This article will focus on evaluation of the three pilasters of sustainability, in economic, social and environmental reality of Italian regions. The methodology of this research is a quantitative model on using data from ISTAT and EUROSTAT, elaborating them and find out new paradigms and methods on the sustainability of water use on farm organization for more sustainable agriculture development and revenue.

Introduction
Aquaponic food production is complex and requires a broad spectrum of knowledge in order to understand and manage the processes involved. If aquaponics is to develop its potential in Europe, it will require an appropriately trained workforce. AQU@TEACH is the first aquaponics curriculum to be developed specifically for university level students. Devised in collaboration as an Erasmus+ Strategic Partnership in Higher Education, the multidisciplinary curriculum covers the basics of aquaponics with a focus on transferable and entrepreneurial skills.

Aquaponics curriculum
The aquaponics curriculum (150 hours, 5 ECTS) can be taught either using blended learning – combining digital media and the Internet with classroom formats that require the physical co-presence of the teacher and students – or as an e-learning course. The fifteen modules were designed using the Learning Designer software, which assists with achieving a balance between the six types of learning – acquisition, inquiry, practice, production, discussion and collaboration, and employ a toolbox of innovative didactic techniques suited to blended learning and e-learning, such as workshops, wikis, discussion forums, social bookmarking, and e-portfolios. The curriculum was pilot tested as an e-learning course with five students from each of the partner institutions, and then optimised on the basis of a combination of student feedback and self-evaluation by the tutors.

The project also afforded a valuable opportunity for the students to take part in a practical experiment which was run concurrently at the partner institutions. The aim of the experiment was to investigate the growth of the same vegetable cultivars in different conditions (system configuration, climate), in order to explore the factors responsible for differences in yield and elemental composition of the dry biomass.

Entrepreneurial skills curriculum
The supplementary entrepreneurial skills curriculum (60 hours, 2 ECTS) was devised on the basis of two surveys: 1) of aquaponics companies around the world, in order to ascertain which entrepreneurial skills are particular to aquaponics; and 2) of European Higher Education institutions which teach courses where aquaponics could be incorporated in the curriculum – such as aquaculture, horticulture, sanitary engineering, ecological engineering, landscape architecture, agronomy, etc. – in order to ascertain which entrepreneurial skills are particular to those disciplines.

The curriculum follows the lean start up methodology, and includes different types of business model, capital and financing, customer development, marketing, and start up pitches. It was piloted during a summer school in Slovenia with students from the four participating countries, and then added to the e-learning modules.

Teaching aquaponics: best practice guide
The best practice guide provides teachers and trainers with fresh ideas for achieving the best possible educational results in teaching interdisciplinary subjects such as aquaponics, which require high-quality knowledge in diverse fields as well as the specifics of interdisciplinary integration. It also encourages them to introduce their students to technical and business skills, and to develop their own specific professional and transversal competences through the use of innovative teaching methods and tools.

All of the outputs – the e-learning course, textbook, module guide, curriculum guide, teaching materials, best practice guide and toolbox of innovative didactic techniques – will be publicly and freely available at the end of the project in March 2020.

DEVELOPMENT OF A *Scrombidae* MODEL MARINE FISH FOR DISEASE ECOLOGY, PACIFIC CHUB MACKEREL - *Scomber japonicus*

Offshore marine aquaculture has one of the greatest opportunities for expansion, yet many questions remain about the environmental and economic sustainability of such operations. Sustainable growth in mariculture production is limited by technical challenges such as hatchery mortalities, growout morbidities from infections, and public concern regarding environmental degradation from disease outbreaks and waste pollution, while proper colonization and development of mucosal microbial communities during early life events are critical for health across vertebrates. Changing ocean conditions driven by anthropogenic activity may have a negative impact on fisheries and aquaculture production by increasing stress and disease with the mucosal microbiome as a potentially important intermediate role. Evaluating and testing hypotheses on disease transfer within marine aquaculture net pens and to and from wild populations remains challenging especially for highly valued species like tunas. Therefore, we have developed a new marine model fish which can be used to test hypotheses on disease ecology including population transfer and effects of abiotic and biological stressors. Using long read (Oxford Nanopore) and short read (Illumina) sequencing we have assembled a draft genome of Scomber japonicus with an N50 of 3.0 Mb. To investigate natural (abiotic and biological) impacts on the fish mucosal microbiome, we sampled 229 individuals surveying five body sites (gill, skin, digesta, GI, and pyloric caeca) collected across 38 time points spanning one year from the Scripps Institution of Oceanography Pier, making this the largest and longest wild marine fish microbiome survey. The skin and gill was explained primarily by sea surface temperature, chlorophyll a, and fish age, consistent with an exposure gradient relationship. A cosmopolitan pathogen, *Photobacterium damselae*, was prevalent across multiple body sites, but highest in the skin, GI, and digesta between June and September (warm water and low nutrients). To validate similarity between the mackerel microbiome to a tuna species microbiome, we sampled 72 Southern Bluefin Tuna samples from South Australia and compared the gill, skin, and digesta communities. This study demonstrates the importance of sampling wild fish to understand underlying disease distribution particularly prior to installation of fish farms. We demonstrate how environmental factors such as temperature influences the mucosal microbial ecology. With the successful establishment the natural microbial variation and genome assembly, we can now begin testing effects of increasing temperature stressors on parasite or bacterial infections as a model for tuna health.

(Continued on next page)

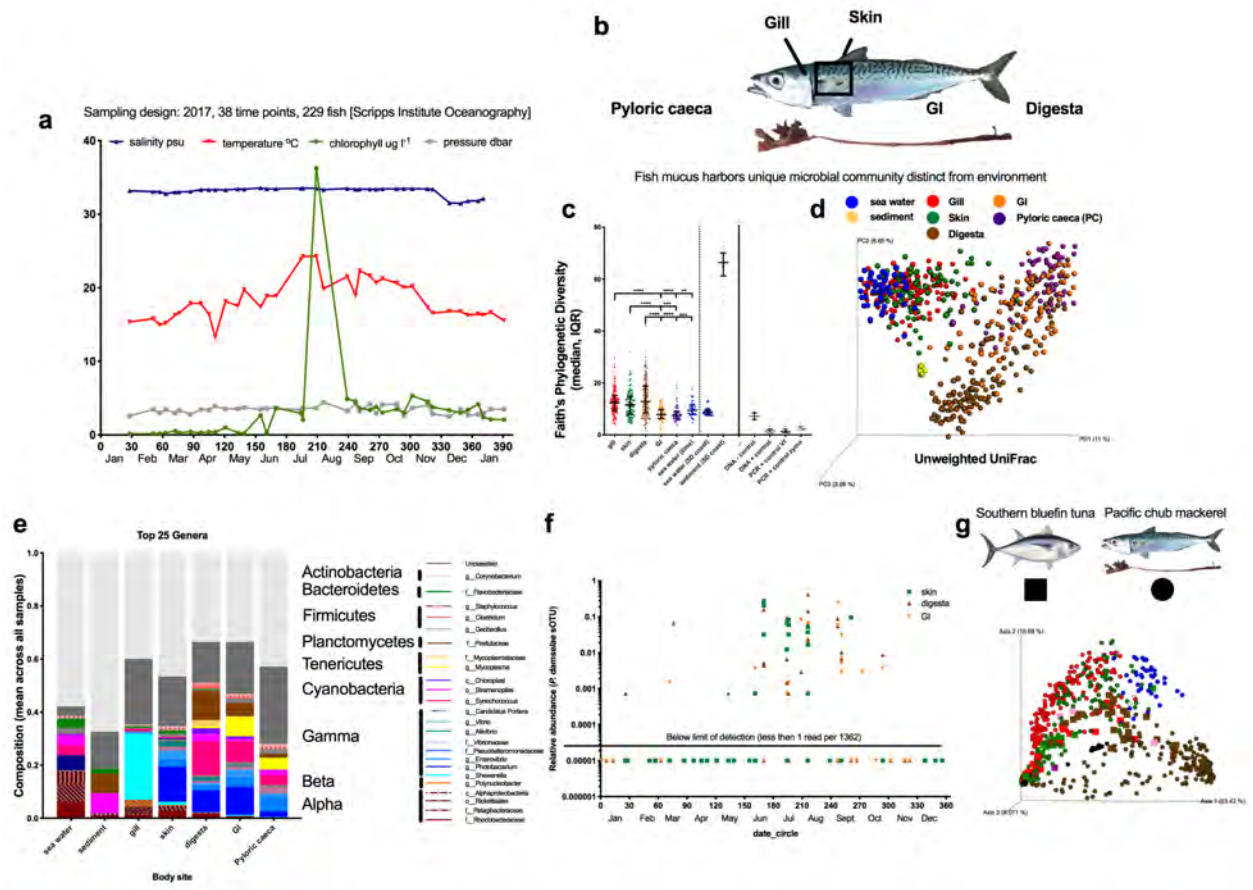

Figure 1. Microbial ecology of mucosal microbiome from *Scomber japonicus*. (a) Fish were sampled on 38 time points during 2017 from SIO pier with water parameters measured by in situ probes. (b) Five body sites were sampled from each of the 229 fish. (c) Alpha diversity as measured by Faith's Phylogenetic diversity was calculated and compared across mucosal sites with the gill, skin, and digesta samples having the highest diversity (Kruskal-wallis test). (d) PCoA plot of microbial communities (Unweighted UniFrac) from fish mucus and environment reveals skin and gill communities most similar to environment (water). (e) Top 25 genera across all sample types reveals high prevalence of Photobacterium sp. in skin, digesta, and GI communities. (f) Prevalence and relative abundance of species level resolution (150 bp sOTU from 16S rRNA V4 region) of *Photobacterium damselae* (fish pathogen) across body sites and sampling time points indicates elevated presence during warm water periods. (g) Microbiome comparison of mucosal sites (gill, skin, digesta) of Pacific chub mackerel (229 individuals) to Southern Bluefin Tuna (72 individuals).

CONSIDERATIONS FOR MICROBIOME RESEARCH IN AQUACULTURE: OVERCOMING CHALLENGES WITH LOW BIOMASS ENVIRONMENTS, REDUCING COSTS, ADDRESSSING TECHNICAL NOISE, AND META-ANLAYSES

Jeremiah J Minich*[1], Eric E Allen[1,2], and Rob Knight[2,3]

email: jjminich@ucsd.edu

The microbial ecology or microbiome of both the organism's body sites along with the environment is important for evaluating and maintaining animal health. Rapidly identification and monitoring of disease outbreaks in clinical cleanroom environments such as hatcheries is essential for preserving life and preventing catastrophic economic loss due to massive deaths. One of the primary challenges with microbiome research is understanding and choosing the current protocols as the variety of methods in continually expanding. Microbiome processing and analyses of low-biomass samples are challenging because of contamination and inefficiencies, leading many investigators to employ low-throughput methods with minimal controls. We introduce a high-throughput low-biomass pipeline (Katharoseq) that reveals the whole bacterial community from inputs as little as 500 cells using automated robotic platforms which we determined by comparing samples processed by 5 different methods (n=300). We apply this method to both the 16S and metagenomics analysis of five unique built environments including a NASA spacecraft assembly facility, a Neonatal Intensive Care Unit, a critically endangered abalone rearing facility, an Atlantic salmon hatchery, and a yellowtail kingfish hatchery revealing spatially resolved, distinct microbiomes, reproducible across hundreds of samples. We have furthered optimized this method to reduce well-to-well contamination during DNA extraction while reducing costs over 20x to a final library prep cost of $1.4 per sample.

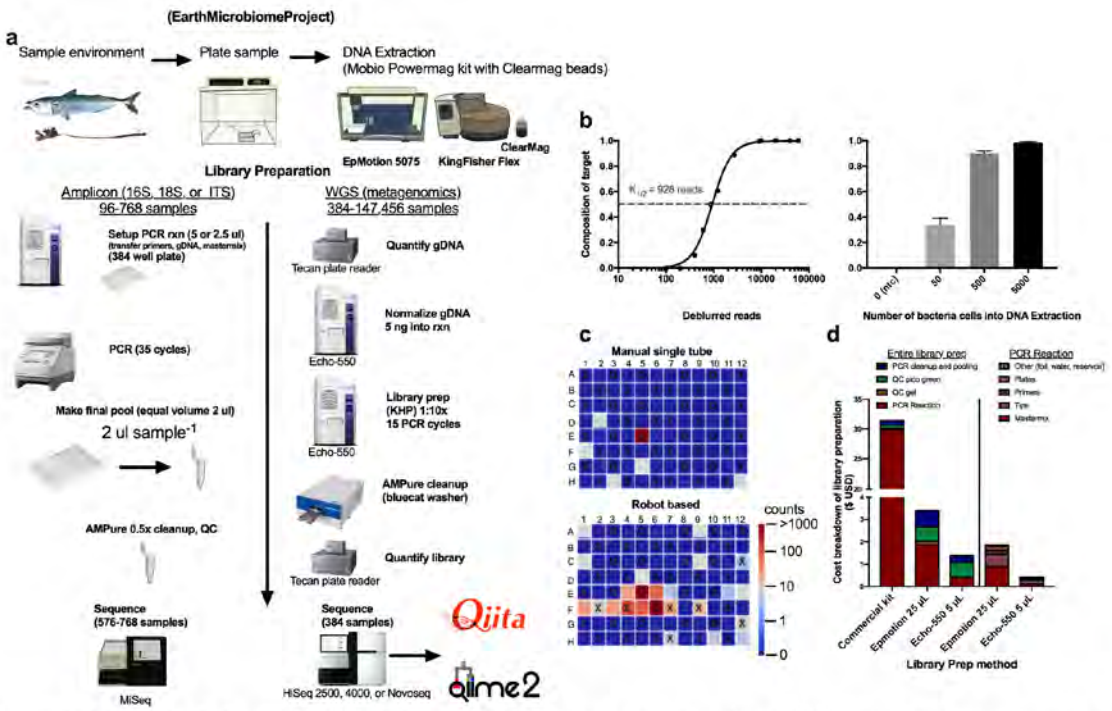

Figure 1: (a) Methods for High-Throughput (96-384 samples), low noise, and low cost metagenomic sample processing of DNA extraction and library preparation (amplicon & metagenomics sequencing) [EarthMicrobiomeProject]. (b) Protocol enables low biomass detection down of 500 cells of bacterial material at 92% accuracy. (c) Well-to-well contamination noise occurs primarily during DNA extraction thus requires a hybrid approach of single-tube and magnetic bead cleanup. (d) Cost reduction enables 5 ul amplicon library prep reactions at $1.4 per sample.

HATCHERY SYSTEM (RAS VS FT) EFFECTS ON FISH MICROBIOTA FOR ATLANTIC SALMON, *Salmo salar*, AND YELLOWTAIL KINGFISH, *Seriola lalandi*

Successful rearing of fish in hatcheries is critical for conservation, recreational fishing, commercial fish through wild stock enhancements, and aquaculture production. Hatcheries however, can have a negative impact on the environment by requiring large volumes of water from local streams or rivers and in turn producing large volumes of effluent waste. The recent development of engineered, enclosed Recirculating-Aquaculture-Systems (RAS) enables up to 99% of water recycling thus significantly reducing environmental impacts. One major concern for RAS systems over traditional flow through (FT) systems is a negative impact on fish health which is in part thought to be due to microbial dysbiosis either to the fish or the environment (water). In this study we evaluated how the built environment of a hatchery is influenced by the hatchery type from three Atlantic salmon (*Salmo salar*) hatcheries (RAS n=2, FT n=1). For Atl salmon, six fish (300 days post hatch - parr) were sampled from three independent tanks in each of the three hatcheries for a total of 54 unique fish. Water and a swab of the tank side biofilm was collected from each of the nine tanks to evaluate the environmental microbiome. To assess the entire mucosal microbiome, three body sites including the gill, skin, and digesta were swabbed from each fish and processed for 16S rRNA analysis using the EarthMicrobiomeProject protocols. The water and tank biofilm communities, especially from the RAS systems, generally had a higher microbial richness compared to the fish mucus. The three body sites each had unique microbial communities ($P<0.001$) and thus were analyzed independently. Within each body site (gill, skin, and digesta), microbiomes were uniquely driven by the various hatchery systems ($P<0.001$) with both RAS systems being more similar. We next investigated the relationship between the tank system and the fish mucus and found that both the water and tank biofilm richness was positively correlated with skin and digesta richness with the biofilm association being slightly stronger. We next tested whether fish mucosal microbiomes were more similar to their origin tank compared to the similarity to other hatchery tanks. Strikingly, the gill, skin and digesta communities were more similar to the origin tank biofilm vs. all other experimental tanks suggesting that the tank biofilm has a direct influence on the fish communities. For water samples, the skin and digesta were more similar to the origin tank compared to all other tanks. Furthermore, the gill and skin communities were always more similar to tank water and tank biofilm than the digesta samples. To determine a biological effect, we compared the gill, skin, and digesta microbial communities to health measures from histopathology analyses and found that both digesta and skin microbiomes were associated with skin mucus cell levels. Lastly, we also repeated this analysis on a marine fish hatchery, Yellowtail kingfish (*Seriola lalandi*). Specificall , we sampled 12 fish (130 days post hatch) each from three FT tanks, and two RAS systems and found similar environmental associations to fish mucosal communities. The results from this study provide evidence for the first time an association and link between the tank microbiome and the fish microbiome. We show how the skin microbiome of the fish is most influenced by the environmental community which in turn is also related to skin mucus health.

FISH FARMING IN TANZANIA AND THE AVAILABILITY AND NUTRITIVE VALUE OF LOCAL FEED INGREDIENTS

F. Mmanda, D. Mulokozi, J. Lindberg, A. Haldén, M. Mtolera, R. Kitula, and T. Lundh

Swedish University of Agricultural Sciences, P.O. Box 7024, S-75007 Uppsala, Sweden

Introduction

Aquaculture industry is one of the fast food-growing activities in Tanzania (URT, 2015). Its expansion has been constrained for decades by limited availability of good quality feeds at affordable prices (Al-Sayed, 2006). Hence, majority of tilapia farmers opt for locally available feed ingredients in the country (Kaliba *et al.,* 2006). However, there is a lack of data on locally available feed ingredients in different regions of Tanzania and their nutritional content. Therefore, an investigative surveyed study was performed from January 2017 to February 2018 to gather baseline data on their availability and nutritive values content.

Materials and methods

The present study was carried out in nine regions of mainland Tanzania and Zanzibar Island during the period of January 2017-February 2018. A structured questionnaire form comprising questions concerning with type of local feed ingredients used and other issues relating to aquaculture was used to collect data. In addition, some local feed ingredients of interest were collected at four different geographical locations were analysed for proximate analysis (Dry matter, Crude protein, Crude fibe , ash, Crude lipid) and their mineral content at Sokoine University of Agriculture according to methods described by AOAC (1990). Moreover, amino acids analysis were also done on an interested feed samples (n=17) at Tanzania Veterinary Laboratory Agency (Dar-es-Salaam) by near-infrared reflectance spectrophotometry (NIRS) according to the manufacturer's instructions.

Results

In total, 202 fish farmers were interviewed and 30 different ingredients were collected from the study sites for chemical and other nutritive values analysis. The findings showed that, majority of respondents involved in aquaculture operations were males (82.7%), with a high proportion (55.0%) in the age group 40-60 years. Most commonly cultured fish species (82.2%) was tilapia, mostly (87.6%) raised semi-intensively at a stocking density of 2-3 fish/ ^{2}. Over 80% of respondents relied on local feed ingredients as supplement diets for cultured fish. The most common feed ingredients were maize bran (28%), Lake Victoria sardines (11%) and sunflower seed cake (11%). Crude protein content in most analysed local ingredients was medium-high, while Crude fat content was high in some animal and agricultural by-products, but was medium-low in other ingredients. In general, agricultural by-products, aquatic plants and industrial by-products had a medium-high content of nitrogen-free extract, while there were major differences in ash content between the feed ingredients analysed. According to mineral content, the results showed a wide range of mineral concentrations in the local feed ingredients used by tilapia fish farmers in Tanzania. On other hand, marine shrimps, freshwater shrimps and prawn head waste were high in tryptophan, lysine and methionine plus cysteine compared to other tested ingredients.

Discussion and Conclusion

There was a great variation in the size of fishponds, tanks and cages between fish farming systems within regions, and between regions, confirming earlier findings for Tanzania (Kaliba et al., 2006; Mwaijande & Lugendo, 2015). Earthen ponds were the most common fish farming system in all regions except Dar-es-Salaam, the findings was similar to previous study done by Kaliba et al. (2006). Moreover, tilapia was the most commonly cultured fish species that was coherent to findings reported by Kaliba et al. (2006). Moreover, the present study found that more than 80% of respondents relied on locally available feed ingredients as a major feed supplement for their cultured fish, which was comparable to data for eight regions of Tanzania reported by Mwaijande & Lugendo (2015). According to the chemical analysis, the results showed that the chemical composition of collected common feed ingredients was generally within the range reported by others (Chiba, 2009). However, there were great differences in the ash content of feed ingredients analysed in the present study, with very high values found in many fishery by-products, but also in some agricultural by-products, plant leaves and aquatic plants. The variation in similar feed ingredients between studies can be due to many factors, such as animal species, contamination, processing, handling and storage, climate conditions, production season, geographical zone, soil type and stage of maturity at harvest. We also found that animal by-products, except for Nile perch fish frames, were

(Continued on next page)

high in lysine, tryptophan and methionine plus cysteine. In some agricultural by-products (i.e. soybean), plant leaves and weeds, aquatic plants (i.e. azolla) and spent brewer's yeast were intermediate in lysine and methionine plus cysteine, but high in tryptophan (0.2-1.5%). This is consistent with findings reported in other studies (Kibiriza et al., 2016). According to El-Sayed (2004), the essential amino acid (EAA) requirement for tilapia species is in the range 1.43-1.62% for lysine, 0.17-0.6% for tryptophan, 0.53-1.13% for methionine and 0.53-2.1% for cysteine. Therefore, the integration of more than two locally available ingredients in fish diets has provided the balanced fish diets that meet amino acid requirements in a farmed tilapia species.

These data provide a good platform for development of feeding strategies for cultured tilapia based on current culture systems, availability of local feed ingredients in Tanzania and their nutritional content.

[b] Department of Fisheries, Faculty of Fisheries and Environmental Sciences, Gorgan University of Agricultural Sciences and Natural Resources, Gorgan, Iran
*modanloo.maryam@gmail.com

Introduction

One of the major challenges in intensive carp farms is related to stressful situation, and subsequently, diseases and destruction of environmental conditions might be happened (Esteban, 2012). To resolve the issue, antibiotics have been usually used as a preventative means of bacterial control (Balcazar et al., 2007).The application of antibacterial agents can induce food and environmental pollution, development of antibiotics resistant bacterial strains, toxic accumulation in edible tissues of fish and suppression of immune system (Cerezuela et al., 2016). The present study was performed to investigated the effects of singular or combined administration of galactooligosaccharide (GOS) and *Pediococcus acidilactici* on cutaneous mucus immune parameters, humeral immune responses and immune related genes expression in common carp (*Cyprinus carpio*) fingerlings

Materials and methods

Carps were fed with experimental diets for 8 weeks as follows: non-supplemented (Control), prebiotic diet (10 g/kg GOS), probiotic diet (1g/kg [0.9×10^7 CFU] lyophilized *P. acidilactici*) and synbiotic diet (10 GOS in combination with 1 g/kg [0.9×10^7 CFU] lyophilized *P. acidilactici*). The blood samples were obtained from three fish per tank and serums were isolated (Zou et al., 2016). Skin mucus samples were obtained based on the modified protocol of Subramanian et al. (2007) and serum immunity parameters were then measured (Demers et al., 1997). The mRNA levels of immune related genes (LYZ, IL1b and TNF-a) were analyzed in intestine tissue using Real-Time PCR (Cerezuela et al., 2016).

Results

Unlike skin mucus, the serum lysozyme activity showed no significant difference between carps fed supplemented or control diets. Remarkable elevation of serum ACH50 activity was noticed in carps fed supplemented diet (pro-, pre- and symbiotic diet) compared control group. Besides, feeding on pro-, pre- and synbiotic supplemented diet significantly increased serum and skin mucus total Ig levels. However, no significant difference was observed between treatments and control group in case of skin mucus proteases activity. There was no significant difference between expression levels of intestinal genes of LYZ and IL1b in fish fed on pre- and synbiotic, compared to the control. However, evaluation of TNF-alpha gene expression in the intestine of carps revealed remarkable down-regulation in treated groups ($P < 0.05$).

Discussion and conclusion

There was no available information about comparative study of pre-, pro and synbiotic on common carp innate immune parameters. However, in accordance with our findings, Hoseinifar et al. (2015) reported that serum ACH50 and lysozyme activity significantly increased in rainbow trout fingerlings following administration of the same pre-, pro- and synbiotic as ours. . Furthermore, Ye et al. (2011) demonstrated that combined administration of dietary fructooligosaccharide (FOS), mannanoligosaccharide (MOS) and *Bacillus clausii* as synbiotic significantly increased innate immune parameters in Japanese flounder (*Paralichthys olivaceus*). However combined dietary supplementation with *Bacillus subtilis* and chitosan or *B. subtilis* and FOS (Geng et al., 2011) did not remarkably elevated immune parameters of cobia (*Rachycentron canadum*) and yellow croaker (*Larimichthys crocea*), respectively. The discrepancies observed in different studies might be in part due to differences in fish species, life stage and the type and dosage of administered pre- or probiotic as well (Hoseinifar et al., 2016).

The present results showed positive effect of supplementation of carp diet with GOS and *P. acidilactici* on some mucosal or serum immune parameters. However, these feed additives down-regulated immune related genes expression in intestine. The present study encourages further studies on different aspect of synbiotic application in carp aquaculture.

DETERMINATION OF HEAVY METALS FROM ALOE VERA BY_PRODUCT IN GOLDEN MULLET (*Liza aurata)*; HEALTH RISK ASSESSMENT FOR CONSUMERS

Selwan Rabia[a,b], Octavio P. Luzardo[c], Raquel Pozo[a], Mostafa Abbassy[b], Manuel Zumbado[c], Lidia Robaina[a], Rafael Ginés[a]

[c] Toxicology Unit, Research Institute of Biomedical and Health Sciences (IUIBS), University of Las Palmas de Gran Canaria, Spain
E-mail: dr.selwanharb@gmail.com

Introduction
Heavy metals have become subject of concern in the recent years because of its potency to cause cardiovascular diseases and other toxic health effects (Alissa et al. 2011). Furthermore, Spain is, after Japan, the world's second fish-consuming country, at over 30 kg per person per year, and consumption is expected to rise in the future (Jose´ Usero et al. 2003). Since a long time, the use of fish as an indicator of heavy metals contamination has been increased which represent a principal health hazard on human health through the food chain and Dietary intake. Therefore, this research was assumed to investigate the level of toxicity in terms of heavy metals accumulation in the fish samples and its benefits and risk for human consumers health and also evaluate the partial replacement of plant sources by canarian Aloe vera diets as a pure product or by-product on growth and toxicological effects on the golden mullet (*Liza aurata*) fillet and whole body and compare it with control.

Materials and Methods
A total of 240 juveniles were chosen for the experiment with an average weight and size of 8.93 ± 1.88 g and 10.08 ± 0.95 cm respectively, which were randomly assigned in 15 tanks (tripled by treatment and fed for 91 days with substitution of plant sources by 5 diets were made with 0% of aloe inclusion (control diet), 2% of pure form of aloe (pure product) (diet P2), and 2, 4 and 6% of Aloe vera by-product (diets BP2, BP4 and BP6). Heavy metal concentration determined using the ICP-MS Agilent 7900 (Agilent Technologies, Tokyo, Japón).

Results
The results showed that fishes doubled their initial weight after three months from the start of the test, resulting in an average of 18.64 ± 4.02 g of weight and 12.38 ± 0.96 cm of full size and there are no statistically significant differences were found in any of the calculated indices. All heavy metal levels in the fish tissue and diets were below the safe limits for consumption which confirmed by various international standards such as European Union (EU) and World Health Organization (WHO). In case of diets it is obvious that the level of metals in both product and by_product was lower than the control in most of metals. However, in whole fish results proved that the diet with by_product 2 % have the highest levels of accumulation of metals compared with the other diets and the accumulation of this metals depend on the fish species, diet and metal concentration.

Discussion and conclusion
Concerning growth parameters, both the specific growth rate and the feeding efficiency were significantly superior to those described for this species by Karapanagiotidis et al. (2014).

The analysis of contaminants represents that all metals were below the safety limits. While some articles used (*Liza aurata*) as an indicator of contaminant levels in the environment and there are no references to heavy metals have been found in the animal's entire body. To our knowledge, there is no articles discussed the topic of determination of heavy metals in fish and by product which feeded on with different concentration as the present study.

It should also be taken into consideration, that muscle tissue, being the less active metabolically, accumulates metals in lower levels than other tissues (Renieri et al., 2014; Squadrone et al., 2016 Nasyitah Sobihah et al., 2018;) however, metals are transported to muscles through other tissues and muscles can serve as indicators of an implemented chronic exposure (Kalantzi et al., 2016).

Thus, it can be concluded that Aloe vera product and by_product were in safety limits for fish and also for humans through the food chain.

Introduction

The body composition of fish in different species may vary under different conditions.This difference is due to different nutritional conditions, different water quality, maturity and sex. Also, the amount of protein, fat, carbohydrate and ash in aquatic muscle varies in different species (Javaid et al., 1992; Ali et al., 2005; Saliu et al., 2007; Sharifian, 2014). The amount of chemical composition in the aquatic body depends on the type of nutrition, living environment, age and sex of the living creature (Kochekian Sabour and Yasimi, 2011: Velayat- Zadeh, 2013). However, these indices vary significantly between and among species, size, sex, nutrition season, and physical activity (Ali et al., 2005). Therefore, in the present study, changes in the composition of common carp meat, which is a valuable bone fish that is bred in many parts of the world, were studied at different weights.

Materials and Methods

For this research, 2 year old carp were used in 5 weight groups as follows: Group A: Average weight 500 gr, Group B: Average weight 700 gr. Group C: Average weight 1000 gr. Group D: Average weight 1300 g and Group E: Average weight 1600 g. To evaluate the quality of carp meat, 5 fish were separated from each weight group after checking for health and abnormal symptoms and disease in the fish. After biometrics and measurement of fish length and weight, 100 grams of muscle was isolated from each fish sample to evaluate meat quality. The AOAC (1990) method was then used in the Food Analysis Laboratory to evaluate and analyze meat quality. SPSS 22 software was used for data analysis.

Results and Discussion

Table 1 shows changes in protein, fat, ash and dry matter quality of common carp in different weight groups. Results showed no significant changes in protein content in different groups and no significant difference was observed between different weight groups (P> 0.05). Fat changes of common carp showed the lowest fat content in the high weight group (1600 g) and the highest fat content in the lower weight group (500 g), but the results showed a decreasing pattern in the meat fat change process with increasing fish weight. But overall results showed that there was no statistically significant difference between different weight groups in fat (P> 0.05). The results of meat ash changes, in spite of the lowest ash content in the 1600 g group and the highest in the 700 g fish, indicated no regular decreasing or increasing pattern in the different weight groups. The results also showed that there was no statistically significant difference in ash content between different weight groups (P> 0.05). Dry matter variations showed no significant difference (P> 0.05) between mean dry matter groups. In general, the results showed that there was no significant difference between different weight groups of common carp in terms of protein, fat, ash and meat dry matter (P> 0.05). The results of this study show that weight gain in a typical carp does not make a difference in fish meat quality, and this is inconsistent with the findings of researchers who have reported that fish meat quality changes in weight and size

Table 1: Changes in protein, fat, ash and dry matter at different weights of common carp

Factor (%)	Protein	Fat	Ash	Dry matter
500 (g)	10.176 ± 3.878 [a]	9.624 ± 1.971 [a]	1.547 ± 0.293 [a]	21.347 ± 2.20 [a]
700 (g)	10.105 ± 1.641 [a]	9.957 ± 0.432 [a]	1.565 ± 0.034 [a]	21.596 ± 1.246 [a]
1000 (g)	9.22 ± 0.841 [a]	9.287 ± 0.134 [a]	1.362 ± 0.071 [a]	19.821 ± 0.43 [a]
1300 (g)	10.837 ± 2.998 [a]	9.399 ± 1.104 [a]	1.296 ± 0.245 [a]	21.533 ± 2.304 [a]
1600 (g)	10.129 ± 1.468 [a]	8.645 ± 0.643 [a]	1.294 ± 0.064 [a]	20.068 ± 0.76 [a]
Average	10.209 ± 2.106	9.429 ± 0.937	1.407 ± 0.198	21.03 ± 1.62

*The small Latin letters show that there are significant differences among different groups

(Continued on next page)

Fish tissue protein is a favorable combination of amino acids as well as a rich source of vitamin B and rich in vitamins A and D (Zmijewski et al., 2006). Based on the results of this study, the average protein of common carp was 10.209 ± 2.106 %, which is higher than that of *Liza dussmieri* (10.13%) (Aberomand, 2012) and much less than fish such as golden mullet (*Liza auratus*) (17.69%), *Hemisynodontis membranacea* (20.26 %), *Clupea harengus* (18.45), *Tilapia zilli* (18.80 %) (Olagunju et al., 2012), *Orcynopsis unicolor* (22%), *Euthynnus affinis* (24%) (Aberomand, 2012), *Otolithes ruber* (19.64 %), *Scomberomorus guttatus* (19.9%), *Scomberomorus commerson* (19.5%) (Velayat-Zadeh and Askari Sari, 2013). Fat is a component of the chemical composition of the muscle that represents the largest difference in the amount of fish muscle (Askari Sari et al., 2016). The average fat of common carp in this study was 9.429 ± 0.937 %, which was higher than the amount of fat in *Liza auratus* (0.74%), *Liza dussmieri* (0.25%) (Aberoumand, 2012), *Otolithes ruber* (1.23 %), *Scomberomorus guttatus* (2.1%), *Scomberomorus commerson* (3.4 %) (Velayat-Zadeh and Askari Sari, 2013) and much less than fish such as *Clupea harengus* (11.14 %), *Scomber scombrus* (12.33 %) (Olagunju et al., 2012), *Tilapia zilli* (18.80%) (Olagunju et al., 2012), *Orcynopsis unicolor* (16 %), *Euthynnus affinis* (14 %) (Aberoumand, 2012).The average ash of common carp in this study was 1.407 ± 0.198 %, which was higher than *Liza abu* (1.36%), *Liza auratus* (1.37%) (Askari Sari et al., 2016), *Liza dussmieri* (1.36 %), (Abromond 2012), *Otolithes ruber* (1.32 %), *Scomberomorus guttatus* (1.13 %) (Velayat-Zadeh and Askari Sari, 2013) and much less than fish such as *Liza macrolepis* (2.6%), *Liza klunzingeri* (2.63%) (Askari Sari et al., 2016), *Scomber scombrus* (1.79 %) (Olagunju et al., 2012), *Scomberomorus commerson* (3.4 %), (Velayat-Zadeh and Askari Sari, 2013), *Clupea harenguss* (1.6%) (Olagunju et al., 2012).

*E-mail:mohammedf21@hotmail.fr

In order to investigate the reproductive performance of five populations of *Oreochromis niloticus* from F1 wild populations collected in Nangbéto, Sohoumè and Togbadji in the Mono watershed, Gobé in Ouémé and Gbassa in Niger, tests were conducted for ten weeks. After selection of breeding stock from different populations, males and females were kept in different ponds and fed for two weeks before mating. All populations were monitored once a week, the laying females were identified, the lay eggs were collected, weighed, photographed, and incubated up to 10 Dpf where the larvae were counted. Overall, for all the populations considered, the rate of females having laid (66.7% to 91.7%), the rate of females having had more than one laying (33.3% to 100%), the average total weight of the clutches (4.1 g ± 1.5 to 7.1 g ± 4.6), gonadosomatic index (2.5% ± 1.9 to 4.8% ± 2.8), average absolute fertility (616.9 ± 380 eggs at 987.8 ± 548.9 eggs), average fertilization rate (89.3% ± 14.4 to 99.3% ± 1.2) and the average hatching rate (58.9% ± 20.3 to 89.1% ± 10.4) varied significantly ($P < 0.05$) with the Sohoumé, Togbadji and Gobé populations who had the best reproduction performance.

SUSTAINING A MOBILE APPLICATION FOR FISH FARMERS IN UGANDA: POLICY CONTRADICTIONS, TECHNICAL CAPABILITIES, AND USER NEEDS

J. Molnar*, I. Omiat, M. Matuha, J. Walakira, G. Atukunda, T. Hyuha, and J. Bukenya

Introduction

Mobile phones have a rapid diffusion rate and facilitate farmers' access to information, helping increase their bargaining power, control over external events, develop new skills and grow revenues (Myhr and Nordstrom 2008). For instance, in Tanzania the arrival of mobile phones, transformed agricultural business performance at all points by augmenting farmers' access to education and vital market information (Timuray 2014). Matuha (2015) found that fish farmers use mobile phones to access technical guidance from intermediary farmers, obtain market information, accomplish mobile banking and receiving, contact family members and make plans for procurement of fish farming inputs. Factors that seemed to discourage mobile phone use included: lack of electricity, poor network coverage, high calling credit and maintenance costs, lack of awareness and promotion. On the other hand, information regarding stocking and harvesting, feeding management, pond construction and management, disease management, water quality management, broodstock management and market prices were information topics most needed by fish farmers. Several different business models have emerged in efforts to provide technical support to African farmers with cell phones. Each varies in the level of public sector control, business model, cost, and flexibilit . One commercial model invites farmers to subscribe to a fish-focused network of producers managed by a service provider who moderates the transactions and may be compensated by subscription fees, transaction fees, or commissions. The entrepreneur firm builds and supports a network of suppliers, producers, and buyers whose transaction costs support the network. The source of technical information may be uncertain, but the responsiveness to technical questions may be rapid because the entrepreneur is motivated to keep and grow the number of participants. This is the approach we take in Uganda. The purpose of this paper is to describe the implementation of a mobile-based application for fish farmers, participation processes, and services provided. The conclusion considers how ICT advances food security and development by empowering farmers and linking them to each other, extension, and input suppliers.

Materials and methods

We examine trends in mobile phone utilization, subscription, and deployment of mobile applications as support mechanisms for training and aquacultural development. We also examine the structure of licensing fees, SMS charges, and mobile time as barriers to the expansion and impact of mobile applications for fish farmers. We discuss the results of focused group discussion with fish farmers conducted during the process of developing and launching the application.

Results

The data outline some of the barriers and opportunities to the spread and augmentation of mobile applications for fish farmers.

Discussion and conclusions

The Uganda policy environment presents significant challenges for mobile phone applications in Uganda. Annual charges for mobile short codes far exceed others in Africa. The mobile network is capable, but the affordability of smart phones is a barrier to many. The Android system is widely used due to its affordability. Government needs to harmonise the ICT policy and the agricultural policy that aims at establishing a knowledge based management and information system for improving agricultural extension service delivery.

THERMAL TREATMENT AND LESIONS ON ATLANTIC SALMON (*Salmo salar*)

Lene Moltumyr[1]*, Kristine Gismervik[2], Anne-Gerd Gjevre[2], Jinni Gu[2], Siri Kristine Gåsnes[2], Tore Sigmund Kristiansen[1], Cecilie Marie Mejdell[2], Jonatan Nilsson[1], Brit Tørud[2], and Lars Helge Stien[1]

2: Norwegian Veterinary Institute, P.O. Box 750 Sentrum, NO-0106 Oslo, Norway
*: Lene.Moltumyr@hi.no

Introduction

Thermal treatment is widely used in Norwegian aquaculture for delousing of Atlantic salmon (*Salmo salar*) (Overton et al. 2018). The treatment procedure is to crowd the fish in the sea cage and pump them past a dewatering strainer into a treatment chamber where they are exposed to seawater at a temperature of 28–34°C for 20–30 seconds (Holan et al. 2017).

High mortality and various lesions (e.g. skin wounds, scale losses, degeneration of nasal mucosa, and bleedings in eyes, palate, gills, thymus, and brain) have been reported on Atlantic salmon after industrial thermal treatments (Hjeltnes et al. 2018, Overton et al. 2018, Poppe et al. 2018, Stien et al. 2018). Clear causal relationships for the mortality and pathological findings, as well as the prevalence of the various lesions, are, howeve , not documented.

The objective of this study was to reveal whether the thermal component of an industrially relevant thermal treatment inflicts lesions on Atlantic salmon.

Materials and Methods

- The study included 60 post-smolt Atlantic salmon ($\overline{WW}$ = 1117 ± 250g) of which 40 got thermal treatment ($\overline{TT}$ = 34.0 ± 0.1ºC) and 20 got control treatment ($\overline{TT}$ = 9.2 ± 0.2ºC) for 30 seconds.
- The fish were collectively sedated (level 1, Iversen et al. 2003) in the stock tank before being individually anaesthetised (level 3) in a bucket and treated in a submerged bag of non-slip fabric.
- After treatment, the fish were immediately euthanised, welfare scored (Noble et al. 2008), and sampled for later histopathological examination. Samples from 28 thermally treated fish and 14 control fish were examine
- The study included skin, fins, eyes, snout, nasal pits/mucosa, palate, gills, thymus, pseudobranch, brain, heart, liver, kidney, pyloric caeca, pancreas, and spleen.

Results and Conclusion

Thermal treatment at 34°C for 30 seconds did not inflict any statistically significant acute lesions on Atlantic salmon except caudal, dorsal, and right pelvic fin injuries (Fisher's Exact Test, p = 0.002, 0.002, and 0.014, respectively). As the fish displayed a strong behavioural reaction in the treatment bag when exposed to warm water, the fin injuries may have been self-inflicted

Introduction

The lumpfish (*Cyclopterus lumpus* L.) is used as a cleaner fish in the Atlantic salmon farming industry providing a non-medicinal treatment against sea lice infection. Lumpfish production relies on the capture of wild broodstock which may not be sustainable in the future, limits year-round production, and the possibility to select for desired traits such as robustness and sea lice grazing efficienc . As most teleost fish, lumpfish develop secondary sexual characteristic when becoming sexually mature and display a sex-dependent growth dimorphism (Davenport 1985). Mature males are smaller, are richly colored and possess a relatively larger suction disc compared to mature females (Davenport and Thorsteinsson 1990). However, small immature fish of either sex cannot be easily distinguished outside breeding season and have similar sized suction discs. Both sexes loose color and separation of the sexes by external characteristics becomes less easy at equivalent weights. The knowledge of lumpfish reproductive biology in captivity is very limited and the lack of non-invasive techniques to identify gender and track maturity stages are common management handicaps in captive broodstock management. In most sexually reproducing species, the gender ratio tends to be close to 1:1. However, due to the high sperm density in males, in commercial broodfish production a ratio of 1 male to 10 females is considered most cost-efficient. It is also unknown if some of the desired lumpfish traits, such as sea lice grazing efficiency or swimming ability differ between sexes. Our goals was therefore to test the use of ultrasound as a non-invasive method for sex determination in lumpfish of commercial size and during broodfish production

Material and Methods

A total of 85 juvenile, commercial size lumpfish were netted randomly from Atlantic salmon sea cages at Hemne fjord, Norway, in September, October and December 2017. At Nofima s Center for Marine Research in Tromsø, Norway, 419 lumpfish produced to become broodfish were examined at increasing sizes during twelve samplings between 30.01.2018 and 14.03.2019. A MyLab Alpha (Esaote, Italy) ultrasound machine was used to determine the sex in all lumpfish. Individuals where an ovary was observed were categorized as females. In individuals were no ovaries could be observed, were categorised as males. After ultrasound examination, body weight and length were registered, and sex was verified by dissection. Ovaries were dissected out and weighed for calculation of gonado-somatic index (GSI).

Results and discussion

In juvenile, commercial sized lumpfish (48 ± 14 to 72 ± 16 g), sex was correctly determined by ultrasound examination in 87 to 100 % of lumpfish, with highest accuracy in lumpfish of 72 ± 16 g. In larger lumpfish (192 ± 53 g to 742 ± 310 g), sex determination accuracy varied between 69 to 100 % for both sexes. In females, an accuracy of 100 % was achieved at a smaller size (392 ± 141 g) compared to males (742 ± 310 g). In all larger lumpfish (up to 1438 ± 872 g), sex was correctly determined and was related to an increase in GSI. Male coloration became visible in males at 392 ± 141 g and increased from 44 % to 96 % during the last examination at 1438 ±872 g. The sex of immature males lacking coloration was determined with 100 % accuracy using ultrasound in 742 ± 310 g and larger males. Ultrasound seems to be will suited as a non-invasive method for sex determination in lumpfish. We will further compare our observations to external morphological measurements of lumpfish and test how the handling during ultrasound examination influences survival

NUTRITIONAL EVALUATION OF SOME ECONOMICALLY IMPORTANT MUSSELS AND SNAILS OF BANGLADESH

M. Moniruzzaman*, P. Chowdhury and Y. Mahmud

Bangladesh Fisheries Research Institute, Mymensingh-2201, Bangladesh
E-mail: moniruzzamanbfri83@gmail.com

Introduction

Mussels, snails and oysters are the most important resources among all the non-conventional food items in Bangladesh. Even though mussels and snails are not traditional food items in Bangladesh, they have great importance in terms of nutritional evaluation especially for tribal communities. In contrast of meat, mussels and snails are regarded as high quality food items because of having high protein, important vitamins, different minerals and omega-3 (EPA, eicosapentaenoic acid and DHA, docosahexaenoic acid) and omega-6 (LA, lenoleic acid and ALA, alpha-linolenic acid) fatty acids.

Materials and methods

In this study, fresh mussel and snail samples were collected from freshwater, coastal region and marine environment of Bangladesh and stored at -20 ^{0}C. Prior to the proximate analyses, muscle portion of each samples were collected for further nutritional studies of micro-nutrients like amino acids, fatty acids, vitamins and minerals as well as heavy metals.

Results

The results of the proximate analyses revealed that 65.3% crude protein, 11.2% crude lipid, 13.8% ash and 88.4% moisture are present in oyster (*Saccostrea cucullata*). Whereas, freshwater apple snail (*Pila globosa*) contained 49.6% crude protein, 3% crude lipid, 16.8% ash and 83.4% moisture. In addition, freshwater mussels, *Lamellidens marginalis* and *L. corrianus* contained 36.9-40.9% protein, 4.4-4.8% lipid, 11.4-13.1% ash and 84.8-85.4% moisture. The results also show that micro nutrients like amino acids profile and fatty acids profile are enriched in oyster in comparison to freshwater mussels and snails. All the amino acid contents are higher in oyster than the mussels and snails. The fatty acid contents especially omega-3 (EPA and DHA) fatty acids are higher in oyster than those in freshwater mussels and snails. However, omega-6 fatty acids like lenoleic acid (LA) and alpha-linolenic (ALA) acids are higher in freshwater mussels and snails than in the oyster. Overall, the results indicate that oyster can be a good source of high quality protein and lipid especially EPA and DHA. On the other hand, freshwater mussels and snails also could be good sources of protein and LA and ALA but scarcity of EPA and DHA.

ENRICHMENT OF *Brachionus* SPP. AND *Artemia* SP. WITH NEW MICROALGAE STRAINS

Microalgae are considered a potential source of nutrient in aquaculture and food industries due their high content and quality of lipid, protein and vitamins. They also have antifungal an antibacterial activities. Focusing on their nutritional value and therapeutic activities, they can play an important role on aquaculture, especially in fish larvae production based on the transference of nutrient through food chain. Trying new microalgal strains is important for improving the feasibility of microalgae in aquaculture. For this propose, a protocol to enrich *Brachionus* spp. and *Artemia* sp. with novel (*Tetraselmis* sp. IMP3, *Chlamydomonas reinhardtii* and a chlorophyte PT FAR14E) and traditional (*Nannochloropsis oculata*, IPMA algae collection) microalgal strains was developed to evaluate the value of fatty acid transference between them. The enrichment took place in 3 l tanks during 24 hours with air supplement for *Artemia* and oxygen for *Brachionus*, and culture density were 200 and 800 ind.mL^{-1} respectively. Samples were collected after 12 and 24 hours of cultivation. Microalgae consumption was evaluated by cell concentration in the culture tank. *Brachionus* and *Artemia* survival performance were obtained by counting the number of live individuals. Results indicate both organisms can graze on that microalgal species (Table I) and they promote *Artemia* and *Brachionus* survival rate (100%). Samples were also collected and preserved to fatty acid analyses.

Table I - Consumption of different microalgae, *Nannochloropsis oculata*, IMP3, *Chlamydomonas reinhardtii* and PTFAR14E (mean ± standard deviation), by *Brachionus* spp. and *Artemia* sp., in terms of cell concentration (n° cell. 10^5.mL^{-1}) variation between samplings 0-12 (Δ T0, T12) and 12-24 hours (Δ T12, T24).

	***Brachionus* spp.**		***Artemia* sp.**

BACTERIAL OUTER MEMBRANE VESICLES - TARGET AND CARRIER FOR FISH ORAL VACCINATION AND CHARACTERIZATION OF THE SYSTEMIC AND MUCOSAL INNATE AND ADAPTIVE IMMUNE RESPONSE

Ruth Tamara Montero[1], Sven Ostermann[1], Tobias Kroniger[2], Dörte Becher[2], Bernd Köllner[1]

1 Friedrich-Loeffle -Instutute Greifswald Insel Riems; 2 Universität Greifswald

The role of the peritoneum as a model for infection has been described previously in rainbow trout (*Oncorhynchus mykiss*), however, most pathogens infect fish via mucosal surfaces such as skin, gills or the mouth oftentimes ends up in the gut. Therefore, we established an oral stimulation model with bacterial antigens to analyze the mucosal and systemic immune response as a model for salmonid fish

Methods: Fish were treated with a bacterial vaccine formulation either by intraperitoneal or oral vaccination. At different time points after vaccination peritoneal, blood, spleen and head kidney leukocytes were isolated and comparatively characterized by flow cytometry in target immune organs (gut, peritoneum) and effector immune organs (spleen and head kidney) labelled with a cocktail of lineage marker specific antibodies. Moreover, using the lineage marker specific antibodies the recognized cell populations were sorted at function related time points after stimulation. Finally, the mRNA was prepared form these isolated cell populations to characterize their mRNA profile

Results: A comparable kinetics of distinct leukocyte populations was seen after both oral as well as intraperitoneal administration especially in the targets immune organs.

Conclusion: The data indicates a similar stimulation of immune cells either after intraperitoneal and after oral vaccination and therefore the potential of the oral vaccination approach.

LETTUCE (*Lactuca sativa*, VARIETY SALANOVA) PRODUCTION IN DECOUPLED AQUAPONIC SYSTEMS

Hendrik Monsees[a], Johanna Suhl[ab], Maurice Paul[a], Werner Kloas[a,b], Dennis Dannehl[b] and Sven Würtz[a]

*E-mail: h.monsees@igb-berlin.de

Introduction

Decoupled aquaponic systems (Kloas et al. 2015, Monsees et al. 2017) have the potential to become one of the most effective sustainable production systems for the combined production of animal protein and plant crops. Here, recirculating aquaculture systems for fish production are combined with hydroponic systems for soilless plant production allowing individual management of each single compartment thereby recycling dissolved nutrients derived from metabolism of the fish. The aim of the present study was to compare a conventional hydroponic lettuce production with decoupled aquaponics using the nutrient rich fish water as basis for the nutrient solution being supplemented with missing nutrients. In addition, one aquaponic treatment became disinfected in order to assess any occurring benefits of the aquaponics derived fish water.

Material & methods

The experiments were conducted in a 75 m^2 compartment of an experimental Venlo-type greenhouse located at the Humboldt University, Berlin, Germany.

Briefl , three different treatments were applied in triplicates (Fig 1). Two nutrient solutions were prepared with fish waste water obtained from a recirculating aquaculture system rearing Nile tilapia (*Oreochromis niloticus*) and supplemental fertilizer. One nutrient solution was used directly for the experiments, whereas the other was disinfected before application. The hydroponic control was prepared with fresh tap water and rain water (50:50, v/v) and mineral fertilizer.

Results

The use of aquaponic fish water saved 62.8% mineral fertilizer and fully substituted the required fresh water for the nutrient solution in comparison to the control. No significant difference in growth of green open butterhead lettuce was observed. Additionally, the content of DOC/TOC as well as RAS derived microorganisms had no obvious positive/beneficial e fects on the growth and phenolic compounds of lettuce.

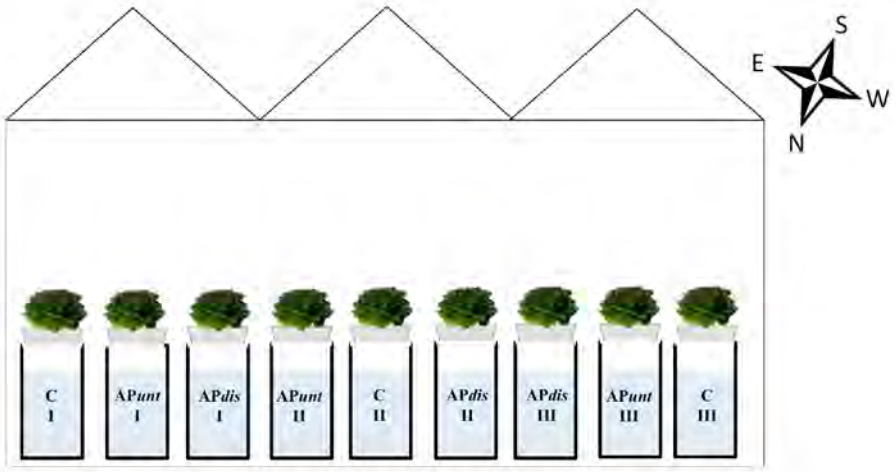

Fig. 1. Schematic description of the arrangement of the experiments. C = control, fresh water based nutrient solution; AP*unt* - untreatend aquaponics, fish water based nutrient solution with supplemented nutrients; AP*dis* - like AP*unt*, but fish water was disinfected before use. The three different treatments were applied in triplicates, each with ten individual lettuce plants.

(Continued on next page)

Discussion

The benefits of nutrient and water recycling caused by a combined production of fish and plants in a decoupled aquaponic approach were clearly shown in this study. The recycling of fish water resulted in a reduction of fertilizer application of nearly 63% and a complete substitution of freshwater which underpins the effective resource utilization in decoupled aquaponic systems. The post adjustment of the nutrient profile using fish water for professional hydroponic application was more challenging as in conventional hydroponics (with rain water or tap water) but it was demonstrated that for most nutrients the set points were reasonable close to the recommended nutrient concentrations as it was also shown in other studies (Suhl et al. 2016, Goddek and Vermeulen 2018). With ongoing professionalization and standardization of practices in decoupled aquaponic technology it is assumable that optimal nutrient profiles in decoupled aquaponic applications will be met with reasonable effort and comparable yields to conventional hydroponic production can be expected.

Additionally, the reduced fertilizer demand using decoupled aquaponics can contribute to reduce greenhouse gas emissions of an annual lettuce production site per ha by 72% due to saving the energy for fertilizer production.

Introduction

During the last years, attention has been focused on marine organisms as a source of substances of therapeutic interest for the prevention and prophylaxis of farmed fish diseases, augmenting host defense mechanisms (Harikrishnan et al., 2011). For this purpose, the ability of algae to produce secondary metabolites of potential interest as immunotherapeutics has been documented (Reverter et al., 2014). Thus, the present research intends to explore novel bioactive compounds produced by macro- and microalgae, assessing antibacterial and antiviral activities against the main bacterial and viral pathogens in aquaculture.

Material and methods

Three macroalgae species were evaluated, *Fucus vesiculosus*, *Gracilaria* sp. and *Ulva rigida*, and two microalgae species, *Nannochloropsis gaditana* and *Chlorella* sp. Algal extracts were prepared from freeze-dried biomass in four binary solvent systems: methanol/water, 80:20 v/v (M80:20); methanol/water, 50:50 v/v (M50:50); ethanol/water, 80:20 (E80:20) and ethanol/water, 50:50 v/v (E50:50).

The antibacterial capacity of algal extracts against the main bacterial pathogens in aquaculture was evaluated using the standard disk diffusion agar method. The most promising algal extracts were selected to determine their possible citotoxicity and antiviral activity. Citotoxity of 10 selected extracts was determined based on cellular morphologic alterations in established fish cell lines, epithelioma papulosum cyprini (EPC) and rainbow trout gonad (RTG-2). Based on the maximum non-toxic concentration (MNTC), antiviral activity of the previous selected extracts against two pathogenic virus, the Viral Hemorrhagic Septicemia Virus (VHSV) and the Infectious Pancreatic Necrosis Virus (IPNV), was assessed by the reduction of virus titers measuring the using Median Tissue Culture Infectious Dose (TCID50).

Results

Overall, *Ulva rigida* provided stronger extracts with broader activity, which suggests it may be richer in antibacterial compounds than the remaining macro- and microalgae covered in this study. However, *Fucus vesiculosus* provided the strongest extracts against *Photobacterium damselae* subsp. *pisicida*, one of the main pathogens in aquaculture.

The MNTC of the extracts in EPC ranged from 6250 μg ml^{-1} to 24 μg ml^{-1}. The least cytotoxic extracts were *Chlorella* sp. E80:20 and *Ulva rigida* M50:50, requiring higher concentrations to induce cytopathic effects. On the other hand, E80:20 extract of *Fucus vesiculosus* was the most harmful against this cell line. Regarding to RTG-2 cell line, the MNTC of the extracts ranged from 6250 μg $ml^{-1}$to 98 μg ml^{-1}. *Ulva rigida* M50:50 and *Chlorella* sp. M80:20 and E80:20 extracts were tolerated at higher concentrations, while *Fucus vesiculosus* E80:20 and M50:50 extracts were the most cytotoxic.

Regarding antiviral activity, *Fucus vesiculosus* E80:20 and M50:50 were the most efficient extracts against VHSV while *Gracilaria* sp. and *Nannochloropsis gaditana* were the most efficient extracts against IPNV. Although M50:50 *Fucus vesiculosus* extract was active at a seven-times lower concentration, it only weakly inhibited IPNV replication.

Discussion and conclusions

Results obtained from this study demonstrated that ethanolic and methanolic extracts of macro- and microalgae showed antibacterial activities against fish pathogenic microorganisms. In particular, algae extracted with M50:50 exhibited stronger antibacterial activity suggesting that the methanol as solvent is capable to extract more compounds with antibacterial action. In fact, organic solvents have been reported to provide a higher efficiency in extracting compounds with antibacterial activities compared to water-based methods (Biswas et al., 2013).

(Continued on next page)

Regarding antiviral activity, the totality of the extracts was active by pre-incubation with EPC or RTG-2 cells before infection, which suggests they may interact with or persist locally on the cell surfaces, preventing the virus replicative cycle. A similar profile of antiviral activity has been found with the rabbit antimicrobial peptide defensin 1 (NP-1), which protected cells *in vitro* from infection by herpes simplex virus type 2 (HSV-2) (Sinha et al., 2003).

This study has shown that macro- and microalgae have a great potential for further development as a promising natural source of bioactive compounds in aquaculture industry, since their potential viral and bacterial inhibitory effects against the main fish pathogens have been demonstrated

Introduction

The expanding aquaculture industry is essential as a source of food for a growing population. Whilst the industry is growing at a fast pace, it continues to face numerous challenges which impact on production potential and overall sustainability. Such challenges include provision of sustainable ingredients for feed production, tackling of diseases and reduction of environmental impacts. Solutions to these challenges typically require the performance of scientifically designed experiments having specific objectives. It can take multiple trials, sometimes over periods of years, before a solution can be provided for a particular problem.

Providing facilities to industry

ABT Innovia (ABTI), the research division of AquaBioTech Group, has been carrying out contracted research for internationally established clients for over sixteen years. The scope of the trials carried out have been very diverse, from the use of live-feed enrichment products for marine larvae to vaccine development, safety and potency (GMP Certification) for major farmed species.

ABTI continues to carry out nutrition trials involving fish feed ingredients, micro-ingredients and supplements, health associated trials related to vaccine development as well as dietary functional ingredients, and ecotoxicology (GLP certification)

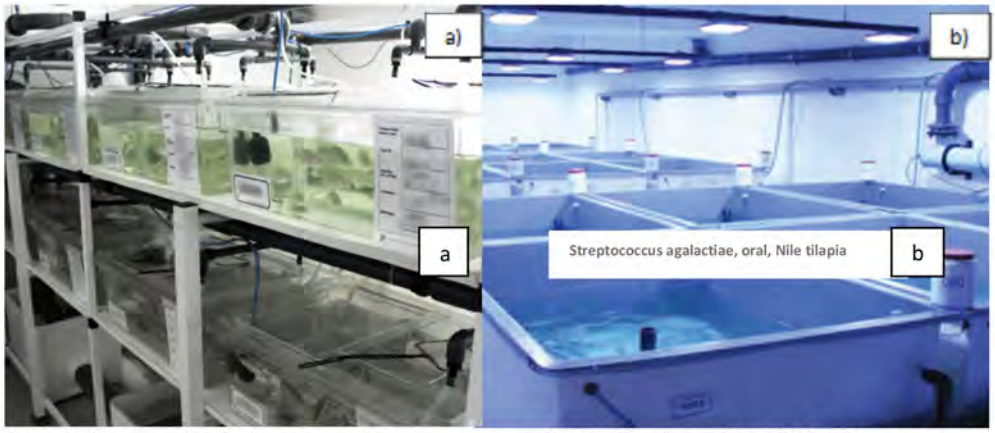

Plate 1: Two recirculating aquaculture systems at ABT Innovia. a) 16 x 40L tanks; b) 15 x 670L tanks.

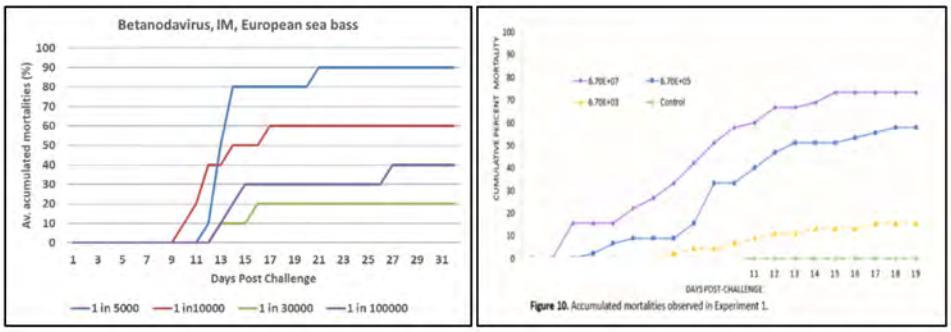

Fig. 1. Results of two challenge models established at ABT Innovia. a) VNN, European sea bass; b) *Streptococcus agalactiae,* Nile tilapia

(Continued on next page)

The majority of the trials carried out are based on recirculating aquaculture systems (RAS), with tanks having capacities ranging from 10L to 1500L (Plate 1). Over 40 individual, biosecure RAS units are available as well as a number of GLP and GMP certified labs used for microbiology ecolog , and ecotoxicology.

Both fresh water (e.g. rainbow trout, *Pangasius*, Nile tilapia, Salmon, barramundi) and sea water species (e.g. gilthead sea bream, European sea bass, Turbot) can be tested and the RAS can be cooled and heated as required for the species being tested. Environmental parameters in the tanks and systems are checked continuously by a monitoring system.

Standard operating procedures are applied during the handling of test organisms in the trials and for any samples taken for subsequent analysis. At the same time, ABTI continuously works to develop new procedures and models for use by companies (Figure 1), whatever the end application, be it research and development, GMP or GLP.

Providing solutions for industry

Through the use of ABT Innovia's facilities, many companies have been able to develop and commercialise solutions to specific problems in the industry. This has been the case for a number of diseases, feed formulation challenges and others.

ABT Innovia will continue to play an important role in industry research and development, more so as it expands further its tank and dry lab facilities and develops new procedures and models.

DEVELOPMENT OF FISH FEEDS AND FEEDING STRATEGIES FOR GENETICALLY SUPERIOR FISH FROM BREEDING PROGRAMMES

E-mail: daniel.montero@ulpgc.es

Introduction

Selective breeding means that individuals that are genetically superior in respect to economic, ecological and ethical breeding objectives are used as parents for the next generation. Several traits that may change genetically during breeding, such as growth, body composition and feed efficienc , also influence nutritional requirements of the fish, which ultimately determine feed formulations. The objective of the present study was twofold: **1)** To provide a conceptual framework, and its practical implications, for developing novel feeds and feeding practices for genetically improved fish originating from breeding programmes, and **2)** to review the degree of evidence that fish traits related to nutrition are expected to change due to breeding programmes.

Selective breeding changes fish traits related to nutrition and feeding

A fish trait can change genetically either when it is directly selected, or if it is genetically correlated with the selected trait. In both cases, the trait needs to exhibit genetic variation. Table 1 illustrates, for groups of traits related to feed utilisation, their potential to be changed by selective breeding.

How this impacts formulation of feeds?

The evidence shows that due to breeding programmes, genetic changes occur and are expected to occur in the fish traits that influence the nutritional requirements and the way feeds are formulated to obtain better growth and healthy fish. This should lead to reciprocal changes in the feed formulations and feeding practices (Figure 1).

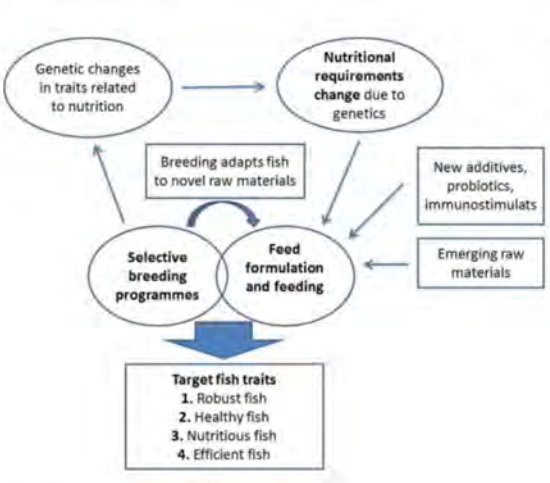

Fig. 1. The logic of how breeding programmes influence feed formulation.

(Continued on next page)

Four examples are highlighted here:
• When growth rate is genetically improved, fish can be reared for a shorter time period to obtain the same body weight. This requires a modified feed and/or feeding practices that account also for limiting factors at farms (e.g. oxygen concentration).
• Selection for growth, fillet yield, or lipid% itself changes lipid% of the fish body, and hence the amount of energy a fis needs for building tissues such as fillet is changed. Energy content of one g of lipid is 39.5 kJ/g, the cost of retention is 1.1-1.4 kJ / kJ, and the energy cost of depositing is 43.5-55.3 kJ/g lipid (Emmans 1994).
• The concentrations of fatty acids in fillets may reduce due to selection rapid growth, or increased lipid%, which may need to be counterbalanced by ingredients in feeds.
• Selection for better performance on plant-based diets permits formulation of more sustainable diets and more efficien utilization of novel dietary ingredients.

Implications for industry

Feed, feeding and genetics do not function independently but influence each other in a way that is important for aquaculture industry:
• Genetically improved fish may need tailo -made feeds that differ from the feeds for non-selected fish
• Feed development that utilizes modern fish material from breeding programmes ensure the synergetic effects of feeds and genetics for the benefit of farmers
• Advanced feeds do not provide the expected advantage for a farmer, if fed to inferior fish material not adapted to the feed.
• Selective breeding adapts the fish to the prevailing feeds and raw materials used. In the long-term, deficiencies in feed can be partly counterbalanced by selective breeding.

Introduction

Vaccination is a widely accepted and effective method to prevent *S. agalactiae* infection and mass mortalities in Nile tilapia, *Oreochromis niloticus* (Liu et al., 2016). Inactivated vaccines represent the majority of commercial vaccines currently used, with formaldehyde as the most common inactivation method (Munang'andu, 2014). Recently, the use of hydrogen peroxide as inactivating agent was tested in others species showing an improvement in the humoral and cellular response (Fan et al., 2019). In addition, adjuvants are often needed to increase the vaccine performance. Freund's incomplete adjuvant (FIA) and aluminum hydroxide (AH) are Signal 1 and Signal 2 type adjuvants respectively and are commonly used in fish vaccines (Tafalla et al., 2013). Thus, the objective of this study was to evaluate the effect of two adjuvants (FIA and AH) over the efficacy of an inactivated vaccine against *S. agalactiae* (inactivated with H_2O_2) and to determine their effects over hematological parameters in Nile tilapia fingerlings

Material and methods

Nile tilapia, *O. niloticus*, from the same spawn (20 g) were randomly distributed into six experimental groups (n=20), in triplicate. The experimental groups were designed as it follows: T1: vaccinated with inactivated *S. agalactiae*. T2: inactivated vaccine + AH. T3: inactivated vaccine + FIA. T4: AH. T5: FIA and T6: control group, none vaccinated (sham vaccinated with sterile PBS). Inactivation was performed with H_2O_2 following Fan et al., (2019) scheme and the adjuvant was added in 1:1 proportion. Tilapias were acclimatized for two months before the vaccination trial. On day zero, fish were vaccinated by intracoelomic injection (0.2 mL) with each vaccine type. Two and four weeks after vaccination (WAV), seven fish from one of the replicates were used to assess hematological parameters (red blood cells number, hematocrit, hemoglobin, and hematemetric values). Later, at 30 days post-vaccination, the remaining replicates (2) were challenged with *S. agalactiae* by intracoelomic injection of 0.2 mL from a bacterial solution containing 1.65×10^6 CFU ml^{-1}. Mortality after challenge was evaluated daily for 21 days, and relative percent survival (RPS) was calculated. Differences on hematological parameters between groups and sampling times were evaluated by one way ANOVA with Tukey's post test or Kruskall Wallis with Dunn's post test.

Results and discussion

Hematological parameters are shown in Table I. Significant differences between treatments were found for hemoglobin (T1-T2), and for MCHC (T1-T2, and T2-T5), in both cases at two WAV. Statistical differences between sampling times were found for hemoglobin (T2, T3 and T5), and MCHC (T2-T6). The RPS for the inactivated vaccine without adjuvant was 40.74%, while for the vaccine + AH was 59.26% and for the vaccine + FIA 77.78% (Table II). The results proved that the T3 vaccine was considered efficient (RPS>70%), while the other two were considered deficient (RPS<70%). The adjuvants alone conferred no protection; nevertheless higher protection was achieved when added to the inactivated antigens.

Discussion

Hematological alterations were mild and related to the vaccine + AH group, mild toxicity for AH has been related in some fish species and my explain these findings (He et al., 2014) as well as the lowest RPS obtained for the vaccine + AH when compared to vaccine + FIA.

Table I. Hematological parameters (mean ± standard deviation) of Nile tilapia two and four weeks after intracoelomic vaccination against *S. agalactiae*.

Group	T1	T2	T3	T4	T5	T6
Two weeks after vaccination

Different capital letters indicate significant differences between treatments and different small letters indicate differences between times (P<0.05).

Table II. Experimental design, mortality rates, percent survival and RPS in Nile tilapia fingerlings vaccinated with *S. agalactiae* inactivated with hydrogen peroxide, two different adjuvants and their combinations.

Treatment group	Challenge dose (CFU mL^{-1})	n	Fish mortality	Percent survival (%)	RPS (%)
T1	1,65x10^6	40	16	60.0	40.74
T2	1,65x10^6	40	11	72.5	59.26
T3	1,65x10^6	40	06	85.0	77.78
T4	1,65x10^6	40	29	27.5	-
T5	1,65x10^6	40	31	22.5	-
T6	1,65x10^6	40	27	32.5	-

A high RPS was achieved for the hydrogen peroxide inactivated vaccine + FIA (77.78%) similar to a *S. agalactiae* subunit + FIA injection vaccine (Zhang et al., 2017), but still below a recombinant vaccine + FIA (90%) (He at al., 2014). The combination vaccine + FIA proved to induce higher protection than vaccine + AH in agreement with previous results for *S. agalactiae* recombinant injection vaccines (He at al., 2014). Also, our results did not reach the efficacy found for a formaldehyde inactivated vaccine + oil adjuvant (Wang et al., 2018). Hydrogen peroxide inactivated vaccine + FIA induce high protection against *in vivo* challenge with *S. agalactiae*, though protection levels can still be improved. Hematological alterations induced by vaccination at early stages were not clearly evidenced, yet more research is needed to clarify the vaccine effects over other physiological parameters.

Introduction

Taste perception of sweet and umami stimuli in vertebrates is largely controlled by a family of G-protein-coupled receptors, the taste receptor type 1 (T1R) family, with three members that combine in heterodimers to form the taste receptors. The mammalian T1R1/T1R3 receptor responds to umami compounds such as amino acids, whereas T1R2/T1R3 is activated by sweet substances. In mammals, it has been well established that taste sensing in the oral cavity (taste buds) not only guides the consumption of foods, but the presence of taste receptors in specialized cells of the gastrointestinal tract (enteroendocrine cells) can also regulate digestive, absorptive and metabolic functions through gut sensing mechanisms (Alpers, 2010; Depoortere, 2014). In fish, however, very little information is available, particularly in species of aquaculture interest. We have previously cloned the full-length cDNA of five T1R genes in *Sparus aurata* (*sa*), including the specific heterodimer subunit of the umami taste (*sa*T1R1), three novel sweet taste duplicate genes (*sa*T1R2x, *sa*T1R2y, *sa*T1R2z) and the *sa*T1R3 gene common to both umami and sweet taste heterodimers. The objective of this study was to further characterize their functional properties and patterns of expression in both larval and adult seabream tissues.

Materials and methods

In order to functionally characterize this family of receptors we developed a stable Ca2+/reporter gene activity cell line assay (NFAT-Luc-HEK-293) to specifically examine the responses of the multiple *sa*T1R(s) heterodimers to amino acid ligands. On the other hand, gene expression of four T1R genes (*sa*T1R2x is not expressed, being likely a pseudogene) was examined through qPCR on different adult tissues to assess possible differences in the profile of tissue distribution. A qPCR analysis was also performed in whole larval tissues from 1 until 12 days post-hatching (dph), spanning life-stage transition from yolk-sac sustenance to exogenous feeding (initiated at 9 dph). To establish the tissue profile of gene expression in larvae, whole-mount *in situ* hybridization (WISH) was also performed to localize the expression of the four genes in pre- and post-exogenous feeding larvae (5 and 12 dph, respectively).

Results and discussion

Cotransfections of the reporter cell line with *sa*T1R1/R3, *sa*T1R2z/R3 and *sa*T1R2y/R3 heterodimers showed a dose-response activation of the putative (mammalian-homologous) umami and the two sweet receptors by several amino acid stimuli suggesting that, unlike mammals but similarly to what was previously reported in zebrafish and medaka (Oike et al., 2007), the three taste subunits may equally serve to transduce umami/amino acid taste sensations. Furthermore, the *in vitro* assays evidenced a fairly promiscuous activation profile of the three heterodimers, although with some differences in the sensitivity to some amino acids (not shown).

Gene expression in adult tissues (figure 1) showed a predominant expression in oral tissues including lips (L), tongue (T) and oral cavity (OC) for all genes, and in particular for *sa*T1R3, in agreement with its common involvement in the three receptor types. However, all the subunits were also found in gills (G), stomach (ST), foregut (FG), midgut (MG), hindgut (HG), forebrain (FB), midbrain (MB) and hindbrain (HB) tissues, even if with different profiles that might indicate a functional specialization.

Quantitative *sa*T1R(s) mRNA expression in whole seabream larvae (figure 2) showed that the four transcripts are stably expressed from 1 dph onwards and greatly increase shortly after exogenous feeding (initiated at 9 dph). WISH (figure 3) reveals the lack of expression of *sa*T1R(s) in oral tissues of both pre- (5 dph) and post- (12 dph) exogenous feeding stages, with the genes being expressed exclusively in the gastrointestinal tract.

These findings indicate an adaptive evolution of *sa*T1R gene repertoire towards amino acid perception, and provide a molecular/cell basis for both oral and gut chemoreception in seabream. Surprisingly, however, results in young larvae suggest only gut sensing capabilities. Studies are underway to determine the ontogenetic onset of *sa*T1R expression in oral taste sensing tissues, by examining later larval stages.

Introduction

Feed intake is a critical variable in aquaculture that limits growth and survival of reared animals. The inclusion of new raw materials in fish diets to meet cost-efficient production and sustainability goals may compromise the organoleptic quality of diets and, by extension, fish growth (Yaghoubi et al., 2016). Therefore, it seems reasonable to evaluate the fish s discriminatory capacity towards feed in order to discern the organoleptic preferences of aquacultured species. The goal of this study was to develop an experimental model to test feed discrimination in the gilthead seabream (*Sparus aurata*), an important species for Mediterranean seawater aquaculture.

Materials and methods

We set up a dual-choice feeding system using self-feeders activated by a string sensor placed 3cm below the water surface. Feeders were connected to a computer system that recorded the date, time and tank from which each feed demand originated (Leal et al., 2009). The feed reward per sensor activation was set at approximately 1g/demand. Initially, 500 juvenile gilthead sea bream of approximately 10g were maintained in two 2500 l tanks provided with self-feeding systems during eight months for accommodation and learning. Subsequently, animals (body weight around 100g) were transferred to eleven 500 l experimental tanks (n=10/tank) provided with a dual choice feeding system consisting of two string sensors, each activating a different self-feeder. During 28 days, all feeders were provided with a control diet (44% CP and 18% CF, containing 12.5% fishmeal) for accommodation to the experimental tanks, but especially to the dual choice feeding system (phase I). Subsequently (phase II), in four tanks, one feeder was filled up with control diet supplemented with quinine (1.5%, negative diet) whereas the second feeder contained the control diet. In other three tanks, the tester-feeder distributed a positive diet (isoproteic and isolipidic but containing 46% fishmeal, 6% squid meal and 6% krill meal) and the second feeder delivered control diet. Finally, both positive and negative diets were confronted in the remaining four tanks. After eight consecutive days, the position of feeders was switched in the tanks and animals were allowed to feed for further 21 days (phase III). At the end of the experiment, the total amount of feed distributed was calculated by weighing the feed remaining in the feed hoppers. This quantity was used to calculate the delivery rate for each electronic feeder. The amount of feed delivered daily was calculated using the feeder delivery rate and number of daily demands. The experimental tanks were inspected daily to ensure the absence of feed on the bottom. Consecutively, and utilizing the same animals from the previous experiment, an additional trial was set up to corroborate the feeding deterrent effect of quinine using a single feeder per tank for 14 days. Three tanks were fed with quinine-supplemented diet and four tanks with control diet. Feed intake levels were calculated as before.

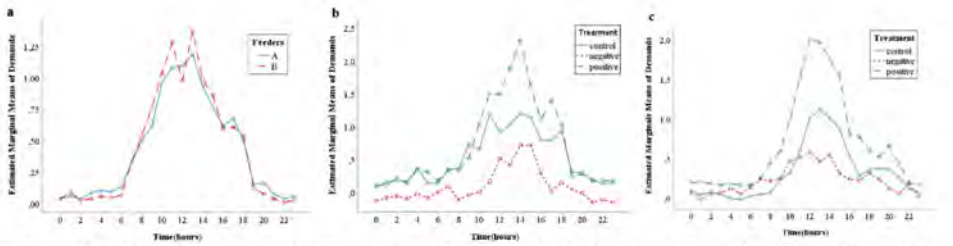

Fig. 1. Feeding demand profiles estimated during 24 h for a) phase I, b) phase II, and c) phase III (estimated marginal means are forecasted means in function of the independent variable).

(Continued on next page)

Results and discussion

During phase I of the dual-choice experiment, using a univariate general linear model that analyzes all sensors jointly, independently of the tank, no significant differences in feeder activation were found, thus demonstrating that fish demanded feed in a similar way independently of feeder. Sensor activation differed according to time (hour of the day), day and tank. It was demonstrated that fish exhibited a similar daily pattern of demands (figure 1a) in all sensors/feeders. Number of demands was different between tanks but also between the different experimental days, thus indicating the instability of feed intake (data not shown). During phase II, when experimental diets were introduced, we found significant differences in sensor activation, with the lowest values being measured in feeders provided with quinine-supplemented diet and highest demand levels being found in those containing positive diet (figure 1b). This demonstrated that fish exhibited preferences towards sensors coupled to feeders delivering positive diets but avoided feeders supplying a deterrent feed (provided by quinine inclusion), when compared to the control diet. Similarly to the accommodation phase (I), feed intake levels differed according to day and tank, but this time we also recorded significant differences in the 24h-feeding pattern. In this respect, the activation period of sensors delivering quinine-rich diet was narrower (figure 1b). Finally, in phase III when the position of feeders was inverted, fish continued to demand less from feeders delivering the quinine diet, and had higher demands from feeders supplying the positive diet. Results suggest that fish are able to discriminate the position of the feeder according to the type of diet delivered or, what is the same, they can discriminate the diet independently of the feeder position. Similar to phase II, feeder sensor activation differed according to day, tank and time (figure 1c).

Finally, using a different experimental set up in which animals were fed exclusively with one type of diet, either control or quinine-supplemented, we confirmed that, when presented with a diet containing quinine, gilthead seabream reduce their voluntary feed intake (data not shown), thus corroborating that the lower preference towards this feed, when an alternative feed is presented, is associated with a feeding deterrent effect.

Conclusions and future directions

Seabream exhibited variable feed intake levels along different days and fish groups/tanks but were able to discriminate the diet's organoleptic properties using a dual-choice self-feeding system. This opens the possibility to use the system to evaluate new raw materials in terms of feed acceptance/preference, as well as the potential of flavorings to overcome the negative effects of antinutritional compounds or medication on feed intake.

Introduction

Salmon Rickettsial Syndrome (SRS), caused by the gram-negative bacterium *Piscirickettsia salmonis*, is one of the most serious infectious diseases affecting Atlantic salmon production, causing significant losses due to its great associated mortalities (30-90% per outbreak) (Almendras et al., 2003). These outbreaks occur in the seawater stage of production where economic losses in relation to biomass constitute a greater impact. In addition to direct losses through mortality, there are indirect losses through reduced growth rates and anticipated harvests (Rozas & Enriquez, 2014).

One potential avenue to tackle SRS is improvement of host resistance using selective breeding, and potentially genome editing in the future. To achieve this, knowledge about the genetic basis of host response and identification of specific genes and pathways involved in that response is valuable. Therefore, the purpose of this research is to discover functional genes impacting on host resistance to SRS using RNA-Sequencing of head kidney and liver samples from a large-scale SRS challenge. Following on from this, CRISPR-Cas9 genome editing of high priority candidate genes will be assessed in cell culture using an in vitro disease challenge with comparison to unedited control lines.

Materials and methods

2,377 Atlantic salmon (*Salmo salar*) smolts from 104 families were challenged against SRS infection by intraperitoneal injection with mortalities recorded for 47 days post infection (dpi). Mortality, days to death, weight and length data was collected daily and fin-clips samples were obtained for genotyping. Head kidney and liver samples for RNA-seq were obtained from a subset of individuals at 3 and 9 dpi. RNA-seq libraries were obtained using the Illumina Truseq stranded mRNA kit. Differential expression (DE) analyses were performed in R v.3.3.1 using the Bioconductor package DESeq2 v.3.4 (Love et al. 2014).

Results

RNA sequencing revealed a clear response to the pathogen in both head kidney and liver (Figure 1), with control, 3 dpi and 9 dpi samples clearly clustered separately (especially in liver) by the first principal component, which explains a large percentage of the variation in gene expression. Differential expression analyses revealed extensive regulation in head kidney in response to SRS, with 4,835 and 4,562 differentially expressed genes at 3 and 9 dpi respectively, while the values observed on the liver transcriptome were lower, with 1,192 and 2,431 differentially expressed genes at 3 and 9 dpi respectively. KEGG enrichment analyses revealed up-regulation of several immune pathway in both tissues, such as "TNF signalling pathway", "Toll-like receptor signalling pathway" or "Complement and coagulation cascades". Particular pathways identified as crucial for the host immune response against SRS were further evaluated, and key genes were selected for further functional studies to analyse their potential use for genome editing (Table 1).

Discussion and Conclusions

Current results have allowed the identification of genes and pathways that are important in host response to *Piscirickettsia salmonis*. A list of candidate genes putatively related to disease resistance was obtained by the analysis of pathways of differentially up-regulated genes during infection. Literature review of the biological function of these candidate genes highlighted the most suitable candidates for functional studies.

NEW HEX-X LINE DRUMFILTERS FOR WARM SALTWATER APPLICATIONS AND END OF PIPE SOLUTIONS

MSc. Biology, Henrik Mortensen

CMAQUA Technologies

Marine aquaculture is expanding as new and valuable species now can be domesticated. Farming of marine species are not easy and it is also a challenge to build RAS with equipment which can last under this very corrosive environment.

HEX filters are build with a view of high corrosion resistance, using high density PE, PVC and POM as main components. The new platform for construction of drumfilters is based on the **HEX-X** versions, where even large drums are constructed of a durable polymer formed as an **X** giving strength to the drum, both for the dynamic and static loading.

Resulting sludge from the backwash process from **HEX-X filters,** in various applications, needs to be concentrated to ease handling and the use of concentrated sludge. Sludge from saltwater installations are more difficult to treat than corresponding freshwater farms, a separation beltfilter system with a three chamber system is a possibility to treat the waste in an effective and safe process.

REPLACING FISH MEAL WITH DEFATTED INSECT MEAL (YELLOW MEALWORM *Tenebrio molitor*) IMRPOVES THE GROWTH AND IMMUNITY OF EUROPEAN SEABASS (*Dicentrarchus labrax, L.)*

C. Motte[1], M. Henry[2]

morgane@hcmr.gr

Introduction

This study was undertaken on behalf of Ÿnsect (France) by the Hellenic Centre of Marine Research (HCMR, Greece). The aim of this study was to assess the effect of 2 doses of dietary insect meal on the immune system of sea bass, *Dicentrarchus labrax, L.* This was achieved by feeding the fish for 2 months with a diet close to commercial diets and based on fishmeal and 2 diets where 30 or 100% of the fishmeal (TM30 & TM100 respectively) was replaced by a defatted meal of *Tenebrio molitor* larvae produced by Ÿnsect. The growth was assessed after 2 months. The digestibility of the 3 diets was assessed by collecting fish faeces for 2 weeks at the end of the growth period. The immune system was assessed using the fresh blood and serum collected after 2 months feeding. Also, fish resistance to disease was compared between fish fed the different diets.

Material and methods

European sea bass were obtained from Selonda (Psachna, Evia, Greece) and were kept in cylindrical 250 l-tanks for 1 month and fed 4 times daily with a commercial diet. Then, groups of 110 fish of initial weight 3.98 ± 0.04 g were anaesthetized using clove oil (diluted 1:10 in ethanol), weighed and randomly distributed in 9 cylindrical 250 l-tanks in an open-circulation sea water system following a photoperiod of 12L:12N (Fish density at 1,8 kg/m3). After 20 days, fish were weighed and 40 fish were removed from each tank to remain with 70 fish/tank (fish density at 2.1 kg/m3 at 21 days and up to 9.4 kg/m3 at the end of the experiment, after 65 days). Water temperature ranged from 25-27ºC.

After 9 weeks of feeding, 8 fish from each tank were anaesthetised and blood samples were collected by a caudal puncture. A histopathology procedure was carried out to assess gut health. Sixty fish per group were kept for an additional challenge test with an important pathogen in marine fish: *Vibrio harveyi.* The cumulative mortality and syndrome score were measured over 10 days.

Figure 1 Feed Conversion Ratio and the Weight Gain after 9 weeks of feeding trial (n=70)

(Continued on next page)

Results

Both the TM30 and TM100 diets improved feed efficiency and weight gain when compared to the control group. The best results were obtained at TM30, with a weight gain of +13.7% higher than the control (29.2g vs 25.7g) and the Feed Conversion Rate (FCR) was significantly lower (-7%). After 9 weeks, the lowest FCR was 0.77 for TM100 and 0.87 for CRTL, a reduction of 11.5%. The Total feed intake was similar between all the treatment groups.

TM30 and TM100 reduced the appearance of abnormal intestinal villi in the gut from 5 in the control group to 2 (n=15). Gut health was improved. During the challenge test, TM30 showed a reduction of cumulative mortality by 45% (TM30: 18.3% vs 33.3% in the control). The symptom scores also showed a similar pattern.

Conclusion and discussion

The dietary meal obtained from *Tenebrio molitor* used to replace partially or totally the fishmeal (69% crude protein content) in diets for European sea bass resembling the commercial type feed with 30% FM and plant proteins with supplementation of some amino acids was very promising. Fish feeding on diets where FM was totally replaced by the insect meal (TM100) showed higher respiratory burst activity and lower trypsin inhibition, while their resistance to *Vibrio harveyi* infection was not affected. Fish fed on diets where FM was partially replaced by insect meal (TM30) tended to resist better to *Vibrio harveyi*. Similar results have been assessed on red seabream (*Pargus major*) when high proportions of yellow mealworm defatted meal were included (Idol et al. 2019).

Introduction

Genetic technologies play a crucial role in modern aquaculture. Genetics can determine a range of production characteristics linked to product marketability (desired color, shape, etc.), cultivability, disease resistance to monitoring and preserving the wild populations. In genetic analysis, it is important to distinguish if genetic differentiation of a given trait of interest for production is a consequence of individual or populational genetic variation. In this study we investigate the genetic structure of different population of *Sparus aurata* and *Dicentrarchus labrax* reared in Mediterranean hatcheries.

Materials and methods

97 samples of *D. labrax* and 218 samples of *S. aurata* were collected during 2018 from Mediterranean hatcheries. Specificall , *D. labrax* samples were collected from 10 Greek and 3 Italian hatcheries and *S. aurata samples* were collected from 8 Greek, 6 French and 8 Italian hatcheries. DNA extraction was carried out based on Aljanabi's protocol (Aljanabi and Martinez, 1997). For the microsatellite analysis, we used 4 validated primer sets to amplify 4 microsatellites for each of the species. Sequencing reads were performed in an ABI 3730XL and the output collected for genotype using GeneScan. The Structure program was used to infer the number of sea bream and sea bass populations (K) in the collected samples by plotting the second order of change of L(K) (Δ(K)) as described by Evanno and colleagues (2005). Phylogenetic analysis was carried out using the R phylogenetic package APE, and was based on the pairwise Fst values for every locus, which was extracted using the MSA 4.05 program.

Results

No clustering according to geographic location was observed in the phylogenetic tree of the *D. labrax* samples (Figure 1). The samples were grouped into two clades, which contained a mix of sea bass samples from Greek and Italian hatcheries. In contrast, two main groups were identified in the phylogenetic tree for the *S. aurata* samples (Figure 2). Group 1 consists exclusively of *S. aurata* from Greek hatcheries, while in group 2 a mix of *S. aurata* from both French and Italian hatcheries were identified. Analysis of the structure of group 2 revealed that the *S. aurata* from French hatcheries clustered in one clade, while *S. aurata* from Italian hatcheries clustered in a second independent clade. Finally, samples from one Greek hatcheries (GR3) was highly divergent from the other clades.

Best K values, calculated by plotting the second order of change of L(K) (Δ(K)), indicated K=2 for *D. labrax* and K=5 for *S. aurata*. Plotting the q-values for each of the individual *D. labrax* samples analysed indicated that the fish are most likely descended from two populations and in most cases reflect the genetic structure of that population (Figure1). In contrast, the *S. aurata* q-value plots were characterized by an admixture patterns. However, the q-value pattern differed between the different groups identified by the phylogenetic tree (geographical) populations (Figure 2)

Discussion

The diversity of fish farms and production tactics means that knowing the population structure is a difficult task, since frequently in fish farms the broodstock may be of unknown origin, there is frequently exchange of eggs and juveniles across the Mediterranean, crossbreeding with wild individuals occurs and breeding programs may be company specific. The results of the present study revealed that two main groups of *D. labrax* were under production in the hatcheries that participated in the study and these results probably indicated that two distinct populations of different origin are used. Moreover, the population structure analysis suggests that there is minimum genetic flow between these two groups. The case of *S. aurata* is more complex and the phylogenetic analysis revealed two main groups (one with the Greek samples and one with French and Italian). The population structure of *S. aurata* in both groups was characterized using the q-value to have an admixture pattern similar to what is observed in hybridization zone patterns. The population pattern of the *S. aurata* could be the result of a combination of an extensive exchange between breeders and selective breeding programs.

Introduction

Eels are the commercial fish in Indonesia, and at least seven species of eels have been recorded in Indonesian waters where three species of these were found in Aceh Province waters (Sugeha et al. 2006; Muchlisin et al. 2017). The tropical shortfin eel *Anguilla bicolor* is one of the promising species to be cultured intensively Muchlisin, 2013), and the local farmers have been initially cultured this species. But the local farmer claims that in the aquaculture system the growth performance and feed utilization were higher and therefore the profit margin was low. Probably, this is caused by the feed quality of the fish does not meet the needs of the fish. The probiotic and papain enzyme are the promising materials required to enhance digestibility of the feed and trigger the growth rate of the fish Therefore, the objective of the study was to evaluate the application of the probiotic and enzyme in the diet for eel fingerling.

Materials and methods

A completely randomized design with three levels of treatments were used in this study. The tested treatment is the application of probiotic and papain enzyme and its combinations with three replications as follows: (A)= Commercial feed without probiotic and papain enzyme, (B) = Experimental diet without probiotic and papain enzyme, (C)= Experimental diet with probiotic 10 ml kg^{-1} of feed, (D)= Experimental diet with papain enzyme 10 g kg^{-1} of feed, (E)= Experimental diet with probiotic 10 ml kg^{-1} of feed + papain enzyme 10 g kg^{-1} of feed, (F)= Experimental diet with probiotic 5 ml kg^{-1} of feed + papain enzyme 5 g kg^{-1} of feed.

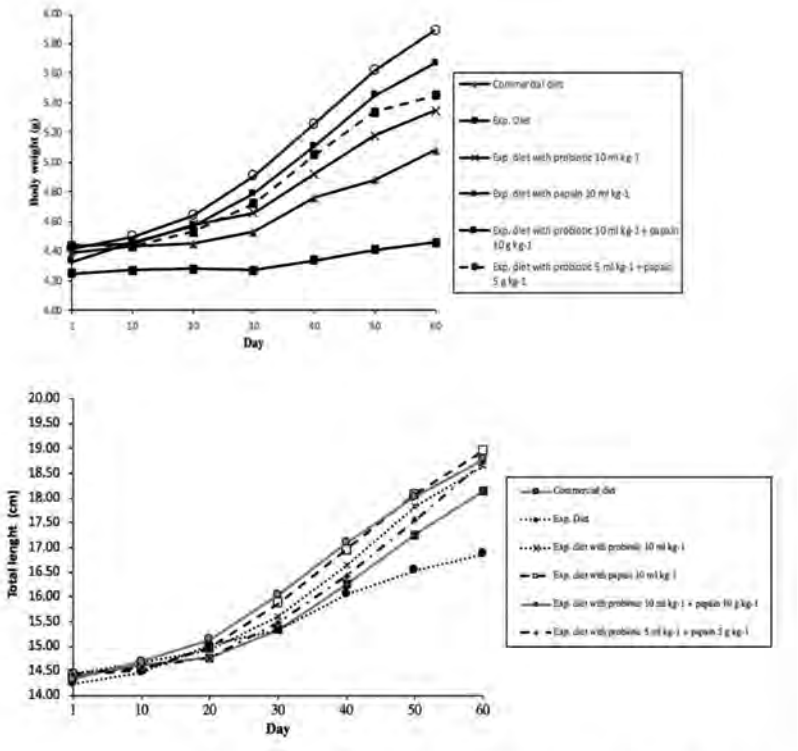

Figure 1. The growth trend of the eel during experiment (a) body weight growth, (b) total length growth

(Continued on next page)

The experimental diet was formulated from raw materials purchased from the local market in Banda Aceh City, Indonesia. It had 30% crude protein and 15% lipids. The raw materials are both animal and plant-based protein source, i.e. fishmeal, ebi shrimp meal, golden snail meal, blood meal, soybean meal, cornmeal, tapioca flou , and fine bran. The commercial probiotic of Raja Lele® containing Lactobacillus bacteria and papain enzyme flour was used. These materials were purchased from the local market in Banda Aceh City. The probiotic or papain enzyme was mixed with 5% egg yolk in the 100 ml distilled water, then sprayed onto experimental diet homogenously, then left for 30 min at room temperature before used for feeding. The fish were fed on a commercial diet two times a day at 08.00 AM and 06.00 PM for satiation during acclimatization process. It was distributed randomly into 18 plastic containers (vol. 25 L) which have been equipped with aeration at the stocking density of 15 fish per container. Individually, The fish initial body weight and total length were measured before been fed on an experimental diet of 10% of their body weight two times a day at 08.00 AM and 06.00 PM for 60 days. The data of every replication was calculated for average value then subjected to one-way Analysis of Variant (ANOVA) then followed by Duncans multiple range test. The percentage of data are arcsin transformation to normalize the data prior to analysis. The analysis was performed using the SPSS software ver. 22.0

Results

The results showed that the weight gain ranges between 4.6 g to 5.9 g with a daily growth rate of 0.06 g day^{-1} to 0.09 g day^{-1}, specific growth rate ranges between 0.72 % day^{-1} to 1.35 % day^{-1}, survival rate ranges between 50% to 73.3%, feed conversion ratio was 4.17 - 2.35, and its efficiency was 41.82 - 58.98%. The ANOVA test revealed that application of probiotic and papain enzyme gave a significant effect on the growth performance, survival rate and feed utilization of the tropical shortfin eel *A. bicolor* ($P<0.05$).

The Duncan multiple range tests showed higher weight gain, daily growth rate, and specific growth rate were found at fish fed on an experimental diet with 10 g kg^{-1}papain enzymes, these values are significantly different with other treatments. In addition, the higher feed conversion ratio and efficiency were also recorded in fish feed on the experimental diet with 10 g kg^{-1} papain enzyme. Moreover, the higher survival rate was also found at 10 gkg^{-1}papain enzyme, but this value was not significantly different from other treatment except to control B (experimental diet with probiotic or papain enzyme). Based on the body weight by 10 days interval, regular monitoring showed that the experimental fish are slow growing during the first 10 days with the body weight of the fish decreased and it consumed less of the experimental diet without probiotic and papain enzyme. However, the fish starts to grow after 10 days of the experiment. The fish that fed on an experimental diet with papain enzyme 10 g kg^{-1} feed was growing faster than other treatment (Figure 1).

Discussion and conclusion

The study showed that application of probiotic and papain enzyme results in the positive effect on the growth performance, survival and feed utilization of the eel *A. bicolor*, this is indicated by the higher value of these parameters compared to control treatments (without probiotic or papain enzyme). In comparison between probiotic and papain enzyme, the study revealed that papain enzyme produced better values of all measured parameters. However, when combined with probiotic at two different dosages, the results were decreased gradually. Therefore, this study shows that the application of the papain enzyme singly produces better results in eel *A. bicolor*. Papain is a proteolytic enzyme that functions to catalyze or breaks the protein into smaller fragments such as peptides and amino acids that can be absorbed by the intestine (Amri and Mamboya, 2012), while Lactobacillus is one of the probiotic bacteria that increase the digestibility rate and immune system of the fish (Feliatra et al., 2018). Lactobacillus hydrolyze the carbohydrates to lactic acid; then lactic acid will create an acidic condition in the digested tracts. In acidic conditions, Lactobacillus has the ability to inhibit pathogenic bacteria (Delgado et al. 2001). As already described previously that probiotic and papain enzyme produces a positive effect on the fish health and growth. However, the performance of probiotics is lower than papain in eel fingerling as reported in this research data. This is probably due to the fact that probiotic bacteria is a living organism that requires the energy sources for growing and produces byproduct materials such as carbon dioxide that is toxic for the cells [24], and in higher density (overgrow) results in the negative effect on the host (Dukowicz et al. 2007). Enzyme is a biological molecule (protein) that functions as catalysator and helps a complex reaction in the body (Cooper et al. 2000), therefore there is no side effect on living organism. In conclusion that probiotic and papain enzyme gave a significant effect on the growth performance, survival rate and feed utilization of the tropical shortfin eel *Anguilla bicolor*. The best results were discovered in fish fed on an experimental diet with papain enzyme 10 g kg^{-1} of feed.

The future of sustainability relies heavily on effective resource management. This includes utilising biomass in means and ways that have not been conceived of previously. Every year, green seaweed (*Ulva* spp.) blooms around our coasts, creating biomass that could be used as a supplement in fish feeds, potentially promoting gut health and integrity, stimulating appetite and feed utilisation, or illicit an immune response. The extraction of this biomass reduces the environmental burden on our coasts and reduces the carbon footprint associated with intensive fish farming. However, this raw product requires processing to unlock oligosaccharides bound in large complex carbohydrate units. These fractions can be used as a bioactive instrument to enact changes in the fish s digestive system, where some fractions provide nutrients and others challenge adaptive responses. The presence of beneficial bacteria within feed can also alter the gut microbiome and aid digestion. This study consolidates recent advancements in saccharification and fermentation while developing the most prudent processing measures that can efficiently scale. Key innovations, which include; novel bacterial lyase to break down structural polysaccharides that restrict access for further degradation; thermal treatment to both extract structural polysaccharides and kill naturally occurring decomposing agents; enzymatic hydrolysis to release oligosaccharides from large carbohydrates; and lactic acid fermentation to fully utilise the carbohydrates of the biomass thereby increasing the bioavailability of nutrients and provide a probiotic culture. These preliminary processes are intended to stabilise and confer enhanced seaweed properties in fish feeds.

THE REASONS BEHIND THE ESCAPES OF *Sparus aurata* FROM MADEIRA ISLAND (PORTUGAL) FISH FARMS - RISK ASSESSMENT THROUGH THE ANALYSIS OF ARCHIVE DATA

Introduction
Offshore fish farming is a well-established industry in southern Europe and the gilthead seabream *Sparus aurata* the most commonly farmed fish species. Around Madeira, an archipelago situated in the North Eastern Atlantic, the species was recorded in the wild shortly after offshore farming started in 1997. Escape-events from fish farms are most likely the reason for the introduction of *S. aurata* to the waters of Madeira. Many factors are involved in escape events. Large scale escape incidents are related to the formation of holes in the net cage, which can be caused by rough sea conditions (e.g. storms), but also through predator attack and the net-biting activity of the farmed fish. Fish farms monitor regularly the condition of the farming facilities, particularly the nets and observed damages are recorded in archive files

Materials and Methods
Historical archive data from 2018 and 2019 collected from fish farms on Madeira Island in Calheta, Caniçal and Ribeira Brava. The data was obtained from regular inspection dives around farming facilities and related with associated operational data (age of nets and time in water, transfers of fish, information on stocks, other), the weather and sea conditions recorded at the time.

Results
Preliminary analysis of data revealed trends of high number of net holes associated with rough sea conditions. Detailed data analysis of present material has yet to be performed and results to be presented at conference may provide information on the most relevant causes of escape events from Madeiran fish farms.

Introduction

Artificial spawning (AS) (or tank spawning) is a simple way of fish propagation. It can be induced by hormonal administration or the manipulation of the ambient water parameters (i.e. temperature, light regime, water conductivity). Many economical important fish species are produced by AS due to several reasons. First of all in case of the hard predictability of the ovulation time (european eel, pikeperch) the small size or sensitiveness (zebrafish), or its simplicity (spawning in pond or cage). In contrast *in vitro* fertilization (IVF) is a better tool for breeding programs, egg and sperm can be manipulated (cryopreservation, producing triploid fish) cross breeding of different lines and species (intra and inter specific hybrids) can be made in several combination. In our former studies (Müller et al., 2018a,b, 2019), we proved that sperm injected into the ovary by catheter through the oviduct 10-12 hours before hormonally induced ovulation, retains its fertilizing capacity for several hours. Using this method, we produced viable larvae via in vitro fertilisation. The aim of this study was to investigate the time-dependent fertilizing capacity of sperm which were introduced into ovary in African catfish as model fish

Materials and methods

Experiment I. Sperm samples (2 mL sperm / bodyweight kg) were incubated in gonad lobes 5, 10, 15, 20, 25, 36 and 48 hours before the gamete stripping. Ovulation was induced by extracted carp pituitary (CPE) hormonal administration (5 mg CPE / BW kg). Stripped and mixed gamete batches were fertilised through activation with aerated water. Five minutes after the water activation, three samples of eggs were collected from each batch and incubated in a Petri dish at 25°C.

Experiment II. Three different inseminated sperm dosages were tested on fertilisation from the same pooled sperm batch; 2 mL, 1 mL and 0.5 mL sperm volume / BW kg. Ovulation was induced by 5 mg CPE / BW kg. Stripped and mixed gamete batches were fertilised through activation with aerated water. Five minutes after the water activation, three samples of eggs were collected from each batch and incubated in a Petri dish at 25°C.

Results

Experiment I. There were no statistical differences ($p<0.05$) among the hatching rates in the 5-25h treatment groups, but we observed large individual fluctuations in fertilisation and hatching rate within the groups. However, at 48 hours the treated group showed low fertilisation and hatching rate indicating loss of fertilizing capacity.

Experiment II. The 0.5 mL sperm dosage showed statistically ($p<0.05$) higher fertilisation and hatching rate indicating that small milt volume was enough to apply for propagation.

Discussion and conclusion

Our improved method can combine the simplicity of induced spawning, with a less time-dependent delivery of the sperm compared to conventional in vitro fertilisation. An advantage of ovarian lavage with sperm and hormone preparations could also be in the fields of aquaculture management where it is important to maintain or increase genetic diversit .

MARKETING OPTIONS ASIDE FOOD FISH PRODUCTION - APPLICABILITY OF RAS DERIVED PIKEPERCH (*SANDER LUCIOPERCA*) AS STOCKING MATERIAL FOR OPEN WATER BODIES

Andreas Müller-Belecke*, Steffen Zienert

Institute of Inland Fisheries Potsdam-Sacrow, Im Königswald 2, D-14469 Potsdam, Germany
Email: andreas.mueller-belecke@ifb-potsdam.de

In several Northern and Central European countries the pikeperch (*Sander lucioperca*) is well known and a highly estimated native food and game fish. It is not surprising, that research and industry intend to establish the pikeperch as an aquaculture candidate (Zienert and Heidrich 2005, Müller-Belecke and Zienert 2008, Brämick et al. 2014, Mylonas and Robles 2014, Steinberg et al. 2018, Zarki et al. 2019). Weaning to artificial dry feeds and production of 5–10g fingerlings within a period of less than three months is accomplished in first commercial hatcheries. Fattening to approx. 1 kg can then been achieved in recirculation aquaculture systems (RAS) at constant temperatures of 22-24°C within about one year. Meanwhile in several European countries pikeperches are produced in RAS at a commercial scale. Nevertheless, when targeting on the food fish market, most of the RAS-farmers suffer from comparably high production costs and concurrence from capture fishery derived pikeperch, imported frozen for low prices, predominantly from the Russian Federation and Kazakhstan (FAO 2019). Marketing individuals alive for stocking issues can be a promising, highly-paid alternative of an often underestimated volume (Pagel and Arlinghaus 2016). The aim of the present study was to evaluate whether pikeperches, intensively produced in RAS on basis of artificial dry feeds, are capable to readapt to their natural feeding basis and survive and grow after been stocked into adequate open water bodies.

In a first approach, five groups of RAS derived pikeperches of different initial mean weighs were stocked in predator protected, static 20m³ outdoor tanks at approx. 20°C together with adequately sized prey fish (*Rutilus rutilus*). After three weeks, the growth performance of the pikeperches and the decline of the offered prey fish biomass was analysed (Tab. I).

Tab. I: Growth performance of five pikeperch groups of different initial mean weights, stocked together with prey fish for three weeks

Stocked pikeperches				**Stocked food fish**		
No. (n)	Initial weight (g)	Output weight (g)	Increment (%)	Initial weight (g)	Output weight (g)	Decline (%)
20	149	170	14	2300	0	100
10	329	396	20	2100	390	81
10	739	715	-3	3640	440	88
8	1103	1129	2	2850	1540	46
5	1946	1811	-7	1700	1020	40

In all five groups, the declining prey fish biomass indicated a fast readaptation potential of RAS derived pikeperches back to life prey fish. Nevertheless, as their body weights stagnated or even decreased, the pikeperch groups of higher initial mean weights seemed to need more effort to readapt.

In a second approach, two summer-turbid flatland lakes (Bauersee, 20ha; Herrensee, 16ha), inhabited by self-recruiting pikeperch populations, where stocked with RAS derived, individually PIT-tagged pikeperch of 280g (n=12 per ha) and 560g (n=5 per ha) in late spring. Approx. 490 days later, after two summers of growth, recapture traits where conducted by trawl nets. Recapture rates, mean weight gains and specific growth rates (SGR) of the recaptured individuals are shown in Tab. II.

Tab. II: Recapture rates, specific growth rates (SGR) and mean weight gains for RAS derived pikeperches after two summers of growth in two natural lakes

	Stocked with 280 g	**Stocked with 560 g**
Bauersee (20ha)		
Recaptured after 2 summers	1.50%	2.00%
Mean weight at recapture	1081g	1587g
SGR d0 - d487	0.25%	0.24%
Weight gain d0 - d487	759g	897g
Herrensee (16ha)		
Recaptured after 2 summers	3.80%	5.00%
Mean weight at recapture	1127g	1397g
SGR d0 - d492	0.26%	0.26%
Weight gain d0 - d492	815g	880g

The recaptured pikeperches in both lakes and both size classes showed weight gains and SGR as expected among natural conditions in Northern Europe (Ložys 2004, Pérez-Bote and Roso 2012).

The obtained results indicate that RAS producers can market their pikeperches as stocking material for open water bodies with good conscience. Especially fish in size classes up to approx. 500g easily readapt to their natural food source and show potential to survive, grow and establish among natural conditions.

The study was supported by EU funds and funds from the Federal State Brandenburg.

In aquaculture the consideration and documentation of animal welfare increasingly gains importance. Compliance with animal welfare in husbandry practices is a socially demanded principle in Europe and for many consumers a non-material criterion for purchase decisions. The aim of the research project was the development and verification of an index based model for the documentation of animal welfare in pikeperch, kept in recirculation aquaculture systems (RAS). The index model, combining several meaningful welfare parameters, can provide a basis for future certification standards. Otherwise it can represent a tool which allows pikeperch producers to present their approaches and results of animal welfare consideration transparently, without certification costs, to consumers, fishery and veterinary authorities.

In a first step ca. 50 potential indicators for animal welfare were grouped for the sections „environment“, „stock“ and „individual“ and evaluated with regard to their explanatory power as well as practicable and confident assessment. For the 18 indicators finally included in the model, practice-orientated levels were defined. Indicator scores, weighting scores, weighting factors and relative weighing factors were derived, following the procedures described by Stien et al. (2013) and Pettersen et al. (2014) to generate their Salmon Welfare Index Models SWIM 1.0 and 2.0.

The developed index model was tested in example surveys in RAS for pikeperch production in Germany. During on-site visits of eight RAS, the operators were informed about the background of the project and the intended procedure within about half an hour. Information needed to evaluate the section „environment“, using environmental parameter mean values from the last month of production, could be obtained within about one hour. Evaluation for the section „stock“ by observation of three separate rearing units and for the section “individual“, examining 10 randomly selected individuals could be conducted within about one hour. Thus, within a reasonable period of time it was possible to collect in-depth knowledge on the reared pikeperches welfare status among on-farm conditions. Tab. I shows the calculated welfare indexes for the different sections and the resulting weighted totals obtained from example surveys.

Tab. I: Pikeperch welfare indexes obtained from example surveys in eight RAS production sites

Section	Production site							
	1	2	3	4	5	6	7	8
„Environment“	1.00	1.00	1.00	1.00	0.96	0.77	0.96	0.91
„Stock“	0.89	0.97	1.00	0.89	0.92	0.88	0.97	0.76
„Individual“	0.97	1.00	1.00	0.96	1.00	0.98	0.97	0.91
Total	**0.95**	**0.99**	**1.00**	**0.95**	**0.96**	**0.89**	**0.97**	**0.87**

The practitioners included in the example surveys evidently placed great value on providing close to optimal rearing conditions for their fish. The examined stocks and individuals showed a correspondingly good condition. At site 6 with a suboptimal pH, slightly increased ammonium and quite high nitrate concentrations several environmental parameters were outside the defined optimum ranges. Despite suboptimal

environmental conditions, the condition of the individuals was close to the optimum. The example surveys finally proved the applicability of the index model for welfare assessment, basing on a methodologically uniform, objectively recorded data basis.

An effect of high stocking densities on the condition of the examined individuals could not be determined during the example surveys. Thus, at site 6, individuals stocked with 110kg per m^3 showed a comparable condition to individuals kept under identical environmental conditions at 60kg per m^3.

Future surveys in further intensively reared pikeperch stocks should be conducted to examine whether a correlation between individual size and eye condition can be manifested. In the example surveys, individuals with lens opacities were more likely to be found in stocks with large individuals than in stocks with smaller fish. Physically plausible, the scales, becoming rougher with increasing size, as well as stronger frictional forces in body contacts between large individuals could justify this observation.

The study was founded by the German Federal Ministry of Food and Agriculture (support code 2817900115).

Processing freshwater fish results in around 50% of by-products with potential for reutilization as fish feed ingredients. Especially in small-scale operations, corresponding by-products are accumulated in low amounts throughout the whole year and have to be protected from spoilage. As deep freezing demands a high input of energy and equipment, approaches to ensilage fish processing by-products by acidification were tested and successfully established. Ensilaged fish processing by-products can now be stored long-term in a sustainable way, until sufficient amounts for centralized transports to fishmeal-plants were collected. The present project stage aimed on the evaluation of fishmeal, derived from ensilaged freshwater fish processing by-products (fish-silage meal) as ingredient for rainbow trout (*Oncorhynchus mykiss*) diets.

Six 1.3m³-tanks of a laboratory scale recirculation aquaculture system were stocked with each 60 rainbow trout with initial body weights of 236±33g (MW±SD) and fed with two diets in 3 replicates per diet close to saturation at rearing temperatures between 13°C and 15°C for 112 days. The control diet (control) as well as the experimental diet including 50% of fish-silage meal (FSM) contained 48% of crude protein and 17% of crude fat. As indicated in Tab. I the fish receiving FSM showed a comparable or even slightly better performance than the individuals fed with the control diet.

Tab. I: Performance of rainbow trout receiving diet with fish-silage meal (FSM) or control diet (mean values from 3 replicated groups per diet)

	Control	**FSM**
Experimental period (d)	112	112
Initial body weight (g)	239.2	232.1
Final body weight (g)	767.1	820.8
Weight gain (g)	527.9	588.7
Specific growth rate (%)	1.04	1.13
Feed conversion ratio (kg/kg)	1.06	0.97
Survival rate (%)	97.6	98.8

The diet containing fish-silage meal had no considerable effects on the carcass composition, but resulted in significantly increased red and yellow levels in the coloration of filets and livers (Tab. II). Furthermore the FSM diet caused a slight but noticeable influence on sensory parameters (in adaptation to DIN EN ISO 5495:2007), with a more pronounced color, odor and taste in cooked filets. The sensory product quality was not promoted by the use of fish-silage meal. However, possible losses in sensory quality parameters could be reduced or eliminated by purging before slaughtering.

With regard to potential environmental impact the FSM diet showed disadvantages. With 7.8% (control) and 7.7% (FSM) both diets contained similar percentages of total nitrogen (N). However, due to the higher proportion of solid structures from bones and carcasses in fish-silage meal derived from fish processing by-products, the total phosphorus (P) content of the FSM diet was clearly higher (3.28%) than in the control diet (1.45%). Assuming contents of 2.72% N and 0.43% P in rainbow trout wet mass (Schreckenbach et al. 2001) and the obtained feed conversion ratios, nutrient emissions resulting from both diets can be balanced as shown in Tab. III.

Tab. II: Differences in brightness and coloration of filet and liver in rainbow trout receiving diet with fish-silage meal (FSM) or control diet (Konica Minolta CIE L a b coordinates analyzed in 29 fish per diet)

	Control		FSM		
Parameter	**MW**	**SD**	**MW**	**SD**	***p***
Filet brightness L	42.05	3.06	41.46	2.54	0.357
Filet color a	4.70	1.54	5.85*	1.03	0.000
Filet color b	1.52	0.88	3.32*	1.62	0.000
Liver brightness L	25.21	4.32	27.71*	5.17	0.016
Liver color a	17.59	2.02	19.59*	2.32	0.000
Liver color b	-0.83	3.13	0.62*	3.39	0.041

MW: mean value; SD: standard deviation. *:significantly different to control ($p \leq 0.05$)

Tab. III: Balance of nutrient releases resulting from administration of the tested diets

	Control		FSM	
	N	**P**	**N**	**P**
Input per kg of administered diet (g)	77.9	14.5	77.1	32.8
Extracted by fish biomass (g)	25.7	4.1	25.7	4.1
Emission per kg administered diet (g)	**52.2**	**10.4**	**51.4**	**28.7**

Compared to the control diet, phosphorus emissions from the FSM diet can be expected to be approx. 2.8 times higher. Especially when applying diets which include fish-silage meal derived from fish processing by-products, approaches to reduce phosphorus emissions, as faeces stabilization by guar gum supplementation (Brinker et al. 2005), effective mechanical purification systems (Sindilario et al. 2009a/b) and/or P-elimination modules (Müller-Belecke et al. 2018) in the farm outlets should be implemented.

This study was supported by the Deutsche Bundesstiftung Umwelt (DBU). Germany.

APPLICATION OF SUNFLOWER PROTEIN CONCENTRATE TO SUBSTITUTE FISHMEAL IN A RAINBOW TROUT (*ONCORHYNCHUS MYKISS*) DIET

Andreas Müller-Belecke[a]*, Tatiana Ryabikova[b]

[a]Institute of Inland Fisheries, Potsdam-Sacrow, Im Königswald 2, D-14469 Potsdam, Germany
Email: andreas.mueller-belecke@ifb-potsdam.de
[b]ESPACE Prozess Technologien GmbH, Helmholtzstraße 2-9, D-10587 Berlin

In line with the production of sunflower oil, press cakes rich in protein were generated as by-products. These press cakes can be processed into sunflower protein concentrates with protein contents of up to 85%. So far, there are only few information published with regard to the implementation and utilization of such sunflower protein concentrates (SPC) in diets of commercially important aquaculture species (Stickney et al. 1996; Lovatto et al. 2017; 2018). The present study aimed on the evaluation of a sunflower protein concentrate, obtained from the ESPACE Prozess Technologien GmbH Berlin, as substitute for fishmeal in a rainbow trout (*Oncorhynchus mykiss*) diet.

The pelleted control diet (control) and the experimental diet (SPC) were nearly isoenergetic and isonitrogenous (Tab. I). Instead of 35% fishmeal as the control diet, the SPC diet contained 17.5% fishmeal and 17.5% sunflower protein concentrate.

Tab. I: Properties of the formulated control and experimental (SPC) diets

	Control	SPC
Dry matter (%)	83.4	87.2
Ash (%)	5.5	4.8
Crude protein (%)	47.7	47.3
Crude fat (%)	17.5	16.8
Gross energy (MJ kg^{-1})	23.1	23.3

Six 1.3m^3-tanks of a laboratory scale recirculation aquaculture system were stocked with each 55 rainbow trout with initial body weights of 158±39g (mean value ± standard deviation) and fed with the two diets in 3 replicates close to saturation at rearing temperatures between 5.9°C and 15.7°C for 84 days. During the first 28 days the rearing temperature was slowly adapted from suboptimal 5.7°C to the optimal range for this species of between 14 and 16°C. In the following 56 days of the performance test the temperature was kept within the optimal range. The performance comparison at the end of the trial was based on (i) feed intake, survival rates, specific growth rates (Busacker et al. 1990) and feed conversion ratios as well as (ii) slaughtering of 24 individuals per diet in order to record the percentages of intestinal fat, the percentages, brightness and coloration (Konica Minolta CIE L*a*b* color space) of livers and fillets.

All control and experimental groups completed the performance test with survival rates of 100%. The substitution of 50 % of the fishmeal by the tested sunflower protein concentrate had no apparent effect on feed intake of the supplied rainbow trout. As indicated in Tab. II at low, slowly increasing water temperatures during the first phase of the performance test and thus suboptimal conditions for the fish, the SPC diet led to noticeably lower specific growth rates and decreased feed conversion ratios. Kept among optimal temperatures in the second phase of the performance test, specific growth rates and feed conversion ratios of the groups fed with the SPC diet declined, when compared to the control groups, but only in a magnitude of 4 %.

The SPC diet, containing sunflower protein concentrate had no considerable effects on intestinal fat percentages, fillet yields and brightness as well as coloration of fillet and liver. Nevertheless, the liver weights (4.00g versus 4.97g) and liver percentages (1.36%

versus 1.63%) of the fish fed with the SPC diet were significantly smaller ($p \leq 0.05$) than from the fish receiving the control diet.

Tab. II: Performance of rainbow trout receiving diet with sunflower protein concentrate (SPC) or control diet at suboptimal and later at optimal rearing temperatures (mean values from 3 replicated groups per diet)

	Temperature range			
	Suboptimal (d0-d28)		Optimal (d28-d84)	
	Control	**SPC**	**Control**	**SPC**
Experimental period (d):	28	28	56	56
Initial body weight (g):	159.9	155.9	180.7	169.1
Final body weight (g):	180.7	169.1	336.1	303.6
Weight gain (g):	20.8	13.2	155.4	137.0
Specific growth rate (%):	0.44	0.29	1.11	1.07
Feed conversion ratio (kg/kg):	1.79	2.71	0.98	1.02

Depending on price and availability, the tested sunflower protein concentrate thus represents an option for the substitution of appreciable amounts of fishmeal in rainbow trout diets, when the fish can be kept among optimal rearing conditions.

ONGROWING OF SOLE (*Solea senegalensis*) SUBJECTED TO THREE FEEDING PATTERS IN A RECIRCULATION SYSTEM

E. Murari* and J.L. Rodríguez

*UVigo (Universidad de Vigo) Ciudad Universitaria de Vigo, Campus Universitario Lagoas-Marcosende, Facultad de Biología s/n, 36310 Vigo, (Pontevedra), España
E-mail: murari.egberto@gmail.com

Introduction

The Senegalese sole (*Solea senegalensis*) is one of the most studied species in the last decades due to its economic value and high market demand (Morais *et al*., 2014; Rodriguez and Peleteiro, 2014). In recent years, important progress has been made in larval culture and ongrowing; however, courtship in F1 is still a key bottleneck for Senegalese sole aquaculture (Morais *et al*., 2014). Selecting and using suitable feed during the growth cycle is crucial to maximize profitabilit . The Senegalese sole exhibits a particular feeding behaviour, as it feeds from the bottom of the tank and it has night feeding patterns. Here we present the results of ongrowing of three batches of Senegalese sole, in which the daily food intake was distributed in three doses (3, 6, 9).

Materials and methods

The experience was carried out in the facilities of the Instituto Galego de Formación en Acuicultura (IGAFA). A batch of 180 individuals was randomly split into 9 tanks, of 1 m^2 and operating with a recirculation system. The fishes were fed with specific dry feed using automatic feeders, in a period of 21h. The feeding rate was initially 1%, and then it was progressively reduced to 0.77% and 0.67%. In batch A, in which individuals were 17.83±1.0 cm and weighed 76.72±17g, the fed was distributed in 3 doses per day. In batch B, in which individuals were 18.10±1.0cm cm and weighed 77.68±19g, the fed was distributed in 6 doses per day. In batch C, in which individuals were 18.10±1.0cm and weighed 77.13±17g, the fed was distributed in 9 doses per day. Culture parameters were kept constant within the optimal range for this species: salinity 38‰, temperature 19 ±1ºC, pH 7.45±0.11. Levels of nitrogen compounds (ammonium, nitrites and nitrates) were monitored twice a week. Water samples for microbial cultures were also regularly taken. Weight and size were regularly measured, and these data were used to calculate the following growth indexes: condition factor (CF), feed conversion rate (FCR), specific growth rate (SGR) and thermal growth coeffic ent (TGC). Both partial (for each sampling interval) and global indexes were calculated. Statistical analysis was performed using Wilcoxon signed-rank test at a significance level of 0.05 (Table I)

Results

Growth during the 165 days of this experience was similar in all 3 batches. The fish in batch A reached a final weight of 303.68±65g and a total weight gain of 226.96g. In batch B final weight was 305.77±68g and weight gain was 228,09g. In batch C final weight was 308.68±65g and weight was 231.55g. CF was similar in batches B and C and slightly higher in batch A. SGR was nearly identical in all 3 batches (0.84 for A and C and 0.83 for B). FCR was 0.92 in all batches; and TGC was 0.77 for batches A and B, and 0.78 for batch C. CF was significantly different between batches A and B, as well as A and C. Differences between all other parameters were not statistically significant. In this experience no pathological problems or deaths were observed.

Day	N	BATCH A						BATCH B						BATCH C					
		L (cm)	W (g)	CF	SGR	FCR	TGC	L (cm)	W (g)	CF	SGR	FCR	TGC	L (cm)	W (g)	CF	SGR	FCR	TGC

Table I. Results obtained from batches A, B and C: L: average length, W: average weight, CF: condition factor, FCR: feed conversion rate, SGR: specific growth rate, and TGC: thermal growth coefficient

(Continued on next page)

Discussion and Conclusion

According to these results, there are not significant differences for most growth indexes in the three populations analyse. However, CF was significantly difference in population A compared to B and C, which could be due to the fact that individuals from population A reached a slightly smaller size. SGR and FCR exhibit good values and similar to those achieved by (Rodríguez and Souto, 2003). The results from this experience in a recirculation system are better than those in an open system (Peleteiro *et al*., 2010; Rodriguez and Peleteiro, 2014). Overall, these results show that the ongrowing phase in Senegalese sole does not depend on the number of doses in which the feed intake is distributed.

1. Introduction

Membrane filtration is one of the most extensively used technique for material separation in various fields such as water and wastewater treatment, biotechnology, pharmaceutics, and food industries [1–3]. However, the major issue that is associated with membrane-based technology is fouling, which causes reduction of membrane performance and operation stability [4]. Typical ways of overcoming fouling includes; optimizing operation conditions, surface modifications and feed pre-treatments. One of the newest anti-fouling approaches, and also arguably the most effective and promising one, is so-called electro-bubble-filtrati n, in which foulants are physically detached from membrane surface by means of micro-bubbles generated directly at membrane surface via water electrolysis. For this method to work, electrically conductive materials must be either used as a membrane, in a pure form or made of composite materials. However, the major issue with electro-conductive membranes is their weak stability and lower electrical conductivity. Therefore, in this study, we propose a novel method for the fabrication of a highly electro-conductive yet stable membrane via relatively simple but yet not reported technology i.e. electroplating.

2. Methods

A Poly(ethersulfon) support membrane was used for the fabrication of the composite conductive thin film membrane. AgNWs were uniformly coated on a polymeric support by means of dead-end vacuum filtration. The coated membranes were dried overnight at 50°C in a controlled heating system. The AgNWs-coating layer was subjected to Ag-based electroplating, in a custom-built electroplating cell, to ascertain durability and filtration performance, properties fit for commercial applications. The Ag electroplated membrane (C-AgNWs) was then washed with an excess of DIW, followed by overnight drying at 50°C. This electro-membrane was characterized, in terms of physical properties and microalgae harvesting.

3. Results and discussion

Preliminary results showed that the fabricated membrane exhibited excellent electrical conductivity (figure 1) along with workable stability (figure 2) of conductive membrane. Moreover, the fabricated membrane performed better performance in both continuous (figure 3) and intermittent mode (figure 4) of microalgae electro-filtrati

4. Conclusions

Findings from this study confirm that the electroplating not only elevates the electrical conductivity but also strengthens the stability of the membrane. This suggests that the electroplating method offers a promising new way of fabricating electro-membranes with finally-workable-qualit , for the purpose of water and wastewater treatment including microalgae harvesting. The electro-filtratio performance of the membrane, when evaluated for microalgae harvesting, was found to be promising both in continuous and intermittent modes of electro-filtration

INDIAN ALMOND TREE (*Terminalia catappa* Linn.) AS HERBAL BIOMEDICINE IN AQUACULTURE

Mahadevi*

Dr. M.G.R. Fisheries College and Research Institute, Ponneri, Tamil Nadu, India
mahadevicof@gmail.com

Aquaculture is growing drastically over the years with intensification. On the other hand intensification increased the stress, occurrence of diseases, introduction of new pathogens and application of the synthetic chemical substances to overcome these problems. Recently adoption of herbal medicine in aquaculture practices is becoming the trend due its advantages over the chemical substances. Plants are storehouses and sources of safer and cheaper chemicals. Numerous herbal plants have been identifi d for its anti-microbial, antifungal, anti-parasitic, growth promotion, appetite stimulation, immunostimulation and stress reducer properties. Indian almond tree (*Terminalia catappa* Linn.) is one among them. Tannin is the major chemical component of *T. catappa* which exhibits the antimicrobial property. The reports on use of Indian almond leaves as herbal biomedicine have been reviewed in the present article. The extensive work need to be done to optimize the dose and duration of treatment against the most common pathogens.

Chemical Composition of Indian Almond leaves	Tannins (punicalagin, punicalin, terflavin A and B, tergallagin, tercatain, chebulagic acid, geranin, granatin B, corilagin), Flavanoids, Isovitexin, Vitexin, Isoorientin, Rutin and Triterpenoiods (ursolic acid, 2α, 3β, 23-trihydroxyurs-12-en-28 oic acid)

Indian almond leaves as Herbal medicine

SL. No	Activity	Principle	Effective against
1.	Antimicrobial	Lyse the cell wall, block the protein synthesis and DNA synthesis, inhibit the enzyme secretions and interfere with the signalling mechanism of quorum sensing pathway	*Staphylococcus aureus, A. Hydrophila,*
2.	Anti-parasitic	Crude extracts of Indian almond at 800 mg/L significantly eliminates the Parasites.	*Trichodina sp, Zoothamnium spp., Gyrodactylus and Dactylogyrus,*
3.	Anti-fungal	Herbal extracts involve the fungal cell wall lysis, altering the permeability, affecting the metabolism and RNA and protein synthesis which leads to death	*Pythium ultimum, Rhizoctonia solani, Sclerotium rolfsii,* and *Aspergillus fumigatus*

MICRO WORMS (*Panagrellus sp)* - NUTRITIOUS LARVAL FEED!

Mahadevi*

Dr. M.G.R. Fisheries College and Research Institute Ponneri, Tamil Nadu, India
mahadevicof@gmial.com

Larvi-culture is the most crucial stage of the aquaculture practices. The survival rate during the nursery period completely depends on availability of nutritious appropriate size feed. Larvae generally get attracted towards the live food and that must be of appropriate size for the mouth of the fry and nutritive. Micro worms are tiny in size than the newly hatched brine shrimps and have less ability to move in the water which enables the fries to easily catch and eat them. Micro-worms are live bearing, releasing 10 to 40 young every 1 to 1.5 days for a 20 to 25 day life span. The young reach sexual maturity in three days. The live nematodes contain 76% water and 24% dry matter. The dry matter contains 48% protein, 21% lipids, 7% glycogen, 1% organic acids, and 1% nucleic acids. The high fat content makes a particularly attractive food source for larval fish

Enrichment of Micro-worms:
Enrichment can be simply carried out by adding a fortification additive (vitamin premix for example) to the culture medium. Micro-worms enriched with fish oils have higher levels of highly unsaturated fatty acids (HUFAs). Micro-worms have also been enriched with the carotenoid astaxanthin, which can enhance pigmentation in some fish species.

Advantages:

1. Nutritionally rich
2. Easily digestible by the juvenile fish which promotes the excellent growth
3. Culture technique is easily adaptable
4. Cost of production is negligible

Conclusion:
Micro-worms are nutritionally rich live feed source with appropriate size. Micro-worms can be easily cultivable with low cost of production. Hence the technology can be applicable in nursery rearing of fish and shrimp

META-ANALYSIS OF GROWTH PERFORMANCE OF FRESHWATER FISHES UNDER SALINE ENVIRONMENTS IN AQUACULTURE

Christopher Naas * [ab], Werner Kloas [b]

a Institute of Inland Fisheries in Potsdam-Sacrow, Im Königswald 2, 14469 Potsdam
b Leibniz-Institute of Freshwater Ecology and Inland Fisheries, Müggelseedamm 310, 12587 Berlin
E-Mail: christopher.naas@ifb-potsdam.de

Osmoregulation is discussed to be responsible for consuming a major portion of the fish s available energy. Therefore, a common aquaculture practice is the addition of salt to the rearing environment, assuming that besides e.g. reducing stress after handling, it has further beneficial effects on the fish. In theory, freshwater fish kept under slight saline conditions require less energy to maintain their body homeostasis and are able to utilize the remaining energy for somatic growth. To investigate this theory, a meta-analysis on growth performance of freshwater fish in saline environments under aquaculture conditions was conducted.

First, a literature search on fixed word terms was conducted. From all suitable references available, general data for a descriptive review were collected and the specific growth rate (SGR) of the fishes in relation to the salt concentration was extracted. After calculating a percentage-SGR-deviation between growth in the control and in the different salt concentrations, somatic growth of fishes was also compared by taking into account their taxonomic allocation

In total, 56 publications including 59 growth studies were used for this meta-analysis, out of which 32 studies were used to calculate the percentage-SGR-deviation. Growth was studied in salinities ranging from 0 to 36g NaCl l^{-1}. On average, 4.7 salt concentrations were investigated per experiment, fish had a start weight of 92.1g, the experimental duration was 51 days, the rearing volume per tank was 0.44m^3 and 518 fish were used in each trial. Based on all authors' statements, an optimal salinity for freshwater fishes is supposed to be 2.6g NaCl l^{-1} whereas the suboptimal salinity was postulated with 10.6g NaCl l^{-1}.

The percent-SGR-deviation of the 32 studies showed a significantly negative correlation with the salt concentration. The higher the salt concentration in the environment, the lower the growth performance of the fishes. Also, the differentiation of the calculated percentage-SGR deviations based on taxonomic orders resulted in significant negative correlations with the exception of Perciformes.

With this meta-analysis, we revealed that the somatic growth of freshwater fishes under saline regimes is by far not as increased as it is expected according to common theory. In the majority of the studies, growth decreased with increasing environmental salt concentrations. We propose not to overestimate salt as a growth enhancer for freshwater fishes in aquaculture.

INDIVIDUAL GROWTH PERFORMANCE OF JUVENILE PIKE PERCH (*Sander lucioperca*) UNDER SALINE CONDITIONS IN RECIRCULATING AQUACULTURE SYSTEMS (RAS)

Christopher Naas * [ab], Werner Kloas [b], Andreas Müller-Belecke [a]

a Institute of Inland Fisheries in Potsdam-Sacrow, Im Königswald 2, 14469 Potsdam

Scientific studies on fish call for individual recognition in order to detect individual performance parameters. For this purpose, either parts or all fish of a group have to be tagged for experiments. In particular, in cases where only a part of the experimental fish has been tagged for economic reasons, it has to be excluded that tagging effects occur. Literature recommends allowing fish to recover for 14 days prior to the start of an experiment in order to avoid tagging induced biases.

RAS-reared juvenile pike perch (22±3g, n=150) were marked using *passive integrated transponder* (PIT, 11x2.2mm, HDX). PIT were implanted between the pelvic fins into the abdominal cavity using a syringe implanter. Fish were allowed to recover post-tagging for 14 days under identical rearing conditions in the same RAS, together with their untagged conspecifics. Subsequently, the growth performance of tagged and untagged pike perch was observed in a 78 days trial under different salinity regimes (0, 3, 6, 9, 12g NaCl l^{-1}) in five RAS.

We did not observe tagging induced mortality. The tag retention from the time of tagging until termination of the experiment was 100%. Even though, tagged pike perch had a significant lower body weight at the start of the experiment compared to their untagged conspecifics, no significant differences were detected at the end of each trial under salinities from 0 to 9g NaCl l^{-1}. In four out of five treatments, tagged pike perch showed signs of compensatory growth. In all tested salinity treatments, both groups of fish responded identically to saline regimes. Based on group comparison, pike perch in 6 and 9g NaCl l^{-1} showed growth depression. However, tagging data revealed that individual growth still occurred. Therefore, tagging allows for individual conclusions that might deviate from generalized group observations. Still, tagging did not affect the overall results of this growth study but additionally allowed for individual based conclusions. A post-tagging recovery period of 14 days is sufficient for juvenile pike perch that are to be utilized in growth studies.

EARTHWORM VERMICOMPOST TO ENHANCE SHRIMP WHITE SHRIMP *Litopenaeus vannamei* GROWTH AND INHIBITE AHPND DISEASE IN A EXPERIMENTAL CULTURE

Gerardo Rodríguez-Quiroz*, Arturo Polanco Torres, Píndaro Álvarez Ruíz.

Introduction

In Mexico the annual shrimp aquaculture rate production is growing, and thus demands more feeding inputs and diseases inhibitors. Among organic fertilizers, *Eisenia foetida* solid humus is considered as a great promoter for plankton growth, helping to develop these aquatic organisms. In other hand, the excessive use of antibiotics in aquaculture has affected negatively those species who are farmed (Marshall y Levy, 2011), and also has decreased shrimp growth (Bray et al., 2006) because bacteria are more resistant to antibiotics (Karunasagar et al., 1994). That's why it is important to find environmental alternatives to reduce shrimp diseases. The aim of this study was to evaluate different solid earthworm vermicompost doses as growth promoter and AHPND inhibitor.

Methodology

Five treatments with three replicates each one were seeded with 120 shrimp larvae in 120L tanks with zero water exchange. The tanks were fertilized with initial doses of: control, 0.00mg·L^{-1} solid Vermicompost [VC], 275, 550, 825 and 1100 mg/L^{-1}. The doses were, thereafter, reduced by half at day fifteen. The experiment lasted 45 days. Growth, Food Conversion Ratio and survival were measured. After the growth experiment, mortality accumulation was evaluated for each treatment when shrimp were challenged against *Vibrio parahaemolyticus* in three liters bowls with three replicates with 10 shrimp of 1.5g each bowl.

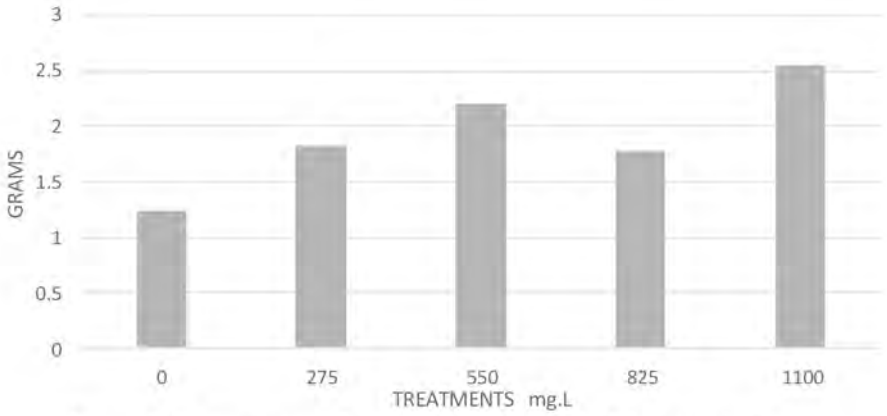

Figure 1. Shrimp growth by treatment at the end of the experiment.

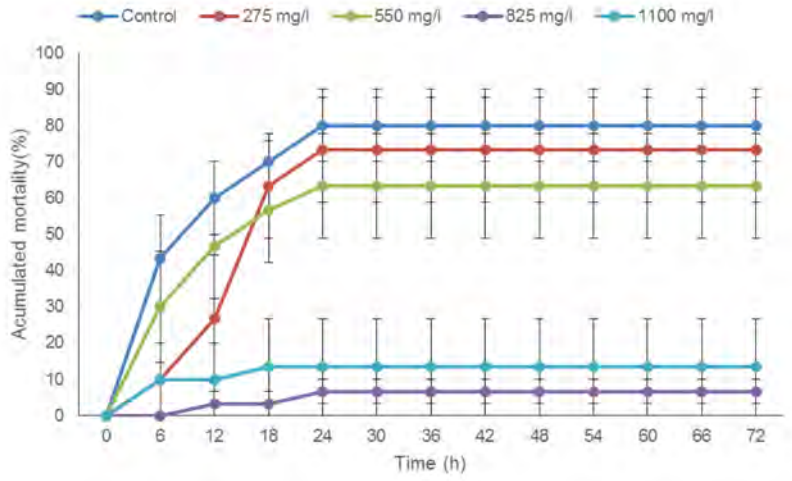

(Continued on next page)

Results

Water quality parameters were not constant during the experiment and had significant difference (P>0.05) between oxygen and pH treatments. We found that shrimp reared with the organic fertilizer had the best growth (Figure 1), and the lowest food conversion average.

On the other hand, we have that treatment over 550mg/l of vermicompost were effective against *V. parahaemolyticus*. Less than three shrimps died in this treatments in a period of 72h, contrary to treatments less than 550mg/l who had over 50% of the mortality in the first 18h of the challenge. Control had the highest mortality with 80% of the shrimp dead before the 24h trail.

Some studies suggest that vermicompost is an important food resource for juvenile shrimp (Chakrabarty, 2008). This organic fertilizers improves water quality and enhanced phytoplankton production (Bwala and Omoregie, 2009; Chakrabarty et al. 2009). We find that vermicompost is a real option to shrimp growth and can lower productions costs. It also can enhance shrimp survival and increase shrimp production when is used in the first stages of shrimp when it is more susceptible to diseases, but further investigation must be done to find what bacterium conglomerate in the vermicompost acts as inhibitor to AHPND .

Introducti
on

Commercial salmon feeds used in Norwegian aquaculture industry are based on a mixture of plant and marine ingredients. Over the last decades the proportion of the plant ingredients in the feeds have increased while marine ingredients decreased. The current ratio of plant : marine ingredient composition is 70:30 (Ytrestøyl et al., 2015). Plant proteins used in the feeds are derived from protein concentrates, usually with reduced content of antinutritional factors (ANFs). Nevertheless, amino acid imbalance and presence of ANFs are still a concern of the aquafeed industry. Furthermore, plant lipids have an unfavorable ratio of n-3:n-6 and does not provide the recommended EPA and DHA to the fish. Hence, ingredient composition of feed may have an effect on the health of the fish (Torrecillas et al., 2015). In addition, dietary administration of probiotics can influence the mucosal immune system of the fish (Hoseinifar et al., 2015). Skin, which is the largest first line defense organ of the fish, plays a key role in protecting the fish from the surrounding environment which is rife with opportunistic pathogens. Therefore, skin mucous morphology (Vatsos et al., 2010) which is considered as an indicator of fish s skin health, may be affected by several environmental factors including those linked to feeds. This study investigated the histo-morphological alterations of the skin of Atlantic salmon (*Salmo salar*) fed different diets with or without probiotics.

Material and methods

A feeding experiment was conducted with Atlantic salmon (mean weight of 146.97 ± 4.9g SD). The fish were fed three types of feeds with different basal diets with or without probiotics. The ingredient composition of the diets were, Diet 1: fish meal/ fish oil based, Diet 2: a commercial like diet dominated by plant ingredients (plant : marine is 70:30), and Diet 3: a fish meal/ fish oil based diet in which soybean meal replaced 20% of the fish meal. Dietary probiotic was cultured in the laboratory and vacuum coated on the diets. Dorsal skin samples were collected from 12 fish (mean weight 201.4 ± 37.8g SD) per treatment and fixed in 4% formalin. Samples were decalcified with 10% formic acid for 5 hours, prior to processing. After paraffin embedding, tissue sections of 4µm were prepared and stained with Hematoxylin and Eosin (H&E) and Alcian Blue – Periodic Acid Schiff (AB-PAS). Images (n= 9/ fish, N=108/ diet) from different locations of skin were acquired using light microscope. Quantitative analysis of skin morphology was performed; average area of mucous cells (AAM), ratio between total area of mucous cells and total area of epithelium (TAM/ TAE), and number of mucous cells per epithelium (M/E) were determined. The analysis was done using Image J (1.52a).

Results and discussion

The results did not reveal any significant differences in the average area of the mucous cells (AAM), and ratio between total area of mucous cells and total area of epithelium (TAM/TAE). However, the number of mucous cells per epithelium (M/E) was significantly influenced by diet and probiotics. Fish fed Diet 2 and 3 had significantly more M/E compared to those fed Diet 1. Addition of probiotics to Diet 1 increased the M/E, an indication of a strengthened skin barrier.

Conclusion

The results of this study revealed that the ingredient composition of diets directly influence the number of mucous cells per epithelium. Dietary administration of probiotics increased the number of mucous producing cells per epithelium, and this increase may have improved the barrier function of the skin of Atlantic salmon.

Introduction

Atlantic salmon broodstock maturation monitoring relies on invasive gonado-somatic index (GSI; gonad weight as percent of total body weight) measurements requiring sacrifice of fish or measurements in deceased individuals that might not be representative of the population. Other invasive and semi-invasive methods available (direct gonad inspection through incision, endoscopy, blood sampling) come with increased risk of handling stress, infection and mortality. The main objective of this study was to establish a non-invasive method for maturation monitoring to reduce stress and improve animal welfare in broodstock management of wild and farmed Atlantic salmon populations.

Materials and methods

One-year old Atlantic salmon smolts of the AquaGen strain were transferred to seawater in May 2013 and kept under regular production conditions until freshwater transfer in May 2015, after to seawater winters. Fish were given additional 24h light during first and second seawater winters to prevent grilsing and advance maturation, respectively. From one year before expected stripping date, in September 2014, 20 males and 20 females were examined monthly until a maturation inducing temperature drop was given in freshwater in August 2015, after which five males and five females were examined weekly until running milt and ovulation was detected. Samplings included body weight and length, ultrasound-based gonad length measurements, blood sample, gonad tissue sample and gonad weight and length.

Results and discussion

Ultrasound measurements were related to measured gonad length and weight and used to establish models for ultrasound-based GSI (US-GSI) estimation in both sexes. US-GSI models had higher correlations and were more usable in females ($R > 0.9$, $p < 0.05$) than in males ($R = 0.8$, $p < 0.05$). Differences between sexes lie mainly in measurement challenges, as ovaries were easier to measure accurately than testes. Observations from ultrasound images were related to plasma sex hormone levels from blood samples and gonad tissue histology and added nuance to US-GSI measurements. This somewhat compensated for less accurate US-GSI measurements in males.

Conclusion

Ultrasound based GSI measurements are very well suited for maturation monitoring in Atlantic salmon females. Adding other information from ultrasound image to US-GSI registrations, ultrasound is also a useful tool for maturation monitoring in Atlantic salmon males.

THE EFFICACY OF VARIOUS FILTER MEDIA IN REMOVING COPPER FROM TREATED SEAWATER

Keshia Govender, Dr. F.Lampen

South African Association for Marine Biological Research, uShaka Sea World, South Africa Durban, 1 King Shaka Avenue, 4001

Antiparasitic copper treatment is an integral part of routine marine aquaria quarantine, and, at times is even used to treat fish on exhibits. It is very effective at treating marine aquarium fish infected with protozoan ectoparasites.Free copper will react with calcareous materials (e.g. coral, rock or limestone), to form insoluble copper carbonate. This will leach out into fresh, untreated saltwater once a bath treatment is completed. As copper is extremely toxic to invertebrates, any residual copper can cause unexpected mortality.

This project investigated and compared the efficacy of various filter systems in removing residual copper in saltwater. The four filter media examined were activated carbon, zeolite, poly-filters and powdered banana peel

The experiment was undertaken using five glass tanks each having seawater, airlines, copper lines and canister filters. The first tank was used as a control. There were three phases to the experiment. The first phase took place from the 26 February 2016- 01 March 2016.The first phase involved copper treatment to all five glass tanks at the same flow rate. Copper tests using copper reagents and a colorimeter was performed daily until therapeutic levels of 0.25mg/l were reached. Temperature (using the LDO) and pH (using wtw 330i pH meter) readings were also taken as these factors influence the absorption of the free copper.

The second phases started on the 1 April 2016 were gravel and rockwork of the same size and quantity were introduced to all five glass tanks. The copper lines were then closed off. This allowed for the free copper to be absorbed by the rockwork and gravel. Copper tests were done once again using the colorimeter together with pH and temperature readings. The results of the copper testing showed that free copper also leached out some instances. The leaching resulted in therapeutic levels been reached. This phase was monitored from 1 April 2016- 31 May 2016.

The third phases started on the 1 June 2016 were various filter media (activated carbon, zeolite, polyfilter and powdered banana peel) was placed in polyester stocking and put into the canister filte . Activated carbon of porous size was used, zeolite (cationic Aquaculture filter medium), Poly-Filter was cut into squares and powdered banana peel were observed. The banana peels were first dried using a food dehydrator and then ground down to a powder form using a mill with a blade of 8 um diameter. During this phase the copper was tested daily using the colorimeter and the pH and temperature readings were recorded. This phase took place from 1 June 2016- 31 September 2016.

My results showered that zeolite together with powdered banana were the most successful in absorbing the most amount of free copper. The pH within this time frame was 7.8-8 and temperatures were relatively stable. After two months the zeolite became deactivated and activated carbon achieved good absorption of free copper. The reason that activated carbon could have took long in the absorption process was due to the pore size were if the pore size was larger the surface area would be larger and be able to absorb more free copper. Powdered banana showed immense absorption however the pH levels would drop on certain days. The Poly-filter showed very slow absorption during the entire experiment through all three phases. In September 2016 I did a few microbiological tests each filter medium was swabbed and plated onto nutrient agar and incubated for 24 hours. Total counts were done on these plates.

In conclusion activated carbon was the best filter media although taking a long period of time to absorb the free copper. Some results were zero or extremely low levels of free copper detected. Powdered banana was the second filter media that absorbed the most amount of free copper however the pH readings took time to come up. The zeolite was also very good absorbent however will have to be reactivated after two to three months or new zeolite to be added to canister filte . The microbiology that was done showed that the filter medium with the most absorption i.e activated carbon had the least amount of microbial load compared to Poly-filter which had the least amount of absorption but had the most amount of microbial load.

Further studies will be conducted with other filter media (with varying pore sizes) to determine which absorbs the most amount of free copper. Nutrient tests (ammonia, nitrites and nitrates) will be performed to investigate the effects of free copper absorption.

(Continued on next page)

The findings of this project will assist quarantine in their copper treatment and will ensure a safe living environment for the marine animals in our care.

Environmentally these filters can be used in waste water treatment plants to remove heavy metals such as copper either by having canister were the media is added in or in biofilters were the various media can be added. The reason to have these filter media is to prevent excessive heavy metal leaching into the ocean especially when treatment water meets the ocean. Many waste water treatment plants around the world are using biological media such as banana peels, orange peels and ginseng beside the typical filter media that can be obtained

Copper accumulation in marine fish can cause toxicity of the precious sea life over time. The public that consume fish which were exposed to high copper levels will be at risk when consuming theses fish over a period of time. During this experiment it was noted that fish also consume the algae that grow on the rocks and gravel which have absorbed the copper over a period of time. By consuming the algae the fish are at high risks of copper toxicit .

EVOLUTION OF THE COMPLEMENT SYSTEM IN FISH

Babak Najafpour*, João CR Cardoso, Adelino VM Canário and Deborah M Power

Comparative Endocrinology and Integrative Biology, Centre of Marine Science (CCMAR)
Universidade do Algarve, Campus de Gambelas, 8005-139 Faro, Portugal
DMP dpower@ualg.pt

Introduction

The complement system is an important component of innate immunity and causes the lysis and elimination of microorganisms. In some teleosts, multiple copies of the complement 3 (*c3*) gene have been described (the functionally active form of complement component C3 exists as the product of a single gene. We have now identified and characterized three functional C3 proteins (C3-1, C3-3, and C3-4Sunyer et al., 1997; the functionally active third component of complement (C3Forn-Cuní et al., 2014) suggesting that the complement system and its regulation is more complex in fish compared to mammals (Sun et al., 2010). Taking into consideration the microorganism rich environment, which fish inhabit we studied complement evolution with a focus on aquaculture species.

Material and methods

Orthologues of the human complement system were procured in fish using BlastX and the ENSEMBL (http://ensembl.org/, July 2018) database. Phylogenetic trees were constructed for C3 and the related C4 and C5 proteins. The deduced protein sequences of the fish and tetrapod genes were aligned and for the complement phylogenetic tree orthologues of two invertebrate deuterostomes genes were included (Vase tunicate and cephalochordate). Sequences were aligned using the MUSCLE algorithm in the AliView platform (Larsson, 2014)i.e. FASTA, Phylip, Nexus, Clustal and MSF. The intuitive graphical interface makes it easy to inspect, sort, delete, merge and realign sequences as part of the manual filtering process of large datasets. AliView also works as an easy-to-use alignment editor for small as well as large datasets. AVAILABILITY AND IMPLEMENTATION AliView is released as open-source software under the GNU General Public License, version 3.0 (GPLv3 and phylogenetic trees were constructed using Maximum-Likelihood (ML) analysis. The ML analysis was performed in PhyML 3.0 software (http://www.atgc-montpellier.fr/phyml/)(Guindon et al., 2010).

Results

The number of predicted *c3*, *c4*, *c5* transcripts was established by sequence similarity and clustering in the phylogenetic tree (Table 1). The C3 clade possessed the largest number of members with two main clusters C3.1 and C3.2. For C4, the tree topology suggests that two distinct clusters exist, and they were named C4.1 and C.4.2. Within the C5 cluster two main branches existed one contained C5 from ray-finned fishes and the other cluster contained C5 from the cartilaginous fish, the coelacanth and tetrapods (Figure 1).

Discussion and conclusion

The expansion of the *c3* gene in teleosts suggests that the alternative complement pathway was favoured during evolution. The acquisition of a strong innate immune response against pathogens may explain the success of teleosts (>25,000 exist). Overall, the results suggest that the humoral component of the innate response may be more complex in the fishes compared to terrestrial vertebrates that are not exposed to such a microbial rich media. We propose that the evolution of the *c3* and *c4* genes was under different pressures and that *c3* gained (and potentially *c4*) a diversity of functions in teleosts suggesting that aquatic environments may have uniquely shaped this system (Meng et al., 2012). A notable expansion of C3 genes occurred in the aquaculture species sea bass, tilapia and Atlantic salmon and most are species-specific. Understanding how the complement system evolved and functions in fish may help to better understand fish immunity and potentially predict species susceptibility to pathogenic agents in aquaculture environment.

NATIVE FLAT OYSTER RESISTANCE TOWARDS *Bonamia ostreae*: A HOLISTIC APPROACH COMBINING OMICS AND PHYSIOLOGY

Jennifer C. Nascimento-Schulze* [1,2], Tim Bean[1,3], Chantelle Hooper[1], Matthew Sanders[1] and Robert Ellis[2]

Introduction

Over-exploitation has dramatically depleted European natural *Ostrea edulis* stocks in the 19th century (Laing, 2006). During the past six decades, wild European flat oyster beds have experienced a further decline in extent and abundance. Consequently, the flat oyster fishery has suffered a ~90% decrease in production, from 30 000 tonnes in 1960 to 3 000 tonnes in 2014 (FAO, 2019). Habitat degradation, competition and primary diseases (e.g. Bonamiosis and Marteliosis) have contributed to the recent decline in production (Haelters and Kerckhof, 2009). *Bonamia ostreae* infection was first diagnosed in Europe in 1979 (Pichot et al., 1979) and since then has been linked to mass mortalities of commercial and wild *O. edulis* stocks, significantly contributing to a loss in production. No treatment is currently available for Bonamiosis. Strict regulation of oyster movement between disease-free and *Bonamia* positive areas is the only preventive measure available to avoid the further spread of this parasite. Selective-breeding has been highlighted as key to the sustainable intensificatio of the aquaculture industry, especially for the development of disease and climate change resilient stocks (FAO, 2016). Despite early experimental indication of heritability of disease tolerance to Bonamiosis, as well as the presence of heavy selection pressure in this oyster disease model, tolerance has not evolved to a meaningful level in either farmed or wild *O.edulis* populations. This project investigated this counterintuitive lack of adaptation in *O. edulis*, and the context (e.g. host response) in which this disease was able to manifest. By challenging naïve oysters with *B. ostreae*, we characterise animals using an integrated approach, combining -omics (genomic, transcriptomic and metabolomic profiling) with the physiological assessment performance and fitness (metabolic rate, condition index and clearance rate) during different disease stages.

Material and Methods

Oysters were collected from a managed *Bonamia* positive UK population and brought to Cefas facilities (Weymouth, UK). *Bonamia ostreae* positive individuals were identified by microscopy and subsequently used to infect naïve animals (West coast of Scotland) by injection, with infected oysters subsequently acting as trojans. Following this, a further 1 500 naïve oysters (West coast of Scotland) were placed into tanks with the trojan animals, initiating a disease challenge. Prior to challenging, oysters were individually tagged and a biopsy from the dorsal posterior end of the gill arch was sampled for genotyping. Disease progression and mortality rates were followed throughout the challenge. During this period, proxies for fitness (condition index; CI) and physiological performance (O_2 consumption (OC) and clearance (CR) rates) were assessed monthly to infer physiological phenotype, highlighting the profile of susceptible and resistant animals.

Results and future outlook

Monitoring physiological and health status of naïve individuals exposed to *B. ostreae* enabled us to follow the gradual effects of this disease on the European flat oyster. We hypothesise that shifts in metabolic energy requirements are related to disease progression and implicate physiological differences between susceptible and resistant animals. A clear understanding of the context and condition of animals in which disease is emerging is vital to clarify disease mechanisms. Results from this study are being combined with transcriptomic, genomic and metabolomic data to provide an extended profile of susceptible and resistant individuals. Moreover, this fully integrated approach will provide important insights on the nature (if genetic or plastic) of physiological traits. Future results will be applied to aid in the development of *O. edulis* breeding programs contributing to the aquaculture industry as well as conservation efforts of this valuable keystone species.

Introduction

Recirculating aquaculture systems (RAS) for Atlantic salmon (*Salmo salar*) are often operated on varying salinities in different production phases of the fish. The nitrification process in RAS may be adversely impacted by salinity changes, leading to the accumulation of ammonia or nitrite, which are toxic to fish (Chen et al., 2006). Thus, salinity changes in RAS must be performed with caution and with the least possible impact on the nitrification process

An increase in salinity can drastically reduce the nitrification rate in freshwater bioreactors, mainly because osmotic stress can reduce cell activity by inhibition or plasmolysis of microbes (Moussa et al., 2006; Uygur and Kargi, 2004). Stress priming is a strategy where bacterial communities exposed to a mild stress become more capable of dealing with a more severe stress in the future (Andrade-Linares et al., 2016). However, studies on osmotic stress priming in microbial communities are limited (Moussa et al., 2006). This study was undertaken to verify if the stress priming strategy was applicable to salinity changes in RAS bioreactors in the production of Atlantic salmon post-smolt.

We investigated the impact of seawater priming on freshwater and brackish water moving bed biofilm reactors (MBBR). It was hypothesized that biofilms that had previously been exposed to seawater (primed biofilms) would be more robust than un-primed biofilms

Methodology

The experimental setup consisted of eight continuously run 37L MBBRs operated on synthetic medium. The biofilm carriers were obtained from two RAS MBBRs that had been started up in freshwater (0‰ salinity) and brackish water (12‰ salinity), respectively. F1 and B1 were primed in seawater (32‰) for two weeks while F0 and B0 were maintained at their native salinities. Thereafter, all treatments were first operated on freshwater (24 days), and subsequently on seawater (31 days). Salinity changes were conducted by changing the salinity of the buffer tank providing makeup flow to the MBBRs, ensuring a gradual salinity change in the reactors overnight. The nitrification performance was evaluated by performing capacity tests to determine the maximum specific oxidation rates of ammonia (AO_{max}) and nitrite (NOR_{max}).

Results & Discussion

After the second transfer to seawater, the primed freshwater treatment F1 showed little reduction in AOR_{max} or NOR_{max}, whereas F0 had a 50% reduction in AOR_{max} and up to 95% reduction in NOR_{max} (Fig. 1). The results contradict those from a study on nitrifying sludge, where prior adaptation did not improve salinity resistance (Moussa et al., 2006). This suggests that biofilms may show different salinity responses than nitrifying sludge. In the brackish water treatments, AOR_{max} was relatively unaffected by the salinity increase. This is in alignment with other studies reporting that brackish water MBBRs (22‰ salinity) may be more robust to salinity changes than freshwater MBBRs (Gonzalez-Silva et al., 2016; Sudarno, 2011). However, in the freshwater phase, AOR_{max} in the brackish water treatments dropped by ~50%, but recovered to the original rate after about 15 days. Further, although NOR_{max} in B0 and B1 was reduced by 50% in seawater, there was no nitrite accumulation, verifying complete nitrification under the prevailing ammonia loading rate.

Conclusions

The results indicate that stress priming by prior exposure to seawater can significantly improve salinity adaptation in nitrifying freshwater MBBRs. In comparison, brackish water MBBRs are not greatly impacted by seawater priming as they are relatively robust to salinity increase. The results highlight how microbial management strategies may be applied to nitrifying bioreactors for the selection of bacterial communities with the desired functionalities. In conclusion, seawater priming of young freshwater biofilms is a feasible strategy for RAS bioreactors operating on varying salinities.

ENHANCING FISH DIGESTIVE EFFICIENCY THROUGH NUTRITIONAL MODULATION AT EMBRYONIC STAGE

C. Navarro-Guillén*, A. Lopes, R. Colen, S. Engrola

Centre of Marine Sciences (CCMAR), *Campus* de Gambelas, Faro, Portugal
*E-mail: cpguillen@ualg.pt

Introduction

New and more efficient methods to "sustainably intensify" Aquaculture production are essential to attain the seafood demand for direct human consumption in the near future. Nutrition has been identified as one strategy of early exposure that might affect animal early development and later phenotype. This strategy may have positive consequences in the modulation of fish digestive physiology, which will correlate with higher performance outputs. Thus, improving fish digestive efficiency will lead to higher productivity and lower biogenic emission from aquaculture facilities. This will minimise the impact on the environment while increasing the biological efficienc . The present work will present results on early metabolic programming in fish, regarding enhancing fish performance through the modulation of digestive capacity during fish embryogenesis

Material and methods

An innovative *in ovo* nutritional modulation technique based on low-frequency ultrasounds was used to enhance the transport of compounds across the embryo membranes. An early stimulus with bioactive compounds (D, E, F) involved in gut maturation was applied in zebrafish embryos at 3.5 hours post-fertilization (hpf). At 22 days post-fertilization (dpf), growth performance, digestive enzyme activities and gut microbiota composition were analysed to evaluate the larval nutrition-induced metabolic plasticity and the effects on fish digestive efficien .

Results and Discussion

The preliminary results showed that fish survival was not affected either by the sonophoresis technique or bioactive compounds supplementation ($p>0.05$). Final dry weight (DW) at 22 dpf was statistically higher in larvae from F treatment when compared to the control ($p=0.027$). In fish supplemented with bioactive compound D, it was observed a progressive DW increase with increasing D concentrations.

The results of the present work indicate that some bioactive compounds may act as promoters of early intestinal maturation, improved digestive capacity and growth performance in fish larvae. We also identified a "developmental window" in which nutritional programming has short-term effects on digestive functionality. Overall, the present study supports sustainable self-sufficiency in fish aquaculture by integrating dietary strategies and relevant data obtained from new tools. The perspective of applying this novel concept to aquaculture industry provides numerous advantages, since digestive capacity is considered key to fish resilience and qualit .

ASSESSMENT OF FEEDING BEHAVIOUR IN JUVENILE SEABREAM Sparus aurata UNDER RECIRCULATION

J. Nazzaro (1,2) *, N. Duncan (1), L. Reig (2), M.L. Bégout (3), A. Roque (1)

Introduction
Studies with self-feeder devices have been carried out previously with seabass (Covès et al., 2006, Di-Poï et al., 2008) but further research is needed with gilthead seabream (*Sparus aurata*). Efforts are focused on establishing links between the social structure and different behavioral patterns derived from divergent stress coping styles (SCS), checking the possible effect of boldness, curiosity or dominance hierarchies in the effectiveness of self-feeding devices and investigating whether they can be used as an operational welfare indicator in farmed fish (Attia et al., 2012; Ferrari et al., 2014; Millot et al., 2008; Millot and Bégout, 2009).

Present experiment consisted in investigating (Sparus aurata) the social structure that builds around a self-feeding system. We tested the functionality of two self-feeding methods also compared with hand-feeding. We determined social structure based on the individual contribution to total food demand, characterizing individuals according to high triggering (HT, >15% actuations), low triggering (LT, 3-15% actuations) and zero triggering (ZT, 0-3% actuations), (Covès et al., 2006). We carried out two group based personality tests to identify individuals of divergent stress coping styles (SCS) and we established links between the social structure around the self-feeding device and behavioural differences between proactive, intermediate and reactive individuals.

Materials and methods
To carry out this experiment, 360 gilthead seabream juveniles were distributed in four tanks (90 fish/tank). Two of them were fed by hand and the other two were under self-feeding conditions throughout the experiment. We characterized the personality of gilthead seabream through the group-based Hypoxia and Risk-tacking tests that allowed us to differentiate between proactive, intermediate and reactive stress coping styles (SCS) and establish the relationship between personality traits and triggering activity. Finally, an acute stress event by hypoxia was conducted to study variations in social structure and food demand when adverse conditions and basal plasma cortisol and glucose were analysed.

Results
Social structure by triggering activity was as it follows: Most of the fish were Zero triggering (ZT) from 89.84% to 93.1%. Low triggering (LT) fish represented 9.30% and 5.75%. Only one High triggering (HT) fish was responsible for about 30.5% and 32.1% of the total number of actuation, representing 1.16% and 1.15% of the population respectively. High triggering (HT) fish weighed 67.1 g (above the average, > 60.26 g) and 47.9 g (below the average, < 58.68 g) respectively. Most of the individuals involved in food demand responded to reactive and intermediate coping styles and showed higher SGR. There were no differences in body weight between coping styles.

Results obtained from the personality tests, showed that the smallest part of fish within tanks belonged to proactive coping style, representing from 4.76% to 26.19%. Reactive ones ranged from 9.52% to 44.05% and the intermediate behaviour included the most part of individuals (51.19% to 64.29%).

None of the two acute stress events caused appreciable alterations in the food demand during the hours or days following the stress event. Nevertheless, the acute stress produced changes in triggering roles. High triggering (HT) fish reduced its contribution to the feed demand, being replaced by LT and ZT fish.

Plasma glucose analysis did not show signifiant differences between tanks nor SCS. Cortisol levels indicated a lower stress in fish under self-feeding conditions, if compared with those fed by hand.

(Continued on next page)

Discussion and conclusion

We verified that in a small population of 90 seabream, the same pattern is always observed, where only one individual is responsible of more than 30% of total food demand, characterized as high triggering (HT) fish.

Consistency through time and situations in responses to group based tests, allowed the characterization of fish as proactive, reactive and intermediate SCS, as demonstrated in Castanheira et al. (2013). Fish belonging to the intermediate SCS represented more than 50% and showed the importance of the intermediate group in reared populations of gilthead seabream.

Results suggest that bold fish (proactive ones) could be highly competitive individuals and have a priority access to the food resources, since they know where the food falls and they frequent the area under the food-dispenser by establishing as routines. Shyer individuals need to find other strategies and actuate the trigger (which feed the entire group) since they do not have that priority to feed themselves, also observed in other studies conducted with seabass (*Dicentrarchus labrax*) (Di-Poï et al., 2008; Ferrari et al., 2014). This link between SCS and the triggering status could explain the social structure built under the self-feeder apparatus.

A regular food demand by fish can be indicative of lower stress and fish welfare in reared fish. Demand-feeding systems could optimise production allowing less stressful culture conditions if provided with regularity and in a sufficient quantity to allow fish expressing their normal feeding behaviour, but further research is needed to better assess growth performances under self-feeding conditions.

EFFECT OF EARLY LIFE HYPOXIA AND DIET COMPOSITION ON GROWTH, FEED INTAKE AND OXYGEN CONSUMPTION OF RAINBOW TROUT (*Oncorhynchus mykiss*) IN LATER LIFE

Marit A.J. Nederlof[*, 1], Ep H. Eding[1], Anne-Jo van Riel[1], Isabelle Leguen[2], Stephane Panserat[3], Patrick Prunet[2], Johan W. Schrama[1]

Introduction

Factors and mechanisms controlling voluntary feed intake (FI) are less studied in fish compared to mammals. However, a good understanding of these factors and mechanisms is required to optimize feeding management in aquaculture practices, but also to achieve maximal FI in control groups during experiments (Saravanan, 2013). It is well known that under hypoxia conditions, FI is regulated by dissolved oxygen concentrations in the water (Tran-Duy et al., 2012). Under normoxia conditions other factors play a role maximizing FI. One of these factors is a low oxygen level in the early life of fish. Here it is hypothesized that exposure to a low oxygen level in early life adjust gene functions (i.e. epigenetics), resulting in an increased oxygen uptake capacity, and therefore potential for a higher maximal FI, of fish in later life. Another factor influencing voluntary feed intake under normoxia conditions is diet composition. Macronutrients differ in their degree of oxidation in aerobic metabolism, and therefore oxygen consumption per unit feed can be altered by dietary macronutrients, resulting in diets contrasting in dietary oxygen demand (DOD) (Saravanan, 2013). When fed to satiation it is expected that diets differing in DOD result in similar oxygen consumption (i.e. based on maximum aerobic capacity), but different FI. This is described by Saravanan (2013) as the oxystatic concept. It is unknown if the oxystatic concept holds true for fish exposed to hypoxia conditions in early life.

This study aims to determine for Rainbow trout (*Oncorhynchus Mykiss*) the impact of early life history (exposure to hypoxia or normoxia) on FI, growth and oxygen consumption in later life, either at a high (i.e. high in starch) or low (i.e. high in fat) oxygen demanding diet.

Materials and Methods

The effect of early life hypoxia on FI, growth and oxygen consumption in later life was studied in a 2 x 2 factorial experiment, with oxygen history and contrasting DOD as independent factors. The oxygen history was created by exposing fish two days post hatching to normoxic (100% oxygen saturation) or hypoxic (60% oxygen saturation) conditions for a period of 17 days. Thereafter all fish were maintained at similar, normoxic conditions until the start of the experiment. For contrasting DOD, two diets were formulated where either fat (low-DOD) or starch (high-DOD) was used as non-protein energy source.

During the experimental period Rainbow trout (average initial weight 201 ± 8 gram) differing in oxygen history were fed ad libitum for a period of 7 weeks with one of the two experimental diets. Growth rate, feed intake, apparent digestibility and oxygen consumption were measured.

Results

Results of this study show that fish exposed to hypoxia at early life, have an increased oxygen consumption and feed intake at later life. The impact of early life on oxygen consumption was dependent upon DOD, indicated by the interaction effect between oxygen history and diet for oxygen consumption.

STRATEGIES TO IMPROVE THE EFFECTIVENESS OF COMMERCIAL PURIFICATION (DEPURATION) IN REMOVING NOROVIRUS FROM OYSTERS

Anna Neish*
Andrew Younger

Centre for Environment, Fisheries & Aquaculture Science, Barrack Road, The Nothe, Weymouth, Dorset, DT4 8UB, UK
Anna.neish@cefas.co.uk

Abstract/Introduction

Norovirus (NoV) is the principal agent of bivalve shellfish–associated gastroenteric illness worldwide. One treatment option for controlling the risks associated with shellfish originating from moderately polluted areas (e.g. class B areas in Europe) is for them to undergo purification (depuration) in tanks of clean seawater to allow them to purge themselves of microbiological contaminants. Whilst bacteria may be rapidly and effectively removed during this process it is well documented that purified shellfish shown to be free of *E. coli* (the statutory faecal indicator in European legislation) have been associated with outbreaks of NoV. This study investigates potential improvements in commercial purification practices to assess their NoV removal potential from bivalves, as recommended by EFSA (2012).

Methods

Experiments were conducted using environmentally contaminated oysters in laboratory scale and commercial scale purification systems see figure 1) during February and March 2019 – a period falling within the usual winter NoV season in the UK. The study focussed on Pacific oysters (*C. gigas*), a species that dominates the oyster trade in Europe and is implicated in most bivalve-associated illness outbreaks. In these experiments, oysters were placed in purification tanks under the typical conditions encountered with commercial practices in the UK and NoV removal compared against potential enhanced strategies. These strategies included the following: elevated temperatures, feeding, salinity and light vs dark.

The depuration kinetics were assessed by testing the shellfish pre, mid and post-cycle for NoV by PCR, bacteriophage by both PCR and by viable culture. The bacteriophage testing by PCR and viability assay was intended to provide a surrogate measure of NoV infectivity. *E. coli* testing was also carried out to confirm clearance of this statutory faecal indicator. The enhanced purification strategies will be validated in experiments using commercial purification tanks and assessed in collaboration with an industrial partner.

Fig. 1. Commercial purification tanks in laboratory conditions during feeding trial

(Continued on next page)

Results

Analysis of samples is currently incomplete, however, preliminary data obtained from this study suggests that NoV is better removed at 18°C then at lower temps (8°C). NoV genogroup II was consistently better removed than GI. A possible beneficial effect was observed with darkness (vs light) and algal feeding (vs no feeding) using a commercially available algae mix, however, further data is awaited for confirmation of this

Conclusions

Whilst NoV GI removal levels were negligible, NoV GII was consistently better removed, indicating that commercial purification may well be effective for some genotypes/strains of NoV. This study underlines the importance of establishing different approaches for reducing consumer risks associated with the consumption of bivalve shellfish

Introduction
The Percidae family contains about 266 fish species distributed in 11 genera. Several of these species are economically relevant in recreational and commercial fish farming. *Sander lucioperca* is one of the species that are considered a particular promise in aquaculture. The relative faster growth compared to other percids, the resilience and diversification potential make S. lucioperca an attractive species for intensive rearing, as these traits are crucial for the potential yields in commercial production. While the global capture production of pikeperch has halved since 2010, its aquaculture production has increased two fold in the same time and reached about 900 tons per year (Food and Agriculture Organization (FAO), 2018). This illustrates the increasing consideration of pikeperch for commercial aquafarming, but also suggests that pikeperch is still a niche-market species. Though, there is still a tremendous lack on genomic tools for pikeperch breeding. In the present work, we report the first draft genome of pikeperch including comprehensive gene annotations. The initial de novo assembly consisted of 1966 contigs with outstanding metrics in term of contiguity, completeness and structural accuracy.

Materials and methods
The genome assembly of pikeperch (*Sander lucioperca*) was constructed using erroneous PacBio long reads and by taking advantage of accurate Illumina short reads. We sequenced one paired-end (2 × 150 bp) short insert library (470 bp) and two mate-pair libraries (2-8kb and 2-10kb) . In addition, a 20kb library was prepared and sequenced with the PacBio Sequel platform. We assembled the raw PacBio reads into draft contigs using Flye vers.2.3.7 (Mikhail et.al, 2018). To annotate protein-coding genes in pikeperch genome, we combined ab initio and homology-based methods along with RNA-Seq evidences.

Results
In total, 530 GB and 62 GB of DNA sequencing raw data were generated respectively by Illumina HiSeq X ten platforms and PacBio Sequel System. These data were assembled into a final assembly size of 900 Mb covering 88% of the 1014 Mb estimated genome size (Fig. 1). The initial draft genome consisted of 1966 contigs with a N50 length of 3.0 Mb. The final assembly yielded 1313 scaffold with N50 of 4.9 Mb. The identified repetitive structures accounted for 39% of the genome. By combining homologies to other ray-finned fishes, and de novo gene prediction methods, we annotated 21,249 protein-coding genes in the *S. lucioperca* genome, which is consistent with the gene content reported for other Perciformes fishes. The orthologous analysis between selected Perciformes fish species suggested that, 35 orthogroups with 317 genes were pikeperch-specific. Finally, the quality assessment of our assembly highlighted that 96% of short reads have been properly aligned to the draft genome with the correct distance to their mates. The assembled genome spans 98.24% and 96.3% of Vertebrate respectively Actinopterygii single-copy genes spaces. This suggests not only that most gene-rich regions have properly been assembled, but demonstrates also the high structural accuracy of the assembly.

Discussion and conclusion
We successfully sequenced and assembled the genome of the pikeperch using long reads from the third generation and taking advantage of the Illumina short reads accuracy. The generated 900 Mb assembly demonstrates outstanding metric in contiguity and structure, compared to other high quality published fish genomes, in particular, species in the Perciformes order. We have annotated 21,249 protein-coding genes in the pikeperch genome, of which 350 are pikeperch-specific. This novel genome assembly is a valuable genomic resource for further genome-wide studies. In particular, it will facilitate the construction of genetic linkage maps and the identification of molecular markers associated with commercial traits. Finally, this draft genome will further enhance investigations of the adaptability of pikeperch in captive conditions.

BIOCHEMICAL AND PROTEOMIC CHARACTERISATION OF EXTRACELLULAR PROTEINS FROM THE PROTOZOAN PARASITE *Paramoeba perurans* REVEALED BY AN *IN VITRO* MODEL

K. N Dhufaigh[1*], E. Dillon[2], E. MacCarthy[1], O. Slattery[1]

[1]Marine and Freshwater Research Centre, GMIT; [2]Conway Institute, UCD
Email: kerrie.nidhufaigh@research.gmit.ie

Introduction

The parasite *Paramoeba perurans* is suspected to have a set of extracellular virulent proteins (Butler and Nowak, 2004; Bridle et al, 2015) that result in the clinical manifestation of AGD in susceptible farmed fish. Bridle et al (2015) demonstrated that extracellular secretions from a virulent 'wild type' *P. perurans* isolate produced a greater cytotoxic response in a Chinook salmon embryo (CHSE -214) cell line compared with secretions from a long-term cultured *P. perurans* isolate. However, the causative proteins responsible for the host cytotoxic response were not determined. This study aims to characterise the extracellular proteome of *P. perurans*.

Method

Media was collected and pooled from *P. perurans* cultures and filtered through a 0.22µm polyethersulfone filter to obtain cell-free supernatants. The supernatants were concentrated 10-fold using centrifugal concentrators and protein quantification measured with the BCA assay. One dimensional (1D) gels coupled with liquid chromatography tandem mass spectrometry (LC- MS/MS) was used in separating out the soluble extracellular fraction of a virulent and non-virulent isolate of *P. perurans*. The extracellular proteins were also subjected to enzymatic activity using a protease assay and extracellular degradation capabilities of the parasite was also determined using gel zymography. An epithelial cell line was used to assess the host cytotoxic effects of the extracellular proteins from *P. perurans*. The epithelial gill cell line viability was assessed using a trio of assays.

Results

Cytotoxicity was detected when the epithelial cell line was incubated with *P. perurans* extracellular proteins. Confirmation of protease activity via the protease assay and gel zymography was also noted for both the virulent and avirulent strain. The proteins responsible for the cytotoxicity are currently being identified via LC MS/MS

Discussion and conclusions

A trio of assays was used to validate cytotoxictiy of the virulent and avirulent *P. perurans* strain on an epithelial cell line. The causative cytotoxic proteins are currently being analysed and identified using LC MS/MS. The proteins are suspected to play a role in Amoebic Gill Disease progression.

Determining the causative proteins will enhance our current knowledge of *Paramoeba perurans* and additionally facilitate future research efforts in developing therapeutics.

IS THERE A NEED FOR FLAT OYSTER (*Ostrea edulis*) RESTORATION IN DENMARK?

P. Nielsen*, C. Saurel, PS. Freitas, P. Barreau, LF. Møller and JK. Petersen

Technical University of Denmark, DTU Aqua, Danish Shellfish Centre, Øroddevej 80, 7900 Nykøbing Mors, Denmark
Email: peniel@aqua.dtu.dk

Introduction

Historically, the European flat oyster (*Ostrea edulis*) population in Denmark has been mainly located in sheltered areas on the West coast, i.e. Wadden Sea, Ringkøbing Fjord and in the Limfjorden, and less so in the Kattegat. The current flat oyster population is located in the Limfjorden, where it has survived for more than 165 years after it re-colonized the Limfjorden again, as the resumed salt water inflow increased the salinity in the Limfjorden when the North Sea broke through at Agger Tange in 1825. Although the population has been fluctuating, the feral flat oyster population is currently thriving and is supporting a sustainable regulated dredge fishery with landings up to 320t in 2018/19. For the last three years, the population has increased substantially from 1,500t to 6,000t and a similar trend is observed in 2019. Although, *Bonamia* disease was registered in 2014 in the Limfjorden and it lost its status as being declared *Bonamia* free. However, no mass mortality has been observed neither in aquaculture facilities nor in the feral population. The reasons for such increase are mainly due to successive successful natural recruitments and the establishment of flat oysters in new areas. Thus, unlike most other European flat oyster populations, which have reduced and sometimes disappeared from overfishing and disease, the flat oyster population in the Limfjorden is flourishing despite external pressure. A natural question could then be if there is a need for a flat oyster restoration program in the Limfjorden

The recent discovery of *Bonamia*, the irregularity in successful recruitment of flat oysters and the recent massive expansion of the invasive Pacific oyster (*Crassostrea gigas*) in the Limfjorden have raised some concerns regarding the future of the feral flat oyster population in the Limfjorden and aquaculture development. Spat collectors for flat oysters are colonized by Pacific oysters and mixed bottom oyster populations are now emerging in some areas of the Limfjorden. Despite the positive development in the flat oyster population in the Limfjorden, research efforts at DTU Aqua are focusing on: i) developing and securing a hatchery production from a potentially genetically diverse wild population of flat oyster to supply both restoration and aquaculture activities, ii) monitoring the possible development of *Bonamia* in the Limfjorden, iii) mapping the development, dynamic and interactions of both native and invasive oyster beds in the Limfjorden and iv) investigating potential areas for flat oyster restoration in the Limfjorden but primarily elsewhere in Denmark

Results and discussion

The presentation will give a short status of the development of both hatchery production and the feral population of flat oysters in the Limfjorden. It will also describe the various challenges facing the industry regarding: i) recent observations of the parasite, *Bonamia ostrea*, ii) competition from non-native species, iii) natural fluctuations in population size and recruitment but also new possibilities for marked development regarding i) breeding programs, ii) restoration and aquaculture production. Furthermore, an outline of perspectives for initiating flat oyster restoration programs in Denmark will be presented.

Introduction

Photobacterium damselae subsp. *piscicida* is a gram-negative bacterium that causes a serious health condition of both farmed and wild fish populations known as pasteurellosis (Pečur Kazazić al., 2019). However, both subspecies of *Photobacterium damselae* have been described as disease causative agent in marine fishes, and due to their genetic proximity are extremely hard to distinguish. This study characterizes genetically the isolate 42019IPMA, obtained from a possible pasteurellosis outbreak in meagre (*Argyrosomus regius*) produced in an open intensive system at Aquaculture Research Station, Portuguese Institute for the Sea and Atmosphere (EPPO-IPMA).

Material and methods

DNA from the isolate 42019IPMA was used to amplify and sequence the *csp*, 16S rRNA, *atp*A, *rpo*A and *rpo*D genes. The amplified PCR fragments were purified and sequenced (SECUGEN, Madrid). BLAST algorism was applied in partial nucleotide sequences obtained and ClustalW software was used to align the sequences. The evolutionary history was inferred by using the Maximum Likelihood method based on the model recommended by MEGA6 software to each partial sequence of 16S rRNA, *atp*A, *rpo*A and *rpo*D genes (Tamura et al. 2013).

The molecular fingerprinting of *Photobacterium* strains was performed with enterobacteria repetitive intergenic consensus (ERIC) PCR and repetitive extragenic palindromic (REP) PCR methods (Rodríguez et al. 2006). The strains used were reference strains *Photobacterium angustum* CECT5690T, *P. damselae* subsp. *damselae* CECT 626T, *P. damselae* subsp. *piscicida* CECT 5895, *P. angustum* CECT 5690T *P. iliopiscarium* DSM 9896T, *P. kishitanii* DSM 19954T, *P. leiognathi* CECT 4191T and *P. phosphoreum* CECT 4192T; the isolate 42019IPMA; and *P. damselae* subsp *piscicida* isolates 316, 319, a321, 354 and 356 recovered from Senegalese sole adults (*Solea senegalensis*), isolates 576 and 577, recovered from gilthead sea bream adults (*Sparus aurata*) and isolates 580, 581 and 582 from wild adult striped mullet (*Mugil cephalus*). Similarity between isolates and the reference strains was estimated using the Dice similarity coefficient with the software FAMD (Schlüter & Harris, 2006).

Results

The isolate 42191IPMA partial sequences of 16S, *atp*A, *rpo*A and *rpo*D genes showed similar percentage of similarity with *P. damselae* subsp. *damselae* and *P. damselae* subsp. *piscicida* strains available in Genebank dataset. The partial sequence of *csp* gene presented, however, 99.5 % of similarity with *P. damselae* subsp. *piscicida* and only 95.3 % with *P. damselae* subsp. *damselae*.

The phylogenetic trees derived from 16S, *atp*A, *rpo*A and *rpo*D partial sequences illustrates the position of the isolate 42019IPMA, clearly associated with *P. damselae*. The housekeeping genes, *rpo*A and *rpo*D, confirmed the clustering of the isolated 42019IPMA with *P. damselae* subsp. *piscicida* strain 91-197 (Teru *et al*. 2017) with a bootstrap value of 98 and 93 %. Therefore, these results support the diagnosis of isolated 42019IPMA as *P. damselae* subsp. *piscicida* strain.

Finally, molecular fingerprintin of *Photobacterium damselae* strains show that the isolated 42019IPMA is clearly grouped with both subsp. of *P. damselae* (subsp *piscicida* and *damselae*) and more closely related with the strains of *P. damselae* subsp *piscicida* CECT 5895 and isolated 316, 319, a321, 354 and 356 recovered from Senegalese sole adults (*Solea senegalensis*).

Conclusion

In conclusion, the genetic results show clearly that the strain 42019IPMA isolated from meagre (*Argyrosomus regius*) at EPPO-IPMA facilities is a strain of *P. damselae* subsp. *piscicida*.

Introduction

The frequent use of antibiotics to prevent the spread of diseases or to control the infections in aquaculture has shown development of antibiotic resistance strains. Hence, overuse and inappropriate usage of antibiotics needs to be minimized to reduce the risk of spreading resistance strains. Phages are gaining high importance as an alternative therapeutic agent to control the rise of multi-drug resistant (MDR) bacteria in aquaculture. In this study, we isolated and characterized a lytic phage (ETP-1), as an alternative bio-control measure of MDR pathogenic *E. tarda,* which causes edwardsiellosis to both freshwater and marine animals.

Methods

ETP-1 was isolated and characterized for its morphology and growth performance and growth inhibition effect of *E. tarda*. *E. tarda* growth inhibition was evaluated using different multiplicity of infections (MOIs) (10-0.01) of ETP-1 phage treatments. We further exemplified the study to identify the traits of growth inhibition by ETP-1 when combined use of ETP-1 plus ampicillin 2.5-25 μg/mL for 24 h.

Results and discussion

Morphological analysis revealed that ETP-1 belongs to *Podoviridae* family. Phage treatment alone showed MOI dependent bacteria growth inhibition, and ampicillin treatment showed higher *E. tarda* inhibition compared to control, but inhibition effect was lower than the phage treatment. Combined treatment was more effective in killing *E. tarda* showing the highest growth inhibition at ampicillin (5 μg/mL) plus ETP-1 (10 MOI). Our results showed that ETP-1 could inhibit growth of *E. tarda* more effectively than ampicillin, suggesting that ETP-1 has potential to be an important tool for controlling bacteria propagation, and combine with low dose of antibiotics (ampicillin) have greater effect.

CUSTOMIZED FEEDING TABLES FOR PRECISION FARMING: DEMONSTRATION FOR THE GILTHEAD SEABREAM

A. Nobre*[1,2], F. Soares[1], L. Conceição[1], T. Silva[1], J. Henriques[1], M. Sardinha[1], R. Serradeiro[2]

[1]SPAROS, Lda. Olhão (Portugal)

Introduction

Optimization of feeding in aquaculture is crucial to ensure the sector sustainability from both environmental and economic perspectives. Herein, a tool that aims to guide farmers to estimate feeding rates for their own targeted growth and the feeds in use is presented and illustrated for the Gilthead Seabream: The customized feeding tables (CFT).

Methodology

This tool is based on the Energy and Protein fluxes (EP model), which is a generic modelling approach (Nobre et al., 2019) derived from the bioenergetic factorial approach (Lupatsch, 2003). The CFT calculates the feed requirements for the user targeted growth, whereby the resulting feeding rates ensure a balanced feed DE/DP ratio. The CFT can be generated per feed or combined for a given set of feeds such that the best feeds concerning energy and protein requirements are selected. The tables can be generated for custom user-defined temperature and weight classes.

Table 1. Comparison of the DP/DE requirements for *S. aurata*: CFT and published data

DP/DE ratios: Digestible protein (mg) / digestible energy (kJ)			
Fish size (g)	**FAO (2019)**	**Lupatsch (2003)**	**CFT ***
0.8–3.3	30.2–27.6	–	–
10	–	30.0	28.9
5.6–29.8	25.9–22.7	–	–
17.5 - 49.9	28.1–21.5	–	–
50	–	24.4	26.2
42.5–146.3	22.4–20.8	–	–
100	–	22.2	24.0
209.0–333.0	23.8–23.8	–	–
300	–	18.9	23.1

* Calculated for the same conditions as for Lupatsch (2003) trials.

$$\text{Feed intake (g fish}^{-1}\text{ day}^{-1}) = 1.38\ (\pm 0.39) * BW^{0.681\ (\pm 0.026)} * e^{0.073\ (\pm 0.012) \cdot T} \quad \text{(Eq.1)}$$

Where, BW is fish body weight expressed as kg, T is temperature expressed as ºC.

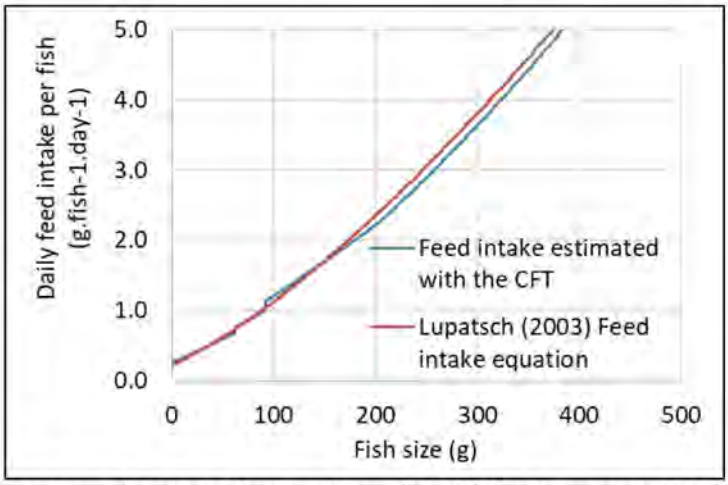

Figure 1. Comparison of the daily feed intake per fish: CFT and Lupatsch (2003) equation

(Continued on next page)

Results

The CFT is herein illustrated for the Gilthead Seabream (*Sparus aurata*). The evaluation of the CFT was carried out by: i) comparing the outputs of estimated ratios DP/DE requirements with those published by Lupatsch (2003) and FAO (2019), shown in Table 1; ii) comparing the generated feeding tables with the outputs of the feed intake equation (Eq.1) defined by Lupatsch (2003), shown in Figure 1.

Conclusions

Herein is shown a tool to calculate feeding rates for a given custom or targeted growth and considering the feeds in use. The CFT will be applied in the context of the MOONSHINE project in order to plan the seabream trials to be carried out for the testing of the control and novel feeds based on algae biomass. The outputs of the ad libitum trials will provide data for further evaluation of the CFT.

Introduction

Currently aquaculture operations generate a large number of variables and data. Data analysis and simulation methodologies can support informed decision making. However, given the level of expert knowledge required, few organizations are using these techniques to improve their decisions and knowledge about their production. Herein, is presented a suit of tools that can be used by fish farmers, to for instance: i) create feeding tables customized for the farm standard growth, ii) predict the impact of different feeding strategies on their farm performance, iii) to extract insights from the historical farm production data. The objective of this presentation is to illustrate the potential of the data analysis and simulation methodologies in a bream and bass farm and main take homes regarding the adoption of these technologies by other farmers.

Methodology

This presentation illustrates the application of several data analysis and simulation approaches to a commercial bream and bass farm located in located in southwest Europe (Ria de Alvor, Portugal): 1. Energy and protein flux model (EP model, Nobre et al. 2019) for generating customized feeding tables. 2. Nutrient based model (Conceição et al. 2018) to predict fish weight, time to harvest, estimate feed consumption, oxygen consumption and nutrient excretion among other variables. 3. Data analysis to extract insights from the farm production data. At an initial stage the datamining process was carried out at a fish farm based on a very limited dataset to illustrate how these techniques can be applied even in early stages of adoption of advanced data management systems.

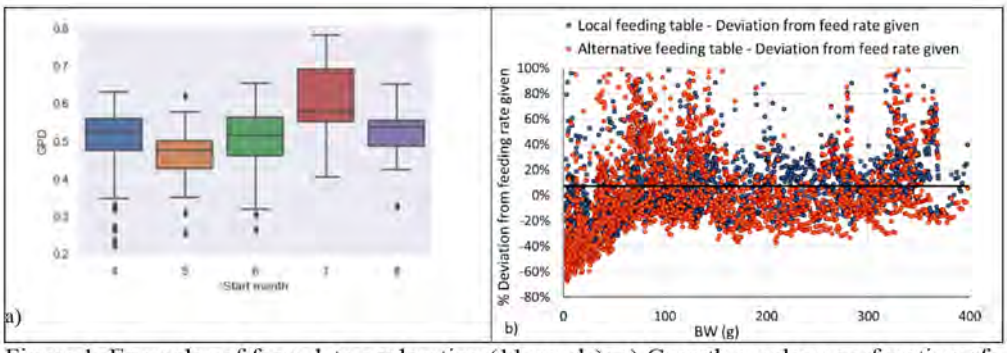

Figure 1. Examples of farm data exploration (11 ponds): a) Growth per day as a function of the start of production, b) comparison of feeding tables with feeding rate given.

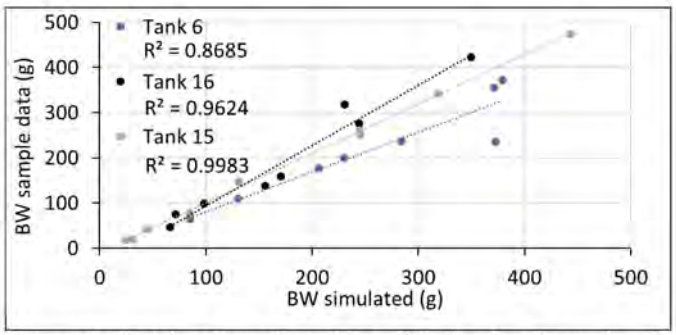

Figure 2. Nutrient based model validation for 3 ponds of seabream at the commercial farm.

(Continued on next page)

Results

As an example of the data exploration carried out at the fish farm, Figure 1 a) shows the influence of the start month of production in the fish growth per day. Figure 1 b) illustrates other application of datamining to provide insights to farm managers: in this case for the farmer to compare the feeding rate given two feeding tables: its own and an alternative based on the EP model. The advantage of the customized feeding table is that it is calculated based on the fish energy and protein requirements for a given feed and on the farm target growth curve.

Figure 2 shows the validation outputs of the nutrient based model for 3 tanks of the commercial farm.

After ensuring confidence on the model a dashboard was prepared to provide updated estimates about fish weight, time for reaching harvestable weight and feeding requirements up to the end of the production cycle.

Discussion and conclusions

Critical points a farmer should consider before carrying out system data analysis and simulations: i) define specific objectives and questions to be analysed given the wide range of possible analysis, and ii) establish a data flo , which requires a data management system for gathering and integration of the relevant data. Analysis and simulation of aquaculture systems is an evolving task, during which are identified new questions, variables to be collected and further analysed.

HOW DO HYDROLYZED INSECT MEALS AFFECT SEA TROUT (*Salmo trutta trutta*) MICROBIOTA?

S. Nogales-Mérida, J. Mazurkiewicz, M. Rawski, A. Józefiak, . Gobbi B. Kierończyk, A. Benzertiha, Z. Mikołajczak and D. Józefia

HiProMine S.A. Poznańska 8, 62-023 Robakowo, Poland
E-mail: silvia.nogales@hipromine.com

Introduction

Insect meals are known mainly as an excellent source of protein which is between 9.5% to 70.1% (Sánchez-Muros et al., 2014), although there are a good source of antimicrobial peptides (AMP) and chitin, which can promote animal health (Gasco et al., 2018; Józefiak and Enberg, 2017). These compounds exhibit activity against bacteria, fungi, and viruses (Józefiak and Enberg, 2017) and they start playing a key role in the animal gut. Besides, Wang et al. (2018) commented that the microbiota of the gastrointestinal tract is modulated by environmental and nutritional factors. Considering these aspects the aim of this test was to evaluate the effect of two hydrolyzes insect meals inclusion in the gut microbiota of sea trout.

Materials and methods

After 60 days, sea trout (*Salmo trutta* m. *trutta*) fingerlings were fed with three experimental diets: control diet with only fishmeal (CON); TMD: 10% of hydrolyzed *Tenebrio molitor* meal; and ZMD 10% of hydrolyzed *Zophobas morio* meal. At the end of the trial, the fish were sacrificed and the samples of the gastrointestinal content were collected and immediately stored at –80ºC. for FISH analysis. The analysis was performed according to Józéfiak et al., (2011) method. The oligonucleotide probes used for this study were selected from the literature. To distinguish the total count (DAPI) of bacteria from other particles in the samples, oligonucleotide probes were labeled with DsRed and Alexa Fluor fluorochromes. The filters were left at -80°C for 24 h in the dark until visualization with the use of a Carl Zeiss Microscope Axio Imager M2. The numbers of detected bacteria are expressed in colony-forming units/g of digesta (CFU/ml) and were calculated according to the equation given below:

$$\log CFU / g = \log(N \times (\frac{WA}{PA}) \times (\frac{Sweight + Dweight}{Sweight}) \times (\frac{1000}{Svolume}))$$

where N = number of visible bacterial cells, WA = the work area of the filte , PA = picture area, S_{weight} = sample weight, D_{weight} = diluting factor weight, and S_{volume} = volume of the sample pipetted onto the filte

Results

The inclusion of hydrolyzed ZM meal decreased significantly the quantification of *Aeromonas* spp (AER 66), *Enterococcus* spp as well as in the *Carnobacterium* spp, which was increased with TM meal too ($P < 0.05$). In the case of the *Lactobacillus* group, the inclusion of TM meal reduced significantl . The total number of bacteria, and *Aeromonas* spp (AER 642), as well as *Bacillus* spp, did not exhibit any significant di ferences among treatments (Table I).

Table I. Microbiology results of the digesta of sea trout fed with different diets at the end of the experimental period

	Treatment		
	Control	*T. molitor*	*Z. morio*
Total number of bacteria	9.49	9.52	9.54
Aeromonas spp. (AER 66)	9.34[a]	9.36[a]	9.24[b]
Aeromonas spp. (AER 642)	9.28	9.18	9.13
Carnobacterium spp.	9.34[a]	9.17[b]	9.10[b]
Enterococcus spp.	9.29[a]	9.29[a]	9.15[b]
Lactobacillus group	9.38[a]	9.18[b]	9.23[ab]
Bacillus spp.	9.13	9.12	9.19

Values in the same row having different superscript letters are significantly different at $P < 0.05$.

(Continued on next page)

Discussion and conclusion

According to Wang et al. (2018), microbiota presence is conditioned by the type of diets and in the case of freshwater fish species, *Aeromonas* is one of the dominant intestinal microbiota. Besides, Egerton et al. (2018) remarked that they are especially found in carnivorous and omnivorous ones. Moreover, Skrodenytė-Arbačiauskienė et al. (2008) reported that 22% of the gut microbiota of sea trout was *Aeromonas* and 6% were *Carnobacterium*, and these amounts were conditioned by the type of insect consumed, which were different from *Salmo salar*. Although, these authors did not report *Enterococcus* genus in sea trout only in Salmon fed with another amount of insect and species. Similar to this genus, *Lactobacillus* and *Bacillus* were not found in sea trout only in salmon (Egerton et al., 2018). Considering that the genera *Enterococcus*, *Lactobacillus* and *Bacillus* are not part of the microbiota of sea trout; beside the "host species" shapes microbial communities in fish (Larsen et al., 2014). As the fishmeal was not totally replaced in this test, the gut microbiota of all the animals kept similarities and insect meals only reduced the number of certain genera of bacteria that in natural conditions would not be presented in the fish gut. To confirm these findings would necessary to do further research to establish these findings.

Introduction
Jellyfish is the major subject of study of "GoJelly - a gelatinous solution to plastic pollution" (2018-2021), a project financed by programme Horizon 2020 of the European Union. The project involves 15 European research institutions and private companies and has the participation of the Chinese Academy of Sciences.

Results
Under GoJelly the closing of the life cycle of several jellyfish species was made in captivity at Madeira Oceanic Observatory (OOM) laboratories namely, *Rhizostoma pulmo* (Rhizostomatidae), *Aurelia solida* and *Chrsyaora hysoscella* (Semaeostomeae) and several trials were performed to evaluate the influence of environmental factors on the reproduction of these species. Experiments using jellyfish in aquafeeds were also performed. This communication reports the preliminary results and comments on the major improvements on biological and ecological knowledge of the species and rearing technology.

Introduction

Aquaculture is developing rapidly at a global scale[1] and sustainable practices are an essential part of meeting the protein requirements of the ballooning human population[2]. Although aquaculture as a whole is expanding, marine aquaculture accounts for a smaller percentage of current production (about one third) compared to more inland fish-farmin [1]. Within the UE, Macaronesia Archipelagos- Madeira and Canary Islands) have been developing aquaculture activities in the last 25 years, mostly devoted to coastal farming of seabream and seabass. Still, the competition for the use of space with other economic activities, namely tourism, has brought attention to public perception and is rising a number of questions that have to be addressed. In order to manage and facilitate economic growth, whilst safeguarding environmental objectives in the marine environment, legislation mandating the development of Maritime Spatial Planning (MSP) was introduced in the UE in 2014. MSP turns to be a place-based, multi-sectoral decision-making approach that is being widely promoted for reducing the conflicts and impacts commonly encountered in conventional sector-by-sector planning[3,4]. Current situation in the portuguese archipelago of Madeira is an example of how public perception and social media can condition the development of coastal aquaculture and MSP process.

Analysis of the aquaculture industry in Madeira Archipelago

Although Portugal has the highest *per* capita fish consumption rate in the EU (54 kg/year in live weight terms)[5], in 2016, national aquaculture production accounted for only 5.9% of fish unloaded in port, demonstrating not only yhat aquaculture was not considered by national consumers as an alternative, but also that efforts were needed to develop the sector. In the last three years, with the support of the European Maritime and Fisheries Fund, national efforts resulted in increase of aquaculture output. In Madeira archipelago, aquaculture as an industrial activity had small expression as until 2016, only one fish farm existed producing between 300-600 tons per year. The recent implementation of MSP and the lawful changes in order to reduce license time, conducted to a sudden increase in the number of companies applying for coastal zones defined within the MSP as Zones of Interest for Aquaculture (ZIA) that would turn Madeira the biggest national seabream "producer", accounting for more than 60% of the production. Consequently. this has risen questions and called social media attention. In less than two years, more than 20 news came out in social platforms, newspapers, local TV and radio. Underlying most of the news were visual impacts in a touristic island and environmental impacts. Experience from other areas of the globe, including the close archipelago of Canary Islands, has shown that accelerated growth of fish farms may lead to important socio-environmental conflicts that decrease or even in some cases stop the expected growth of the industry. Consumers are exposed to numerous, and often contradictory, messages with respect to issues such as food safety and environmental conflicts. The media coverage of an issue therefore may have an impact on the public's demand for (politically) solving an issue[6].

Material & Methods

Analyses of newspaper articles, national and regional was done through content analysis, with the common ground of extracting the meaning from the context of text to understand what that text meant to the audience[6].

Results & Discussion

Analysis of newspapers and Tv programmes showed that confusing messages were being diffused to the consumers. Although there was a broad representation of actors that contributed to the newspaper articles and debates in TV shows, where local scientists, NGO's, Public Administration and Political parties were represented, final messages regarding the characterization of the sector were not clear. It is clear that opposition political parties and NGO's make their statements underlying their position trough fear of environmental impacts and consequences to the tourism activity. Newspaper articles were either 100% positive, announcing Madeira´s ambition to increase the production or either reporting the controversy around the installation of new fish cages. Technology was only included in the news by means of explaining that collar fish

(Continued on next page)

cages are the most common equipment used that justify coastal aquaculture. Human food and food security were hardly mentioned and most time were referred by the NGO´s. Public Administration comments were regularly directed to the importance of MSP process, already implemented in the archipelago and the fact that the ZIA´s were established after a public process consultation. Industry actors were hardly present in the news and in all cases expressed positive opinions towards coastal aquaculture. Scientific experts and public administrators not directly involved in the licensing process, represented more neutral positions or conservative opinions presenting both positive and negative contributions written by these groups. Major explicit negative opinion was on the environmental impacts, using the salmon industry as an example. Expressions such as "Degradation of the water quality", "water pollution" and "aquafeeds" were the words used to contextualize those negative impacts. Implicitly there was an association with tourism negative reaction to the visual observation of the collar cages, but no inquiries were made.

These findings can be seen easily understood by contextualizing today´s society. We live on an era in which the media desire to attract consumers by preferring conflict over success (e.g., by sensationalizing problems)[6]. General public many times is not aware of the amount of aquaculture products consumed on daily basis in their houses. Often there is also poor knowledge and understanding of aquaculture biological and ecological principals as most of the available information is of scientific character and not available.

The current situation on social media leveraged by public unawareness has delayed the authorization of several projects in the archipelago questioning the entire MSP implementation.

FROM LARVAE TO PLATE – AN EXPERIMENTAL LAND-BASED RAS CULTURE OF *Litopeanaeus vannamei* IN POLAND

M. Normant-Saremba*, H. Łądkowska, H. Kendzierska, B. Dmochowska and K. Smolarz

Institute of Oceanography, University of Gdańsk, Al. Marszałka Piłsudskiego 46, 81-378 Gdynia (Poland)
E-mail: monika.normant@ug.edu.pl

Introduction

The Pacific whiteleg shrimp *Litopenaeus vannamei* is a key shrimp species in global aquaculture. The European market is dominated mainly by frozen or cooked shrimps imported from Asia or South America, where they are grown mainly in ponds. Such breeding is however possible only in warm climatic zones. In order to become independent from imports as well as to introduce a fresh (unfrozen) product to the market, a number of farms producing *L. vannamei* in the recirculating aquaculture system (RAS) have recently been created in Europe. This way of breeding not only allows the production of exotic species beyond their native ranges, but also the control and optimization of growth conditions. So far, two farms producing *L. vannamei* have been established in the Baltic Sea region. However, cultivation of this exotic species using innovative techniques raises an interest of many potential producers, including those from Poland. To support small and medium-sized enterprises representing the aquaculture sector in Poland, which are potentially interested in production of *L. vannamei*, an experimental culture of this species was initiated at the University of Gdańsk (Poland) under the InnoAquaTech project. In addition to the demonstrative character, the culture also served as a study site to examine growth rate, health status and nutritional value of the studied shrimps.

Materials and methods

Two laboratory RASs, each consisting of three units: (1) culture tank (500 l of volume), (2) main unit with filters (solid, ammonia and protein removal) and set of sensors for controlling water parameters (temperature, salinity, pH, redox) and (3) water preparation tank (250 l), were installed at the University of Gdańsk (Poland) in 2017. Specific pathogen free larvae and post-larvae of *L. vannamei* (approx. 2000) were imported from a hatchery in Florida, US. They were gradually acclimatized to a higher temperature (25°C) and lower salinity (28ppt). Two breeding cycles, lasting 18 and 32 weeks respectively, were carried out and in each of them different feed was used (Gemma DIAMOND, Scretting, Norway and CreveTec, AQUABIO, Belgium). During the experiment, shrimp behavior and mortality were observed. In addition, every two weeks, the length (± 1mm) and weight (± 0.001g) of 20 randomly collected shrimps were determined. After the end of experiment the shrimps were killed by chilling in an ice slurry and then preserved for further analyses which included health status (examination of any bacterial, fungal and viral diseases as well as abnormalities in digestive, circulatory and respiratory systems), elemental composition (contents of carbon, hydrogen, nitrogen) and calorific value (Grodzinski et al., 1975).

Results

During the breeding, cannibalistic behavior was observed, resulting in the increased mortality of individuals, as well as mechanical damage to appendages such as antennas, rostrums, paraeopods, pleopods, telson and uropods. In majority of cases, such an exoskeleton lesions were accompanied by melanization, i.e. the accumulation of blood cells at the site of infection and the deposition of pigment (melanin). The morphological and anatomical changes indicating the poor health condition were observed only in single individuals. The exceptions were fungal infections and inflammation. More than half of the analyzed shrimps had fungal infections in the form of white spots, mainly on the inner side of the carapace, on paraeopods and uropods, less frequently seen on antennas and rostrum. Regardless, the shrimp mass increased at a rate of 0.41-0.54g per week. In both breeding cycles, the final shrimp mass was about 10 g. The mean content of carbon, hydrogen and nitrogen in the dry weight (DW) of abdominal muscle was respectively 45.5 ± 1.6%, 6.8 ± 0.4% and 13.5 ± 0.5%, whereas energy value amounted to 19.9 ± 0.9J mg^{-1} DW.

Discussion and conclusion

Despite the relatively high mortality rate of shrimps caused mainly by cannibalism and RAS system failure, the experimental seems to be successful. Shrimps were characterized by good condition and health, and their weight gain was satisfactory. Thanks to the culture, it was possible to learn the biology and ecology of *L. vannamei*, and the acquired skills can be transferred in the future to stakeholders developing production of this species in Poland.

VALINE REQUIREMENT OF AFRICAN CATFISH (*Clarias gariepinus*) JUVENILES

L.C. Nwanna* and C.S Olaniyi

Department of Fisheries and Aquaculture Technology, Federal University of Technology Akure-Nigeria
Email: drlel@yahoo.com

Introduction

Valine is an essential branched amino acid (BCAA) that has great impact on lipid and glucose metabolism. It could prevent high–fat diet induced obesity in animals. Valine can be used as an energy source in the muscles, and preservation of glucose usage. It has been associated with maintenance of the lean body mass during prolonged exercise in both man and mammalian models; and assists in the synthesis of glutamine and alanine and in balancing of other BCAAs such as leucine and isoleucine. However, over dosage causes skin crawling and hallucinations. As there is dearth of information on valine metabolism in African catfish, the study investigated and determined the optimum level of valine required for the production of African catfish

Materials and Methods

African catfish were fed to apparent satiation daily for 56 days, with five diets containing different levels of valine at, 0.00, 0.40, 0.80, 1.20 and 1.80% making treatments 1-5. The feeding trial was conducted in triplicates in glass tanks. Standard methods were used in the generation of data and analyses, while fourth polynomial degree regression analysis was used to estimate the valine requirement based on the specific growth rate of the fish. ANOVA was applied while Duncan Multiple range test was used to separate the means.

.

Results and Discussion

Although there was no definite pattern of increment in the dietary amino acids as a result of the supplemental valine, addition of valine in the diets slightly increased other amino acids in the diets particularly the other BCAAs, Leucine and Isoleucine. Supplementation of valine in the diets improved the growth performance until in the fish fed diet containing 0.8% of valine and then declined consistently, suggesting that level as the optimum. Nevertheless, a fourth degree polynomial regression analysis indicated 0.72g/100g diet as optimum (Fig. 1). Similarly, supplemental valine significantly improved the carcass minerals (Table 1) but slightly increased some amino acids. Interestingly, the carcass cholesterol decreased with increasing values of the supplemental valine (Table 2). Manipulation of the dietary valine will reduce the minerals required for the production of aqua-feeds, thereby reducing the unit cost of aquaculture production. Also valine can be used to produce fish with low level of cholesterol which will reduce cardiovascular related diseases in people that consume the fish. This supports the work of Huang et al. (2018).

Conclusion: Addition of valine in the diets improved fish growth performance and nutrient utilization. And the valine requirement of African catfish was estimated as 0.72g/100g diet

INFESTATION PRESSURE OF SALMON LICE (*Lepeophtheirus salmonis*) ON RETURNING ATLANTIC SALMON (*Salmo salar*) IN CENTRAL NORWAY

A. V. Nytrø[a]*, R. E. Olsen[a], B. Finstad[b]

[a] Department of Biology, Norwegian University of Science and Technology, Trondheim (Norway)
[b] Norwegian Institute for Nature Research, Trondheim (Norway)
*E-mail: ane.v.nytro@ntnu.no

Introduction

The salmon louse (*Lepeophtheirus salmonis*) is a directly transmitted marine ectoparasite found on salmonids in the North Atlantic and North Pacific oceans. The parasite grazes on skin, mucus and underlying tissue of the fish, causing osmoregulatory dysfunction and physiological stress responses, making the fish more susceptible to secondary infections and mortality (Finstad, et al., 2000).

The parasite has 8 developmental stages, where the infective copepodite stage attaches to the young post-smolt salmon as the fish migrate out to open sea to graze. During this sea phase the lice molt to become gravid females on the host, producing egg-strings that hatch to produce new generations of infective copepodites. Louse have been recorded to survive for up to 15 months under laboratory conditions (Hamre, et al., 2009), but information regarding the survival and life cycle of salmon lice in the open ocean is scarce (Costello, 2006). Jacobsen and Gaard (1997) observed densities of up to 30 adult female lice per fish returning from the sea, and early developmental stages of lice have previously been observed on trout returning from the ocean in Caster, England, indicating that lice infections can occur in areas where host densities are low and salmon farming is non-existent (Tingley, et al., 1997). The possibility of open sea re-infection of copepodites from gravid females, originating from chalimus from near-shore waters is therefore hypothesized (Jacobsen, et al., 1997), and may contribute to explain the observed stability of sea lice densities in areas with low impacts from farmed salmon.

Materials and methods

This work will address the potential impact of sea lice infections from lice on the annual return of salmon, analyzing historical data from the returning salmon to Agdenes years 2012-2018, accounting for lice and biomass data for <1000 individuals annually in order to contribute to existing knowledge about the association between lice infestations on Atlantic salmon, timing for return and molting stage of *L. Salmonis*.
Further, such information is important as very little is known about survival of salmon lice during the sea migratory stage of salmon. The effect of sea lice on salmon population size, age- and size distribution will be evaluated.

Results and discussion

The main outcomes will be presented.

Introduction

The aim of the current study was to determine the stimulation of a microencapsulated *Malpighia umbellata* phenolic extract of the immune response of *Litopenaeus vannamei*, in laboratory conditions, against the white spot syndrome virus (WSSV). The phenolic composition and carotenoid contents of leaves, bark, and fruits of *M. umbellata*; the changes in the phenolic composition and contents of carotenoids and vitamin C of its fruits in different stages of maturity; and the antioxidant properties of its leaves, bark, and fruits were assesed. Leaves accumulated the highest levels of flavonoids (10.55 mg/g dry extract), tannins (21.16 mg/g dry extract), and carotenoids (424 63 µg/g dry tissue); whereas, the highest level of total phenolics was found in bark (47.12 mg/g dry extract). Twenty-two phenolics were characterized by high performance liquid chromatography with diode array detection (HPLC-DAD). Apigenin-7-O-glycosides, phenolic acids, and flavonols were predominant in leaves, bark, and fruits, respectively. Important chemical variations were found during fruit ripening. A three-days bioassay was carried out to evaluate the imunoestimulating effect of microencapsulated extract added to food, evaluating the genic expression of six antioxidant enzymes, forming part of the immune system of *L. vannamei*. The bioassay treatments were: I) control diet (Camaronina®), II) 0.1 mg of microcapsuled per gram of food, III) 0.5 mg of microcapsuled per gram of food, and IV) 1.0 mg of microcapsuled per gram of food. The semiquantitative expression of six immune system genes were carried out by RT-PCR. The addition of microencapsules containing the leaf extract of *M. umbellata* stimulated the expression of antioxidant enzyme genes, mainly at 48 h and especially the proPO gene (Fig. 1).

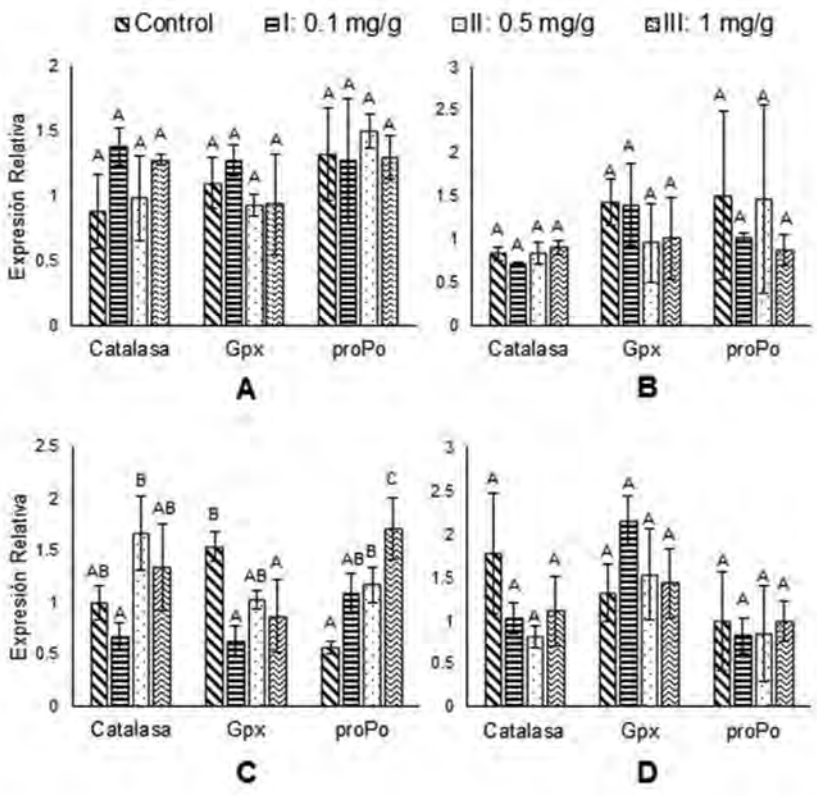

Fig. 1. Relative mRNA expression of SOD and lysozyme in hemocytes and, HSP70, HSP90, chymotrypsin, and trypsin in hepatopáncreas of *L. vannamei*. Values are mean ± SE (n = 9). Different superscript indicates significant differences (P<0.05).

(Continued on next page)

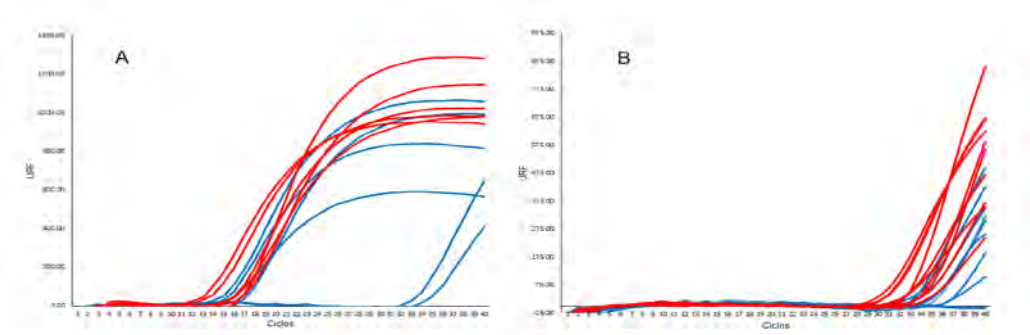

Fig. 2. Análisis de qPCR en la detección de SVMB en Litopenaeus vannamei a los 15 (A) y 30 (B) días de la alimentación con 1 mg g-1 de extracto microencapsulado foliar de Malpighia umbellata. Camarones control: rojo; tratamiento (1 mg de microencapsulado/g de alimento): azul

A second bioassay for 30 days revealed that the addition of microcapsules to food had no effect in the growth of shrimp. survival was significantly different between treatment and control. The shrimp fed the microcapsule diet remained alive during the 30 days of the bioassay, while the survival of the control shrimp decreased to 93.8 ± 5.57%. The addition of the microencapsulated phenolic extract in the feed revealed a positive effect on the immune response of *L. vannamei*, since in the control shrimp, higher expression of viral protein was found than in those fed microcapsules mixed in the feed. The addition of microcapsules to food significantly increased shrimp survival and significantly decreased the prevalence of white spot syndrome virus on *L. vannamei* (Fig 2.).

The 15-day infection of the bioassay revealed a survival of 80% in the shrimp fed microcapsules in the formulation of their diet, while the control showed a survival of 66%. Survival and prevalence of SVMB in shrimp fed microcapsules (1 mg g^{-1}) at 15 and 30 days of the bioassay (Table 1).

The addition of microencapsules containing leaf extract of *M. umbellata* stimulated the expression of antioxidant enzyme genes, mainly at 48 h and especially proPO. The addition of microencapsulates containing leaf extract of M. umbellata had no effect on the Shrimp Specific Growth Rate. On the contrary, it had a positive effect on the survival and prevalence of SVMB, mainly at 30 days of bioassay. *M. umbellata* represents an alternative for the prevention and treatment of SVMB of shrimp *L. vannamei* that can contribute to improve the culture and production of this crustacean.

LIVER TRANSCRIPTOME OF JUVENILE DIPLOID AND TRIPLOID ATLANTIC SALMON (*Salmo salar* L.)

D.K. Odei[1,2*], S. Peruzzi[2], Ø. Hagen[1] and J.M.O. Fernandes[1]

[1]Faculty of Biosciences and Aquaculture, Nord University, 8049 Bodø, Norway

E-mail: odei.d.kvame@uit.no

Introduction

Triploid fish are of interest to solve key issues for the sustainable development of Atlantic salmon (*Salmo salar* L.) farming in Norway and other producing countries, namely the impact of farmed escapees on wild stocks and pre-harvest sexual maturation. Despite this, uncertainties regarding the performance of cultured triploid stocks have hindered the widespread adoption of triploid salmon by the industry, excluding in Tasmania (Benfey, 2015). The liver is the main organ involved in fish metabolism and plays roles in detoxification and immunity with effects on fish health, welfare and growth. Previous work has focused on the molecular mechanisms occurring in the liver of diploid and triploid salmon in fish fed plant-based diets up to 24 weeks after start-feeding (Vera et al., 2017). In this study, we compared the liver transcriptome of diploid and triploid salmon fed a standard fishmeal commercial diet from fry stage to the completion of parr-smolt transformation.

Materials and methods

The detailed description of the experimental set up, fish and feed used in this experiment is reported in Peruzzi et al. (2018). Fish were reared following standard husbandry procedures and sampled at 21, 30 and 38 weeks post start-feeding (2370, 3010 and 3665 degree days, dd) corresponding to fry, parr and smolt stage, respectively. Transcriptome techniques involved the extraction (QIAGEN) and use of total RNA from fish liver for RNA-seq library preparation (NEBNext), next-generation sequencing on the NextSeq500 (Illumina), and bioinformatic analysis using TopHat2 for mapping and DESeq2 (Love et al., 2014) for differential expression (Odei et al., in preparation).

Results

The PCA (Principal Component Analysis) plot for sequenced data did not indicate clustering by ploidy; instead, the data clustered in fry, parr and smolt groups, with the exception of one smolt fish (Fig. 1). There were 34 DEGs (Differentially Expressed Genes) with an absolute fold-change > 2 and an adjusted *p*-value <0.05 for comparisons which define the ploidy effect. In contrast, comparisons between ontogeny stages from fry to smolt within each ploidy resulted in 5642 DEGs. GO (Gene Ontology) enrichment analysis for all DEGs returned no significantly enriched GO terms associated with ploidy while comparisons for ontogeny in each ploidy group showed significantly enriched GO terms within down-regulated DEGs only (Benjamini correction < 0.05).

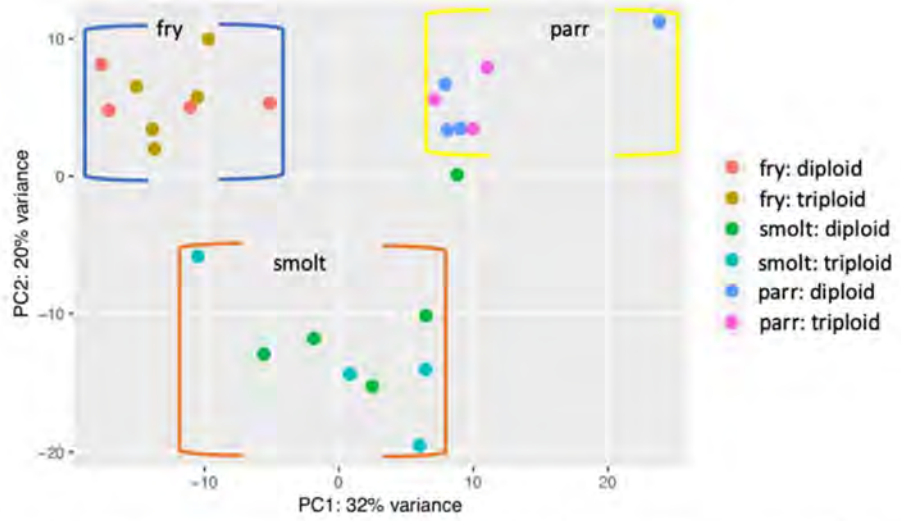

Figure 1. Principal Component Analysis (PCA) plot for all sample points. Individual samples (n=4-5 fish/ploidy/stage) of diploid and triploid individuals cluster by ontogeny stage (fry, parr and smolts) rather than ploidy.

(Continued on next page)

Discussion and conclusion

Findings from this study revealed a relatively small number of DEGs between ploidy groups, which suggests a close similarity in the liver transcriptome between diploid and triploid Atlantic salmon. In contrast, the effect of ontogeny assessed by comparing fry, parr and smolt showed very high liver transcriptome responses for both diploid and triploid fish. Similar functional categories identified for top DEGs for both ploidies contribute to parr-smolt transformation, while few top DEGs were ploidy-specific. The majority of significantly enriched biological processes for GO terms down regulated in fry compared to parr were related to nucleotide and energy metabolism, while immune system processes were significantly down regulated in parr when compared to smolts in both ploidies. The striking resemblance in GO terms for both ploidies is likely due to a phenomenon of genome dosage compensation, which may be involved in polyploidy regulation (Shrimpton et al., 2007).

A MACHINE-LEARNING-BASED APPROACH TO FORECAST HARMFUL ALGAL BLOOMS

Fearghal O'Donncha[1] and Scott C. James[2]

[1]Cognitive IoT, IBM Research, Damastown Ind. Park, Mulhuddart, Dublin 15, Ireland
Email: feardonn@ie.ibm.com
[2]Baylor University, Departments of Geosciences and Mechanical Engineering, Waco, TX

Introduction

Harmful algal blooms (HABs) and the environmentally persistent toxins they produce affect virtually every coastal region. HABs are a natural phenomenon resulting from mass proliferation of phytoplankton in waterbodies and are generally caused by diatoms and dinoflagellates in seawater or cyanobacteria in freshwater (Sanseverino et al. 2016). These blooms can have devastating effects on aquaculture leading to fish kills in cage systems (Anderson and Rensel 2016) or the closure of shellfish growing sites (Hoagland and Scatasta 2006) resulting in economic losses in the millions of euros and hampering industry development. The causes and consequences of these blooms have spurred interest in developing a capacity for predicting HAB events facilitate public and private decision making.

The challenges of predicting HABs relate to the broad spatial and temporal scales involved in conjunction with the complex relationships between environmental drivers and varied algal species. These complexities have led to concern that forecasting HABs in dynamic ocean environments is not possible and is an area of ongoing research (Anderson and Rensel 2016). The most common approach defines algal cells as passive particles or tracers within a hydrodynamic model and simulates their fate and transport within a waterbody (e.g., Velo-Suárez *et al.*, 2010). More sophisticated approaches also consider the biological activity of the algae by coupling hydrodynamic models with biogeochemical submodules that consider advection, diffusion, and reaction of cells (e.g., McGillicuddy *et al.*, 2011). Current challenges in predicting HABs relate to developing regional models, the transferability of these models to other geographies, and the integration of real-time data with predictive models.

An alternative to physics-based modelling, is to leverage the large volumes of data collected by satellite and in-situ sensors to develop data-driven approaches. In this work, we developed a computationally lightweight machine-learning-based approach to make seven-day forecast of algal blooms (using Chlorophyll-*a* (Chl-*a*) as a proxy) and applied the model at 718 locations globally. The predictions demonstrated accuracies comparable to state-of-the-art models at a fraction of the computational cost, while the data-driven nature means the model can be easily applied at arbitrary locations (because the model predicts based on data not any parametrisation related to species or geography).

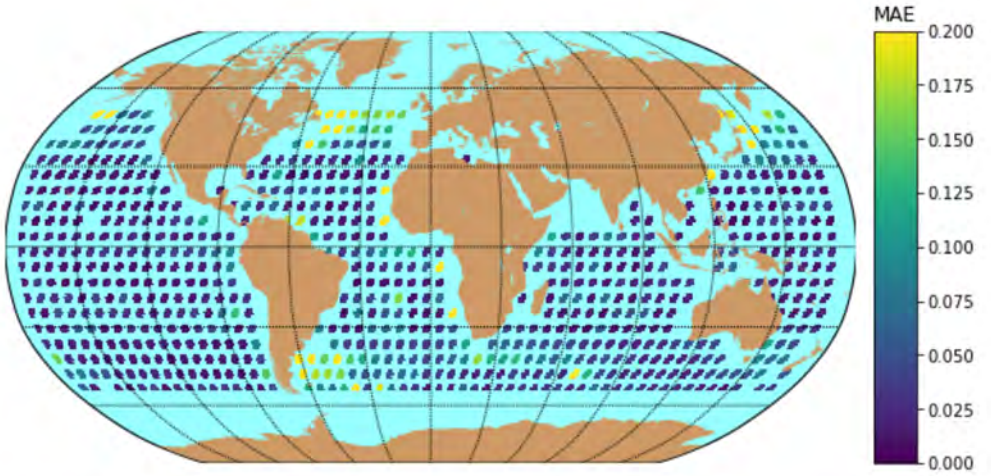

Figure 1: MAE between seven-day model forecasts of Chl-a and MODIS measurements at all global locations (mg/m^3).

(Continued on next page)

Methodology and Results

Training data for the machine learning models was 17 years' worth of Chl-*a* data from the MODIS instrument aboard the NASA Aqua satellite. Although global coverage can nominally be achieved every 1–2 days, the actual temporal resolution is reduced to 5–10 days because of cloud cover. A multilayer perceptron model was developed to learn Chl*a* forecasts based on: (a) MODIS-measured Chl-*a* concentrations, (b) sea surface temperatures (SST), and (c) light intensities (LI). An automated hyperparameter tuning exercise was undertaken at an initial mid-Atlantic location using data from 2002 through 2018. The optimised MLP network consisted of eight hidden layers and 32 nodes, which closely captured measured dynamics of Chl-*a*.

Model performance was evaluated at 718 points equally distributed around the globe. For each location, the model was trained (using the same set of hyperparameters) from data at that coordinate and validated against the 10% of data held back (approximately 19 months). For each point, mean-average-error (MAE) was computed by comparing the seven-day forecast against measurements. Figure 1 presents the MAE for each location. The machine-learning approach adapted readily to the notably different dynamics across the geographically distinct locations. Average MAE was less than 0.12 mg/m^3 and, notably, the data-driven approach produced consistently accurate results for all locations. The applicability of the approach can be of significant value toward managing and responding to HABs in coastal and freshwater sites

TOOLS FOR NEW AND FLEXIBLE APPROACHES FOR AQUACULTURE LICENSING AND REGULATION

P. O'Donohoe*, F. Kane, J. Casserly and S. McLoughlin

Marine Institute, Rinville, Oranmore, Co. Galway, Ireland
Email: pauline.odonohoe@marine.ie

Introduction

While the annual consumption of fish is increasing, overall EU production is considerably lower than global volumes. Aquaculture is one of the pillars of the EU's Blue Growth strategy and its development forms part of the Europe 2020 strategy. The stagnated growth of the EU aquaculture industry is well-documented and the consenting process has been highlighted as a key bottleneck to growth. There is a need for improvements to the consenting system to facilitate growth within the sector. Key to growth and development is a reduction of administrative burdens, costs and uncertainties related to the approval of production licences. Europe plans to help increase the sector's production and competitiveness and key priorities to facilitate the sustainable development of aquaculture include simplifying administrative procedures; ensuring access to space; enhancing competitiveness; and promoting a level playing field for operators

The H2020 project TAPAS, Tools for Assessment of Planning and Aquaculture Sustainability (http://tapas-h2020.eu/), aims to support EU member states to establish a coherent and efficient regulatory framework to support sustainable growth of the aquaculture sector in line with the EU's Blue Growth Strategy. The project, aims to establish new strategies and models for sustainable growth in the aquaculture industry. With the intention of creating new, cost-efficient, management tools and flexible approaches for the European aquaculture secto .

Methods

As part of this process a critical review of existing legislation and practises across European countries and sectors and analysis to identify the perceived impacts and bottlenecks of the current regulatory frameworks, was carried out. Extensive consultation with stakeholders and regulators was conducted to identify the key bottlenecks and issues in the licensing regulation across jurisdictions. These consultations and responses were categorised to identify areas of commonality and key areas. Recommendations were collated that could lead to efficiencies and improvements in licensing and regulation.

Results and Discussion

The results of the consultation process identified key issues and bottlenecks in the licensing process. Based on the collected data, research was conducted to resolve issues through the suggestion of novel approaches and the creation of tools to improve efficiency in the regulatory and licensing process. The flexible approaches and tools were ground-truthed during continuous consultation with stakeholders and industry to ensure acceptability and utility of the approaches. This presentation outlines the results from the final stakeholder input and makes concluding recommendations on the establishment of new, flexible approaches and tools for aquaculture licensing and regulatory policy.

TOXICITY STUDY ON *Allium cepa* LINN. BULB IN HEALTHY *clarias gariepinus* (BURCHELL, 1822) SUB-ADULT

Oghenochuko, M.T.O.[ab*], Olukunle, J.O.[b], Ajayi O.L[b], Mshelbwala, F.M.[b], Adenubi, O.T.[b], Alegbeleye, W.O.[b], Omoniyi, I.T.[b], Ezeri, G.N.O.[b], Abdulraheem, I.[b], Apantaku, J.T.[b], Takeet, O.V.A.[b]

[b] Federal University of Agriculture, Abeokuta, PMB 2240, Ogun State, Nigeria

Introduction

Allium cepa Linn. (Onion) is widely researched for its biological activities in animal health management and had been well documented to have a wide range of therapeutic potentials (Griffith et al., 2002; Augusti, 1996) but little has been reported on its toxicity potential on experimental animals because of the belief that it is natural and therefore safe (King et al., 2009) . Hence, this study assessed the toxic potentials of *A. cepa* by exposing healthy *clarias gariepinus* sub-adults to varying concentrations (200, 150, 100, 50 and 25 g/Kg) of *A. cepa* via diet and bath (5, 3, 1.5, 0.7 and 0.4 g/L) for two weeks.

Materials and methods

The fish were sacrificed and the liver and kidneys collected, processed and examined for histopathological changes. Proximate analysis of the bulb, qualitative and quantitative phytochemistry was determined using standard methods. Brine Shrimp lethality assay (BSLA) and mean lethal dose of the onion on experimental fish was investigated using Finney linear regression.

Results

The protein content of the onion was 8.48% while that of carbohydrate was 5.94%. Saponins, tannins, phenols, flavonoids and alkaloids were found in trace amount. The LC_{50} of the onion extract was between 0. 51mg and 0.64mg in the BSLA while mean LC_{50} for experimental fish exposed via diet and bath were 447.1g/kg and 12.2g/l fish. Histopathological changes observed in the liver were vacuolar degeneration of the hepatocytes and congestion of the central vein (Plate 1), while necrosis of the epithelial cells and haemosiderosis (Plate 2) were the most consistent findings in the kidney, especially in fish exposed via bath.

Discussion and conclusion

Toxic effect of the fresh onion bulb was observed in the livers and kidneys of fish treated with different concentrations of *A. cepa* bulb in this study. The BSLA categorized the onion bulb as a plant with mild toxicity which was confirmed by the various degeneration stages observed in the livers and kidneys of the experimental fish. This finding is in agreement with previous reports by various authors on the ability of the *Allium* species to cause a clinical condition referred to as 'toxicosis'. This could be due to the presence of n-propyl disulphide, S-methyl and S-propenyl cysteine sulphoxides in the onion bulb (Parton, 2000). These compounds may be broken down into various sulphides with hemolytic capability (Parton, 2000). Moreso, secondary renal failure may result due to hemolytic crisis (Al-Salahy, 2002). *Allium cepa* bulb though have high therapeutic ability could be toxic to fish when administered via feed and/or by bathing at higher concentrations

IDENTIFICATION OF EGG SPECIFIC TRANSCRIPTS IN FERTILIZED EGGS OF JAPANESE EEL (*Anguilla japonica*)

HJ Oh*, JH Kim, *JY Kwon

Dept. of Aquatic Life Medical Sciences, Sunmoon University, Asan 31460, Korea
E-mail: orange1114@sunmoon.ac.kr

Introduction

Survival rates of *Anguilla japonica* embryos and larvae are extremely low and still far from industrial scale, although artificial production of glass eel was succeeded in some laboratories (Tanaka et al., 2003; Kim et al., 2013). This is largely due to the poor quality of eggs. However, assessment of egg quality in this species is not properly established. Egg specific transcripts, particularly maternal origin, could be placed on the checklist for the quality assessment. In this study, we identified transcripts specifically expressed in fertilized eel eggs by RNA-se

Materials and Methods

Total RNA was extracted from fertilized eel eggs produced by artificial maturation and fertilization, and also from tissues (brain, testis, ovary, liver, kidney, muscle) of immature eels (TL 64±3 cm, BW 445.3±55.1 g) using TRIzol® Reagent (ambion, USA). RIN values for all samples were higher than 8.1 (Bioanalyzer, Agilent). RNA-seq was carried out according to the manufacturer's instructions (Illumina Truseq stranded mRNA library prep kit + Illumina cluster generation system + Illumina Novaseq 6000 sequencing system). To obtain quantification scores for eel transcripts in all tissues, TPM (transcripts per kilobase million) values were calculated. This value was used to create a heatmap and identify egg specific transcripts. Identified egg specific genes was confirmed by the conventiona T-PCR.

Results

Transcripts obtained from RNA-seq were mapped to previously constructed reference transcriptome for this species (30,847 transcripts; 16,720 genes). TPM values for these genes were used to calculate a correlation matrix and produce a heatmap (Fig. 1). This hierarchical clustering helped us identify 10 most highly expressed genes in fertilized eggs of eels (Fig. 2).

Discussion

Identified top 10 genes include genes for *nadh dehydrogenase, hnrpa01, cyclin-b1, myristoylated alanine-rich c-kinase, upf0054 protein c2orf43-like protein, sal-like protein 4, nynrin-like protein, pcna-interacting partner, cytochrome c* and *lamin-b1*. Fertilized eggs and tissue of eel was investigated by real-time PCR (RT-qPCR). Tissue specificity of these genes were also confirmed by RT-PCR. All of these genes are highly likely to be maternal origin because the eggs were sampled far earlier than MBT (mid-blastula transition).

Many of these genes are known to have an important role during oocyte growth and early development (*Sal-like protein 4, cyclin-b1 and lamin-b1* / Wang et al., 2011; Deborah et al., 1993; Izumi et al., 2016). This implies that the identified egg specific genes might be associated with egg quality of this species. Further study is required to relate these transcripts to hatching and survival of fertilized eggs.

EFFICACY OF *Ocimum gratissimum* (BASAL SCENT LEAF) POWDER AS ANAESTHETIC AND ITS EFFECT ON THE HAEMATOLOGY OF *Clarias gariepinus* JUVENILES

I.B. Okey

Department of Fisheries and Aquatic Science, Cross River University of Technology Calabar, Nigeria
piusbass@yahoo.com, iromokey@crutech.edu.ng

Introduction

Clarias gariepinus is the most cultured fish in nigeria due to it wide acceptability, commanding market value, high tolerance to diseases and ability to withstand wide changes in water quality. the practice of aquaculture has increased tremendiously in recent years, marking it the the fastest food producing venture in the world (FAO, 2018). Intensive nature of aquaculture have subjected farmed fish to a number of stressors due to handling proceedures and transportation from hatcheries to final stages (Akinrotimi *et al* 2015). These stressors have most often been responsible for high mortalities recorded, hence hindering the growth of fish farming. Anaesthetics are used in aquaculture, fisheries and biological researches, as a way to minimize hypermotility during handling and transportation to reduce stress and mortality (King *et al* 2005; Ross Ross 2008; Okey *et al* 2013). Previous studies have reported the use of some plant materials to anaesthetized various fish species including *C. gariepinus* (Olufayo and Ojo 2018; Ademale *et al* 2017; Adebayo and Olufayo 2017; Okey *et al* 2018). This studies aimed to investigates the efficacy of *Ocimum gratissimum* as anaethetic and determine itn some haematological parameters of *C. gariepinus* juveniles.

Materials and methods

Clarias gariepinus juveniles of mean weight and length (24.50±4.25g and 27.60±6.75cm) were procured from University of Calabar Fish Farm and transported to the Department of Fisheries and Aquatic Science Cross River University of Technology (CRUTECH). Fresh leafs of *O. gratissimum* were obtained from within the university campus, identified in Forestry Department, air dry for 5 days and blended to powder. The experimental treatment were prepared from a stock solution of 2g in 10 litres of water (200mg/l) into five concentrations (0, 50, 100, 150 and 200mg/l) in 20 litres of water. Stages of induction and recovery were monitored and recorded using a stop watch as descibed by Coyle *et al* (2004). Blood was ollected by severing the caudal peduncle into Ethylene Diamine Tetra acetic Acids (EDTA) for the analysis of various hemaetological parameters using standard methods.

Results

The result revealed that *O. gratissimum* caused anaesthesia which was concentration dependent. Induction time (min) reduced with increase in concentration while recovery increases as induction time reduces (Table 1 and Figure 1).

Discussion and Conclusion.

The observed behavioural changes including initial hypermotility, hyperventilation, loss of equilibrium and no reaction to handling suggest the fish were immobilised (anaesthetized) by the plant material. This was in line with the reports of several researchers who used anaesthetics on fish during handling and transportation (Agokei and Adebisi 2010; Velisek *et al*. 2011; Simeos *et al*. 2011). Slight changes in the haematological parameters reported in this study corroborates with the studies of many other researchers who have use plant materials as anaesthetic (King *et al* 2005; Sudagara *et al* 2009; Adebayo and Olufayo 2017). Minimal changes in RBC, Hb and PCV recorded on fish exposed to 150mg/l which were not different ($P > 0.05$) from the control but induces anaesthesia in 6.22 mins shows it is an ideal concentration. However, Sudagara *et al* (2009) reported a 48 hours reversal to the haematological paramters of fish exposed to clove powder. Further research will be required to investigate the effects of *Ocimum* of the biochemical paramters of *C. gariepinus*.

(Continued on next page)

Table 1: Induction and recovery time (min) of of *Clarias gariepinus* juveniles' exposure to *Ocimum gratissimum* powder anaesthetic for 30min.

Concentration (mg/l)	Induction		Recovery	
	Induction 1	Induction 2	Recovery 1	Recovery 2
0	-	-	-	-
50	26.61 ± 2.34	-	-	2.82 ± 2.44
100	11.12 ± 1.54	15.26 ± 0.81	1.26 ± 1.38	4.43 ± 0.36
150	4.16 ± 2.36	6.08 ± 0.34	2.35 ± 2.14	6.76 ± 2.18
200	1.24 ± 4.56	3.22 ± 1.26	4.81 ± 0.19	11.67 ± 1.44

Mean with the same superscript are not significantly different at p< 0.05, Induction1 (loss of equilibrium), induction2 (deep anaethesia), recovery 1 (regain equilibrium), recovery2 (normal swimming).

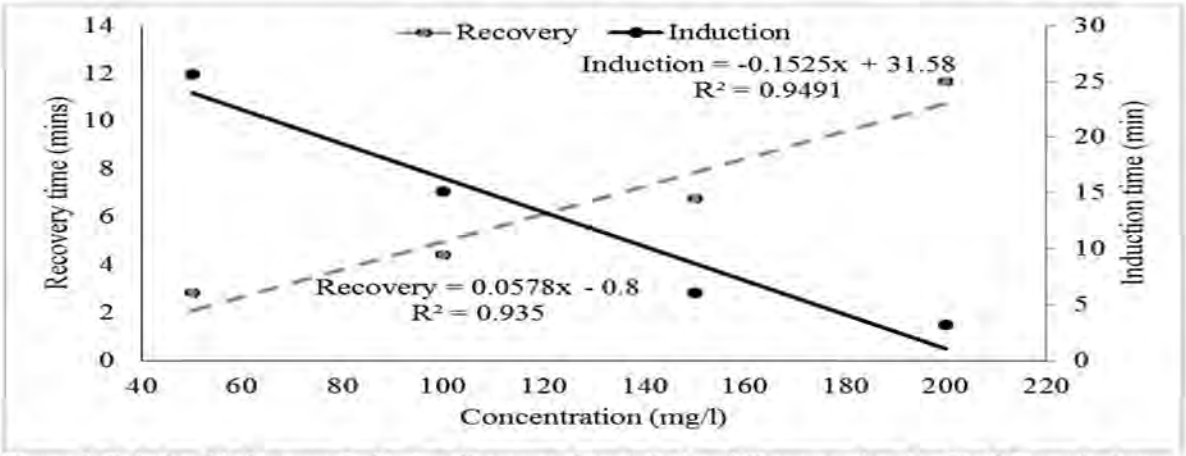

Figure 1: Relationship between Induction, Recovery time (mins) and Concentration (mg/l) of *O. gratissimum*

Haematological parameters showed some slight changes exspecially at higher concentration however some were not significant (p> 0.05). the mean values of red blood cells, haemoglobin, pack cell volume, mean cell haemoglobin, mean cell haemoglobin concentration, basophile, eosinophile and neutrphile were decreasing with increased concentration of clove powder. Others such as white blood cells, platelets and lymphocytes increased with concentration (Tables 2 and 3). Fish exposed to 150mg/l cause induction shows that RBC, Hb and PCV were not significantly (P > 0.05) from those exposed to 50mg/l which were however not different from the control (0.0mg/).

Introduction

The functioning and performance of food value chains are affected by the way stakeholders are embedded in the chains, by the coordination modes, and by the type of governance (Carbone, 2017). An industry can have various types of governance structures in a given location or across varying segments of the chain and these can develop with time. The global value chains (GVC) approach (Gereffi *et al*., 2005) provides a theoretical framework for understanding the governance of commodity production. The governance types can range from market, relational, modular, captive to hierarchy governance forms, which are characterized based on e.g. the degree of complexity of inter-firm transactions and the decision making process of the lead firm.

This research is part of the VALUMICS project with the overall aim to develop tools for decision makers to assess the impacts of policy in food value chains. The main goal of this study was to provide a better understanding of the functioning of the salmon value chain and identify practices and structural elements where fairness is or could be an issue. The focus is on assessing the perception of actors and stakeholders in the salmon value chain on power asymmetries and how power is exercised, the fair value distribution in the chain, the role of government and industry oversight groups in the power dynamics and the transparency and trust in the chain that would support fairness.

Methods

A governance framework for global value chains according to Gereffi *et al.* (2005), was applied to identify the characteristics of the governance forms along a buyer-supplier power continuum from farming to final product in retail. Six interviews were conducted with business experts from Norway, UK and Iceland in the salmon chain according to a semi structured interview guideline. The interviews lasted for approx. one hour, they were recorded, transcribed and anonymised and further input has been gained from discussions with stakeholders in workshops conferences and via teleconferences.

Results

The salmon value chain is producer driven which is contrary to agriculture farms who have a weak position in the value chain and are susceptible to be captive suppliers. The large integrated aquaculture companies are competing on the global market and have a strong bargaining position against the concentrated supermarket chains who are the lead firms in the value chain. The inter-firm relations of producers and their buyers is characterized by free market exchanges where products are sold on the spot market, however, there is a trend of long term contracts in particular between large integrated companies and retail or large secondary processors. "Market" governance is thus applicable for salmon producers and primary processors who are selling commodity products on the spot market, where transactions are easily codified and suppliers are capable of making products based on technical standards and there is no input from buyers. The specifications are based on industry standards and the complexity of information exchanged is low, and therefore transactions need no explicit coordination. The standards facilitate transactions since information about the products and their specifications according to best aquaculture practices can be codified. The essential point is that the costs of switching to new partners are low for both parties. This is typical for free market exchanges where buyers respond to specifications and prices set by sellers (Gereffi *et al.,* 2005). The linkages between secondary processors and retail can be characterized as modular or relational, for example, when producing a differentiated branded product. "Relational" linkages emerge if a product specification is hard to codify, transactions are complex, and supplier capabilities are high, where trust and reputation are built up over time. "Modular" linkages are distinctive in that they are based on codified knowledge rather than on prices, and suppliers take full responsibility of the process technology. Secondary processors are stuck in the middle of the chain, and are reliant on farmers / primary processors or wholesalers for raw materials where they buy on the spot market. They are vulnerable when prices on the spot market are high and have little influence to negotiate the price with retailers, who normally operate at a fixed ma gin.

A “Hierarchy” governance is characterized by high incentives to centralize control of strategic investments and this is typical for the vertically integrated large companies of the salmon value chain who mainly target high end retailers. The increasing number of requirements from large retail chains has been a main driver for vertical and horizontal integration of aquaculture companies as well as the food industry globally. The objective has been to increase the negotiation power towards the retailers with respect to price, product, and volume.

The salmon value chain governance is influenced by network governance, contracting and informal relationships and the governance structure is perhaps best described as a “Hybrid” form. The large integrated firms and their subsidiaries constitute a network of firms that organize their transactions through a combination of different arrangements. This is characteristic of plural hybrid forms whereby a firm (or a network of firms) could partially produce in-house (or distribute through its own outlets), outsource other parts of its activity through contracts with specific firms, and possibly use spot markets, all at the same time (Menard, 2017).

Discussion and Conclusion

Price is considered to be one of the most important factors that will increase a supplier’s perceptions of fairness. As far as suppliers are concerned, the impact of price on a long-lasting supply chain is complicated due to the complexity of the relationship, the cooperative nature of relationships, and various market circumstances. In agricultural supply chains, suppliers lack pricing power because of their inferior position. Therefore, suppliers will pay more attention to retailers’ procurement pricing criteria, which involves examining product quality, purchase quantity, geographic position, and relationship. It can be argued that the impact of price satisfaction on fairness perception is not only related to whether suppliers can fairly gain profits but is also connected to the endurance and stability of the cooperative relationship in question. Therefore, suppliers are sensitive to prices and high levels of price satisfaction will effectively enhance the cooperative stability of the supply chain in question. The interviewees with agents across the salmon value chain suggest that producers are satisfied with the value distribution in particular with respect to the current high prices of salmon, while secondary producers and feed producers are less content.

Introduction

Optimization of feed efficiency and growth are main goals in fish production. Thus, for sustainable growth of aquaculture it is of outmost importance to understand the processes that regulate feed intake (FI) in fish. It is well known that diet composition affects FI; hence, it is important to increase knowledge on the physiological effects of dietary replacement of fishmeal (FM) by plant-feedstuffs (PF), or protein (P) by carbohydrates (CH). Several studies linked FI with endocrine control and metabolic pathways in different fish species (Ronnestad et al. 2017). Nonetheless, little is known about appetite regulation in gilthead seabream (*Sparus aurata*) and the respective link with diet composition. Thus, the present study aimed to obtain an insight on how nutritional parameters such as P/CH ratio and protein sources (FM vs. PF) affect appetite regulation mechanisms in seabream.

Materials and Methods

Gilthead seabream (140g) were fed four isolipidic (18% lipids) diets with two P/CH ratios (P50/CH10 or P40/CH20) and protein sources (FM or a mixture of 20% FM/80% PF), respectively named FMP50/CH10, FMP40/CH20 and PFP50/CH10, PFP40/CH20. Each diet was fed to triplicate groups of fish twice daily until visual satiation, 6 days a week, during 6 weeks. At the end of the trial, fish were bulk-weighed after 1 day of feed deprivation. Three fish per tank were also sampled 5 hours after the morning meal for collection of brain, intestine, liver, and stomach for gene expression analysis. Quantitative real-time polymerase chain reaction (RT-qPCR) was performed according to Salmerón et al. (2015) to assess the expression of genes involved in growth and appetite regulation. Statistical analysis was carried out by two-way ANOVA, using a probability level of $p<0.05$ for rejection of the null hypothesis. In case of interaction, one-way ANOVA was performed for protein source within P/CH ratio and for P/CH ratio within protein source.

Results

Fish fed diet FMP40/CH20 presented lower final body weight (FBW) than fish fed diet FMP50/CH10. Feed efficiency (FE) was higher in fish fed diet P50/CH10, independently of protein source. Gene expression of leptin receptor (LepR) in brain, cholecystokinin (CCK) in intestine, and growth hormone receptor (GHR II) in liver were influenced by P/CH ratio. LepR expression was higher in fish fed P40/CH20 diets, while for CCK, and GHR II the opposite was observed. Insulin-like growth factor I (IGF-I) expression was higher in fish fed FMP50/CH10 than PFP50/CH10, and within the FM diets it was higher in diet P50/CH10. The remaining analyzed parameters were not affected by dietary composition. These included FI; cocaine-amphetamine-related transcript (CART), corticotropin-releasing hormone (qCRH), ghrelin receptor A (GhrR A), leptin, and neuropeptide Y (NPY) in brain; ghrelin receptor B (GhrR B), and leptin in liver; and ghrelin (Ghr) in stomach. Undetectable levels of expression of the following genes was detected under the present experimental conditions: Ghr and GhrR A in intestine and liver; GhrR B in brain; and leptin in intestine and stomach.

Conclusions

P/CH ratio had a stronger effect than PS on the analyzed parameters. Despite of the observed modulation in the expression of appetite regulatory genes, these effects were not reflected in differences in FI. From a commercial point of view, it is important to observe that growth, FE, FI, and appetite regulation related genes expression were not affected by the PF dietary incorporation.

The aquaculture industry is the world's fastest-growing food protein producer. It is indispensable to satisfy the world's fish demand, being responsible for 50% of global seafood consumption. However, aquaculture development and expansion is constantly challenged by bacterial disease outbreaks, a major constraint to the economic profitability of the industry according to the United Nations. *Aeromonas* spp., *Vibrio* spp., *Photobacterium* spp., *Tenacibaculum* spp., and E*dwardsiella* spp. are among the most common bacterial agents affecting marine aquaculture fish. Although antibiotics have been extensively used as prophylactic and therapeutic agents to treat bacterial infections, the selective pressure created by their misuse has contributed to the development and spread of antibiotic-resistant bacteria, posing a serious threat to public health. In a post-antibiotic era, where decreasing efficacy of antibiotics might turn minor infections into global problems, it is urgent to find new and natural alternatives that assure an advanced and integrated health care for humans, animals, and the environment. One promising strategy is the use of probiotics, "live organisms which when administrated in the adequate amounts can confer a health benefit on the host". *Bacillus* spp. have been recognized as attractive probiotics for aquaculture due to their endospore-forming nature, which represents an advantage for industrial applications. Moreover, *Bacillus* spp. are known for the production of Natural Antimicrobial Compounds (NACs) antagonistic of the growth, biofilm formation, and communication (quorum-sensing) of several Gram+ and Gram- bacteria. Harnessing the fish-gut microbial potential, we aimed to isolate and characterize different *Bacillus* spp. from the gut of aquaculture fish, capable of producing NACs active against fish bacterial diseases

For that purpose, *Sparus aurata*, *Diplodus sargus*, and *Dicentrarchus labrax* were fed with the same commercial diet for 6 weeks and their heat-treated intestinal contents were used to obtain the gut spore-forming community. All isolates were screened for NACs production against major bacterial pathogens, including *Aeromonas hydrophila*, *A. salmonicida*, *A. veronii*, *A. bivalvium*, *Vibrio anguillarum*, *V. harveyi*, *V. parahaemolyticus*, *V. vulnificus*, *Photobacterium damselae* subsp. *damselae*, *Ph. damselae* subsp. *piscicida*, *Tenacibaculum maritimum*, *Edwardsiella tarda*, and *Shigella sonnei*. The NACs production by *Bacillus* spp. was accessed through different antagonistic assays: (i) colony-overlay assay, to screen the entire collection for NACs production; (ii) well-diffusion and 96 microplate assays, to evaluate NACs extracellular nature; (iii) anti-biofilm assay, to evaluate the potential of extracellular NACs in reducing biofilm formation, and (iv) anti-quorum-sensing (QS) assay, to access NACs ability to interfere with acyl-homoserine-lactone signals used in QS. Significance of inhibition was evaluated by repeated measures ANOVA or by one-way ANOVA. Sporeformers with the most promising characteristics were identified by 16S rRN gene sequencing.

A total of 176 isolates representing different colony morphologies and samples were selected. Spore production was confirmed by phase-contrast microscopy revealing 172 isolates as producers of endospores with different sizes and shapes. Screening for NACs production revealed that 52% displayed antimicrobial activity against at least one pathogen tested. Using the colony-overlay assay, we selected the 8 most promising isolates based on the size of the inhibitory halos produced. These 8 isolates were capable of inhibiting the bacterial growth of *Aeromonas* spp., *Vibrio* spp., *Photobacterium* spp., *Tenacibaculum* sp., or *Edwardsiella* sp. By characterizing the localization of the inhibitory molecules, we further observed that cell-free supernatants of 3 isolates (identified as *B. subtilis* by 16S rRNA sequencing) inhibited the growth of all pathogens tested, except for *A. salmonicida*. Additionally, the extracellular NACs were capable of interfering with

(Continued on next page)

biofilm formation of *A. salmonicida*, *A. hydrophila*, *V. anguillarum*, *V. parahaemolyticus*, *Ph. damselae* subsp. *damselae*, *T. maritimum*, and *S. sonnei.* Although the extracellular NACs were not capable of interfering with the growth of *A. salmonicida* they significantly decreased its biofilm formation. Moreover, the 3 isolates produced extracellular NACs capable of interfering with acyl-homoserine-lactone signals, used in Gram- bacterial communication. Further, the 3 isolates were sensitive to all antibiotic classes demanded by the European Food Safety Authority (EFSA) as mandatory to comply with the minimum safety requirements to be considered as probiotics. Based on these *in vitro* tests, the 3 isolates were considered the most promising to be used as probiotics or as a source of bioactive molecules able to inhibit important bacterial fish pathogens

The extracellular NACs responsible for the anti-growth, anti-biofilm and anti-QS activities are being identified and characterized, to be used as future disease-preventive molecules in aquaculture.

Introduction

The presence of non-starch polysaccharides (NSP) in most plant feedstuffs (PF) has been associated with adverse effects on carnivorous fish nutrient digestibility and, ultimately, on growth and health. The lack of enzymatic machinery and well-developed microbiota in the digestive tract of carnivorous fish for processing NSP are possible causes for such effects. A promising nutritional strategy to improve nutrient digestibility of plant-based diets is the use of exogenous enzymes (e.g. carbohydrases, proteases) as feed additives. Solid-state fermentation (SSF) is an eco-friendly and cost-effective biotechnology process that allows converting inexpensive agro-industrial by-products into added-value products such as carbohydrases. As a low-cost and lignocellulosic by-product of the brewing industry, brewery spent grain (BSG) is an attractive substrate for microbial enzyme production by SSF. The present study was designed to assess the potential of a carbohydrase enzyme extract obtained by SSF to release total amino acids (AA) and monosaccharides (pentoses) from plant-based diets in an *in vitro* gastrointestinal model with enzyme extracts of European sea bass (*Dicentrarchus labrax).*

Material and methods

Three isoproteic (48% crude protein) and isolipidic (16% crude lipids) diets were formulated with 15% fishery products (fish meal and fish protein concentrate), 5% hemoglobin, and 61% plant feedstuffs (wheat gluten, soybean, wheat, rice bran, sunflowe , rapeseed). In all diets fish oil was the main lipid source. Diets were similar in starch (10%), hemicellulose (2.4%), cellulose (1.6-%) and lignin (2.3%) contents. The diets were unsupplemented (control) or supplemented with an enzyme extract obtained by SSF at 0.1 or 0.4%. The enzyme extract was obtained from SSF of BSG using *Aspergillus ibericus* MUM 03.49 as the inducer for enzyme production. The enzyme extract was a combination of cellulase (1343U g^{-1} crude extract) and xylanase (15885U g^{-1} crude extract).

Table I. Total amino acids (AA, mg g^{-1}) and pentoses ($\mu g\ g^{-1}$) released by gastric (G) and intestinal (I) digestion of the experimental diets with active (A) or inactive (W) fish enzyme extracts[1]

Diet	Control				0.1% BSG				0.4% BSG

3-way ANOVA (P-value)

Factor	diet	digestion phase	incubation mixture	diet x digestion phase	diet x reaction mixture	digestion phase x reaction mixture	diet x digestion phase x reaction mixture
AA	≤0.001	≤0.001	≤0.001	≤0.001	≤0.001	≤0.001	≤0.001
Pentose	≤0.001	≤0.001	≤0.001	0.179	0.663	0.103	0.774

[1]Value are mean ± SD (n = 3). When significant interaction between factors was found, one-way ANOVA was performed for each factor. Different superscript letters stand for statistical differences across experimental diets as determined by the Tukey test ($P < 0.05$).

(Continued on next page)

The *in vitro* methodology involved two-step hydrolysis designed to simulate stomach and intestinal digestion of European sea bass, as described in Morales and Moyano (2010). Briefl , the digestion was simulated using the following conditions: samples of each diet (between 20 and 80 mg mL^{-1}) were incubated in triplicate in a 10 mL closed reactor at 25ºC simulating gastric and intestinal digestions. The gastric digestion was done at pH of 5.0 with 9846 U mg^{-1} acid proteases and the intestinal digestion was done at pH of 8.5 with 507 U mg^{-1} alkaline proteases from sea bass stomach and intestine, respectively. A negative control assay including inactivated fish enzyme extracts was also carried out. The release of hydrolysis products, AA and pentoses, were monitored along the course of each digestion phase (at 0, 0.5, 1, 2h for gastric digestion; at 3, 4, 5, and 6h for intestinal digestion). Results are presented as total amount of product released during the different digestion phases.

Results and Discussion

After the pelleting process, 0.1 and 0.4 % BSG supplemented diets presented 1.76 and 5.76 U g^{-1} cellulase activities and 5.11 and 8.80 U g^{-1} xylanase activities, respectively. The simulated gastric and intestinal digestion demonstrated that AA release remained unaffected by dietary treatments (Table I). In contrast, a significant increment of pentoses release in the presence of increased incorporation of extracts in the diets was observed throughout gastric and intestinal incubations. Independently of dietary treatment, AA and pentoses release were higher at intestinal than at gastric digestion. In all dietary treatments, inactivation of fish enzyme extracts (W), promoted higher pentoses release than active fish enzyme extracts(A). Contrarily, inactivation of fish enzyme extracts did not affect AA release from experimental diets, except in the 0.1% BSG diet.

In conclusion, dietary supplementation of plant-based diets with 0.1 or 0.4 % enzyme extracts obtained by SSF of BSG seems to contribute to enhancing monosaccharide availability. Results also suggest that fish enzyme extracts interact with carbohydrases extract reducing their ability to hydrolyze NSP. Thus, coating the enzyme extract should be considered to maximize their potential. Studies *in vivo* still need to be performed to confirm the results of the present *in vitro* results.

Introduction
The replacement of fishmeal by plant ingredients in aquafeeds imposed new formulation strategies to overcome some nutritional restrictions associated with these alternative ingredients. Thus, supplementation of plant-based diets with feed additives, as exogenous enzymes and antioxidants compounds, has recently attracted increasing interest to improve feed utilization and to promote animal health. Solid state fermentation (SSF) of agro-industrial wastes has a high potential for the production of these additives, being a practical, economical, and environmentally-friendly process. Olive mill and winery wastes have valuable compounds that may be valorized thought SSF and that may be used as additives for aquafeeds. This study was conducted to optimize the production of non-starch carbohydrases through the SSF of the olive mill and winery wastes and to test its efficacy to improve the release of pentoses during digestion of a plant-based diet in European seabass.

Materials & Methods
Olive mill wastes (crude and exhausted olive pomace; COP and EOP, respectively) and winery wastes (exhausted grape marc and vine trimming shoots; EGM and VTS, respectively) were fermented by *Aspergillus ibericus* MUM 03.49 (10g solid; 75% moisture; $2*10^6$ spores). A simplex-centroid design was performed to optimize the production of cellulases, xylanases, and β-glucosidases with the four solid wastes in 15 different mixtures (4 runs with single wastes; 6 runs with binary mixtures; 4 runs with ternary mixtures; and three central points with quaternary mixture of wastes). After SSF, the enzymes produced were extracted with distilled water. The recovered extract was lyophilized and added (0.4% diet) to a plant-based diet (15% fish meal + 60% plant feedstuffs), and an *in vitro* assay simulating European seabass sequential acidic and basic digestion was performed according to Morales & Moyano (2010).

Results & Discussion
Compared to the use of single wastes as substrate, mixtures olive mills and wineries wastes increased the production of lignocellulolytic enzymes by SSF. The mixture of solid waste that maximized xylanases, cellulases, and β-glucosidases production was 30% EGM + 36% VTS + 34% EOP (Fig.1a-c). The SSF of this mixture leads to an enzymatic activity of 78.2 U xylanase; 39 U cellulose; 21 U β-glucosidase per g of lyophilized extract.

In vitro digestibility trials confirmed that supplementation of a plant-based diet with 0.4% of this extract increased the release of pentoses during alkaline digestion (Table 1). During acid digestion, this effect was significant only when the fish enzymes were inactivated.

Conclusions
Solid-state fermentation by *A. ibericus* of olive mill and winery wastes mixtures allowed higher production of lignocellulolytic enzymes compared SSF of the wastes separately. Overall, the mixture of 30% EGM + 36% VTS + 34% EOP was the one that provided better results. Further, the enzymatic activity of the extract was more active during alkaline than acidic digestion.

SHOULD THE AQUACULTURE INDUSTRY USE BLOCKCHAIN TECHNOLOGY FOR DATA RECORDING?

P. Olsen[1*]

[1] Nofima, PO Box 6122 Langnes, NO-9291 Tromsø, NORWAY
E-mail: petter.olsen@nofima.n

Introduction

Blockchain technology has existed since 2008 and it is expected that this technology will disrupt many traditional business sectors and models, in particular those that are virtual in nature; online banking is one such example. Blockchain technology will definitely have relevant applications also in the aquaculture industry, but there is no doubt that the blockchain suppliers are currently overselling their products and they are promising more than they can deliver. This presentation aims to disentangle hype from truth when it comes to the capability of blockchain technology to achieve traceability in aquaculture supply chains by attempting to answer two fundamental questions:

1. How does blockchain compare and contrast with alternative technologies and methodologies to achieve a similar outcome and what are the key selection criteria for deciding which technology to adopt?
2. What are the costs, benefits and practical considerations of blockchain as applied in the aquaculture industry

Blockchain-based traceability in the aquaculture industry

This presentation outlines applications, limitations, costs, and benefits related to the use of blockchain technology in the aquaculture industry, and in particular evaluates the pros and cons of having a blockchain-based traceability system compared to a traditional electronic traceability system. The core principles of blockchain technology are outlined, as well as the fundamental requirements and drivers relating to an electronic traceability system. The presentation compares the functionality of traditional vs. blockchain-based food traceability systems, evaluates costs and benefits, and provides some practical advice on implementation issues.

Discussion and conclusion

The overall conclusion is that unless speed of operation or confidentiality are considered to be the most important characteristics of the traceability system, a blockchain-based implementation may be very suitable. The main benefit related to a blockchain-based traceability system is that, at least for now, the blockchain-based systems are more homogenous than traditional electronic traceability systems, so interoperability between different blockchain-based systems is likely to be easier to implement than interoperability between different traditional electronic traceability systems. Lack of interoperability is one of —, or probably the biggest current obstacle preventing system-wide, farm-to-fork aquaculture product traceability, so this advantage associated with blockchain-based implementations is significant

Introduction

Glutaredoxins (Grxs) are known as glutathione-dependent thiol-disulfide oxidoreductases that are ubiquitously distributed in all living organisms (Bräutigam et al., 2013)we present a biochemical and biophysical characterization of zebrafish glutaredoxin 2, focusing on iron-sulfur-cluster coordination. The coordination of [2Fe2S]2+-clusters in monomers of this protein was revealed by both absorption and Mössbauer spectroscopy as well as size exclusion chromatography. All other holo-glutaredoxins represent [FeS]-cluster bridged dimers using two molecules of non-covalently bound glutathione and the N-terminal active site cysteines as ligands. These cysteine residues were not required for [FeS]-cluster coordination in zebrafish glutaredoxin 2. A crystal structure of the teleost protein revealed high structural similarity to its human homologue. The two vertebrate-specific cysteines as well as two of the teleost-specific cysteines are positioned within a radius of 7Å near the C-terminus suggesting a potential role in [FeS]-cluster coordination. Indeed, mutated proteins lacking these teleost-specific cysteines lost the ability to bind the cofactor. Hence, the apparent mode of [FeS]-cluster coordination in zebrafish glutaredoxin 2 could be different from all yet described [FeS]-glutaredoxins. © 2013 Elsevier Inc.","author":[{"dropping-particle":"","family":"Bräutigam","given":"Lars","non-dropping-particle":"","parse-names":false,"suffix":""},{"dropping-particle":"","family":"Johansson ","given":"Catrine","non-dropping-particle":"","parse-names":false,"suffix":""},{"dropping-particle":"","family":"Kubsc ","given":"Bastian","non-dropping-particle":"","parse-names":false,"suffix":""},{"dropping-particle":"","family":"McDonough","given":"Michael A.","non-dropping-particle":"","parse-names":false,"suffi ":""},{"dropping-particle":"","family":"Bill","given":"Eckhard","non-dropping-particle":"","parse-names":false,"suffix":""},{"dropping-particle":"","family":"Holmgren","given":"Arne","non-dropping-particle":"","parse-names":false,"suffix":""},{"dropping-particle":"","family":"Berndt","given":"Carsten","non-dropping-particle":"","parse-names":false,"suffix":""}],"containe -title":"Biochemical and Biophysical Research Communications","id":"ITEM-1","issue":"3","issued":{"date-parts":[["2013"]]},"page":"491-496","title":"An unusual mode of iron-sulfur-cluster coordination in a teleost glutaredoxin","type":"article-journal","volume":"436"},"uris":["http://www.mendeley.com/documents/?uuid=ba31254f-1f59-4c23-af7b-d922d4aae154"]}],"mendeley":{"formattedCitation":"(Bräutigam et al., 2013. They are small antioxidant enzymes that belong to the thioredoxin superfamily but exhibit more versatile substrate activity than thioredoxins (Trxs) (Vlamis-Gardikas and Holmgren, 2002). Grx family proteins have several isoforms with quite different structures and catalytic activities. They regulate essential and distinct biological functions in organisms. Seahorses are a group of aquatic animals that have exploited for years for their medicinal and ornamental properties. Big-belly seahorse (*Hippocampus abdominalis*) is the largest seahorse species and is naturally distributed in the Korean peninsula and around the ocean. Being a large, smooth-skinned species provides a high market value for big-belly seahorses. However, fulfilling the demand for seahorses is still a problem as they are extremely difficult to culture. One of the major threats for seahorse cultivation is their poor adaptability to higher densities and stressful environments, thus increasing their vulnerability to pathogenic infections (Woods, 2007). Therefore, understanding the immune responses of big-belly seahorse against bacterial and pathogen-associated molecular pattern (PAMP) stimuli as well as assessing the functional aspects will facilitate the development and maintenance in seahorse cultivation. Accordingly, the present study investigated the molecular, transcriptional, and functional properties of Grx1 and Grx2 from big-belly seahorse (HaGrx1 and HaGrx2) to understand its role in immunity and redox homeostasis.

Materials and methods

In order to assess sequence characteristics, the *in-silico* analysis was performed by, ExPASy Protparam, SWISS model workbench, Clustal Omega, EMBOSS needle tools and MEGA7 software. Tissue specific expression of *HaGrx1* and *HaGrx2* was analyzed using 14 tissues of healthy seahorses. Temporal expression analysis of *HaGrx1* and *HaGrx2 in* blood was carried out by using lipopolysaccharides (LPS), polyinosinic:polycytidylic acid (poly I:C), *Edwardsiella tarda* and *Streptococcus iniae*. Further, Insulin reduction and dehydroascorbate reduction assays were proceeded to find out the redox activity.

(Continued on next page)

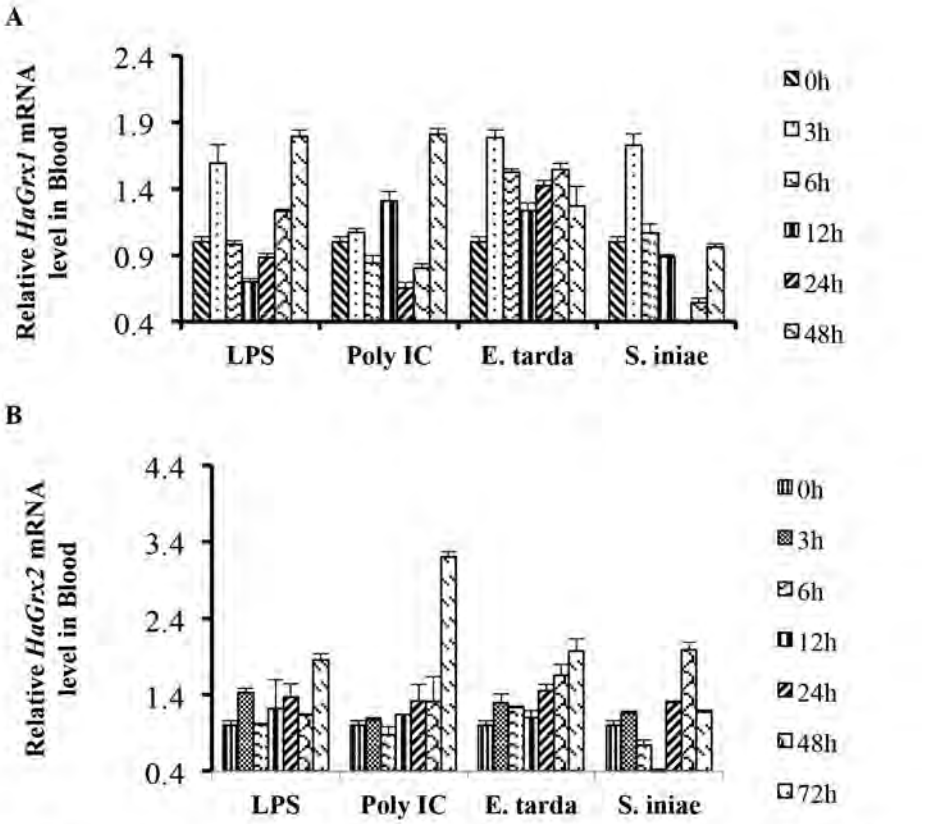

Fig. 1. Temporal expression profiles of (A) *HaGrx1* and (B) *HaGrx2* in the blood after immune stimulation. For the immune challenge, PAMP (LPS and poly I:C) and bacterial (*Edwardsiella tarda* and *Streptococcus iniae*) were used. The Livak method was used to calculate the fold changes in mRNA expression, and seahorse 40S ribosomal protein S7 gene was used as an internal control gene in the qPCR experiment. The relative fold changes in expression were compared with those of the PBS-injected control at different time points. The data are represented as mean values (n = 3) ± S.D.

Results

In-silico analysis showed that HaGrx1 contained the classical glutaredoxin 1 structure with a CSYC thioredoxin active site motif. HaGrx2 possess Glutaredoxin 2 structure with CPYC active site. According to multiple sequence alignment and phylogenetic reconstruction, HaGrx1 and HaGrx2 presented the highest homology to the Grx1, and Grx2 ortholog from *Hippocampus comes* respectively. Transcriptional studies demonstrated the ubiquitous distribution of *HaGrx1* and *HaGrx2* transcripts in all the seahorse tissues tested. HaGrx1 represented the highest expression in muscles whereas HaGrx2 highly expressed in brain and skin. Significant modulation ($p < 0.05$) of *HaGrx1* and *HaGrx2* transcripts were observed in blood upon stimulation with pathogen-associated molecular patterns and live pathogens (Figure 1). Further, dehydroascorbate reduction and insulin disulfide reduction assays revealed the oxidoreductase activity of HaGrx1 and HaGrx2

Discussion and conclusion

According to the study, HaGrx1 and HaGrx2 consist of typical glutardoxin structure and showed highest identity and similarity with *Hippocampus comes*. HaGrx1 and HaGrx2 can be expressed by immune stimulant and its redox activity might be act as a barrier for invading pathogens and PAMP stimuli. Altogether, results in this study suggests that HaGrx1 and HaGrx2 actively involved in host redox homeostasis as well as immune responses.

Introduction

Reservoirs in Nigeria are primarily constructed for public water supply and characterized by artisanal fishery (Daramola *et al.*, 2007). Most of the reservoirs are surrounded by large expanse of land that could be assessed for fish culture. However, utilising these areas for successful and sustainable aquaculture operations requires assessing different environmental factors (soil, hydrology, topography, drainage and climate) that would guide in site selection (Andi *et al.*, 2013). Such approach as defined by Andi *et al.* (2013) is a strategic planning tool that could predict the expected benefits and constraints of productive land use and environmental degradation that might occur due to the use of land. The study was purposively conducted in Ekiti State, Nigeria due to the need to increase fish production; attributed to the landlocked nature (neither enclosed by land with neither sea nor ocean surrounding for fishing purposes) of the State (Omobepade *et al.*, 2014).

Materials and Methods

Landsat 8 OLI satellite datasets and Shuttle Radar Topography Mission were acquired from the Global Land Cover Facility to determine the land use/land cover and the digital elevation model respectively within a 500m buffer. Soil samples were collected from a 1.5m (0 – 37.5cm, 38 – 75.5cm, 76 – 112.5cm and 113 – 150cm) profile dug at three locations and analysed for physiochemical properties. Hydrological, soil, land use/land cover, vegetation, and elevation parameters were subjected to an analytical hierarchical process to develop a suitability map for aquaculture development in the study area according to standard methods.

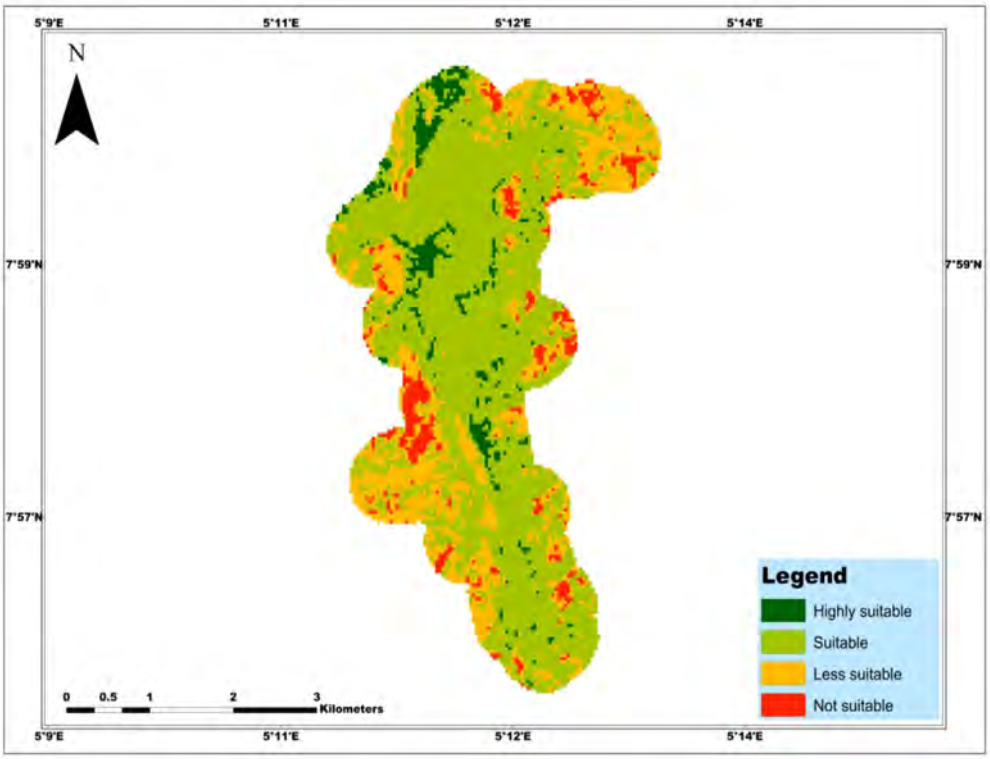

Figure 1: Land suitability model for Aquaculture Development in and around Ero Reservoir, Nigeria

(Continued on next page)

Results

Results indicated that 20.99%, 47.74%, 12.96, 6.03% of the buffered area were water body, light vegetation, dense vegetation and built up areas respectively. Soil classifications in the study area were Lixisols (Sandy-clay-loam) which covered lesser land mass (11.63%) while Nitisols (Clay-loam) covered the higher land mass (88.37%). Suitability model for the study area ((Figure 1) showed that land mass unsuitable for aquaculture development represents 6.07% (89.73 hectares) of the study area, 359.88 hectares (24.35%) were less suitable, and 950.76 hectares (64.33%) were suitable while 77.63 hectares (5.25%) were highly suitable. Despite the large sparse of the reservoir and its environ belonging to the suitable classes, land unsuitable for aquaculture could be attributed to the presence of hills, rocks, undesirable soil parameters, high slopes and dense vegetation.

Conclusion

Hence, individuals and corporate bodies could invest in the suitable areas for aquaculture development, which at the long run will increase the fish availabilit , create employment, improve livelihood and enhance economic profile of the State

Introduction

The geometric increase in world population and need to boost daily dietary protein intake, fish remains the major source of protein in most developing countries. However, due to poor handling, crude processing methods, inadequate storage facilities and lack of proper preservation techniques, about 30 – 50% of fish harvested are wasted in Nigeria, Bate and Bendall (2010). Infestation of smoked / dried fish by *Dermestes maculatus* results in quality and quantity deterioration, hence, the need for preservation. In the past, chemicals have been used to preserve fish products, thus, leaving an after effect detrimental to human – the end consumer. Furthermore, the high cost of these chemicals has led to the use of natural plants to reduce the cost. *Allium sativum* a naturally and readily available plant contains one of the active ingredients (allicin) known for insect repellant.

Materials and Methods

The study was carried out at the Teaching and Research Farm of the Federal University of Technology, Akure, Nigeria. Fresh *A. sativum* bulbs harvested form the crop section of the Uiniversity's farm was oven-dried at 50^{o}C for 72 hours. Dried bulbs was grinded into powder using a kitchen blender. Adults and larva of *D. maculatus* were isolated from heavily infested dried fish and cultured under laboratory conditions for 21 days. Fifteen *Clarias gariepinus* (150±5)g from the fish farm were smoked at 60˚C in a coal-powered kiln for 12 hours. Smoke-dried fish samples were placed in separate plastic containers while *A. sativum* powder was sprinkled on fish at varying proportions (0.0, 0.1, 0.3, 0.5 and 0.7)g. Each treatment (in triplicate) was infested with 20 adults of *D. maculatus*, containers were covered air tight and kept for 7days.

Results

Mortality of *D. maculatus* was higher in treatments with higher quantity of *A. sativum* after 7 days (figure I)

Biochemical composition analyzed in fish samples following AOAC (1995) methods also showed significant variations ($p<0.05$) in parameters with the least infested fish treatments having values closer to the initials (able 1).

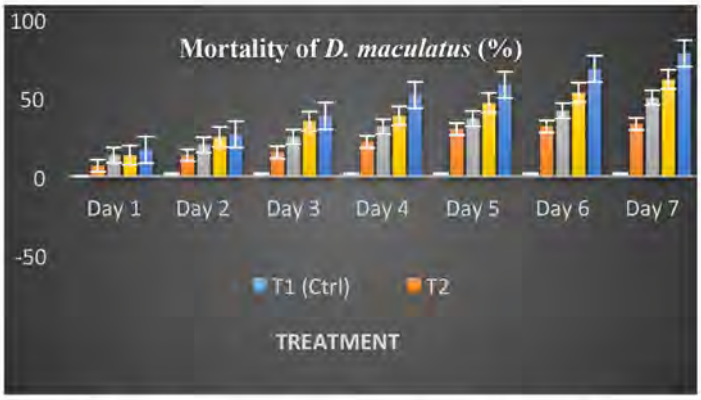

Fig. I: Toxicity of *A. sativum* on *D. maculatus* in smoke-dried *C. gariepinus*

(Continued on next page)

Discussion and conclusion

High mortalities recorded in the adult stage of *D. maculatus* observed on smoke-dried catfish treated with *A. sativum* powder could be attributed to the active bio-components (allicin, ajoene, flavonoids and alkaloids and some phenolic compounds) found in the plant. This agrees with the assertions of Ayeloja et al. (2016) that garlic is an effective insecticide against *D. maculatus*. Andargae et al. (2013) reported that some ethnobotanicals such as garlic have been found to be effective against short-lived insects or pests in the field as well as in food (during storage). Lawson (1998) reported that the most biologically active compound in garlic is allicin, and its present both in fresh and dry garlic bulbs. The insecticidal property of any plant material is dependent on the active constituents of the plant material. Similarly, Saad et al. (2006) reported that this component (allicin) contributes to antibacterial, fungicidal, insecticidal and anti-parasitic properties of garlic. *A. sativum* has been reported to possess repellant properties which deter insects from infesting smoked fish Ayeloja et al. (2016). The mortalities caused by *A. sativum* which in linked to the secretion of allicin by the plant that blocks the spiracles of insects when it comes in contact with their bodies. Egwunyenga et al. (1998) attributed this repelling function to the olfactory sensation in *D. maculatus*.

Analysis of fish samples showed significant variations in biochemical compositions of smoke-dried fish samples upon exposure to *D. maculatus*. Uneke (2015) confirmed variations in biochemical components of dried catfish infested with insects. Douiri et al, (2013) reported that *D. maculatus* caused losses in the amount of nutrient available to consumers resulting in loss of quality and quantity of smoked *C. gariepinus*. Atijegbe (2004) opined that protein, fat and nitrogen free extract contents in smoked/dried fishes reduce significantly as the days of infestation increases, suggesting that *D. maculatus* impairs the fish quality. Similarly, observations from this result is connected to the assertions of Fasakin and Aberejo (2002) that *D. maculatus* needs a good supply of protein, vitamin and minerals for optimal growth according to their nutritional requirements adequately supplied by *C. gariepinus*.

Preservation of smoked dried fish with *A. sativum* powder against the infestation of *D. maculatus* has been proven highly effective to curb the menace of post-harvest losses, maintain quality and promote sustainable aquaculture. Therefore, *A. sativum* is a potential replacement for chemical preservatives against *D. maculatus* in smoke-dried *C. gariepinus*.

Introduction
Genetically improved farmed tilapia (GIFT), an enhanced strain of Nile tilapia (*Oreochromis niloticus*), exhibit better growth and survival rates than routinely available strains of tilapia. Currently, intensive culture systems are common for tilapia culture and often cause stressful conditions that reduce fish growth and wellbeing. The use of functional feed additives as bio-friendly agents is a sustainable way to improve cultured fish performance, and the use of functional ingredients with immune modulatory properties has become more prominent across the animal feed industry.

Heat-killed *Lactobacillus plantarum* (HK L-137) can positively impact the performance and wellbeing of aquatic animals, as reported in several studies.

Thus, the present study investigated the potential value of HK L-137 as a dietary probiotic for GIFT.

Materials and methods
For 12 weeks, fish were fed a control diet (HKL0) or a diet supplemented with HK L-137 at a concentration of 50 (HKL50), 100 (HKL100) or 1000 (HKL1000) mg kg^{-1} feed.

Results
At the final sampling, the HKL100 group had significantly ($P < 0.05$) increased performance parameters (FBW, WG, SGR and FER) compared to the control group, while the HKL50 and HKL1000 groups showed weaker improvements. Mucosal thickness and villus length were significantly ($P < 0.05$) increased in the HKL50 and HKL100 groups in the anterior, middle and posterior intestine, but muscle thickness was significantly ($P < 0.05$) improved only in the anterior and middle intestine. Amylase, lipase and protease activity was significantly ($P < 0.05$) increased in fish fed 50 or 100 mg HK L-137 per kg diet compared to control fish. Significant modulation of blood haematocrit, haemoglobin levels, and RBC and WBC counts ($P < 0.05$) occurred in fish fed HK L-137, while total cholesterol and GPT were decreased by HK L-137. Furthermore, antioxidative enzyme (SOD and CAT) activity were significantly ($P < 0.05$) higher in the HKL100 group than in the control group, while MDA levels were lower. Furthermore, fish fed HK L-137 showed enhanced total serum protein and IgM levels. Interestingly, qRT-PCR revealed significant ($P < 0.05$) upregulation of the growth-related gene IGF-I and the glucose regulation gene G6PD but downregulation of the fatty acid synthase (FAS) gene in all HKL groups compared to the control group.

Conclusion
Thus, we conclude that the use of HK L-137 is an efficient strategy to achieve economically feasible and sustainable tilapia production.

Introduction

Organic sludge, the principal residual product from recirculating aquaculture systems (RAS), is one of the main environmental and logistical challenges associated with aquaculture production (Martins et al., 2010; van Rijn, 2013). Polychaetes have been described as potential remediating organisms of aquaculture sludge due to its ability to survive in organic enrichment conditions and its capability to assimilate particulate organic waste from intensive aquaculture (Brown et al., 2011; Robinson et al., 2015). The aim of this study was to evaluate the removal performance of *Abarenicola pusilla* when fed with organic sludge from a marine RAS.

Materials and methods

A. pusilla (mean weight 2.00 ± 0.07g) were implemented in a prototype system with biofiltration and water recirculation. The polychaetes were fed with aquaculture sludge from a marine RAS with *Seriola lalandi* (average weight=3000.2 ± 110.4g, culture density = 10.85kg.m-3). The experiment consisted of the addition of 10% of fish sludge respect to the total sediment in the experimental units, at different densities of *A. pusilla* (60, 75, 150 and 200 organisms.m-2), with three replicates each, and during 45 days.

Results

The total organic matter (TOM) removal rate achieved by *A. pusilla* is shown in Table I. The results showed higher TOM removal at 150 and 200 organisms.m-2. In addition, total nitrogen (33.63 ± 0.003mg.d-1) and total carbon (236.78 ± 0.003mg.d-1) removal rates were obtained with the highest density of polychaetes.

The results also showed the assimilation of organic components presented in the sludge, with a significant increase ($p<0.05$) in total carbon (24.75%), organic carbon (24.68%) and lipid content (0.65%) in the biomass of the organisms. The highest specific growth rate (SGR) of *A. pusilla* was 3.06% per day. The survival rate was 91.67% over the 45 days trial period.

Discussion and conclusions

The results of this study indicated that *A. pusilla* can be used as a bioremediating species for organic compounds contained in marine RAS aquaculture sludge. Other research in bioremediation with polychaetes reported lower TOM removal rates (Palmer, 2010; Fang et al., 2016; Marques et al., 2017). These results agreed with Palmer (2010), where the highest TOM removal rate was obtained at the highest density of organisms per area. Total nitrogen and carbon removal rate from the sludge by *A. pusilla* was also higher than reported in other species (Honda and Kikuchi, 2002; Fang et al., 2016).

The biomass production of *A. pusilla* (approx.. 400g.m-2 in 45 days) demonstrated that this species is able to consume aquaculture sludge as the only source of feed. The significant assimilation of lipid content, total and organic carbon obtained, suggested that this species is a potential candidate for nutrient recycling from marine RAS. Further studies should determine the possible changes in the fatty acid profile of *A. pusilla* in order to use it in aquaculture feeds.

Table I. Total organic matter (TOM) removal rate by *A. pusilla* during the trials (mean ± S.D.). Significant differences ($p<0.05$) respect to units with 60 y 75 org.m-2 are expressed with (†).

Density (org.m-2)	60	75	150	200
Biomass (g.m-2)	58.48 ± 9.77	71.11 ± 9.10	155.21 ± 16.49	195.86 ± 11.07
TOM removal rate (g.m-2.d)	13.65 ± 0.04	18.53 ± 0.05	33.86 ± 0.05†	35.77 ± 0.05†

EFFECTS OF REPLACING FISH MEAL WITH COCKROACH *Periplenata americana* MEAL IN THE DIET OF *Clarias gariepinus* FINGERLINGS

Abdullahi M. Orire*[1] and Fasomo G. B. [2]

[1]Department of Fisheries and Aquaculture, Federal University Dutse, Jigawa State, Nigeria
[2]Department of Water Resources, Aquaculture and Fisheries Technology, Federal. University of Technology, Minna, Niger State, Nigeria
Author of correspondence: abdullahiorire@gmail.com

Introduction

High cost of fish meal necessitates need for non-conventional protein source like feather meal, poultry droppings, Insects, worms, garden snails and tadpoles among others (Devendra, 1988). Housefly maggots have been reported to be a dietary supplement in tilapia and *Clarias gariepinus* and *Heterobranchus longifilis* by (Madu and Ufodike, 2003). American cockroach *(Periplaneta americana)* can be cultured to supply protein in fish feed and thus, this research investigated the effect of cockroach *(Periplaneta americana***)** meal on the performance of *Clarias gariepinus* fingerlings

Materials and Methods

Materials used included cockroach meal, fish meal, groundnut cake (GNC), soymeal meal, maize meal, vitamin mineral premix, palm oil, electronic sensitive weighing balance (SF-400;Capacity 3000gx1g/106ozx0.1oz) etc. one hundred and eighty (180) catfish fingerlings were randomly distributed in triplicate of 20 fish per tank for three treatment

Three 45% cp experimental diets (Table 1) were fed to the fish for 56 days.

Statistical analysis

Statistical package minitab release 14 was used to analysis the data generated.

Results

The highest mean weight gain, lowest FCR and high SGR, PER, ANPU and survival were recorded for diet 3 (cockroach meal) than other diets (P0.05) (Table 2).

Discussion

The high protein content in the test diets could be responsible for high growth performance of catfish fingerlings, which is in agreement with the report of (Tran *et al*., 2015) and could be attributed to high performance of catfish fingerlings fed with cockroach meal in this experiment. The lipid content of fish meal based diet was higher than that of cockroach meal diet which could be responsible for high diet consumption than cockroach meal diet though with no significant differences. Kiriratnikom and Kiriratnikom, (2012). The optimum dietary protein levels however depend on the fish growth rate, feed intake, amount of non-protein energy in the diet, protein quality, presence of natural food and management practices (Davis *et al*., 2009). This could be responsible for high performance of catfish fingerlings fed with cockroach meal in this experiment. Fats are highly digestible and an important source of concentrated energy and play several key roles in the growth and development of fish (Robinson and Li, 2009

Table 2: Growth Parameters of *Clarias gariepinus* fingerlings fed experimental diets for 56 days.

Growth Parameters	Diet 1	Diet 2	Diet3	SD±
Initial weight gain (g)	1.13 ± 0.03^{a}	1.10 ± 0.00^{b}	1.10 ± 0.00^{b}	0.02
Final weight gain(g)	1.87 ± 0.27^{b}	2.08 ± 0.23^{b}	2.49 ± 0.39^{b}	0.30
Mean weight gain (g)	1.15 ± 0.48^{a}	0.98 ± 0.23^{a}	1.39 ± 0.39^{b}	0.38
Feed fed (g)	3.63 ± 0.90^{a}	3.81 ± 0.29^{a}	3.53 ± 0.29^{a}	0.57
FCR	2.01 ± 0.79^{a}	1.86 ± 0.32^{a}	1.43 ± 0.15^{b}	0.50
SGR (%/day)	0.89 ± 0.30^{c}	1.13 ± 0.19^{b}	1.44 ± 0.29^{a}	0.27
PER	0.69 ± 0.15^{b}	0.58 ± 0.17^{b}	0.87 ± 0.20^{a}	0.17
ANPU (%)	1.78 ± 1.26^{b}	4.19 ± 4.87^{b}	16.23 ± 7.19^{a}	5.07
Survival (%)	37	42	62	2.31

Means on the same column with different superscripts are significantly different (P< 0.5)

(Continued on next page)

Table 1: Formulated diets containing cockroach meal.

Feed ingredients (%)	Diet 1	Diet 2	Diet 3
Fish meal	0.00	100.00	0.00
Groundnut cake	416.50	284.90	294.50
Soybean	416.50	284.90	294.50
Cockroach meal	0.00	0.00	100.00
Maize meal	67.000	230.30	211.10
Lipid	50.00	50.00	50.00
Vitamin mineral premix	50.00	50.00	50.00
Total	1000.00	1000.00	1000.00

Table 2: Proximate Compositions of formulated diets

Diets %	Crude Protein	Lipid	Ash	Moisture	Fibre	Carbohydrate
Diet 1	45.05	9.08	14.88	7.81	1.80	21.38
Diet 2	45.09	13.85	14.89	7.18	0.80	18.19
Diet 3	45.04	8.88	12.04	8.20	4.50	21.34

Conclusion

Cockroach meal in the diet of *Clarias gariepinus* fingerlings as a protein sources was evaluated, and from the study it can substitute fish meal without compromising the nutrient utilization, growth and survival

GROWTH PERFORMANCE AND NUTRIENT UTILIZATION OF *Clarias gariepinus* FINGERLINGS FED WITH ROSELLE (*Hibiscus sabdariffa*) CALYX AS DIETARY ADDITIVE

Justina O. Oshoke*, Salele . Hauwau Abubakar

Department of Fisheries and aquaculture, Federal University, Dutsin-Ma, Katsina State, P.M.B 5001, Dutsin-Ma, Katsina State, Nigeria
joshoke@fudutsinma.edu.ng

Introduction

Antibiotics are chemical compounds used in treating and preventing diseased in aquaculture. Farmers also use antibiotics in fish feed to enhance growth. Antibiotics growth promoters (AGP) were supposed to increase growth rate as a result of improved gut health, resulting in better nutrients utilization and improved feed conversion. However, these drugs are expensive, promotes microbial resistance, breakage of the animal intestinal micro-ecological balance and the presence of antibiotics residues in resultant fish produce. Natural materials such as medicinal plants could be widely accepted as feed additives to enhance fed utilization and sustainability and aquaculture productive performance. World Health Organization encourages using medicinal herbs and plants to minimize the use of chemicals. Hence a call for research into accessible, potent, cheaper, eco-friendly, alternative natural antibiotic. A particular medicinal plant of interest is the Roselle, *Hibiscus sabdariffa*.

Materials and Methods

The study was conducted at the research farm of the Department of Fisheries and Aquaculture, Federal University Dutsinma, Katsina State, Nigeria. Dried flower (Calyx) of *Hibiscus sabdariffa* was purchased, milled with a blender into powder form, sieved and stored in an air tight container until when ready use. The dosage values of the Roselle used in the experimental diet were 4g, 6g and 8g / Kg, while the control, 0g had no Roselle Calyx. Four diets (40%) crude protein) were formulated and coded Diet 0 control, Diet 1 (4.0g), Diet 2 (6.0g) and Diet 3 (8.0g). Feed ingredients were bought, ground and measured using a sensitive weighing scale. The ingredients were mixed thoroughly and pelleted, sundried, labeled accordingly and stored at room temperature until it was ready for use. Ingredients used were fishmeal, Soybean meal, Yellow maize, palm oil, Vitamin/mineral, Premix, Cassava starch (acted as a Binder),common salt, bone meal and *Hibiscus sabdariffa* (Roselle). Two hundred *Clarias gariepinus* fingerlings with initial mean weight of 4.25 ± 0.04g were obtained from a reputable fish farm and transported in oxygen bags to the experimental site. The fish were acclimatized for 14 days in holding tanks and fed commercial diet (Copens feed). After which they were randomly stocked in triplicates per treatments. The fish were fed twice daily at 5% body weight at 9:00 am and 5:00 pm for 12 weeks. Fish in each aquarium were sampled biweekly and the amount of feed adjusted accordingly. Dead fish were daily recorded and removed. At the end of the study, fish were individually weighed

Results

Table 1: Growth performance and nutrient utilization of *Clarias gariepinus* fingerlings fed experimental diets.

Parameters	0	1	2	3	Mean	SD	S.E±
Initial mean weight (g)	4.3^{a}	4.27^{a}	4.23^{a}	4.20^{a}	4.25	0.04	0.022

(Continued on next page)

Discussion and Conclusion

The mean weight gain (MWG) of the fish fed diet 0, 1, 2, and 3, were 17.01g, 16.53g, 17.43g and 23.77g respectively. The group of fish fed diet 3 had the highest mean weight gain, and this is significantly different ($P<0.05$) from the weight gain of the group of fish fed on diet 0, 1 and 2. An interesting characteristic of Roselle calyx is the presence of polyphenols, ascorbic acid (Escribano-Bailón et al, 2006) http://www.epj.eg.net/article.asp?issn=1687-4315;year=2016;volume=15;issue=2;spage=78;epage=87;aulast=El - ref38, and red pigments (anthocyanin), which show antioxidant activity (Sáyago-Ayerdi, et al, 2007). These components could participate in fish metabolism, helping to improve health and growth. These results are also in agreement with the results of Pérez *et al.* (2012), who showed that increasing anthocynain in Roselle calyx/kg diet increased the growth rate, weight gain and specific growth rate of goldfish (*Carassius auratus*). In the present study, feed intake was higher for fish fed diets containing *H. sabdariffa* calyx at all levels, except fish fed with the Diet. 1 This gradation, which was in the favor of fish on *H. sabdariffa* calyx, could be attributed to a high content of vitamins and minerals in *H. sabdariffa* calyx, which enhanced appetite (Mahadevan 2009) and it is evidenced by higher weight gain. The fingerlings fed diet 3 had the highest specific growth rate (SGR) of 1.64. Those fed with Diet 1 and Diet 0 had the least value of 1.45 and 1.46 respectively. The present data also showed that feed efficiency ratio was significantly higher ($P<0.05$) for 8% *H. sabdariffa* calyx diet, whereas there was no significant difference in protein efficiency ratio between the control and 4% of *H. sabdariffa* calyx. This is in agreement with El Mesallamy AM (2016).These results suggested that *H. sabdariffa* calyx supplementation did play a role in enhancing feed intake with a subsequent enhancement of the fish body composition. Moreover, Pérez et all 2012 showed that increasing anthocynain in *H. sabdariffa* calyx/kg diet, increased feed conversion rate of goldfish (*C. auratus*). The feed conversion ratio (FCR) observed in fingerlings fed diet 0 (2.13) was higher than those fed other diets, with the lowest value in fingerlings fed diet 3 (0.93). The lower FCR value in treatment Diet 3 showed that it was highly digested by the fish than other treatments which may be due to the high content of vitamins and minerals in *H.sabdariffa calyx*.

The Protein efficiency ratio (PER) results indicated that there was no significant difference ($P<0.05$) between the control Diet 0 and Diet 1 but there was a significant difference ($P> 0.05$) between the control Diet 0, Diet 2 and Diet 3.The PER was highest in fish fed Diet 3 and lowest in fish fed diet Diet 0. This indicates that the protein content of diet 3 was efficiently utilized by the fish. Olaniyi (2009a &b) asserted that the higher SGR and smaller FCR values, the better the feed quality. Also Adikwu (2003) reported that a lower FCR value implies efficient feed utilization by fish. Based on these result, fish fed with 8% roselle calyx inclusion (Diet 3) performed better without compromising growth rate or causing any deleterious effect on the fish. It is hence concluded that 8% inclusion of roselle calyx as an additive in the diet of *Clarias gariepinus* fingerlings supported growth and nutrient utilization of the fis

ASSESSMENT OF ABUNDANCE AND DISTRIBUTION OF FISH SPECIES IN SOME DAMS IN EKITI STATE, NIGERIA

*Oso, James Abayomi, Aluko, Ayodeji Anthony

Department of Zoology and Environmental Biology
Ekiti State University, P.M.B 5363, Ado Ekiti, Nigeria
james.oso@eksu.edu.ng

An assessment of abundance and distribution of fish species in Ureje, Itapaji and Egbe dams in Ekiti State, Nigeria was conducted where samples were collected fortnightly with the assistance of artisanal fishermen operating in the study areas. The population structure and distribution patterns were determined using the number of occurrence index (NOI) and histogram. A total number of 148 individuals comprising 5 species occurred throughout the sampling period. *Oreochromis niloticus, Tilapia zillii* and *Sarotherodon melanotheron* occurred in the three dams, *Mormyrus hasselquistii* occurred in two of the three dams i.e. Itapaji and Egbe while *Hemichromis fasciatus* was found in Itapaji dam only. *Oreochromis niloticus* was abundant in Ureje and Egbe dams with 52.38% & 52% respectively, but occurred in a low quantity in Itapaji dam with 15.66%, *Tilapia zillii* had 28.30%, 22%, 6.67% at Ureje, Itapaji and Egbe dams respectively; *Sarotherodon melanotheron* had 51.1% in Itapaji dam where it was dominant and recorded 18.87% and 8% in Ureje and Egbe dam respectively. *Mormyrus hasselquistii* had 18% and 8.89% in Egbe and Itapaji dams respectively and *Hemichromis fasciatus* recorded 17.7% at Itapaji dam where it only occurred. *O. niloticus* dominated the entire catches in all the dams with 41.2% followed by *S. melanotheron* 25%, *T. zillii had 19.6%, M. hasselquistii* had 8.9% and *H. fasciatus* had 5.5%. The study revealed that there was a generally high similarity among the freshwater fish communities in the selected dams. It is worthy of note that these dams have capacity for fish production that could serve as a sustainable means of livelihood for the populace around the areas if properly managed.

BACTERIAL OUTER MEMBRANE VESICLES OF *Aeromonas salmonicida* INDUCE A PRO INFLAMMATORY IMMUNE RESPONSE IN VITRO AND IN VIVO

Sven Ostermann[1], Ruth Tamara Montero[1], Tobias Kroniger[2], Dörte Becher[2], Bernd Köllner[1]

1 Friedrich-Loeffle -Institute Greifswald Insel Riems; 2 University Greifswald
E-Mail: bernd .koellner@fli.d

High mortality rates after bacterial and bacterial-viral superinfections cause high losses for the aquaculture industry. As treatment with antibiotics is not an alternative, bacterial vaccines for intramuscular or intraperitoneal injection were developed resulting in inflammatory granulomas and stress. Within the project "Modular oral applicable Multi-Vaccine – principle solutions (MoMV)" we propose therefore the design of a modular vaccine based on outer membrane vesicles (OMV´s) of the bacterial fish pathogen *Aeromonas salmonicida*. The simple preparation, the safety due to their non-replicative nature as well as the composition of natural surface exposed membrane antigens in their native confirmatio are the advantages of such a vaccine design. In the present study we are focusing on characterization of the immunogenic potential of the OMV´s.

Methods: Fish were treated with a bacterial vaccine formulation either by intraperitoneal or oral vaccination. At different time points after vaccination peritoneal, blood, spleen and head kidney leukocytes were isolated and comparatively characterized by flow cytometry in target immune organs (gut, peritoneum) and effector immune organs (spleen and head kidney) labelled with a cocktail of lineage marker specific antibodies. Moreover, using the lineage marker specific antibodies the recognized cell populations were sorted at function related time points after stimulation. Finally, the mRNA was prepared form these isolated cell populations to characterize their mRNA profile

Results: A comparable kinetics of distinct leukocyte populations was seen after both intraperitoneal administration of inactivated bacterin as well a preparaed OMV from *A.salmonicida* especially in the targets immune organs. Moreover after 14 and 28 day post vaccination a high titer of *A.salmonicida* specific antibodies was measured in both treated fish groups indication an antigen specific immune response

DO DOWN-STREAM PROCESSING OF BAKERS YEAST (*Saccharomyces cerevisiae*) AFFECT DIGESTIBILITY AND IMMUNE RESPONSE IN ATLANTIC SALMON (*Salmo salar*)?

Jon Øvrum Hansen[1*], Leidy Lagos[1], Peng Lei[1], Felipe Eduardo Reveco-Urzua[1], Ricardo Tavares Benicio[1], Line Degn Hansen[2], Liv Torunn Mydland[1], Margareth Øverland[1]

[2] Faculty of Chemistry, Biotechnology and Food Science**,** Norwegian University of Life Sciences, P.O. Box 5003, NO-1432 Ås, Norway

Introduction

The increased demand for high-quality feed ingredients for the aquaculture industry have given increased focus on microbial ingredients as sources of both protein and lipids. However, limited information exist on the effect of different down-stream processing of yeast on nutrient digestibility and immune response in fish. In the present study, we used three different down-stream processing methods for yeast: spray drying, autolysis or cell crushing and evaluated their effects on nutritional and health for Atlantic salmon (*Salmo salar*).

Materials and methods

In detail, we first re-suspended fresh live bakers yeast (*Saccharomyces cerevisiae*) in deionized water and then processed using one of the following six methods: spray dried at 1) 180 or 2) 250°C, treated with a high shear processor LM20 Microfluidizer with a force of 3) 10 000PSI or 4) 20 000PSI, and autolyzed using a 30l Bioreactor system at 50°**C** for 5) 8 or 6) 16h. Nitrogen leakage and fixation of yeast cells for electron microscope were performed before final spray drying. Solubility of β-glucan and mannan were tested in pre-digested (*in vitro*) spray dried yeast. The experimental diets consisted of 700g kg^{-1} of a fishmeal based reference diet (including yttrium as a digestible marker) and 300g kg^{-1} of one of the processed yeast candidates. Fish were fed with one of the seven resulting diets for 30 days, and faeces, spleen, head kidney, distal intestine and plasma were collected from fish at the end of the experiment

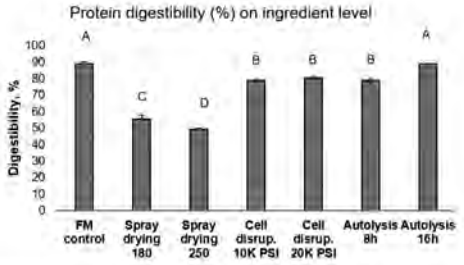

Fig. 2. Protein digestibility of different processed *S. cerevisiae* in Atlantic salmon.

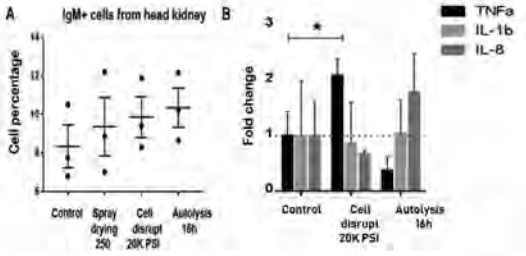

Figure 5. A. Percentage of leukocytes IgM+ from head kidney of Atlantic salmon fed different processed *S. cerevisiae*. B. Detection of immunological markers by indirect ELISA in distal intestine from *Salmo salar* fed processed yeasts by cell disruption (20k PSI) and autolysis (16 hours). *: $p<0.05$ (Dunnett's multiple comparisons test).

(Continued on next page)

Results and discussion

Processing of yeast resulted in increased level of soluble protein in the yeast cream post-treatment, with the highest level for yeast disrupted at 20K PSI. This was confirmed with scanning electron microscopy, were disrupted and cracked cells could be observed (Figure 1). Fish fed yeast that was only spray dried resulted in a lower growth and higher FCR compared to the FM control. Significant lower protein digestibility of spray dried yeast support the growth performance data (Figure 2). Autolysis for 16h resulted in the highest protein digestibility, which was similar to the FM control.

There was normal histology observed in DI of all fish. Interestingly, 16h autolyzed yeast induced the secretion of IL-8, while cell crushed yeast induced the secretion of TNFα in the distal intestine, analyzed by ELISA. The expression of IgM in leukocytes was analyzed by flow cytometry. Thus, processing of yeast could have an effect on immune stimulation on fish.

Conclusion

Different down-stream processing methods of *S. cerevisiae* led to:

- Increased protein and β-glucan solubility of yeast
- Increased protein digestibility in Atlantic salmon
- Enhanced immune stimulatory effect in Atlantic salmon

DECIPHERING THE GENOME OF THE RIVER MONSTER - THE EUROPEAN CATFISH (*Silurus glanis*)

M. Ozerov*[1], A. Vasemägi[2,3] and R. Gross[2]

[1]Department of Biology, University of Turku, 20014, Finland
[2]Chair of Aquaculture, Estonian University of Life Sciences, Tartu, 51014, Estonia
[3]Department of Aquatic Resources, Institute of Freshwater Research, Swedish University of Agricultural Sciences, Drottningholm, 17893, Sweden
E-mail: mikoze@utu.fi

The European catfish (*Silurus glanis*) is one of the largest freshwater fish species, top predator and an iconic trophy-fish for recreational fishermen. *S. glanis* is a highly valued species for its high quality boneless flesh and has a long tradition of aquaculture in Eastern and Central Europe. The interest of rearing European catfish continues to grow and the aquaculture production of this species has almost doubled during the last decade. However, despite its high ecological, cultural and economical importance the available genomic resources for *S. glanis* are very limited.

To fulfill this gap we generated *de novo* assembly of the whole genome sequence of a female European catfish. The linked-read based technology with 10X Genomics Chromium chemistry and Supernova assembler produced a highly continuous draft genome of *S. glanis*: ~0.8Gb assembly (scaffold N_{50} = 3.1Mb; the longest individual scaffold 13.7Mb; BUSCO completeness of 85.5%), which included XXX Mb of putative repeated sequences.

By using *S. glanis* transcriptome assembly based on RNA-seq data from eleven tissues we subsequently annotated catfish genome. A total of YYY protein-coding genes were predicted, ZZZ (NN%) of which were annotated functionally from either sequence homology or protein signature searches. Finally, we demonstrate the power and usefulness of the annotated catfish genome by sequencing of 62 individuals in three DNA pools (Pool-Seq) comprising one albino and two normal strains of *S. glanis* from the Czech Republic and by identifying the molecular basis of albinism.

The highly continuous genome assembly will be an invaluable resource for aquaculture genomics, genetics, conservation, and breeding research of the European catfish

DO TROPICAL CORALS GET STRESSED DUE TO SHIPPING?

Ana P.L. Costa*, Andreia C.M. Rodrigues, Davide A.M. Silva, Catarina R. Marques, Amadeu M.V.M. Soares and Rui J.M. Rocha

Department of Biology & CESAM, University of Aveiro, Campus Universitário de Santiago, 3810-193 Aveiro, Portugal
*anaplcosta@.pt

Introduction

Live corals are being increasingly shipped worldwide, either from the wild or from *in situ* coral farms located in tropical regions, to supply wholesaler aquarium companies, hobbyists, researchers and general public (Leal et al., 2015). Corals are usually shipped, over long distances, in plastic bags filled with seawater and oxygen. During this period corals can be affected by temperature fluctuat ons, mechanical damage or hypoxia. These stressors can compromise organisms' wellbeing and induce several stress responses, which ultimately can lead to death. It is important to understand the physiological effect of transport on different coral species. Stress biomarkers can be a valuable tool to access the sub lethal impacts on organisms' metabolism, oxidative stress and oxidative damage (Rodrigues et al., 2017). Thus, it is possible to evaluate the resistance and resilience of different coral species submitted to a shipping practice, and even identify biochemical parameters to predict whether the coral is in good shape to be transported, or otherwise, if harvesting and shipping may lead to coral death. In this way, two soft coral species *Sinularia polydactyla* and *S. asterolobata* were submitted to a usual 48 h shipping, and their oxidative stress response, oxidative damage and energy budget changes were evaluated.

Materials and methods

Corals were purchase to wholesaler company, which transported them in plastic bags, containing seawater and oxygen. Shipping lasted approximately 48 h, since harvest in Batam, Indonesia, until arrival at our laboratory facilities in Ecomare, Aveiro, Portugal. Coral colonies were sampled at arriving (Ti – initial time) and after 3 months (Tf – final time), to analyze biochemical biomarkers of antioxidant defenses (catalase – CAT, glutathione S-transferase – GST, total glutathione – tGSH), oxidative damage (lipid peroxidation – LPO) and energy consumption (Ec – estimated by the electron transport system activity).

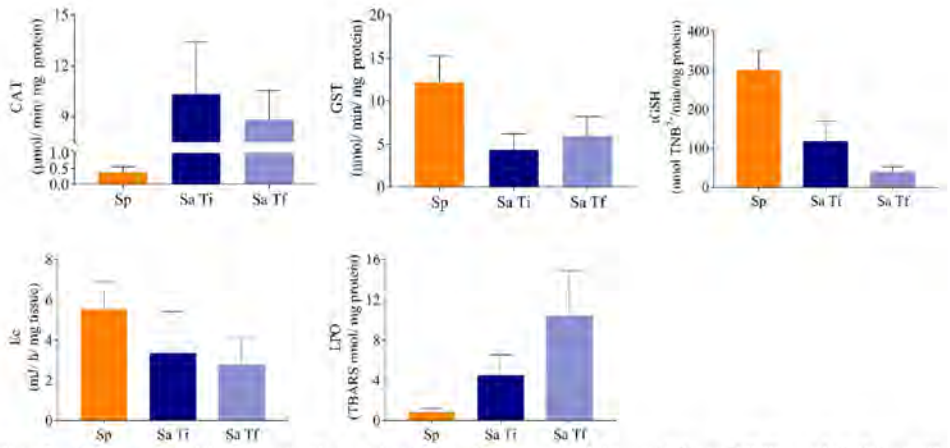

Fig. 1 - Effects of shipping on the antioxidant defenses: CAT – catalase, GST – glutathione S-transferase, tGSH – total glutathione; on metabolic respiration: Ec – energy consumption; and on oxidative damage: LPO – lipid peroxidation, of *Sinularia polydactyla* (Sp - orange) and *Sinularia asterolobata* (Sa - blue), in two different sampling points (Ti – initial time, and Tf – final time). All values are presented as mean ± SD.

(Continued on next page)

Results

S. polydactyla colonies did not recovered and died one week after arrival. Results of oxidative stress response of *S. polydactyla* for Ti show high values of antioxidant defenses activities and levels (GST and tGSH), combined with a high metabolic activity (Ec values). Regarding *S. asterolobata* results, it had high values of CAT activity at Ti sampling, but low GST activity and tGSH levels. Surprisingly, LPO values were slighter higher at Tf than in Ti samplings.

Discussion

The *Sinularia* species had different reactions to handling and shipping. The transport induced more stress in *S. polydactyla* than in *S. asterolobata*, ultimately leading to *S. polydactyla* colonies dead. In Ti, CAT activity was partially suppressed in *S. polydactyla,* and antioxidant activity was mainly performed by GST and tGSH. As expected, stress caused a higher energy consumption for *S. polydactyla*. The low lipid peroxidation observed may be explained by cell apoptosis, leading to a stage that LPO cannot be measured. In terms of antioxidant defenses and metabolic respiration for *S. asterolobata* we do not verify any damage and see a visible recovery after shipping. In this way, the LPO values observed for the Tf sampling may be close to normal, as these organisms live in association with photosynthetic dinoflagellates, and have a daily cycle of ROS production, but further investigation on this matter needs to be done. In sum, shipping can cause cellular damage, depending on corals species resistance, even in organisms belonging to the same genera.

Note that this work does not encourage the harvest of wild animals from their natural habitat and it mainly focuses on a procedure commonly performed. Besides, it can add value to tropical corals sustainably produced *in* or *ex situ*.

*anaplcosta@.pt

Introduction

The increasing demand of corals led to the need to create a sustainable solution for coral delivery without compromising natural stocks, already affected by climate change and human impact. Coral aquaculture *ex situ* can be a viable option to meet the needs (Leal et al., 2013)growing evidence suggest that their symbiotic bacteria produce most of these bioactive metabolites. The ex hospite culture of coral symbiotic microbiota is extremely challenging and only limited examples of successful culture exist today. By contrast, in toto aquaculture of corals is a commonly applied technology to produce corals for aquaria. Here, we suggest that coral aquaculture could as well be a viable and economically feasible option to produce the biomass required to execute the first steps of the NP-based drug discovery pipeline.",”author”:[{“dropping-particle”:””,” family”:”Leal”,”given”:”Miguel C.”,”non-dropping-particle”:””,”parse-names”:false,”suffix”:””},{“dropping-particle”:” ,”family”:”Calado”,”given”:”Ricardo”,”non-dropping-particle”:””,”parse-names”:false,”suffi ”:””},{“dropping-particle” :””,”family”:”Sheridan”,”given”:”Christopher”,”non-dropping-particle”:””,”parse-names”:false,”suffi ”:””},{“dropping-particle”:””,”family”:”Alimonti”,”given”:”Andrea”,”non-dropping-particle”:””,”parse-names”:false,”suffix”:””},{“dro pping-particle”:””,”family”:”Osinga”,”given”:”Ronald”,”non-dropping-particle”:””,”parse-names”:false,”suffix”:””} ,”container-title”:”Trends in biotechnology”,”id”:”ITEM-1”,”issue”:”10”,”issued”:{“date-parts”:[[“2013”,”10”]]},”pa ge”:”555-561”,”publisher”:”Elsevier Ltd”,”title”:”Coral aquaculture to support drug discovery”,”type”:”article-journa l”,”volume”:”31”},”uris”:[“http://www.mendeley.com/documents/?uuid=1f15707b-e78a-4214-931f-7cbece2580d5”]}],”mendeley”:{“formattedCitation”:”(Leal et al., 2013, but is important to take into account species requirements and economic questions for an optimal culture (Rocha et al., 2013). Symbiotic corals, that live in association with unicellular photosynthetic dinoflagellates, require an appropriate supply of light intensity and spectra, but still needs the input of heterotrophy for supplementary essential nutrient acquisition (Houlbrèque and Ferrier-Pagès, 2009)that they are both auto- and heterotrophs, was recognized early in the twentieth Century. It is generally accepted that the symbiotic association between corals and their endosymbiotic algae (called zooxanthellae. Thus, understanding coral development-related questions, as mixotrophy, can be crucial for the appropriate control of culture parameters and maximization of coral growth (Costa et al., 2016). Four coral species commonly reared and with potential for bioactive compounds production were selected. Three microencapsulated diets' prototypes formulated by SPAROS were provided and their effect on growth, photosynthetic efficiency and cellular ene gy allocation evaluated.

Materials and methods

Colonies of the four selected species (*Sinularia brassica*, *Sarcophyton glaucum*, *Zoanthus* sp. and *Palythoa* sp.) were purchase from wholesaler company, which collected them in Indonesia. After an acclimatization period in the culture systems, all coral colonies were fragmented in mini colonies using a sterilized scalpel and sewed in aragonite and cement bases. Recovered coral fragments were placed in four independent recirculated systems (for system detail see Rocha et al. (2015) to test 3 prototype diets. the corals of the fourth system were not fed during the whole experiment. Each experimental system was stocked with 9 replicas (mini colonies) of each species. Experimental diets (squid and fishmeal-based diet, artemia-based diet, and microalgae-based diet) were provided two times per week. During feeding time experimental culture tanks were disconnected from the filtration tank for a period of 30 minutes, to allow corals to feed before the experimental diets begin removed from the system by the protein skimmer. This experiment will have a duration of 5 months. At the beginning (Ti) we performed measurements of: (1) coral size to assess growth - photographic registration of octocorals and polyp count of hexacorals, (2) *in vivo* chlorophyll fluorescence, using a pulse amplitude modulation (PAM) fluoromete , (3) biochemical biomarkers of cellular energy allocation. At the end, the same methodologies will be performed for all treatments. Additionally, the polyp number count and *in vivo* chlorophyll fluorescence measurements were made in the middle of experimental period, as non-invasive methods, to obtain some early results.

(Continued on next page)

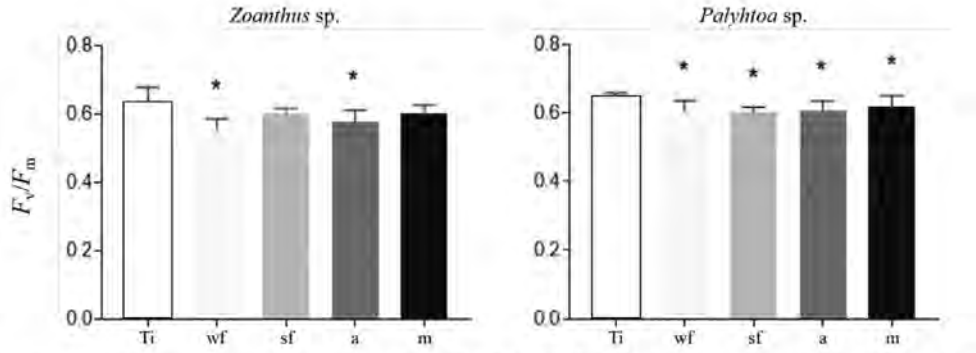

Fig. 1 –Maximum quantum yield of PS II (F_v/F_m) of coral fragments (mean ± SD, n = 9) at the beginning (Ti) and at the middle (wf – without feed, sf - squid and fishmeal-based diet, a - artemia-based diet, m - microalgae-based diet) of the experiment. Statistically significant differences between treatments are distinguishable by symbol (*) ($p < 0.05$ for all comparisons).

Results

Results of coral growth show that Zoanthus sp. had a higher percentage of polyp growth with squid and fishmeal-based diet, whereas Palythoa sp. had higher polyp development without feed. Comparisons between intial F_v/F_m of coral fragments from same species show that they had the same photosynthetic performance. The mid-stage results show statistical differences in Zoanthus sp. F_v/F_m, between squid and fishmeal-based diet and artemia-based and initial sampling. For Palythoa sp., all treatments had differences in F_v/F_m values comparing with initial sampling.

Discussion

It is visible a different response by Zoanthus sp. and Palythoa sp. towards feed after 2,5 months of supply. Zoanthus sp. colonies seem to have a greater growth with squid and fishmeal-based diet, presenting an approximate photosynthetic capacity towards initial values. In contrast, Palythoa sp. fragments had a greater development without feed, although all treatments showed a reduction on the photosynthetic capacity through the experiment. This contrasts to what it was expect for hexacorals, as the availability of external feed induces a photosynthesis enhancement (Anthony and Fabricius, 2000; Houlbrèque and Ferrier-Pagès, 2009)phototrophic energy gains can be diminished due to light absorption by suspended particles, and stress from particle abrasion or deposition on tissues. However, energy gains are enhanced if organisms are able to use SPM as a food source. For photosymbiotic benthic suspension feeders, increases in SPM concentrations may require both phototrophic and heterotrophic acclimation to sustain a positive energy balance. This study provides an experimental analysis of the effects of contrasting light and SPM regimes on the energy budget (scope for growth. Photobiological and biochemical changes will be presented and discussed into further detail, but overall our data highlights the differences in nutritional requirements among coral species.

Introduction

Consumption of bivalve molluscs may represent a risk to human health (Campos and Cachola, 2007) and so, depending on the microbiological load, bivalves require depuration before commercialization, to ensure food safety. European legislation requires the classification of production areas in class A, B or C, based on *Escherichia coli* load, which must not exceed 230, 4600 and 46000 *E. coli*/100 g of flesh and intravalvular liquid, respectively. Class C areas are the most problematic, due to the requirement of transposition of bivalves to relying areas for more than two months prior to depuration, leading to organism's mortality and economical costs, that may be unbearable. Marine bivalve depuration can be performed in flow through or recirculating systems using filtered seawater during a period of 24 h or more. Usually, the depuration systems used in Europe are equipped with mechanical filters, UV sterilizers, temperature control systems (water chillers), and, in some cases, protein skimmers, using the same water parameters for all purified species. However, due to physiological specificities, it might be relevant to adapt water parameters, namely temperature, to the physiological requirements of each species, in order to optimize the depuration process. This study aimed to assess whether it is possible to depurate marine bivalves reared in class C areas, reducing *E. coli* to legally accepted levels in 24 h, using different water temperatures.

Materials and methods

For this study were selected three species of bivalves with a broad distribution and high economic value in Europe: clam (*Ruditapes decussatus*), razor clam (*Solen marginatus*), and cockle (*Cerastoderma edule*). Bivalves were harvested in class C zones in Algarve, South Portugal, transported to laboratory facilities and depurated in different temperature scenarios: 10, 15, 20, and 25 °C. Experiments were performed during 24 h in 250 L modular depuration systems, individually equipped with filtration (UV-C unit and protein skimmer) and temperature control systems. Before and after the depuration process, edible tissue and intravalvular liquid from bivalves were sampled to analyse microbiological content. The most probable number (MPN) of *E. coli* present in the bivalves was calculated according to the method described by ISO 16649-3:2015 (ISO, 2015).

Results

The better temperature for depuration, regarding *E. coli* values, differ between species. While *R. decussatus* depurated better at 20 ºC, *S. marginatus* presented lower values of *E. coli* at 10 and 15 °C. For *C. edule*, depuration process was more efficient at 20 and 25 ºC.

Discussion

According to the European legislation, bivalves produced or harvested in class C areas cannot be commercialized for direct human consumption, which can represent significant economic losses, hindering the aquaculture of bivalves in many areas with conditions for the development of this activity. However, the results obtained for studied species suggest that it is possible to depurate bivalves harvested in class C areas in 24 h, using adequate methodologies, guarantying the quality and safety of the product for human consumption. It is clear that different species may have specific physiological requirements that must be considered during the depuration process. In this study the results shown that temperature can have a preponderant effect in the depuration process, which might be related with physiological or morphological aspects, or even, with the ecological niche occupied by the different species, since studied bivalves live buried at different depths in the substrate. In the future, other tests should be carried out to study the interaction between temperature and other water parameters (e.g. salinity), in order to optimize the purification process, considering the physiological requirements of each species.

(Continued on next page)

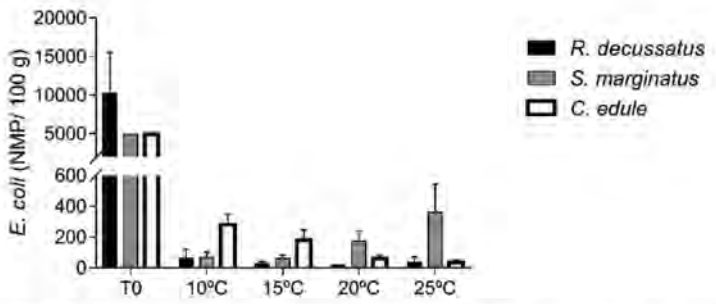

Fig. 1 – The most probable number (MPN) of E. *coli* per 100 g of flesh and intravalvular liquid before (T0) and after a 24 h depuration process, at each tested temperature (10, 15, 20, and 25°C), for *Ruditapes decussatus, Solen marginatus* and *Cerastoderma edule*. All values are presented as mean ± SD.

IMPLEMENTATION OF LOW COVERAGE GENOTYPE BY SEQUENCING IN THE SELECTIVE BREEDING PROGRAM OF ARCTIC CHARR (*Salvelinus alpinus*) IN SWEDEN

Christos Palaiokostas[1], Henrik Jeuthe[1,2], Dirk-Jan De Koning[1]

Introduction

The Arctic charr breeding program has been a main driving force for developing the aquaculture industry in Sweden. Selection has been performed for over 30 years using only animals from a closed breeding nucleus. Substantial growth improvement compared to wild stocks has been realized over the years (Eriksson *et al.* 2010)a breeding programme and the study of the biological and behavioural characteristics of the species. Traits of three different Arctic charr populations differing in ecology and appearance were compared during initial 2-year trials under farming conditions. The best-performing population with respect to the growth rate and the lowest frequency of early sexual maturation was a piscivore form and this became the foundation for a breeding programme intended to select for an Arctic charr strain suitable for farming. After 23 years and 7 generations, our selective breeding has resulted in a fast-growing, late-maturing strain much appreciated by farmers. The biological and behavioural characteristics studied included annual and diel locomotor activity, feeding, social and thermal behaviour. Applying our findings in these areas has greatly improved both profits and conditions for the fish. Other investigations have focused on the application and further evaluation of the results from research in practical farming trials, such as evaluation of growth at different farms with different temperature conditions, optimal time and stocking density for start-feeding and evaluation of different feeding schedules. In Sweden, Arctic charr is mainly farmed in net pens situated in nutritionally depleted and extremely unproductive water reservoirs formed by damming rivers to create electric power. Judicious farming of Arctic charr in such reservoirs can restore their nutritional and productivity state to that which existed before regulation. Site selection criteria for Arctic charr farming in such waters have been developed. The development of intensive farming of Arctic charr in Sweden is discussed together with current limitations and future possibilities. © 2010 Springer Science+Business Media B.V.”,”author”:[{“dropping-particle”:””,”family”:”Eriksson”,”given”:”Lars Ove”,”non-dropping-particle”:””,”parse-names”:false,”suffix”:””},{“dropping-particle”:””,”family”:”Alanärä”,”given”:”Anders”,”non-dropping-particle”:””,”parse-names”:false,”suffi ”:””},{“dropping-particle”:””,”family”:”Nilsson”,”given”:”Jan”,”non-dropping-particle”:””,”parse-names”:false,”suffix”:””},{“dropping particle”:””,”family”:”Brännäs”,”given”:”Eva”,”non-dropping-particle”:””,”parse-names”:false,”suffix” ””}],”container-title”:”Hydrobiologia”,”id”:”ITEM-1”,”issue”:”1”,”issued”:{“date-parts”:[[“2010”]]},”page”:”265-274”,”title”:”The Arctic charr story: Development of subarctic freshwater fish farming in Sweden”,”type”:”article-journal”,”volume”:”650”},”uris”:[“http://www.mendeley.com/documents/?uuid=c18f1f29-9421-4532-abf5-c013d8977afd”]}],”mendeley”:{“formattedCitation”:”(Eriksson et al. 2010. Nevertheless, up to date selective breeding has been practiced solely relying on estimating breeding values through traditional pedigree-based approaches. A main advantage of genomic tools over pedigree lies on the ability of providing higher resolution relationships amongst the breeding candidates. Genotype by sequencing (GBS) technologies offer a cost-effective approach for utilizing modern genomic-based selective breeding practices. Low sequencing coverage GBS has the potential of further lowering genotyping costs, while maintaining the ability of accurately estimating relationships amongst the tested population (Dodds et al 2015).

Materials and methods

Arctic charr of year class 2016 from the national Swedish breeding program was used for constructing GBS sequencing libraries. In particular, 372 animals from 12 full-sib families were chosen for genotyping purposes. The aforementioned animals were reared in three different farms in Sweden. GBS libraries were constructed according to Elshire et al (2011) with modifications described in Dodds et al (2015). Sequencing was performed in two sequencing lanes of an Illumina HiSeq2500. Read demultiplex was performed using GBSX (Herten et al 2015) and SNP discovery using Stacks (Catchen et al 2011). Genomic relationship matrices were constructed following the methodology of Dodds et al (2015). Finally, single-step GBLUP approaches (Aguilar *et al.* 2011; Legarra *et al.* 2014) using the genotyped animals and additional pedigree records of 8,903 animals were tested to investigate the potential of low coverage GBS on improving the accuracy of breeding values regarding growth traits in Arctic charr.

(Continued on next page)

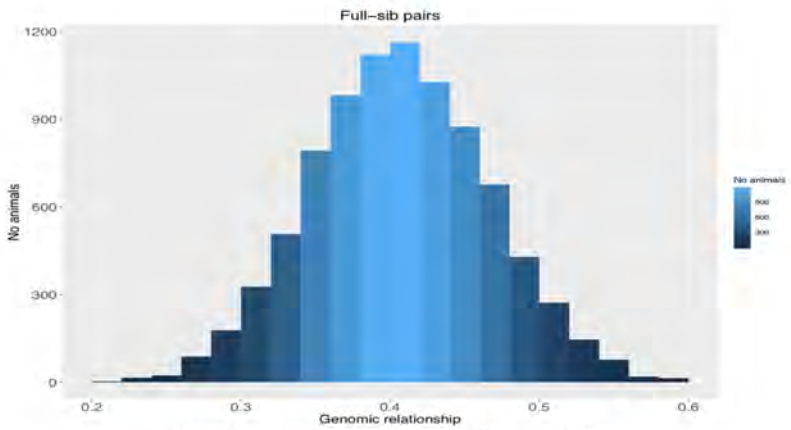

Figure 1. Relationships amongst full-sibs.

Results

Approximately 14,500 SNPs with minor allele frequency and call rate above 0.05 and 50% respectively were detected. The mean obtained coverage was 4X across the genotyped samples. A mean relationship of 0.44 was estimated across all tested full-sibs (Figure 1).

Using a cross-validation scheme (replicated 5 times) with 1/3 of genotyped animals being used as a validation set ssGBLUP resulted in 10 – 14 % increase of breeding value accuracy compared to pedigree BLUP (best linear unbiased predictor).

Discussion and conclusion

The current study provides the first identification of SNP markers in the selective breeding stock of Arctic charr in Sweden. Application of low-coverage GBS was efficient in identifying relationships amongst the tested animals. A higher resolution of realized relationships was obtained as opposed to traditional pedigree-based approaches. Despite the small number of genotyped animals (372) ssGBLUP resulted in 10 – 14 % increase in the accuracy of estimated breeding values. Increasing the number of genotyped animals is expected to provide more accurate measures regarding the advantages of genomic technologies. Overall, the incorporation of GBS is expected to boost the Arctic charr breeding program allowing more efficient management of inbreeding accumulation through estimating realized relationships and increase the accuracy of selection amongst the breeding candidates.

Introduction

Domestication is an indispensable element of expansion of aquaculture sector. By phenotypic modifications domestication makes the organisms more adapted to the culture conditions (Diamond, 2002). There is very few fish species with the highest level of domestication in aquaculture (Teletchea and Fontaine, 2014). And these fully domesticated ones are among the best performing species (exhibiting high survival, feed conversion ratio, spawning performance etc.) in aquaculture. Therefore, any new species in aquaculture, having huge importance in the expansion of the sector as a whole, is exposed this complicated process. However, there is very little known about the mechanisms conditioning adaptability of the fish to the intensive culture environment. Consequently, reaching higher levels of domestication is a very difficult and slow process.

Larval rearing in intensive culture conditions is the first challenge test for the fish being, in fact, first step of selection. Only the most adaptable individuals will survive and grow during this period. During this period quality of the commercial feed is one of the biggest challenging factor during as it highly deviates from the food available in the nature. Understanding of this adaptation process is crucial in development of effective rearing protocols as well as selection strategies.

The aim of this study was to investigate the effect of two different types of compound diets with different protein sources – easily digestible fish-meal-based (control; C) diet and hardly digestible soy-bean-meal-based diet (experimental; E) – on growth and survival of Eurasian perch (*Perca fluviatilis*) larvae. In this study two separate rearing trials were performed where larvae coming from domesticated and wild fish were used

Materials and methods

Eurasian perch larvae were originated from "Żurawia" pond system (wild fish) or from commercial intensive farm (SARL Asialor, France) (domesticated fish). Both populations were reproduced with the same method (as described by Żarski et al. 2017). Larvae, following incubation, were reared in recirculating aquaculture system, for 18 days at temperature 23°C. After 18 days fish were weaned sharply (without co-feeding) to compound diet. Photoperiod was constant (24L:0D) throughout the study.

As a control feed (Perla larva, Skretting, Norway) was used. Experimental feed was prepared in extruder and the composition was as follows: 50% protein, 12.7% fat, 6.03% and 1.7% fibe . Fish were fed with compound diet 6 times a day, each time until apparent satiation for 12 days.

During the study larvae were monitored for growth (total length [TL] and wet body weight [WBW]) and survival. Data between the two populations (domesticated vs wild) were compared using t-test ($P<0.05$).

Tab. 1. Results of 12-day-long rearing trial with control (C) and experimental (E) diets offered to Eurasian perch larvae. Data in rows, among the respective parameter and between wild and domesticated population, marked with different letter index were statistically different ($P<0.05$).

Type of feed	Wet body weight [mg]		Total length [mm]		Mortality [%]	
	Wild	Domesticated	Wild	Domesticated	Wild	Domesticated
C	48.87 ±14.86^{b}	60.79 ±18.71^{a}	15.17 ±2.28^{b}	17.14 ±2.06^{a}	19.25 ±0.89^{a}	12.04 ±1.26^{b}
E	31.1 ±9.87^{a}	20.69 ±6.12^{b}	13.54 ±1.29	13.46 ±0.94	72.25 ±2.12	69.23 ±1.98

(Continued on next page)

Results

At the time of weaning domesticated fish were found to have significantly higher ($P<0.05$) TL (12.15 ±0.81 mm) and WBW (13.02 ±1.26 mg) than the wild-origin larvae (TL=10.84 ±1.23 mm; WBW=9.53 ±2.08 mg). After 12 days of rearing with the use of C feed domesticated fish were found to perform much more better as all the zootechnical parameters were significantly higher than recorded in wild-origin fish (Tab. 1). However, following application of E diet wild fish were found to grow better reaching significantly higher WBW at the end of the experiment ($P<0.05$). Even though, the TL were similar between the groups at the end of feeding period with E diet, it need to be emphasized that wild fish compensated growth differences recorded at the beginning of the challenge. The domesticated perch larvae performed lover mortality rate in diet C ($P<0.05$), but in diet E, no significant changes were found ($P>0.05$) (ab. 1).

Discussion

The results of our study indicates that domesticated fish were performing much more better – whenever typical rearing procedure is applied along with the high quality commercial feed. Interestingly, however, the same fish fed with feed having lowered expected digestibility, were found to utilize offered food less efficiently when compared to the wild-origin larvae. Digestion capabilities were reported to undergo diet-caused modifications which were then further inherited in higher vertebrates (Axelsson et al. 2013). This allows to suggest, that domesticated fish are very well adapted to particular composition of the feed (in this study protein source being crucial during larval period), but significant changes in composition had negative effect on their growth rate. High mortality rate (c.a. 70%) in both groups suggest that only some fish are able to adapt to such an ‘inadequate’ food, though wild-origin larvae were found to cope with this unfavorable diet much more better. This can be associated with the fact that wild fish over generations had to preserve adaptability to various food sources and their plasticity remained at higher level than the fish ‘selected’ on the base of their adaptation to specific compound diet.

Findings of the present study indicates that domesticated fish has narrowed adaptation capabilities when compared to wild fish. Even though, domestication improves adaptability of the fish to culture environment, it may be speculated that this applies only to the particular conditions they used to be exposed to. Therefore, any changes in production strategy (such as compound feed) may require longer re-adaptation to the new conditions, than it would take place when the domestication would start from the very beginning (with the use of wild-origin fish). In addition to that, it remains unclear whether such a re-adaptation would not lead to deprivation of some commercially valuable traits, what should be reconsidered in further studies.

THE NEW DEFINITION OF AQUAPONICS: FUTURE PERSPECTIVES AND CONSTRAINTS

H.W. Palm*, U. Knaus, S. Appelbaum, G. Burnell, B. Kotzen

Aquaculture and Sea-Ranching, Faculty of Agricultural and Environmental Sciences, University of Rostock, Justus-von-Liebig-Weg 6, 18059 Rostock, Germany.
Email: harry.palm@uni-rostock.de

Introduction

Traditional aquaponics is known to combine aquaculture and soilless plant production without details on production scales or species preferences. So far, many different aquaponic systems have been developed that show a wide range of production scales for private and commercial purposes. The European network "The EU Aquaponics Hub COST Action FA1305" has presented a new classification, nomenclature and definition of modern aquaponic systems in order to support their future development (Palm et al. 2018).

Aquaponics can be divided into I) open aquaponics, II) domestic aquaponics, III) demonstration aquaponics and IV) commercial aquaponics (Palm et al., 2018). Common systems range from outdoor facilities that involve pond fish farming (open aquaponics) to large industrial facilities that operate entirely indoors. The different production sizes enable private use with mini/hobby or backyard systems (domestic) for home-grown production, aquaponics for education and exhibition (demonstration units) or small-scale/large scale commercial ventures with access to the wholesale or retail markets. The main difference of each scale is found in the new nomenclature of aquaponics in the narrower sense (sensu stricto - *s.s.*) with traditional hydroponics compared to aquaponics in the wider sense (sensu lato - *s.l.*) with the use of aquaculture wastewater in horticulture or in agriculture (Palm et al., 2018).

The common feature of all aquaponic facilities is the combined production of aquatic organisms with different plants that are cultivated with the help of feed-derived nutrients converted through bacteria. Most aquaponics have been constructed as closed systems (*coupled aquaponics*) for freshwater fish and plants such as basil, mint, salad, greens, and tomatoes. They are often small or medium sized and operate economically only under both an optimal choice of location and an adequate market outlet. It is also known that salinity is a major ecological barrier in commercial crop production, and saltwater or marine aquaponics designers are still searching for suitable fish and plant combinations for inland production, in deserts, and along the coasts (Gunning et al., 2016, Appelbaum & Kotzen, 2016). New systems separate the fish and plant units at the larger commercial scale (category IV, *decoupled systems*) with fertilizers to support plant growth. Such systems have been tested especially with tomatoes as the main target crop, and compete with technologically advanced hydroponics production systems that can reach 100 kg of tomatoes per plant. A mixture of aquaponics and freshwater with fertilizer might be counter-productive in achieving the best plant yields, and economically successful production in these systems, of tomatoes for example, still awaits verification

Future perspectives and constraints

Aquaponics is defined as "a production system of aquatic organisms and plants where the majority (> 50%) of nutrients sustaining the optimal plant growth derives from waste originating from feeding the aquatic organisms" (Palm et al., 2018). This definition opens new options for aquaponic products but on the other hand enables authorities to clearly distinguish these products from hydroponic plants or produce originating from regular agricultural production systems.

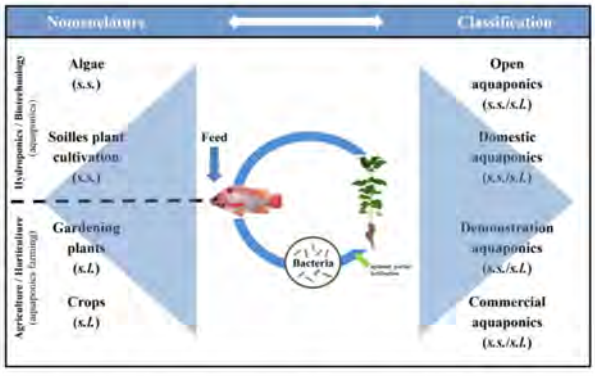

Figure 1 The correlation of new aquaponics nomenclature and classification (*s.s.* sensu stricto, *s.l.* sensu lato according to Palm et al., 2018) that allows new products.

(Continued on next page)

Future areas of development include the demarcation and expansion of the classical cultivation method. The soilless plant production principle is only one variant of integrated aquaponics production. In addition to hydroponic subsystems such as DWC, NFT, ebb and flo , drip or aeroponics, the use of algae is also possible at an industrial scale. The use of aquacultural process water in horticulture or on the open field by regular farmers, termed aquaponics (*s.l.*) farming, represents two new categories with soil or soil-like substrates (aquaponics *s.l.*- horticulture and agriculture). Native peat alternatives or humus substrates such as Biohumin® (Knaus et al., 2019) can replace fertilizers and upgrade the plant quality even under the direct use of the process waters. This allows the production of a wide range of other aquaponic products from ornamental plants to agricultural crops by the integration of nomenclature items to different scales of aquaponic systems (Figure 1).

One future challenge of modern aquaponics is the spread of these new aquaponics products in often saturated markets, requiring the proof of concept and economical business models. At the same time, the growth of aquaponics plants must have a relative agronomic effici ncy of over 50%. In addition to the use of aquacultural process water on cereal fields or for vegetable cultivation outdoors, other cultivation methods that do not rely on the process water but reuse the (processed) sediments or regained nutrients from aquaculture are also possible. This allows the processing, transportation and reuse of aquacultural waste based nutrients to other agricultural production sites and decouples the fish from the plant production facilities.

There is no doubt that we must move towards a circular economy. Aquaponics (*s.s.*/soilless; *s.l.*/with soil) allows a better reuse of aquacultural waste products. Because of the nearly unlimited possibilities for system designs, local adaptations and a wide range of produce, these systems still have high potential for further development.

Introduction

The sustainable development of aquaculture still relies in the substitution of fishmeal for alternative ingredients, especially for carnivorous fish (Oliva-Teles et al., 2015; FAO, 2018). Glycerol has been already used as an alternative energy source in diets for farmed animals, sparing amino acids to other functions such as growth (Lall and Dumas, 2015; Rito et al., 2019). The aim of the work was to evaluate the effects of dietary glycerol supplementation in European seabass (*Dicentrarchus labrax*) and rainbow trout (*Oncorhynchus mykiss*) muscle and liver metabolome, as two of the most representative species for freshwater and saltwater aquaculture in Europe.

Material and Methods

Fish juveniles were fed diets with 0%, 2.5% and 5% glycerol, and groups were assigned respectively as S0, S2.5 and S5 in European seabass; and T0, T2.5 and T5 in rainbow trout. Muscle and liver aqueous fraction was extracted. ^{1}H 1D Nuclear Magnetic Resonance spectra were acquired and its metabolite profile was assessed. Multivariate (Principal Component Analysis – PCA) and univariate statistical analysis were applied. The energy charge was determined in muscle.

Results

In European seabass, PCA scores plots of both muscle and liver aqueous fraction shown no separation between groups. Univariate analysis revealed a decrease in L-leucine, isoleucine and valine between both experimental groups and the control group. Glycerol concentration in muscle had an increase of around 11 times between control group and S5.0 group. In liver, taurine, glycine and glycerol increased around four, three and five times respectively, from control to S5.0 group (Table I). Regarding the energy charge, no differences were identified between groups. The mean values of the three groups were around 0.8.

Table I. Summary of the metabolites identified in the muscle and liver aqueous fraction and its fold-change variation, between groups fed with the control diet with no glycerol (D0); and two experimental diets, supplemented with 2.5% (D2.5) or 5.0% (D5.0) glycerol. Key: (-) fold change with non-significant variation; (*) $p < 0.05$; (**) $p < 0.01$; (***) $p < 0.001$.

	Muscle	D2.5/D0	D5.0/D0	Liver	D2.5/D0	D5.0/D0
European seabass	L-leucine	0.78 *	0.78 *	Taurine	-	4.11 *
	Isoleucine	0.72 ***	0.73 ***	Glycine	-	3.18 *
	Valine	0.75 ***	0.75 ***	Glycerol	-	5.57 **
	Glycerol	-	11.79 **			
Rainbow trout	Choline	-	0.62 ***	Sarcosine	0.16 *	-
	Betaine	-	0.68 ***			
	Lactate	-	-			
	Niacinamide/Nicotinurate	1.56 *	-			

(Continued on next page)

Concerning rainbow trout, PCA scores plots of both muscle and liver aqueous fraction showed no separation between the metabolite composition of samples from the three groups. Regarding univariate analysis, in muscle, choline and betaine decreased around 0.6 times from T0 group to T5.0 group. On the other hand, niacinamide/nicotinurate increased 1.5 fold between T2.5 and T0 groups. In liver only sarcosine revealed a slight decrease from control group to T2.5 group (Table I). The mean values of energy charge of all groups were around 0.9 and no differences were identified between them

Discussion and Conclusion

Generally, dietary glycerol inclusion seems to promote different responses in rainbow trout and European seabass. Muscle seems to be more affected than liver in both species. In rainbow trout, muscle is more affected by the higher glycerol content diet, while in seabass variations were observed in both glycerol concentrations. Regarding liver, trout had only one metabolite with significant differences at 2.5% glycerol group, while in seabass metabolites varied only at 5% glycerol group.

In trout, regardless of the tissue and the dietary glycerol concentration, results were indicative of variations in choline-related metabolism. Differences in seabass were in general related with protein biosynthesis pathways. Only seabass showed increased glycerol concentrations in both tissues, which suggests its higher incorporation into tissues or its slower and/or incomplete metabolic utilization. Noteworthy, the triacylglycerol turnover rate in rainbow trout is indeed higher than the one in other fish species (Magnoni et al., 2008)

Regarding the effects on the general metabolism, at the tested concentrations, rainbow trout seems to be more prompt to this dietary glycerol inclusion.

NMR-metabolomics approach generates an optimized data output, requiring simple extraction procedures and short NMR time acquisitions. Concerning aquaculture production, this approach also allows an easy proceeding to assess muscle/fillet composition that could be applied in several experimental designs.

Introduction

Mariculture continues to rise in response to increased demand for seafood and stagnating wild fisheries. However, expanding shellfish aquaculture in intertidal areas, where cultivation traditionally takes place, is spatially limited. The possibility of expanding production offshore offers a solution to this problem, and its potential has been demonstrated *in situ* for several sites (e.g., Pogoda et al., 2011). Through modelling and mapping, this work examines the biological suitability of the offshore environment for Pacific oyster (*Crassostrea gigas*) cultivation across Europe and northwest Africa, and investigates the potential impact of climate change on future growth.

Materials and methods

Daily maps (0.1° spatial resolution) of various physical and biogeochemical parameters that influence the spatial range suitable for *C. gigas* cultivation and that underlie its growth rate were generated using the POLCOMS-ERSEM model (Butenschön et al., 2016; Ciavatta et al., 2016, 2018) for the North East Atlantic Ocean, North Sea, and Mediterranean Sea (see model domain in Fig. 1). Chlorophyll (Chl), as a proxy for phytoplankton (picoplankton size class excluded), and water temperature were used to force Dynamic Energy Budget (DEB) modelling, which quantitatively describes energy uptake and flow through an organism, including storage, growth, and reproduction (Kooijman, 2010). Growth of both *C. gigas* adults and spat was modelled and mapped.

Parameterization of *C. gigas* DEB modelling was as per Thomas et al. (2016), except for the half-saturation coefficient (Xk), which was calibrated using *in situ* data collected during offshore experiments by the *Syndicat Mixte pour le Développement de l'Aquaculture et de la Pêche en Pays de la Loire* (SMIDAP). Modelled results were then independently corroborated, using *in situ* data from the same site from a different year, as well as different years from another site from the literature (German Bight; Pogoda et al., 2011). In addition to an early-century reference period, a late century period (2090-2099) was also modelled and mapped, under varying climate change scenarios (RCP 4.5, 8.5).

Results and discussion

Several industry-relevant indicators were elaborated from the mapped growth data, including time to minimum market size, size in time for key markets (Fig. 1), and quality index, underlying market classification as "special", "fine", or "normal". Areas where salinity, current speed, temperature, and Chl ranges preclude *C. gigas* cultivation were masked, and two bathymetric ranges were considered: < 25 m depth, suitable for smaller-scale farmers, and < 200 m depth, with larger-scale operations with greater investment capacity in mind. Following the transformation of daily growth maps for the early- and late-century period scenarios into indicator maps (e.g., Fig. 1), several growth "hot spots" were revealed at the regional level, to be looked at in greater detail. Some were found to have high growth, but over a relatively small spatial area, and some were found to have high growth in the early-century reference period, but to be negatively affected by climate change. Areas where growth is consistently high across an area, and into the future, as well as under different climate scenarios (i.e., climate robust) are suggested to be better choices to investigate, as they offer a sort of buffer against the uncertainties of future climate change. Likewise, from a policy and industry-development standpoint, areas where growth is currently not exceptional, or where farms are currently not situated, but for which modelling suggests high and climate-robust growth in the future may be of interest.

Introduction

The current protocol for the induced maturation of female European eel consists of long-term weekly injections with carp or salmon pituitary extract to stimulate sexual maturation and with 17α,20β-dihydroxy-4-pregnen-3-one (DHP) to induce ovulation (Palstra et al., 2005). However, egg quality is often poor and when larvae are produced they die before functional exogenous feeding.

As these problems may well originate from the used protocol and broodstock background, we commence the conditioning of female broodstock from the glass eels stage by feminization, simulated migration and steroid implants. This study is the second in a series of ongoing experiments in our lab aiming to replace treatment with pituitary extract by highly stable eel-specific recombinant gonadotropins in order to improve gamete quality and reproductive success. In a preliminary trial with wild eels we managed to mature one female with recombinant FSH up to a gonadosomatic index (GSI) of 38.

Materials and methods

Single chain recombinant gonadotropins (recFSH and recLH) were obtained by fusing the respective β and α European eel specific subunits with a linker peptide. These sequences were expressed in a mammalian cell line (CHO) and subsequently the gonadotropins were semi-purified by ion exchange chromatograph .

Experimental eels had been subjected to a simulated lifecycle approach: A batch of wild glass eels was feminised by feeding them with 17β-estradiol (E2) coated pellets over a 6 month-period. After an additional 6 months of feeding them with a custom-made broodstock diet, eels of ~400 g were selected, transferred to seawater and fed no longer. For 2 months, eels were then subjected to simulated migration: constant swimming in the dark at daily alternating temperatures between 10 and 15 °C to make them silver (Mes et al., 2016).

Sixteen of these eels were then randomly selected, PIT-tagged, weighed and measured for body girth, body length and eye diameters to calculate the Pankhurst eye index. For an additional 2 months, eels were treated with a steroid implant (Thomson-Laing et al., 2019) containing 17-methyltestosterone (5 mg) and E2 (0.5 mg). Again, eels were weighed and measured, and GSI was non-invasively determined by applying ultrasound. Eels were then divided between two groups for hormonal stimulation of sexual maturation by weekly intramuscular injection of either carp pituitary extract (CPE at a dose of 20 mg kg^{-1}; CPE group; N=8) or recFSH (12 µg; REC group; N=8).

Starting in week 7, two days after each injection, eels were weighed to determine whether oocyte hydration had commenced as indicated by an increased body weight index (BWI). At BWI increase and at recFSH injection 16, final oocyte maturation (FOM) was induced by injecting CPE in the CPE group, or by injecting recFSH in combination with recLH (8 µg) in the REC group. Ovulation for eels in both groups was induced by injecting DHP (2 mg kg^{-1}). Eels were stripped for eggs which were fertilised and reared.

(Continued on next page)

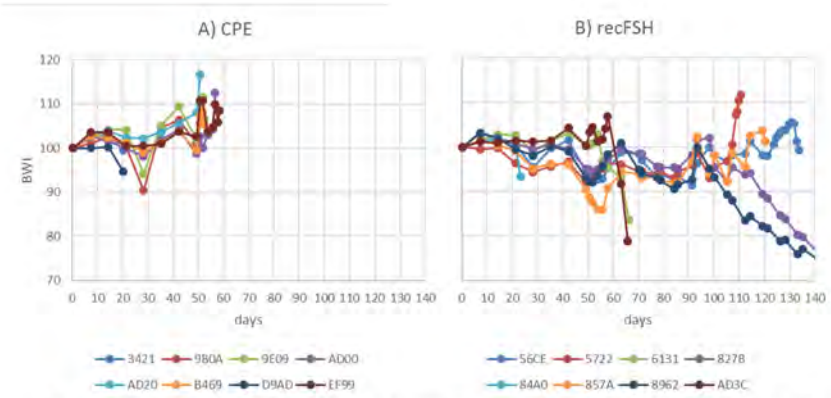

Fig. 1. Body weight index (BWI) during the period of weekly hormone injections with (A) CPE and (B) recFSH.

Results and discussion

At the end of migration and start of injecting implants, eels were 59 ± 3 cm long, weighed 402 ± 33 g, body girth was 11.5 ± 0.4 cm and eye index was 7.19 ± 1.46. At the end of this period when dividing both treatment groups, eels increased significantly in weight up to 418 ± 33 g, in body girth up to 12.7 ± 0.5 cm and in eye index up to 10.64 ± 1.09, indicating initiation and progression of vitellogenesis. Indeed, the GSI values were between 3.1 and 7.3, well above values of 2-2.5 which mark the initiation of vitellogenesis (Jéhannet et al., 2019).

Eels from the CPE group matured much faster than eels from the recFSH group: 8 ± 1 vs. 19 ± 3 injections (i.e., after combining recFSH with recLH). Six eels (75%) in the CPE group matured of which two yielded batches of larvae surviving for 4 and 9 days post hatching. Three eels (38%) in the REC group matured and from one eel (AD3C) eggs could be stripped (80% floated). However, no larvae were obtained from eels from this group. Four other eels in the REC group increased in BWI just before dropping weight and dying. Recombinant FSH appeared to work very well but the FOM protocol using recLH needs further improvement and is under current investigation.

[c] IRTA- SCR. C/ al Poblenou SN Km 5.5 43540 Sant Carles de la Rapita. Spain

Introduction
The flow regime can have great physiological impact resulting in enhanced growth and increased robustness (Palstra and Planas, 2013). By holding juvenile Gilthead seabream (*Sparus aurata*) on-land to sizes of ~20 g, and with a future perspective of holding them on-land even longer, farmers can benefit from applying an optimal flow regime. In a first study in RAS tanks (IRTA facilities, Sant Carles de la Ràpita), experimental fish were conditioned to flow regimes inducing swimming exercise at 0, 1 and 2 Body Length (BL) s^{-1} for a period of 8 months (Feb.-Oct.). Subsamples of these fish (N=100 per treatment) were then transferred to an experimental seacage in Mallorca (LIMIA facilities, Port d'Andratx) of which ten PIT tagged fish per treatment were implanted with accelerometer tags to investigate activity patterns. Activity will then be related to growth and robustness parameters of seabream in a cage in general, and to the effects of flow conditioning in particular. Accelerometry has been performed on Atlantic salmon in floating sea-cages (Føre et al., 2011, 2018), this is the first study investigating the activity of seabream in an experimental seacage

Materials and methods
Sizes of the experimental fish that were used for accelerometry were BL 174 ± 10 mm, BW 157 ± 28 g for fish conditioned at a flow of 0 BL s^{-1}; BL 185 ± 12 mm, BW 173 ± 36 g for fish conditioned at a flow of 1 BL s^{-1}, and BL 188 ± 24 mm, BW 189 ± 47 g for fish conditioned at a flow of 2 BL s^{-1}, indicating the exercise-enhanced growth that had occurred during flow conditioning in the RAS tanks. These fish were anaesthetized and then accelerometer tags (AccelTag AT-LP7; 21 x 7.3 mm, 1.9 g in air, 1 g in water; Thelmabiotel, Trondheim, Norway; Fig. 1) were implanted by a surgical incision on the ventral side in the body cavity and then sutured (Arechavala-Lopez et al. 2012). The accelerometers record every 60 s the gravity forces and movement along the three axes which can be converted to acceleration in m s^{-2} which is then used as a proxy for activity. Recordings were monitored by one receiver (TBR700; Thelmabiotel) placed at the bottom of the cage. Activity patterns were monitored for a period of 6 weeks (Nov.-Dec., with decreasing temperatures from max. 17.9 to min. 15.5 ºC) in a 2 x 2 x 2 m experimental sea-cage (fish density ~10 kg m^{-3}). Fish were fed manually once per day *ad libitum* in the morning at 11 h. After the 6 weeks period, fish were collected measured, weighed, and heart, liver, intestine, spleen, intestinal fat and fillet were dissected and weighed.

Results and discussion
Day/night rhythms in swimming activity under the experimental conditions were characterised by more active periods from 6 to 14 h and 18 to 0 h and less active periods from 0 to 6 h and 14 to 18 h. The peak in activity was not during but just before feeding indicating that experimental fish may have good ability to predict and time a re-occurring event such as feeding.

Growth performance was similar between fish of all three treatments. The initial differences that were due to exercise-enhanced growth therefore remained similar. Significant differences were found in overall activity patterns between flow conditioned groups. Exercised fish conditioned at 1 BL s^{-1} were more active than the 0 BL s^{-1} controls. This group of exercised fish also showed the largest relative heart size. Exercised fish conditioned at 2 BL s^{-1} were less active than the exercised fish at 1 BL s^{-1} and the 0 BL s^{-1} controls. These fish had the lower relative spleen size. These results indicate that the flow conditioning at 1 BL s^{-1} was optimal for robust juvenile seabream, a conclusion that was also supported by the results of the first study in RAS tanks

Activity patterning can be useful for timing feeding events. Under these conditions it may be advisable to feed seabream at the start of active periods; for example from 6 to 11 h and from 18 to 22 h, to favour muscle building at the cost of intestinal fat deposition. During the on-land phase in tanks, fish and farmer can benefit from applying flow enhancing swimming exercise at 1 BL s^{-1}.

Introduction

Recycling of nutrients from fish sludge is needed to close the nutrient loop and make aquaculture and aquaponic systems more resources efficient and sustainable. Until now, only a few authors have examined the recovery of nutrients from fish sludge. While discussed to some extent in theory (Goddek et al. 2016; Yogev et al. 2017), practical investigation is further needed to better understand organic reduction and nutrient mineralisation performance of aerobic and anaerobic treatments of fish sludge, and its effect on the water composition and plant growth. Therefore, we investigated the mineralisation and sludge reduction performance of pikeperch RAS sludge aerobically digested in a long-term unique experiment. Hence, the first objective was to obtain the nutrient mineralisation performance by using specific mass balances equations developed in that specific purpose (Delaide et al. 2018). The second objective was to calculate the sludge reduction performance. The last objective was to test the suitability of aerobic effluent as a nutrient solution for direct use in a hydroponic system.

Materials & Methods

The experimental setup was divided in two parts running in parallel. One part consisted into a lab scale experiment to focus on nutrient mineralisation and sludge reduction performances using a setup of 3 blocks of 4 reactors each to assure repeatability and accuracy. The reactors were run in a fed-batch mode. Once every 7 days, supernatant was removed and of fresh sludge was added. This led to a hydraulic retention time (HRT) of 30 days. No sludge was discharged during the experiment thereby the sludge retention time (SRT) corresponded to the duration of the experiment. In order to determine the performances of the reactor, a mass balance approach was used based on Delaide et al.(2018) The experiment was run for 121 consecutive days. The second part focused on the yield and quality of lettuce grown in aerobic reactor effluents. The experimental setup consisted of growing lettuce in deep flow technique (DFT) filled with 3 different nutrient solutions (i.e. 3 different treatments): a standard hydroponic solution for lettuce (Std treatment) used as a control, the aerobic supernatant (AE treatment) and the hydroponic aerobic solution (HPAE treatment). The HPAE solution was made with rain water and chemical fertiliser for mimicking the AE solution. Each DFT contained 6 lettuces and 4 replicates were used. *Lactuca sativa* cv. Presteria were sown on turf blocs on the 26th of October 2018. On the 13th of March 2019, after 57 days of growth in the DFT the lettuces were harvested. The head and roots fresh mass were recorded, and their head colour was scored.

Results and discussion

Part1-Aerobic digestion: pH and EC were monitored weekly during the experiment. During the first six weeks, the pH decreased from 8 to 6 while the EC increased continuously. From the 10th week until the end of the experiment pH and EC stayed relatively stable, oscillating around 6,75 and 3,20mS/cm, respectively. An organic reduction performance of 40 ± 3% was observed during this experiment. The mineralisation performances were in a range of 10 to 40% for the macronutrients, except for P. Interestingly, P had a negative value indicating that instead of being mineralised this element stayed in its solid insoluble forms or precipitated or was assimilated by the microorganisms developing into the reactor. Except for B, the microelements had a very low mineralisation performance, i.e. < 1.6%. The aerobic treatment seems not efficient to mineralise the microelements. However, in the point of view of plant fertilisation suitability of the treatment effluent, the examination of the nutrient concentration profiles in pikeperch rearing water and then in the AE supernatant showed that the macro- and micronutrients were substantially increased by the aerobic treatment.

Part 2-Lettuce growth in aerobic supernatant: The HP standard treatment presented the highest head mass (675 ± 70g) while significant differences were not found ($P \uparrow$ 0.05) between aerobic supernatant and HP aerobic treatment, with a final head fresh mass of 528 ± 62g and 562 ± 68g respectively. During the experiment until the harvest day, no shape disorder was noticed for the lettuce heads in all treatments. However, a yellowing of the leaves was noticed in the AE and HPAE treatments. Nutrient monitoring revealed that P, K and Mn were relatively low in AE and HPAE solutions compared to the standard and were totally uptake by lettuce until depletion after 36 days (or even before) of culture. It is therefore supposed, that lettuce grown in these treatments suffered from nutrient deficiencies which influenced the final growth. Curiously, the AE treatment had no more yellowing leaves at the harvest time. It is presumable that other factors were present in the AE supernatant that allowed the lettuce to overcome the yellowing. This seems to be indicated by the significant differences in head to root ratio and a higher root mass that was observed in this treatment.

(Continued on next page)

Conclusion

This experiment investigated the feasibility of treating RAS sludge directly onsite by an AE treatment and the reuse of its effluents as nutrient solution for growing hydroponic lettuces. The lack of P and Mn observed in the DFT experiment could easily be linked to the poor performance of their mineralisation observed during the aerobic treatment. While they were present in substantial amount in the solid fraction of the sludge, they stayed in their insoluble forms. Regarding this low mineralisation performance, especially for P and the microelements, improvements of the treatment should be explored as adding an acidic step that can promote P mineralisation (Conroy and Couturier, 2010)"ISSN":"00448486","abstract":"Bio logical degradation of fish waste solids in the anaerobic zones of settling basins can reduce water quality and increase the environmental impact of aquaculture farms. The objectives of this study were to measure the rate of hydrolysis of waste solids from a salmon smolt hatchery and to investigate the concomitant dissolution of phosphorus and nitrogen. Hydrolysis followed first order kinetics with a reaction time constant of about 2 days. The rate of production of volatile fatty acids (VFA.

EFFECT OF PHOTOPERIOD ON PIKEPERCH (*Sander lucioperca*) LARVAE PERFORMANCE IN RECIRCULATING AQUACULTURE SYSTEMS

E. Panana*, S. Teerlinck

Inagro, Practical Research Aquaculture Center, Ieperseweg 87 8800 Rumbeke- Beitem (Belgium)
E-mail: Edson.pananavillalobos@inagro.be

Introduction

Pikeperch is considered to have the highest potential for inland aquaculture diversification in Europe. Throughout the last decades the culture of pikeperch in recirculating aquaculture systems (RAS) has increased. Nevertheless, larvae culture phase still represents a main bottleneck during commercial production. Several studies have described the influence of density, feeding strategy and tank designs in the performance of larvae reared in RAS (Kestemot et al. 2015). However, few studies about the influence of light conditions during this phase can be found (Tielmann et al. 2017). The aim of the present study was to investigate the influence of photoperiod on the performance of pikeperch larvae reared in intensive conditions until 30 days post hatch (DHP).

Materials and Methods

Pikeperch larvae, coming from the off-season reproduction in 2018 at Inagro Practical Research Aquaculture Center, were reared under 3 different photoperiod regimes Light: Dark (12L:12D, 16L:8D, 24L:0D) until 30 (DPH). Twelve 220 l RAS tanks (4 replicates per treatment) were used with and initial density of 110 larvae per liter. Light intensity at water surface was kept at 100 lx and water temperature at 16^{0}C. Feeding regime was similar amongst treatments using a constant feeding protocol (mixed diet: enriched artemia + dry feed). Performance parameters like length, body weight, survival rate, specific growth rate (SGR), swimming bladder inflation and % of deformities were measured at different DPH during the trial (n = 30 per tank). Data recorded was statistically analyzed to find significant d ferences ($\alpha = 0.05$) amongst treatments.

Results

Differences in larvae performance were observed amongst treatments during the experiment. In the first 15 days of rearing, an equal growth ($P > 0.05$) of larvae in weight and length was recorded (Figure 1). However, at the end of the trial, significant di ferences were found ($P < 0.05$).

Larvae reared in 16L:8D photoperiod presented the highest growth in wet weight (55.03±7.1mg) and standard length (19.23±2.1mm) compared to larvae reared in 12L:12D (41.35±3.2mg, 17.56±1.8mm) and 24L:00D (48.98±7.04, 18.1±2.59mm) respectively.

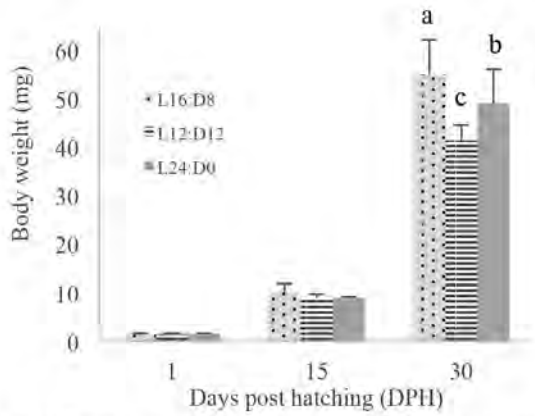

Figure 1. Body weight (wet weight) in pikeperch larvae reared until 30 days post hatching (DPH) under 3 different photoperiods Light: Dark (16L:8D, 12L:12D, 24L:D0). Data (mean ± SD), different letters mean significant difference amongst the groups ($P < 0.05$).

(Continued on next page)

Discussion and conclusion

The results obtained during this experiment indicate that pikeperch larvae reared under the photoperiod 16L:8D have a better performance compared to larvae reared under photoperiods of 12L:L12 and 24L:00D. Between 11- 15 DPH, important morphological changes on pikeperch larvae occurred (swim bladder inflation). After this period, larvae with noninflated swim bladders have higher metabolic demands due to erratic swimming and constant movement, which compromise their feeding capacity and therefore affecting their growth (Demska-Zakęś et al. 2003). More results and conclusion of this experiment will be presented.

e-mail: ligia.panasiak@phdstud.ug.edu.pl

Introduction

European grayling (*Thymallus thymallus*) is a freshwater salmonid fish species. . Unfortunately populations of grayling have declined mostly due to the water pollution, overfishing and construction of dams. In several European countries stocking programs have been established to compensate for this loss. Unfortunately, this process included domesticated and non-native stocks and affected genetic pools of the grayling non-indigenous populations. To prevent local populations, sterile triploid graylings might have been used for stocking. However to date no protocol for induction of triploid development in grayling is available. Thus, the main goal of the present research is to elaborate conditions of successful triploidization of grayling.

Material and methods

Gametes for the experiment were provided from the grayling broodtsock kept in the Dept. of Salmonid Research in Rutki (Poland). Grayling eggs were inseminated and subjected to the High Hydrostatic Pressure (HHP) shock (8500psi for 5min) 10, 12.5, 15, 17.7, 20, 22.5 and 25 minutes after fertilization (*maf*). Part of the fertilized eggs were not subjected to HHP to develop as normal diploid (2n) specimens (controls). Fertilized eggs were placed in a hatching apparatus and incubated at 9°C under routine conditions. The survival of embryos was calculated at the eyed stage. Cytological examination of the hatched larvae including chromosome counting, measurement of the cell size and staining of the Nucleolar Organizer Regions (NORs) was performed on the

Results

Diploid graylings (2n= 100) from the control group exhibited high survival during the embryonic development (c. 80%). The highest survival rates in the experimental variants of the experiment were observed among embryos developing eggs that were HHP treated 17.5 *maf* and 20 *maf* and equaled 61.7% ± 0,6 and 63.2% ± 1.2, respectively. Larvae hatched from eggs exposure to HHP 20 maf had also significantly bigger cells when compared to cells from the diploid specimens and individuals from other experimental groups. Modal number of NORs in the interphase cells varied from 1 to 3 however three NORs were found only in larvae that hatched from the ggs shocked 20min after fertilization. Triploid number of chromosomes (3n= 150) was found in graylings that were developing in eggs exposure to HHP 17 to 22.5 maf.

Discussion and conclusions

Provided results confirmed that High Hydrostatic Pressure shock (8500psi) applied from 17 to 22.5min after fertilization for 5 minutes enabled successful triploidization of the European grayling. However, further studies including histology of the gonadal development is indispensable to confirm functional sterility of the triploid graylings and their application for the stocking programs.

Introduction

Carp farming has a long tradition in Eastern Europe and current yearly production is about 60 000 tonnes for the 5 top countries. Cultivation is typically extensive and takes place in earthen ponds, and Poland's production is 20% of the total volume. In multi-pond systems, fish reach a market size of 1.5 - 2 kg in a three-year period—however, the production (kg ha^{-1} y^{-1}) depends on water temperature, which can both influence growth rates and affect resistance to pathogens. Water temperature also directly influences fish immune responses and pathogen replication, leading to the development of specific host–pathogen interactions that can lead to manifestation of disease. The greatest threats faced by carp farmers are spring viremia of carp virus (SVCV) and koi herpesvirus (KHV), two economically important pathogens [2,3]. However, in recent years carp edema virus (CEV) has been described as a new pathogen which may induce substantial mortalities in common carp aquaculture in mixed infections together with KHV[4]. Tools which can aid carp farming stakeholders to plan for potential changes in water temperatures, under different climate change scenarios, can be valuable in mitigating the impacts of pathogens on the sector and supporting optimization of the farming process.

Material and methods

Our study aimed to develop a mapping tool capable of assisting the farming sector by estimating water surface temperatures using available air temperature data as a predictor (Figure 1), based on the methodology developed by Thrush and Peeler, 2013[4],.

GIS tools were employed to produce these maps, indicating the number of days per year where water temperature in ponds is above a specific threshold. These thresholds cover temperatures required for carp growth, and which condition disease expression caused by SVCV and KHV. Maps were developed using climate model data obtained from Plymouth Marine Laboratory on complete land surface temperature (LST) values for Poland for three time periods: 1. Present: 2000-2019; 2. Mid-term: 2040-2059 and 3. Long-term: 2080-2099, which were converted to water surface temperature (WST) values using an algorithm: and empirical data on water temperatures in ponds.

Results

The maps produced (Figure 2) show the estimated number of days per year with WST above the established threshold under two Radiative Concentration Pathways (RCPs), i.e. RCP 8.5 and RCP 4.5. The temperature time series for various climate change scenarios were also used to drive the Aquaculture, Biosecurity and Carrying Capacity (ABC) model, in order to examine direct effects of climate change on growth and environmental externalities. These tools are of use to carp farmers, and for the industry in general, as well as for government stakeholders, to understand the direct and indirect effects of climate change on the triple bottom line of people, planet, and profit.

NUMERICAL SIMULATION OF THE MACROALGAE MOVEMENT WITHIN IMTA-RAS SYSTEMS

Stepan Papacek[1], Radek Filip[2], Karel Petera[2]

[1]University of South Bohemia in Ceske Budejovice, FFPW, CENAKVA, Institute of Complex Systems, 373 33 Nove Hrady, Czech Republic. Email: spapacek@frov.jcu.cz
[2]Czech Technical University in Prague, Faculty of Mechanical Engineering, Technicka 4, 166 07 Prague 6, Czech Republic

Integrated multitrophic aquaculture (IMTA) production systems, where the synergic effect of an aquaculture (usually in form of a Recirculation Aquaculture System -- RAS) and a macroalgae (seaweed) culture system is exploited, could reduce the pressure on both, the open sea fishing and the use of terrestrial and inland water resources [1]. IMTA-RAS systems represent a promising emerging research topic due to their biotechnological potential with an impact on human health and wellbeing [2].

However, there are some limiting factors or drawbacks in case of seaweed, e.g., *Ulva* sp. cultivation, integrated within RAS: (i) the large area required, (ii) the energy cost, (iii) lack of reliable mathematical models. The second point, energy issue, depending of the system designed to make move (to tumble) seaweeds either by the bottom aeration or by an impinging jet system, was studied experimentally in the work [3]. Here, we shall treat the third point, i.e., we aim to make one step towards modeling and *in silico* simulation of the multiphase flow in tanks for macroalgae cultivation. Modelling and eventually optimization of macroalgae photosynthetic growth within IMTA-RAS systems is left to the near future.

The cornerstone of modeling of the hydrodynamic conditions in seaweed tanks is the problem consisting in how to describe the tumbling pattern of seaweed within the tank in function of the operating conditions (air flow rate or the liquid velocity in the jet outlet in case of the impinging jet system) and tank geometry. Afterwards, having a mathematical model describing the relation between the hydrodynamics (flow pattern of algae) and the nutrients uptake and photosynthetic activity of seaweeds, e.g., in form of some constraints to be fulfilled, an optimization of IM A-RAS can be carried out.

Experiments at laboratory scale or at field are scarce [3], since they are laborious and time consuming. In this context, it becomes of utmost importance to develop a Computational Fluid Dynamics (CFD) based methodology for IMTA-RAS design since it can provide the full flow field description and a further coupling with the algal growth model. Finally, an ease of performing a large range of parametric studies for optimization is a crucial issue [4].

The present work gives guidelines to apply the CFD code STAR-CCM+, which offers an efficient and accurate set of fluid dynamics models and solvers with excellent parallel performance and scalability [5]. The circular tank (with diameter of 20 cm) with bottom air injection and a height of water equal to one diameter is used for our analysis. This set up ensures the formation of two rotating flow cells placed, in the vertical section of the tank, at both sides of the aeration inlet. Both 2D axi-symmetric and full 3D simulation of seaweds-like particles clumps movement are being performed. Based on the selected clumps trajectories, the probabilistic description of the random variable T_{cycle} describing one period of rotational movement, detected by passing through a horizontal plane, was assessed. Obviously, the numerical results have to be verified in subsequent laboratory or field studie

CFD SIMULATION OF FLUID FLOW AND RTD ANALYSIS FOR AQUACULTURE SYSTEMS: WITH AND WITHOUT FISH

Stepan Papacek[1], Petr Cisar[1], Karel Petera[2]

[1]University of South Bohemia in Ceske Budejovice, FFPW, CENAKVA, Institute of Complex Systems, 373 33 Nove Hrady, Czech Republic
Email: spapacek@frov.jcu.cz
[2]Czech Technical University in Prague, Faculty of Mechanical Engineering, Technicka 4, 166 07 Prague 6, Czech Republic

The improved design of aquaculture systems is needed facing the demand for increased production as well as increased concern of fish wellbeing. Here, we make a step towards use of computational fluid dynamics (CFD) for design and operation of fish tanks. The proposed CFD based methodology allows the modeler (the designer) to have an overall picture about hydrodynamic conditions within the fish tank and to manipulate (*in silico*) all key phenomena involved, both physical (i.e., the tank geometry and operating conditions) and biological (fish density). Further optimization of the tank hydrodynamics, mainly to ensure the optimal rearing conditions (including the fish exercising) and fast biosolids removal, is being expected.

The cornerstone of modeling of the hydrodynamic conditions in fish tanks is the problem consisting in how to describe the flow pattern of water within the tank as a function of (i) tank geometry, (ii) the operating conditions (water recirculation rate or the liquid velocity in the inlet and all details concerning the boundary conditions), and (iii) fish biomass. Although there are some studies predicting the three-dimensional field of water velocity within aquaculture systems using computational fluid dynamics (CFD), see e.g. [1] for floating closed sea cages, and [2] for circular aquaculture tanks, the CFD simulation of a real system including the influence of fish swimming is still a big challenge, in point of view of both numerical and biological complexity. Therefore, some assumptions are further undertaken. First, we limit ourselves to perform numerical simulations of the stationary flow of incompressible viscous fluid in three-dimensional domains corresponding to the respective fish tank (all simulations were performed using Reynolds-averaged Navier-Stokes equation system and a suitable turbulence model). Second, the fish were simulated as a set of immobile objects (with the corresponding fish density

Obviously, this is not the first work where the influence of fish swimming was studied. Nevertheless, to the best of our knowledge, there are only two works presenting the field measurements, see [3] and [4]. These works are used for the validation of our CFD model. Let us remind that experiments at laboratory scale or at field are laborious and time consuming. In this context, it becomes of utmost importance to develop a reliable CFD based methodology being able to provide the full velocity flow field description and an ease of performing a l ge range of parametric studies for optimization.

Finally, based on the comparison of experimentally measured and simulated values of velocity profiles, we argue that CFD code ANSYS Fluent [5] represent a modern and reliable tool for the simulation of hydrodynamic flow field within a production unit, as well as for design and optimization of aquaculture systems.

Introduction

The medicinal plant extracts can reduce the use of chemicals in aquaculture. Essential oils have antibacterial, antifungal, antioxidant, anti-inflammatory, anthelminthic, anesthetic and digestive properties (Asbahani et al., 2015). Disinfection involves the use of physical or chemical agents to remove microorganisms. In aquaculture disinfection of eggs is important for the treatment of diseases and increases the chance of hatching (Swaef, 2015). In addition, the disinfectants include compounds used to destroy microorganisms living on the surface of fish eggs (Assefa, 2018). Presently, the hatching parameters of gilthead seabream (*Sparus aurata*) eggs disinfected with natural substances, was assessed verifying the benefits found from the usage of non-chemical substances as disinfectants

Materials and methods

The seabream eggs arrived at the laboratory in tanks. Upon arrival, they were weighed and disinfected with the essential oils and NaCl for a specific period of 15 minutes. The disinfectant essential oils used were oregano oil (*Origanum vulgare*) 100, 250, 500 ppm, tea tree oil (*Melaleuca alternifolia*) 100, 250, 500 ppm and NaCl 500, 1000, 1500 ppm. Also a control group (CON) with no disinfectant, was assessed. For each quantity three reps were made. Then they were washed out with saltwater, weighed and divided equally in 2lt water tanks. Salinity was 33 ‰ and temperature was 18 °C. Each tank had an oxygen supplier and a slight ascent to keep the eggs on the surface. Post-treatment the hatching rate of eggs (A), the percentage of dead larvae (B) and the percentage of egg compared to larvae in each tank (C) were recorded. For the observation, a stereoscope was used. All data were analyzed using "SPSS 17 Statistical Package" while differences were considered significant at $p<0,05$ using chi-square tests

Results

The results (Table I) were positive for use of natural substances as disinfectants, since the percentage of dead larvae was statistically significant higher in the control group compared to oregano oil (500ppm), tea tree oil (100,500 ppm) and NaCl (500,1000,1500 ppm). In contrast, the hatching rate was not statistically significant smaller than the control group. Also, it's obvious that the percentage of egg is statistically significant smaller in the control group, compared to others treatment groups.

(Continued on next page)

Discussion and conclusion

The main disinfectants that are used in aquaculture are chemical. Iodine is mostly used for eggs of fish of the Salmonidae family, whereas for marine species, glutaraldehyde and ozone is used (Animal Health Standards Commission, 2009). The effects of essential oils are well known. Oregano oil has antibacterial, antifungal, antioxidant properties (Mabrok et.al 2016; Baydar et al.,2003) and tea tree oil is used as antibacterial agent (Souza et.al, 2016). In this research there are positive results for replacement of chemical disinfectants. The hatching rate was higher for tea tree oil compared to other disinfectants. Also, the natural substances increased the survival of larvae after the hatching. In control group, more dead larvae were observed. It is important to mention the fact that there has been a delay in egg hatching after the use of natural substances. Although no other researches about essential oil for disinfection of eggs have been carried out, it is important to have in mind that the subject requires further research.

Introduction

Parasites infestations are expected to be the major health risk of Mediterranean fish farming in the years to come. Variability of parasitic infestations is due to different life cycle strategies, host-parasite interactions and constantly changing environmental impacts, all of which require different defense practices. The opportunities to minimize the impacts through non – invasive strategies such as the selective breeding should be examined thoroughly. The aim of the present research was the investigation of the resistance of the European sea bass to parasites of high occurrence at the Mediterranean fish farming, namely the monogenean *Diplectanum aequans* and the copepod *Lernanthropus kroyeri*.

Materials and Methods

Natural exposure challenge tests were executed from September 2017 to January 2018 and from August 2018 to December 2018, by introducing naïve populations of seabass juveniles produced in a disease-free Breeding Hatchery into infection prevalent cage farms. In total four trials were conducted; two trials at each period, at two different sites Nafpactos and Sagiada, of confirmed heavily infected environment by the *D. aequans* and the *L. kroyeri* respectively. For all four trials, European sea bass juveniles were used, which originated from Nireus Research Center. Every year, 25 offspring coming from different full-sib and half-sib families were individually pit tagged at 15g and transferred to the selected open sea farming area sites. Offspring members of the same families were farmed also in a third site (Palairos) where the two parasites of interest were not dominant, to be used as the reference/control samples.

Individual weight recordings were conducted to the experimental fish every 2 months. The final weight measurement was conducted 6 months after the transfer to the open sea farming area. At the termination of the experiments, fish were sampled in small groups over a period of 2-3 weeks and the target parasites were counted by a team of experts. The number of parasites was counted on each gill arch on both sides of the fish with the use of microscopes in case of *D. aequans* and stereoscopes in case of *L. kroyeri.*

The growth performance of the populations at the two trial sites was compared to the population of the reference/control site. The average z-scores of average family growth was estimated using pedigree information from Nireus breeding program. Information regarding genetic variability of the parasite counts was revealed via the genetic parameters estimation. The genetic parameters were estimated using an animal model with the site and the year (in the case of *D. aequans* trial) as fixed effects and the animal as random effect. The VCE 6.0 (Geonevelt *et al*., 2010) software was used for the analysis.

Results

For the *D. aequans* infection trials, satisfactory survival rates were achieved in both years. The average number of parasites at family level for 2017 and 2018 was 19 and 47 parasites, respectively, ranging from 3 to 45 parasites and from 12 to 100 parasites per fish, respectively. The average family growth has negligible phenotypic correlation with parasite count (-0.03 and 0.15 for two trial periods). Nevertheless, the parasite count for *D. aequans*, was found to be a medium heritable trait (h^2=0.2) which does not seem to affect bodyweight (phenotypic correlations -0.03 to 0.05) but it is slightly affecting its genetic potential (genetic correlations 0.2 to 0.3 with bodyweight at different ages and 0.37 with growth at sea).

For the copepod *L. kroyeri* trials, satisfactory survival rates were achieved only in 2018. The average number of parasites per family ranged from 12 to 44 parasites. The heritability estimated for *L. kroyeri* presence was 0.28, a quite high value for a disease resistance trait. However, parasite count exhibited larger phenotypic correlation with bodyweight at different ages (0.14 to 0.32), but similar value with growth at sea cages compared to *D. aequans* (0.00 and 0.05, respectively). Moreover, the number of *L. kroyeri* parasites on the fish seems to slightly affect bodyweight and growth genetic potential (genetic correlations 0.09 to 0.4).

(Continued on next page)

Growth performance in three different sites shows that the possible impact of parasitism in fish growth is evident due to the different values of thermal growth coefficients (TGC) presented in the three different areas. The ranking of the families, from the best to the worst, was based on the average z-score of offspring growth, and the comparison of ranking of female breeders based on offspring's growth in different sites, provided helpful insights about a potential genetic component of parasites impact in growth of fish.

Discussion and conclusions

Heritability of parasite resistance in the case of *D. aequans* was medium and more or less equal with heritabilities recorded for other disease resistance trials. On the other hand, the high heritability of *L. kroyeri* recorded in the current trial has to be verified further with a larger number of fish. The results are indicative of the potential to increase resistance to parasites through selective breeding.

The ranking of the families in the three different sites in terms of growth can provide an indication about the severity of the effect of parasitism in the selection process and more specifically in the characterization of an individual as preferable or non-preferable. High correlation between the evaluation among different sites for both female breeders and families, provides us a certainty that the effectiveness of selection process will not be disrupted by the abundance of the specific two parasites and the selected offspring will continue to grow faster even under these special environmental conditions, compared to their non-selected counterparts. Additionally, the inclusion of parasite resistance as a selection trait will not impair selection on growth.

Nevertheless, the results of the present study look quite promising in terms of the existing potential for genetic improvement for a resistance trait. Families showing high variability in parasite count and phenotypic measurements are going to be genetically screened through a powerful genomic tool developed in the PerformFISH project, a SNP-array encompassing both European sea bass and gilthead sea bream markers, and Genome Wide Association Studies (GWAS) are expected to shed light into the genomic regions linked to disease resistance.

Introduction

The marble trout (*Salmo marmoratus*) is an endemic species of North Italy and represents one of the most important faunal entities in the European panorama, threatened by numerous human activities and by the hybridization with brown trout. The strong contraction, both numerical and areal, led to the inclusion of this species in the European Union Habitat Directive and in the 2013 IUCN Red List, classifying it as a "Critically Endangered" (CR). The genetic analyses and the sperm cryobank have proved to be two important tools for a more efficient management of conservation of endangered species (Zuccon et al., 2017). The aim of the research was the development of a cryopreservation protocol to create a cryobank for the conservation of genetic material of pure breeders.

Materials and methods

The purity was verified following genetic method, amplifying the mitochondrial D-loop marker for the identification of the main trout haplotypes (Atlantic, Marble, Adriatic, Mediterranean). The identification of hybrid individuals was carried out by analyzing the LDH-C1* nuclear marker using the RFLP technique (Restriction Fragment Length Polymorphism) and the Ldhxon3F/ Ldhxon4R primers. Before freezing, sperm was analyzed for motility and concentration. Then, after a short equilibration at 4°C, sperm was addicted to cryopreservation solution (DMSO 10% v/v, according to Horvath et al., 2014), and loaded into French straws (0.5 ml). Semen-freezing was conducted in a programmable freezer (Micro Digitcool IMV) using a freezing curve (from +4°C to -140°C, 30°C/min). In order to verify the motility, the thawed sperm was activated by Actifish (IMV), according to Hor **á**th et al., 2015.

The frozen semen of 5 breeders was tested at 3 different concentrations (Test 1: 0.109 ± 0.05. 10^9, Test 2: 0.219 ± 0.01. 10^9, Test 3: 0.438 ± 0.02. 10^9 sperms/ml) of mobile spermatozoa, using batches of about 500 pooled eggs recovered from 28 females. The controls (C) consisted of batches of eggs fertilized by fresh milt of the 5 breeders. The fertilized eggs were incubated in vertical hatcheries and monitored (hatching time for marble trout: 420 day-degree). Fertilization rate was determined according to Bromage and Cumaranatunga (1998). The hatching rate was estimated by daily larval counting.

Results

The taxonomic diagnosis carried out on 66 individuals by genetic analysis showed the presence of 49 pure marble trouts and 17 hybrid individuals, which were discharged from the cryobank.

After thawing sperm, motility resulted 35.5% ± 7.6 (ranging from 20 to 50%) with an average duration of 89 ± 12 sec. The fertilization rate was similar for all the tests performed (average 96.6% ± 0.7) and not statistically different from the control carried out with fresh semen ($p > 0.05$). The hatching rate resulted 26 ± 5% in the Control, 8 ± 4.2% in Test 1, 10 ±1.9% in Test 2 and 13 ± 0.8% in Test 3. Tests carried out using frozen semen show an average drop in hatching of about 55% compared to the control.

(Continued on next page)

Discussion and Conclusion

The data obtained in this work showed a high-quality variability of the of frozen semen, which would seem to be breeder-dependent. The genetic analysis has proved a useful tool for verifying the purity of individuals of marble trout, really important for conservation management plans. Furthermore, a strong discrepancy between fertilization data and hatching results was found out. Preliminary data seem to show a relationship between the number of sperms used in fertilization and the hatching rate.

Further experimental design in field is necessary in order to confirm and optimize the cryopreservation protocol and the use of the semen fertilization techniques.

Introduction

There is an extensive range of helminthic parasites of fish, but only a moderate number of species are capable of producing foodborne diseases in humans. These diseases are either caused by an infection following ingestion of viable parasites, or by an allergic reaction against parasite antigens which occurs, so far, due to nematodes of the family Anisakidae. *Anisakis simplex* is the species most frequently associated with human disease, followed by *Pseudoterranova decipiens* (Adams, Murrell et al. 1997) and *Contracaecum osculatum* (Strom, Haarder et al. 2015). In fact, *A. simplex* is the second most predominant biological hazard, constituting 33% of the reported hazards in 2009 (Kleter, Prandini et al. 2009). Other fish helminths of zoonotic concern are cestodes and trematodes (especially Diphyllobothriids and Opisthorchioidea, respectively). They have received less attention despite of the reported human cases in Europe caused by these freshwater fish-borne zoonotic parasites Thus far, the available epidemiological data for farmed freshwater fish are scarce and necessary. For these main reasons in 2010, EFSA recommended studies to evaluate the effects of different farming practices on the prevalence of parasites in aquaculture (EFSA 2010). As a matter of fact, one of the conclusions of this report suggests that Atlantic salmon (AS), reared in floating cages and fed compound foodstuffs, are unlikely to contain live zoonotic parasites and therefore the risk of infection is negligible. However, a later survey detected anisakid and raphidascarid larvae (*A. simplex* and *Hysterothylacium aduncum* respectively) in AS runts (Mo, Gahr et al. 2014) which contrasts with a number of previous studies that confirmed no anisakids larvae in sea-farmed salmonids (Inoue, Oshima et al. 2000; Skov, Kania et al. 2009; EFSA 2010; Wootten, Yoon et al. 2010). These discrepancies were solved in a very recent study were 4,184 farmed AS, including runts, were sampled and examined in 2014/15. The fish were collected from 37 different salmon farms and confirmed that the presence of zoonotic parasites was restricted to runts and occurred in a very reduced number of runts (3/657); suggesting that the risk of any parasitic nematodes to occur in the flesh of farmed Norwegian salmon intended for human consumption is very low (Levsen and Maage 2016). In addition, a qualitative risk assessment analysis, developed in 2016, remarked that attending to the current knowledge of the biology of the system, and the practices adopted in the AS farming, the overall risk of commercialization of product infested by viable larvae appears to be very low (Crotta, Ferrari et al. 2016). Another conclusion of EFSA report stated that, apart from farmed AS, sufficient monitoring data are not available for any other farmed fish and therefore it is not possible to identify which fish species do not present health hazard with respect to the presence of parasites (EFSA 2010). The only work that shed light on this matter is a survey focused on farmed European sea bass (ESB), turbot (TB) and gilthead sea bream (GSB) bred in Spanish farms. This survey remarked that, similarly to AS, the presence of viable larvae appears to be indeed very low and therefore these species do not present a significant risk due to the presence of zoonotic parasites (Apromar 2012)

Concluding, it is generally assumed that farmed fish products have a very low or null prevalence of these helminths. However, this assumption has not been demonstrated scientifically and even less globally for the main European farmed fish species. The objective of the current work is to clarify the potential sources/routes of infection and design management strategies to decrease the occurrence of zoonotic helminths in farms.

(Continued on next page)

Material and Methods

From spring 2016 to spring 2017 a total of 9,333 farmed fish have been examined from the following species: GSB, ESB, TB, AS (including smoked fillets), Marine Rainbow Trout (MRBT), Rainbow Trout (RBT) and Common Carp (CC); obtained from a representative number of fish farms located in Spain, Italy, Greece, Denmark, Norway and Hungary. A random polietapic and stratified sampling plan was selected with a confidence level of 99%. In addition, primary processed products (fresh ESB and GSB from Greece, Croatia and Turkey) from supermarkets in Italy and Spain were also included in the study. As the first round resulted to be negative for zoonotic helminths in all the species and locations, a second round in 2018 was focused in i) sampling fish that are normally discarded for commercialization (runts), ii) in sampling farms close to marine environments with abundance of cetaceans (involved in the life cycle of the zoonotic helminths) and iii) common carp farms with incidence of other helminths. In the second round, a total of 1,480 GSB, ESB, CC and RBT fish runts were also collected from Spanish, Danish, Hungarian and Italian farms in 2018. The sampling of smoked AS was carried out in local supermarkets in the Basque region (Spain and France) and Italy during 2016. Sub samples size was split per suppliers, reflecting their AS commercial production volume in 2015 in the countries under study. In addition, from spring 2016 to spring 2017, 13 samples of smoked fillets of wild sockeye salmon, 2 from supermarkets in Spain and 11 from Italy, were also collected as control samples. Identification of parasites was carried out with different methodologies depending on the type of sample (viscera, fillet, etc.) and fish species including visual inspection, UV-press method, artificial digestion, candling, muscular compression/artificial digestion followed by microscopic examination and PCR. Species identification of parasites were done by sequencing

Results

No zoonotic parasites were found in any of the examined marine fish at the level of confidence of 99% with a margin of error of 4-8%. Only one L4 specimen of the raphidascarid nematode *H. fabri* encapsulated on the surface of the liver in one ESB from one Italian farm has been found. Conversely, 10 (76.9%) out of 13 smoked fillets of wild sockeye salmons were positive for Anisakis larvae.Similarly, no zoonotic parasites were found in any of the examined freshwater fish at the level of confidence of 99% with a margin of error of 4-8%. However, we have found muscle samples harbouring metacercaria of *Holostephanus spp*. in CC with an overall prevalence of 10.64% (114/1122) from Hungarian fish farms. During the first yea , 36 of 258 carp fingerlings (13.9%) were infected in the Northeastern farm. In addition, in the second year survey of the infected farm, heavy infection was found again, with prevalence ranging from 100% (30/30, in one-year-old) to 70% (21/30, in two-year-old) and 90% (27/30, in three-year-old carps). When the metacercariae from this CC were fed in an infection experiment to rodents (mice and hamsters), the trematodes were not able to develop in mammals. Therefore, it seems that *Holostephanus* species does not have any zoonotic potential based on both this negative results from experimental infections and literature review. As expected, the already known zoonotic helminth, the *Metagonimus* sp. used as positive control, were found in the intestines of rodents, 22 metacercariae and 5 adult *Metagonimus* were isolated from two hamsters.

Conclusions

In conclusion, no zoonotic helminthic parasites were detected in 10,813 marine and freshwater samples, even in runts, thus the prevalence is zero. Attending to the results obtained from different surveillances across Europe, besides the current work, we can establish that the overall risk of parasite infection in the selected farmed fish species is negligibl

Acknowledgments

Our study was carried out within the framework of ParaFishControl (n º 634429), an EU H2020-funded project that aims at increasing the sustainability and competitiveness of the European aquaculture industry through control and mitigation of the most harmful parasites affecting the main European farmed fish species

A NOVEL AND RAPID METHOD FOR THE IDENTIFICATION OF EUROPEAN MUSSEL SPECIES BASED ON REAL TIME PCR MELTING CURVE ANALYSIS

Ane del Rio[1], Elisa Jiménez[1], Miguel Ángel Pardo[1]

[1]AZTI- Tecnalia, Food Research Unit, Parque Tecnológico de Bizkaia, Astondo Bidea, Edificio 609 E-4816

Introduction

The abundance in coastal waters and the growing demand for human consumption has made mussels a target species for aquaculture. On a global scale, Europe is a major contributor of mussels, supplying over a third of the total production, being *Mytilus edulis* and *Mytilus galloprovincialis* the two main species harvested and cultivated here (FAO, 2019).

Mussels are widely distributed along the coast of Europe and are known to create extensive hybrid zones in the regions where they coexist (Bierne et al., 2003). In particular, *M. galloprovincialis* occurs throughout the Mediterranean and the Atlantic coasts from Portugal to France, creating a hybrid zone with *M. edulis* between the South West France and the Basque coasts. Mussel farming is an emerging activity in the Basque coast (DDEC, 2016), and the experiences of mussel culture carried out in long-lines in the Southeastern Bay of Biscay have shown very promising results.

Given the ecological and economical importance of these species, and the importance of seafood products labelling for traceability, there is a need for clarifying the distribution of farmed mussel species populations around Spain. Species identification based on morphological characteristics is controversial due to their plasticity, and even more problematic for *Mytilus* species from hybrid zones (McDonald et al., 1995). The most common PCR (Polymerase Chain Reaction) molecular methods for mussel species identification targets the polyphenolic adhesive protein gene using the specific primers Me15-16 (Inoue et al., 1995, Santaclara et al., 2006). However, these conventional methods are laborious and time consuming due to the number of steps needed for result visualization.

For this reason, there is a need to apply fast, reliable, and cost-effective methods for species verification. In this study, a real-time PCR assay with a SYBR Green post-PCR melting curve analysis was successfully developed and validated for mussel species identification.

Material and Methods

From autumn 2018 to winter 2019 a total of 244 samples of farmed mussels were collected at five production areas in Spain: Basque Country (Mendexa and Mutriku), Galicia (Ría de Arousa and Ría de Betanzos-Sada) and Catalonia (Ebro Delta); and 59 samples were collected in Algarve (Sagres) and Túnez (Lagoon Bibane). In addition, 37 mussel samples labeled as *M. edulis* were also collected from local markets. DNA from 340 samples was isolated with Wizard® Genomic DNA Purification Kit (Promega). Real-time PCR amplification was performed on a LightCycler® 480 Instrument II (Roche Diagnostics). The 10 µL reaction mixture contained 5 µL of Brilliant III Ultra-Fast SYBR® Green QPCR Master Mix (Agilent), 20 ng of template DNA and 300 nM of each primer previously described by Dias et al., (2006). The reaction conditions were 3 min at 95 °C, followed by 45 cycles of 5 s at 95 °C and 60ºC for 10s. The dissociation curves of the PCR products were monitored on the same instrument, from 65ºC to 95ºC with 0.11 ºC increases. The validation of the method was performed using the PCR-RFLP (Restriction Fragment Polymorphisms Pattern) Me15-16 *Aci*I method as described by Santaclara et al. (2006).

Results

The real time PCR assay developed showed specific peaks in dissociation curves with unique melting temperature (T_m) values for each species. The T_m obtained were the following: 78.87 **ºC ± 0.11 for** ***M. galloprovincialis*** (n=60) and 80.48 **ºC ± 0.19 for** *M. edulis* (n=25). The hybrids (n=10) showed a double peak which correlated with the T_m of both species analyzed. These results were successfully validated by analyzing samples using the conventional PCR-RFLP Me15-16 *Aci*I method. All collected mussel samples were analyzed using the developed methodology, obtaining the following results: from 303 samples analyzed, 289 were identified as ***M. galloprovincialis***, one sample as ***M. edulis*** and 13 samples as *M.galloprovincialis* x *M. edulis* hybrids. Hybrids where found in five of the production points, specificall , 1.5% of the samples from Catalonia, 6% of the samples from Galicia and 6.98% of the samples from the Basque Country were identified as hybrids.

(Continued on next page)

Conclusions

In conclusion, the real-time PCR assay with a SYBRGreen post-PCR melting curve analysis developed is suitable for the identification of most important commercial mussels species in Europe, as well as their hybrids. This method has proven to be fast and cost-effective in comparison to other methods previously described, holding the potential to become a routine methodology.

Acknowledgments

Introduction

Pseudoplatystoma fasciatum is a native fish from the continental water in the Amazonian Región from South America, which rearing is increasing for production. The objective of the present research was to contribute for improving fish production in the Amazonian by identifying the pathology and the causal agent of *Pseudoplatystoma fasciatum* mortality in a stuary from the IIAP, located in Pucallpa, Ucayali Region, Peru.

Materials and methods

Pseudoplatystoma fasciatum fingerlings 3.5 months old, 15 cm long and 65 g weight average were evaluated clinically in the estuary; hematocrit, and hemoglobin levels were determined. At the necropsy, anatomic changes were evaluated and ascitic fluid from the celomic cavity, gills and natatory bladder inocula were obtained and streaked on blood and Mc Conckey agar and the growth was replicated on TSI and cetrimide agar.

Results and discussion

Clinically, fish were floating on the water surface showing breathlessness and loss of equilibrium. Hematocrit and hemoglobin levels were 2.8% and 1.8g/dl respectively. At necropsy, pale color and edema in gills, abdominal bloating containing abundant yellowish bloody fluid in the cavity were found. Peritoneum showed a bloody coloration and edema and the natatory bladder a whitish fluid content. The liver was yellowish and the pancreas whitish-gray, and both showed increased size. In lumen of the intestine, abundant fluid was found. In the blood, Mc Conckey, TSI and cetrimide agars, *Pseudomonas sp* was identified.

Several infectious diseases in fish have been associated with haamorrhage, anaemia and ascites similar to those found in the present study. Viral agents as cat fish disease virus and the iridovirus from the siluronids (Boom and Huisman, 1996; Plumb and Hanson, 2011) have been reported worldwide. As bacterial agents associated with these infectious diseases, isolation and identificati n of Pseudomonas sp. as *Pseudomonas anguilleseptica, P. putida* and *P. fluorescens*, *P. aeuroginosa*, *P. plecoglossicida* have been reported. Those bacteria have aquatic environments as natural habitats and they are part of healthy fish gastrointestinal microorganisms, but they can cause mortality in fish when poor environmental conditions arise (Austin and Austin, 2007). Similar diseases pictures have been described in the infection by *Edwardsiella ictalury* in catfish (Plumb and Hanson, 2011) and *Aeromons hydrophila* in Surubin hibrido (*Pseudoplatystoma corruscans* x *Pseudoplatystoma fasciatum*) (Correa da Silva, et al., 2011). Conclusively, in the mortality of *Pseudoplatystoma fasciatum* fingerlings, haemolitic anaemia and ascites associated with *Pseudomonas sp*. infection was identified. *Pseudoplatistoma fasciatum* mortality resulted from a hemolitic anemia and ascitis associated with *Pseudomonas sp.* infection.

Introduction

Offshore aquaculture fish cage uses the neighboring water current to purify the water in the fish cage. A change of the neighboring flow field can change the efficiency of the purification work. The influence of the empty fish cage on the neighboring flow field has been widely investigated (Løland, 1991). However, the study on the influence of the stocked fish cage is sparse (Gansel et al., 2014).

In the present study, Pseudo Fish school Structure (PFS) was developed to simulate the neighboring flow field of a stocked fish cage by Circulating Water Channel (CWC) tests. The result of the CWC tests was compared with the field survey for qualitative verification

Materials and methods

The study site, Kurose fish farming area, is a part of Shibushi Bay in Japan. A target cage had 8.0 m height with a square base of 10.0 × 10.0m. The cage had wire netting, and so it could not show major deformation. The stocking density of the cages ranged 30 – 40kg/m^3. About 10 000 of 1.5-year-old yellow-tails (*Seriola quinqueradiata*) were cultured in the cage.

An overall 1/25 length scale model cage of the full-scale fish cage was used for the CWC tests. It had 0.3m height with a square base of 0.4 × 0.4m. The model cage had PE nettings and a steel frame. Therefore, the model cage also did not show major deformation. The netting of the model cage was made following the Tauti's similarity law (Tauti, 1934).

The stocked fish were observed through the underwater video camera. Their fork length was assumed to be 560mm. Two horizontal swimming patterns were observed: swimming randomly (Fig. 1); swimming together (Fig. 2). Their instant swimming speed was roughly estimated from the video record (about 0.2m/s).

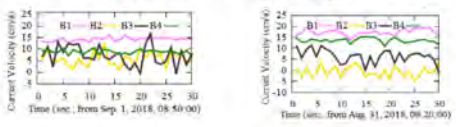
Fig. 6 Times series velocities at the neighboring points of the model cage



(a) weak motion of fish school (b) revolving fish school

Fig. 7 Times series velocities at the neighboring points of the full-scale cage

(Continued on next page)

The fish were imitated by PVC pipes. The displacement of PFS was 3.76% of the whole volume of the model cage. Two types of the moving patterns were imitated by PFS: maintaining the position; revolving in counterclockwise.

The model tests were completed in the Horizontal Circulating Water Channel with Wave Maker and Wind Tunnel (24m long × 1.8m wide × 1.0m depth) in The University of Tokyo. The current velocities at neighboring four points (Fig. 4) of the model cage were measured by a current meter (ACM2-RS, JFE Advantech) in CWC.

The time series current velocities at four neighboring points (Fig. 5) of the target full-scale fish cage were measured from Aug. 29, 2018, to Sep. 3, 2018, by four COMPACT-EM current meters (JFE Advantech). The periods that showed the time-averaged velocity directions at points B1 and B4 ranged 133 ± 22° from the North were chosen; the direction from the North can be referred to Fig. 5.

Results

Time series velocities of the four points in CWC test show qualitative consistency with the field data (Fig. 6 and 7). When PFS was motionless, the average velocities at A2, A3, and A4 showed similar value (Fig. 6a). During the period of Fig. 7a, the average velocities at B2, B3, and B4 showed similar value as well. Therefore, it can be inferred that the stocked fish was swimming relatively randomly and gently during the period.
When PFS was revolving, the velocities at A2 and A3 showed significantly different aspect (Fig. 6b). Because the pipes of the PFS moved against the main current next to the point A2, the velocity at the point shows a significant decrease. However, the PFS moved with the main current next to the point A3, the velocity at the point shows only a slight decrease. During the period of Fig. 7b, the velocity at B2 is significantly lower than that at B3. It can be inferred that the fish school revolved in counter clockwise.

Conclusion

The qualitative similarity between the neighboring flow fields of a stocked model fish cage and those of full-scale fish cage was observed. The flow field inside of a stocked fish cage is highly depending on the moving patterns of the stocked objects. And the flow field was non-uniform and complex. Further research to obtain the quantitative similarity between the laboratory test result and the field survey result can deepen the understanding of the neighboring flow field of the stocked fish cage

Introduction

The optimization of feeding strategy in relation to the environmental condition needs further investigation in order to maximise performance, fish health and fish quality of Mediterranean farmed species. Environmental temperature during seasonal changes may affects fish metabolism, digestive enzymes activity and gut bacterial community which may exert an effect on performance and tissue composition (Couto et al., 2012; Guerreiro et al., 2016). Data relating interaction between different dietary protein and energy ratio and water temperature changes on digestion condition, gut bacterial community and fat deposition of gilthead seabream fed current aquafeed formulations are scarce. For this reason, the purpose of this study was to evaluate the effects of two dietary protein and dietary energy ratio (DP/DE) during temperature changes on growth, feed efficienc , fat deposition, plasma biochemistry, digestive enzyme activity and gut bacterial community of gilthead sea bream (*Sparus aurata*).

Material and Method

Two experimental practical extruded diets formulated with 15% fishmeal and with different protein energy ratio (44/16; 44/21, protein/lipid, %) were tested in triplicated fish groups of 30 individuals (initial weight: 67.5g) and raised at two different water temperatures (23 °C and 17°C) in the same recirculation system over 119 days. Fish were fed manually to visual satiation twice a day. After 58 days fish were exposed to a switch in temperature (fish kept at 23°C were transferred to 17°C and the fish kept at 17°C were transferred to 23°C, 23/17 and 17/23, respectively) while continued to receive the same diet in each group. Specific growth rate (SGR), feed intake (FI), feed conversion rate (FCR), somatometric indexes and nutritional indices were performed in the intermediate periods and at the end of the trial to assess growth performance during seasonal changes. At the same times digestive enzyme activity (n=9 per treatment), plasma biochemistry (n=9 per treatment), and gut microbial community by Next-generation sequencing were determined. Data were analysed by Two-way ANOVA followed by a Tukey's multiple comparison test. Differences among treatments were considered significant at $P < 0.05$.

Results

At the end of the trial no significant diet effect on final body weight and SGR were detected in fish firstly exposed to 23 °C (23/17) compared to those firstly exposed to 17 °C (17/23). Similarly, no significant differences in FI and FCR were observed. In the intermediate periods, low water temperature negatively influenced SGR, FI and FCR under both dietary treatments. In those periods similar ($P > 0.05$) growth and feed utilization were detected between diets in fish reared at the same temperature even if in the second intermediate periods (days 58-119 after the temperature changes), FI was higher ($P = 0.01$) in 44/16 diets compared to 44/21. No significant dietary effect on perivisceral fat and HSI was detected at the end of the trial. Fat index was significant reduced in fish firstly exposed to 23 °C (23/17) under both dietary regime while HSI showed an opposite trend.

Discussion and conclusion

This study provided novel insight on the effects of DP/DE ratio on fat deposition, digestion condition and gut bacterial community of gilthead sea bream fed in summer before entering winter and fed in winter before entering in spring. Preliminary results suggest that different dietary lipid level did not improve growth performance and feed efficiency during seasonal changes, while a reduction in water temperature from 23 to 17 °C reduced feed intake and feed utilization under both dietary regimes. The increase in dietary lipid level from 16 to 21% seems to not affect lipid deposition.

GROWTH OF MOROCCAN MINT (*Mentha spicata*) IN THREE HYDROPONIC SUBSYSTEMS (DRF, RAFT, NFT) UNDER DECOUPLED AQUAPONIC PRODUCTION OF *C. gariepinus*

J. Pasch*, U. Knaus, H. W. Palm

Aquaculture and Sea-Ranching, Faculty of Agricultural and Environmental Sciences, University of Rostock, Justus-von-Liebig-Weg 6, 18059 Rostock, Germany
Email: johannes.pasch@uni-rostock.de

Introduction

Mint (*Mentha* spp.) is known for good performance under different aquaponic conditions and has a high economic potential due to essential oils and short growing periods (Knaus, 2016; Kotzen and Appelbaum, 2010). However, comparative studies of mint cultivation in different hydroponic subsystems are scarce. Best plant weight, length and number of leaves were obtained by using the nutrient film technique (NFT) and floating rafts with root aeration by air diffusers, while insufficient results were achieved in a gravel decoupled aquaponics system without additional aeration (Zimmermann, 2017).
The type of hydroponic aeration might play an important role for the provision of nutrients at the root inner space and surface allowing good plant growth. Beside active aeration with the help of air diffusers or an increased direct oxygen supply through the water surface by circulating the solution, the passive root contact to atmospheric oxygen was described by Silva et al. (2015) as the "dynamic root floating" technique or DRF. In this case, a small aerated space e.g. 5cm is left between the plant trays and the nutrient enriched water. The DRF system results in the formation of "oxygen roots" or "hair roots" in pak choi (*Brassica chinensis*) combined with Nile tilapia (*Oreochromis niloticus*) under coupled aquaponics conditions (Silva et al., 2015) and can minimize investment costs by the elimination of energy consuming active aeration.

The present study compared the growth of mint (*Mentha spicata*) in different hydroponics subsystems with active aeration in raft, active aeration by circulating the aquaponic nutrient solution in NFT and the passive root aeration in a DRF hydroponic subsystem under conditions in northern Germany.

Material and Methods

The experiment was performed in the FishGlassHouse, an experimental aquaponic facility in Northern Germany (Mecklenburg-West Pomerania, University of Rostock) during spring 2018. African Catfish (*C. gariepinus*) were fed with Alltech Coppens Special Pro 4.5mm (42.0% protein, 13% fat, 1.5% crude fibe , 7.6% ash, 1.02% total P) and *C. gariepinus* was held in an intensive aquaculture unit (104-156 fish tan $^{-1}$; max. 200kg m^3).

The hydroponics cabin contained one collecting tank and 9 individual hydroponic sub-systems with 7 plants, respectively. The aquaponic principle was decoupled and used effluents from *C. gariepinus* production without additional fertilizer. Three techniques were tested in triplicates and randomized block design:

a) dynamic root floating technique (DRF): 25 days after the plants were introduced into the system, a 5 cm air space was installed for root aeration (passive root aeration) and oxygen diffusers were taken out;
b) floating raft culture (raft): polystyrene rafts held the plants on the water surface and the water was enriched by oxygen diffusers (active aeration);
c) nutrient film technique (NFT): plants were embedded in a tube (12.5cm) where a constant flow of water supplied the roots with oxygen (active aeration).

The water of the collecting tank (537 L) was exchanged twice a week with the nutrient enriched water. The experiment lasted for 55 days and during this period the plants were examined for the relevant growth parameters (dry and wet mass). These also included the number of leaves (No), total length (cm), shoot length (cm), root length (cm), total weight (g), shoot weight (g), root weight (g) and the two leaf lengths and widths of the second shoot node from above. Physical water parameters were measured daily and chemical parameters biweekly.

(Continued on next page)

Table I. Comparison of *Mentha spicata* growth parameters cultivated in three different hydroponic subsystems (DRF, raft, NFT) under decoupled aquaponics conditions with effluent water of *C. gariepinus*, different letters show significant groups ($p < 0.05$).

Parameter	DRF	RAFT	NFT
Number of leafs (No)	482.3 ± 163.4^{b}	532.2 ± 180.3^{ab}	639.7 ± 207.7^{a}
Total plant weight (g)	139.4 ± 81.1^{b}	200.4 ± 97.2^{ab}	220.6 ± 113.5^{a}
Total plant length (cm)	109.2 ± 19.6^{b}	132.0 ± 17.8^{a}	128.1 ± 21.7^{a}

Results and Discussion

The best growing results with mint were achieved in the NFT system. The number of leaves and the total weight were higher for NFT compared with DRF (Table I, $p < 0.05$). Total plant length was lower for raft and NFT compared with DRF ($p < 0.05$). The shoot axis length and leaf weight were better for raft compared with DRF ($p < 0.05$). Total dried plant biomass and root mass were higher for NFT than for DRF ($p < 0.05$), with raft and NFT not differing from each other ($p > 0.05$). The growth potential of *M. spicata* showed the following order: NFT > raft > DRF. With regard to the economically most important parameters number of leaves and total weight, results by Zimmermann (2017) for *M. spicata* in the NFT system were confirmed. It could be verified that the hydroponics subsystem NFT is best suitable for the cultivation of *M. spicata* under decoupled aquaponics conditions.

The passive aeration in the DRF system was not suitable for the cultivation of *M. spicata* and showed brown colouring and lignification of the oxygen roots, and a reduction in root growth activity. This can be explained by the reduced air humidity indoors and higher temperature fluctuations at the sensitive hair roots, caused by season and location in northern Germany. We suggest that further studies should increase the DRF air space gradually by automatic control of the water level without using energy to minimize operational costs or the present setup should be repeated during the warmer summer season.

Introduction

Nowadays, aquaculture provides up to 50% of the world's aquatic food consumption (FAO, 2018). However, its development has been seen as unsustainable because the current production model jeopardises wild environments, human food security, and economic prospect (e.g. Martinez-Porchas and Martinez-Cordova, 2012). This places a premium on the improvement of sustainability of the aquatic food production. In this context, the research program, ICHTYOSERV, aims at applying an agro-ecological-like approach on fish farming. Indeed, environmental-based alternatives could be considered to design innovative and agro-ecological production systems (Dumont et al., 2013). In such systems, special attention should be given to biodiversity since it could allow enhancing the resilience and the efficiency of aquaculture. To this end, ichtyodiversity should be considered according to a functional approach, with the study of fish traits and of their relationships (Violle et al., 2007). Such data are being compiled into the *Traits OF Fish* (TOFF) database that lists morphological, phenological, physiological, and behavioural data coupled to ecological characteristics (Thomas et al., 2017). Exploitation of this database allows defining different scenarios, which take account the compatibility among the fish species (in terms of living environment) and the absence of competition for used resources. The aim of this work is to explore a specific scenario from TOFF database. It consists to compare monoculture of *Sander lucioperca* with a polyculture option combining the latter species with one or two other species in recirculated aquaculture systems (RAS) so as to determine how ichtyodiversity could impact some key processes in agro-systems and improve the efficiency of fish rearing systems.

Materials and methods

The selected scenario involves pikeperch *Sander lucioperca* (Percidae), associated or not with sterlet *Acipenser ruthenus* (Acipenseridae) and tench *Tinca tinca* (Cyprinidae). Fish were obtained at juvenile stage from fish farmers. After the acclimatisation period, the mean weights of fish were 58.1 ± 11.2 g, 40.8 ± 6.2 g and 17.6 ± 4.6 g respectively for *S. luciorperca*, *A. ruthenus* and *T. tinca*. Then, fish were reared for two months in a 300 L tank with aerated recirculated water according to four modalities. In more details, it consists to keep one, two, or three species together, systematically with 36 fish per experimental unit. It corresponds to 36 pikeperch (for the modality P), 18 pikeperch and 18 sterlet (PS), 18 pikeperch and 18 tench (PT) or 12 pikeperch and 12 sterlet and 12 tench (PST). All these modalities have been tested in triplicates. Fish were fed daily with commercial pellets, at a rate of 1.5% body weight per day. The physico-chemical parameters of the water were checked three times a week (temperature: 20.5±0.7°C; dissolved oxygen > 6.1 mg/L; pH 7.5±0.2; $N\text{-}NH_4^+$ < 0.2±0.2 mg/L; $N\text{-}NO_2^-$ levels < 0.1±0.1 mg/L). During the experimental phase, the light / dark period was 10h / 14h, using white neon light (20 lux). All fish of each experiment unit were measured and weighed after 0, 29, and 60 days of rearing to calculate the following zootechnical parameters: percentage of survival, final body weight, weight heterogeneity, specific growth rate, Fulton's condition factor, biomass gain, and feed conversion ratio. Behavioural responses are also recorded according to two rounds of video recording (i.e round 1 between days 5 and 11; round 2 between days 31 and 35). Videos concern the fish spatial repartition in the water column, the group structure (distance from the nearest neighbour, mean distances between all individuals of the group and variances of these distances), fish activity (swimming), and relationship (contact) between fish with media player software. For the data analysis, we used ANOVA after checking that they were normally distributed (Shapiro's test) and that their variances were homogeneous (Leven's test).

Table 1. Recorded zootechnical parameters for pikeperch reared in monoculture (modality P) or in polyculture: pikeperch with sterlet (PS), pikeperch with tench (PT) or pikeperch with sterlet and tench (PST).

Modalities	Initial body weight (g)	Final body weigth (g)	Weight hetero-geneity (%)	Specific growth rate (%)	Fulton's condition factor	Biomass gain (%)	Percentage of survival (%)
P	58,1 (11,2)	99,5 (21,1)	21	0,83	0,756 (0,069)	71	100
PS	58,3 (10,3)	109 (25)	23	0,93	0,755 (0,049)	83	98
PT	57,5 (10,9)	107 (26,6)	25	0,96	0,764 (0,064)	86	100
PST	59,6 (10,2)	115 (25,8)	22	1,01	0,751 (0,077)	93	100

Results

Overall, our results indicate that it could be interesting to raise *S. lucioperca* in polyculture compared to monoculture. From the zootechnical aspects, survival rates for pikeperch are always higher than 98% whatever modalities. On the other hand, final body weight, specific growth rate, and biomass gain appeared higher when pikeperch are associated with sterlet, tench, or both compared to monoculture of pikeperch (Table 1).

Concerning the behavioural approach, some differences are also recorded between pikeperch alone or associated with one or two other species. Thus, *S. lucioperca* are swimming the entire well volume in monoculture whereas they are living at the bottom of tank in polyculture options. In the same way, distances from the nearest neighbour are higher when *S. lucioperca* is reared alone. Finally, pikeperch developed more direct physical contacts of intra-specific type compared to inter-specific nature

Discussion

The relevance of these new options of polyculture approach by experimental approach is fundamental to determine the best combination between pikeperch and other fish species. These first results demonstrate a complementary utilization of trophic resources between the three taxa in relation to a best exploitation of spatial resources.

Introduction

The sea urchin *Paracentrotus lividus* (Lamarck, 1816) was selected as new candidate for aquaculture in European countries. Wild seaweeds are harvested to feed sea urchins, but this practice should be replaced by farmed seaweed or prepared feeds to be economically and environmentally sustainable (Carboni et al, 2013). Formulated diets were effective in increasing gonad size but sometimes failed to produce gonads with optimal organoleptic characteristics (Robinson et al, 2002). For these reasons, the addition of macroalgae in the diets, as a mix or included in the formulation, had been detected to increase the palatability and efficiency of prepared feed (Cyrus et al, 2014). However, all these previous studies were conducted on wild specimens. As far as we know, nobody has studied the attraction or the palatability of diets nor the feeding behaviour of reared sea urchins. The aim of this study was to evaluate the first choice of food and the feeding behaviour of reared *P. lividus* among two prepared diets and a macroalgae (*Ulva sp.*) considering light and dark experimental conditions.

Materials and methods

A total of 120 sea urchins (test diameter 22.3 ± 2.6mm) were collected from the stock of reared sea urchins by the experimental hatchery of the University of Cagliari. Before the experiment they were kept in starvation for 7 days. Sea urchins were subjected to the choice of three diets: A, fresh green-macroalgae *Ulva sp.*; B, experimental diet manufactured by SPAROS Lda; C, commercial feed known as Nofima diet (Prato et al, 2018). The experimental unit consisted on a white circular tanks of 150l of volume, provided by a digital camera set in the "time lapse function" (60 picture.h.-1, definition 12 megapixel), which was used to monitor the behaviour of sea urchins. Four sea urchins were positioned in the centre of the tank and the diets were positioned equidistant from the centre. Each experiment lasted 24h and was replicated thirty times. For each experiment were calculated the first choice of food, which was the first food selected by each sea urchin, and the feeding behaviour. The feeding behaviour was determined by measuring the number of sea urchin in contact with different diets as categorized above (A, B, C). When sea urchins were not in contact with any diet, were categorized as N. The number of urchins in each feeding behaviour category was calculated every hour under Light (15 replicates from 11 am to 4 pm) and Dark conditions (15 replicates from 11 pm to 4 am).

Results

The first choice of food was 45% for the diet A, 25% for the diet B and 30% of diet C. Over the total of sea urchins, the 40% of reared sea urchins did not choose any diet. Considering the light and dark behaviour, the average number (± se) of sea urchins in contact with the different diets in light and dark conditions is reported in Figure 1. Significant differences occurred between the behaviour categories in Light and Dark conditions.

Discussion and conclusion

The results confirmed our assumption, suggesting that the feeding behaviour is not affected by the captivity or by the food history of reared sea urchins. Indeed, results of the first choice showed that reared sea urchin preferred the macroalgae *Ulva sp.* instead of prepared feeds. This confirm that the choice is controlled mainly by the food shape, morphology and texture, rather than the nutrient content as observed for wild specimens (Vergés et al, 2011). Regarding the feeding behaviour, a significant increase of sea urchins interaction with the feeds occurred during the night hours. It is also interesting to highlight that the video recording showed a high number of specimens that never interacted with the feeds. These specimens with lack appetite were probably the sea urchins known as small "outliers" where the numbers ranged from 11% to 35% of the total sea urchin produced in a hatchery (Grosjean et al, 2001). These sea urchins growth was apparently inhibited by the other specimens, which, probably, interacting more quickly with the feed grew faster. The results suggested some practical recommendations for feeding practice in echinoculture: 1) it would be advisable to administer food at sunset, which had the advantage to give to sea urchins a more palatable food because it not may remain uneaten for several hours; 2) don't use fresh macroalgae and prepared feeds as mixed together in the tank because sea urchin eat first the macroalgae and in the meanwhile the prepared diets could dissolve in the water; 3) split frequently the "small outlier" sea urchins in separate tanks or cages for better growth performances.

Introduction

Eutrophication is one of the largest threats to the Baltic Sea manifested by algal blooms, turbid waters, loss of submerged vegetation and hypoxic and anoxic conditions at the sea bottom in large areas (Holmer et al., 2015). The potential of using bivalves such as blue mussels to mitigate effects of eutrophication in the coastal zone has been proved environmental effective in Danish waters (Timmermann et al., 2019). Mussels remove nutrients from the water through filtration of particles, which are incorporated into mussel biomass and removed from the system by harvesting. However, it is still a challenge to optimize mussel farms and mussel production. The farm design and locations need to be adapted to different environmental conditions in order to handle e.g. high predation pressure, low salinity, exposure to high wind, waves or ice coverage, but also in terms of efficient mussel larvae settling on the long-lines. Spawning takes place in the natural mussel beds in spring and the resultant larvae are spread by the water currents to other areas before settling on the bottom or on the long-lines in the mussel farms. In the following study, we use 3D ecosystem modelling to estimate the mussel larval distribution on fine spatial and temporal scales in a local set-up of the Limfjorden

Materials and methods

We couple a 3D physical Limfjord model with an agent based model (ABM) using the Flexsem system (Larsen et al., 2017). The hydrodynamic model has been validated against observations. Mussel larvae are defined by two main biological parameters: the pelagic larval duration (PLD) and a main spawning event in spring. To simulate the dispersion of mussel larvae we use numerical particles released from the mussel bed sampling stations acting like a source area (figure 1). The mussel densities in the stations are considered for the amount of larvae released. The individual trajectories of the particles are stored for the temporal extent of the pelagic phase. No random vertical or horizontal movements of the particles are included. At the end of the pelagic larval duration, settling occurs once for particles ending anywhere within the model domain. The model provides maps of mussel larvae distribution and connectivity between sub-areas, which can be used for site-selection processes of mussel farming in the Limfjorden.

Results and Discussion

Preliminary results on larval connectivity in the area show that there is a high probability of larvae to be recruited in the same location where they were originally released (self-recruitment). This is the case in all areas except for 1, 2, 4, 6 16 and 17 where no mussel were released. Self- recruitment is higher for short PLDs, and as we increase the number of days that the larvae remain in the water column, larvae will move to other areas within the Limfjorden (results not shown). Main donor and receiver areas can also be identified by the model for different scenarios. For 2010, area 5 corresponding to Kås Bredning is the main donor area and areas 10 and 11(Løgstør Bredning) and 13 (Risgårde Bredning) the main receiver areas. These connectivity results can be explained by the circulation current patterns in the area. Current mean speed and standard deviation in the studied month was calculated and it was observed to be higher in area 5. This area is a strait and therefore we expect higher current speeds that disperse the larvae to the inner parts of the Limfjorden (not shown).

Conclusion and Outlook

Larval dispersal is a complex process mediated by several factors acting at different scales. In this study, we are able to identify the main donor and receiver areas, as well as the areas with high self-recruitment and isolated areas for the specific year and season modelled. Note that the model does not account for post-settlement survival. Other factors such as bottom trawling, oxygen depletion and marine protected areas are also important to consider when modeling the spawning areas and potential settlement sites. Thus, this variability in density of larvae newly settled is caused by complex interactions between hydrodynamics, habitat structure, predation and species-specific traits. Further work will include (1) annual variability in mussel larvae distribution, (2) changes in climate affecting the physical conditions and biological traits of the species and (3) model validation against mussel beds densities, genetics and larval sampling. The tool developed in this study can provide useful information for decision makers to be used for management applications and aquaculture purposes in the inner Danish waters.

Introduction

The Green Aquaculture INtensification in Europe (GAIN) project is a 42 month long collaborative research programme funded by the European Union (EU), through Horizon 2020 (Grant Agreement 773330) (www.unive.it/gainh2020eu). GAIN started in May 2018 and is designed to support the ecological intensification of aquaculture in the EU and European Economic Area (EEA), with the dual objectives of increasing production and competitiveness of the industry, while ensuring sustainability and compliance with EU regulations on food safety and environment. Eco-intensification of European aquaculture is a challenge that requires the integration of scientific and technical innovations, new policies and economic instruments, as well as addressing social considerations, in order to promote the implementation of the principles of circular economy in aquaculture.

Materials and methods

GAIN aims at enhancing eco-intensification by pursuing the specific objectives listed bel .

1. Design and test an innovative range of finfish feed
2. Develop and test a platform for supporting the implementation of precision aquaculture by combining sensors, Big Data analysis, and predictive models;
3. Add value to cultivation of both finfis and shellfish by means of innovation in co-products from improved re-use of secondary materials, thus increasing profit and minimizing the environmental footprint of aquaculture
4. Support integrated policies concerning aquatic food production, by addressing current barriers to the circular economy;
5. Promote market access and help consumers, both in Europe and elsewhere, to understand the true value of quality production from European waters;
6. Provide guidelines for sustainable ecological and economic intensification of European aquaculture, and disseminate and exploit these findings and recommendations to farmers, managers, and policy-makers

Results

During the first year, GAIN has already obtained several relevant results, which are described in detail in seven public deliverables and summarized below.

Implementation of Precision Fish and Shellfish Farming: Innovations and decrease in costs of sensors are now making it possible to implement the framework of "Precision Fish Farming" (PFF) (Fore et. al., 2018), which in GAIN will be extended to "Precision Shellfish Farming" (PSF) (Brigolin et al. 2017). GAIN instrumented ten pilot sites with state-of-the-art sensors for real-time detection of both environmental and animal variables, e.g. fish length/weight distribution. Data will be processed using a range of process and data driven models.

(Continued on next page)

Design and performance assessment of novel feeds: novel feeds for salmon, trout, seabream and turbot combining emerging sustainable ingredients, e.g. insects, heterotrophic microalgae, and fisheries/ animal production byproducts, were designed and tested on the above species.

Valorisation of secondary products of the aquaculture supply chain: optimal conditions (e.g. pH, temperature, hydrolysis time ...) for the production of Fish Protein Hydrolysates (FPHs) from salmon and rainbow trout heads and trimmings were determined.

Valorisation of wastewater from land-based farms: an innovative process, combining sono-electro flocculation with vacuum filtering is being tested. Preliminary results indicate that the end-product can be used as a fertilize .

Valorisation of mortalities: an innovative process combining using mechanical fluidization and superheated steam is being tested, in order to reduce economic and environmental cost of disposal of fish farm mortalities

These components of GAIN will allow farmers to grow more and grow better within the space currently available, and an economic analysis of the performance of farms will help build trust in the innovative products that GAIN will make available.

Discussion and conclusion

The results outlined above provide early indications that there is considerable scope for reducing the environmental impact of European aquaculture and simultaneously enhancing its profitabilit . Crucial to that is the reuse of co-products and side-streams which, to some extent, is still limited by current EU and national legislations. GAIN is inventorying and analysing such legislation, in order to identify barriers to a full-scale implementation of the circular economy also in the aquaculture sector. The sustainability of innovative processes should additionally be demonstrated: to this aim, a new, comprehensive sustainability index, based on Life-Cycle Analysis (LCA) and including also welfare indicators, is being designed and will be applied to the supply chains of the main GAIN target species, i.e. salmon, rainbow trout, seabream and seabass.

GAIN has direct links with partners in the US, Canada, and China, as well as strong connections to other parts of the world. Our Affiliate Farm Programme is designed to broaden the reach of the innovations we develop, and to ensure a strong and continuing legacy.

INVESTIGATION OF SPERM AGGLUTINATION AND A NEW METHOD FOR MEASURING SPERM CONCENTRATION IN COMMON CARP (*Cyprinus carpio*)

Bernadett Pataki[1], Logan Andrew Goddard[2], Béla Urbányi[1], Tímea Kollár[1], Ákos Horváth[1]

[1]Department of Aquaculture, Szent István University, Páter Károly u. 1, Gödöllő H-2100, Hungary
[2]Department of Animal Science, Cornell University, 149 Morrison Hall, Ithaca, NY 14853 USA

Introduction

In this work, two independent experiments were carried out to improve the circumstances and the results of sperm cryopreservation in common carp (*Cyprinus carpio*). Sugar based extenders, which are required as extracellular cryoprotectants (Horváth et al. 2003, Bernáth et al., 2016, Marinović et al. 2017) cause jelly-like agglutination after thawing in common carp sperm (Horváth et al. 2003). Although Horváth et al. (2003) pointed out this agglutination does not reduce the fertilization or the hatching rates, Bernáth et al. (2017) found that it can negatively affect post-thaw motility and also the fertilization rate. In our research we tested whether removal of the seminal plasm inhibits agglutination or not. In the second experiment, the concentration of common carp sperm was measured by spectrophotometric analysis based on the research of Ciereszko et al. (1992) who found linear correlation between sperm concentration and absorbance in yellow perch. The main goal of this experiment was to find a fast and high-throughput method to estimate the concentration of common carp sperm.

Materials and methods

In the first experiment, fresh progressive motility from six individuals was measured by a CASA (Computer Assisted Sperm Analysis) system. After that 1 mL from the samples was put into 1.5 mL Eppendorf tubes and was centrifuged at 500 g at 4 ˚C for 10 minutes. Subsequently, the seminal plasma was removed and replaced with grayling extender (200 mM glucose, 40 mM KCl, 30 mM Tris, pH 8.0). This procedure was repeated 3 times. After that the samples with and also without seminal plasma were cryopreserved in the presence of 10% methanol in 500-µL French staws and in the vapour of liquid nitrogen 3 cm above its surface for 3 minutes. After cryopreservation the samples were plunged into liquid nitrogen. The samples were thawed (for 13 sec, at 40 ˚C) and post-thaw progressive motility was measured by CASA.

In the second experiment, sperm concentration of the same six individuals was measured with two different methods. Firstly, 10 µL of each sperm sample was diluted in 990 µL grayling extender (100-fold dilution) and the absorbance was measured at 505 nm by a spectrofotometer. At the same time, 100 µL from the pre-diluted sample was diluted further into 900 µL grayling extender (1000-fold dilution) and spermatozoa were counted using a Bürker-Türk type hemocytometer. Results coming from the same individual were correlated.

Results

In the first experiment we found that removal of the seminal plasma and its replacement with grayling extender did not inhibit the agglutination process. However, it significantly affected the post thaw progressive motility of the groups ($p= 0.018$): it was 28±13% in the group without seminal plasma and 44±16% in the group with seminal plasma (group B). The fresh progressive motility was not significantly different ($p=0.22$) in the two groups (group without seminal plasma: 86±6%, group with seminal plasma: 80±11%; Figure 1).

In the second experiment, we found a linear relationship between sperm concentration and optical density (at 505 nm) and spermatocrit which can be described with the following equation: $Y = 3.416\times10^{11}X - 6.658\times10^{9}$ ($R^2=0.7027$).

Discussion and conclusion

In the first experiment we proved that replacement of the seminal plasma with grayling extender did not inhibit agglutination of the sperm during cryopreservation, which means a process occurring in spermatozoa (and not in seminal plasma) leads to agglutination of sperm. In addition, replacement of the seminal plasma with grayling extender caused a significant reduction in progressive motility. Consequently, replacement of the seminal plasma does not offer a solution to post-thaw sperm agglutination.

In the second experiment we found that there is a linear correlation between the concentration and the absorbance of common carp sperm which was not described before. The linear relationship will enable easier and faster assessment of the concentration of common carp sperm in the future which will be useful for further research and even for breeding process.

Introduction

Coral reefs have a substantial social, economic and environmental value (Birkland, 2015). However, climate change and the degradation of the environment, due to pollution and other anthropogenic pressures, are seriously threatening these ecosystems. In the last years, the rising interest on corals for ornamental aquaria, pharmaceutical or biotechnological purposes are placing additional pressure on wild reefs. Coral aquaculture is raising as a sustainable solution to avoid harvesting of wild populations and to assist in the process of reef restoration. However, the rearing of corals brings in numerous challenges to optimize production and maintain (or even increase) corals' performance and appearance. The presence of microplastics (synthetic polymers with size < 5mm) in coral farms is a real threat since *in situ* facilities may be contaminated with microplastics present in seawater and *ex situ* farms, even operating with synthetic seawater, mostly rely on plastic material that likely undergo processes of fragmentation and deterioration over time (Lusher et al., 2017). Nevertheless, studies on the potential adverse effects of microplastics on corals and other ornamental organisms remain scarce. That said, this study wanted to evaluate the effects of two important polymers used in aquaculture facilities (low density polyethylene – LDPE, and polyvinyl chloride – PVC) in zoanthids, considering relevant concentrations in natural (Cheang et al., 2018) and aquaculture (Lusher et al., 2017) environments. For that, ingestion and epidermal adherence of microplastics, photobiological and biochemical biomarkers related with oxidative stress were evaluate.

Material and methods

Zoathus sociatus (Anthozoa: Hexacorallia) was selected as test species due to their farming plasticity, endosymbiosis with zooxanthellae, and quick regeneration. Two commercially available polymer type (LDPE, PVC – irregularly shaped, size between 63-125 µm) and two concentrations (1 and 10 mgL^{-1}; corresponding to ~0.5 x 10^5 - 4 x 10^5 LDPE or ~0.7 x 10^5 - 1.5 x 10^5 PVC) were used, resulting in a total of four treatments plus a control, in triplicate. Each replicate consisted of five colonies of three polyps distributed centrally (to receive the same light intensity) in glass aquaria containing 38 L of synthetic seawater. The test endured 96h at 25 ºC, pH~8, salinity 35, with no food supply. The evaluated endpoints included the ingestion and epidermis-adhesion of microplastics, initial (T_0) and final (T_{96h}) maximum photosynthetic efficienc (chlorophyll *a* fluorescence - Fv/Fm), oxidative damage (LPO – lipid peroxidation), antioxidant and detoxification capacities (Catalase activity – CAT; glutathione S-transferase - GST), and energy consumption (via electron transfer system – ETS).

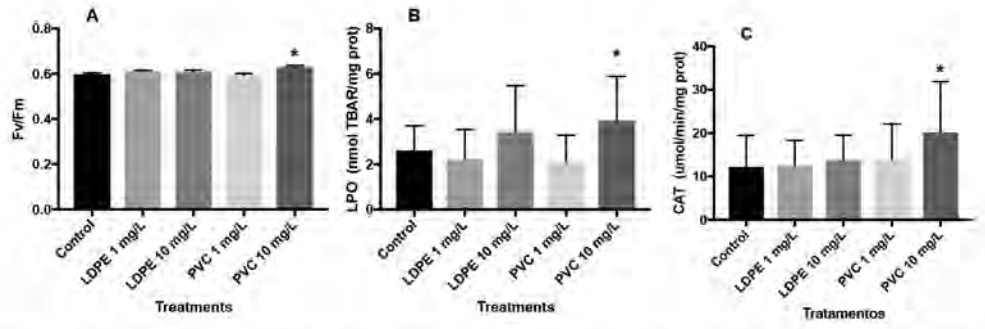

Figure 1: Effect of short-term exposure (96h) to 1 and 10 mgL^{-1} of low-density polyethylene (LDPE) or polyvinyl chloride (PVC) in the photochemical efficiency (A), lipid peroxidation (LPO – B) and catalase (CAT) activity (C) of *Zoathus sociatus*.

(Continued on next page)

Results

Zoathus sociatus polyps were able to ingest few particles of LDPE and PVC microplastics, independently of the tested concentrations and polymer type (nr. of particles up to 5). The number of microplastics adhered to the skin was dose- and polymer- dependent (nr. particles up to 85). Significant effects at photobiological and biochemical levels were only observed for the highest tested concentration of PVC microplastics (Figure 1). A 96h exposure to 10 mgL^{-1} caused a significant increase in the maximum photosynthetic efficiency (Fv/Fm; Figure 1A), induced oxidative damage (LPO; Figure 1B) and increased antioxidant defenses (CAT; Figure 1C). Yet, there were no effects in terms of energy consumption (via ETS) and detoxification capacity (via GST).

Discussion and conclusion

Short-term exposure to environmental-relevant concentrations of LDPE microplastics did not alter photochemical efficiency or induce oxidative stress or damage in *Z. sociatus*. Conversely, the presence of 10 mgL^{-1} of PVC microplastics caused a significant increase on the photochemical efficienc , probably related with the adhesion of a high number of particles to the zoanthids' epidermis (characterized by the presence of a surface mucus layer), which likely blocked some of the light that would otherwise reach the endosymbiotic zooxanthellae, as also observed in scleractinian corals (Polystyrene, 50 mgL^{-1}, Tang et al., 2018). Zoanthids exposed to PVC revealed a higher number of microplastics adhered to their epidermis compared with the similar concentration of its less dense counterpart (LDPE microplastics), which likely explains the lower effects in the latter. In addition, at 10 mgL^{-1} of microplastics, a significant lipid damage (i.e. lipid peroxidation) and increased catalase activity was observed once more for PVC, suggesting an increment of the reactive oxygen species (ROS) in the corals caused by such particle. Such ROS increment could result from direct effects, such as the ingestion followed by an alteration in the digestion processes or by an induced inflammatory response. However, due to the differences between both polymers, such results may be due to indirect effects such as the PVC polymer surface chemistry or due to the presence of potential PVC plasticizers (e.g. phatalates) that could have leachate during exposure. Although our results provide the first evidence for the potential short-term effects of realistic concentrations of microplastics (particularly PVC) in aquaculture facilities or even in the ocean to *Z. sociatus* populations (or potentially other corals), it is of extreme importance to investigate such scenarios in long-term exposure.

Monitoring the health status of aquatic ecosystems is of crucial importance in a context of sustainable development of aquaculture activities. Different groups of organisms sensitive to changes in their surroundings are used as bio-indicators for monitoring environmental impacts. However, their morphological identification requires a lot of time and expertise. The metagenomics makes it possible to quickly and accurately describe the biological communities inhabiting an environment. However, a large proportion of the metagenomic data cannot be used to conduct large-scale environmental health diagnoses because many DNA sequences are not referenced in existing databases.

Here, we present a new innovative approach that combined metagenomics and automatic learning tools to assess the environmental impact of marine aquaculture. Our tool was developed for benthic monitoring of salmon farming in Norway, but it can be applied to any kind of finfis farms biomonitoring worldwide. It consists in predicting ecological status from metagenomic data using artificial intelligence tools, such as machine learning. Comparing to conventional methods, our approach allows (1) improving sensitivity of bioassessments by expanding the range of potential bioindicators, (2) enabling wider and more frequent applications by reducing the costs and time of analyses, and (3) limiting the uncertainties by standardizing protocols for genomic data acquisition and analysis. Based on cutting-edge technological and analytical advances, this new approach significantly increases the observation capacity of ecological impacts associated with finfis farming, offering a very efficient tool for future routine biomonitoring programs

The EU project CERES (Climate change and European aquatic RESources, www.ceresproject.eu) is designed to advance a cause-and-effect understanding of how climate change (CC) will influence Europe's most important fish and shellfish resources and the economic activities that depend on them. Integrating physical, biological, economic and social science, the project highlights both the risks as well as the opportunities of CC to the European aquaculture and fisheries sectors. The role of aquaculture in supplying fish and shellfish for human consumption is projected to continue growing in the future. Understanding and potentially mitigating the effects of CC on aquaculture will be critical to ensuring the sustainable growth of this industry to maintain global food security. We summarize i) the socio-political scenarios developed for the European aquaculture industry, ii) work being conducted on both the direct (physical to physiology) and indirect (disease to food-web) effects of CC on Europe's seven most valuable aquaculture targets, and iii) the CERES approach to quantifying climate vulnerability through the exposure and sensitivity of aquaculture key targets and adaptive capacity of production systems.

The CERES Work is focused on the most valuable European finfis and shellfish to the aquaculture sector (Atlantic salmon, trout, sea bass, sea bream, carp, mussels, oysters and clams). We focus on species/production types which offer logical contrasts in the projected vulnerability and opportunities of CC in terms of coastal shellfish and finfis farms (e.g. in southern versus northern European waters and in fresh versus marine waters). Special emphasis in this presentation is on our efforts to rank the vulnerability of species / production types across European waters. Our vulnerability ranking is based on projected changes in 2050 in the exposure to abiotic stressors (e.g. higher temperature, lower dissolved oxygen, decreased rainfall, increased storminess) as well as the sensitivity of specific species (e.g. physiological tolerance) and results of a GAP analysis of the direct effects of CC. Indirect effects of CC such as the risks of specific diseases are also included. Adaptive capacity is also discussed in terms of stakeholder perceptions of available mitigation measures to help prevent unwanted consequences of climate change and the likelihood that those measures are adopted.

INNATE IMMUNE STATUS AND OXIDATIVE STRESS IN SENEGALESE SOLE (*Solea senegalensis*) POST-LARVAE FED MICRODIETS WITH NANNOCHLOROPSIS OR ISOCHRYSIS INCLUSION

Introduction

Senegalese sole (*Solea senegalensis*) is a highly valuable flatfis species targeted for aquaculture in Southern-European countries. This species, as most farmed fish, is potentially subjected to stress and pathogens due to environmental factors. Now, more than ever, the industry and science have focused their attention on the development of diets that promote the welfare and health of farmed fish, as well the fish final quality. Microalgae has been included in diets for farmed aquatic animals due to their antioxidant capacity, high-quality protein content and bioactive compounds, promoting an optimal growth and health. For these reasons, this study intended to evaluate the effects of dietary microalgae inclusion in both health status and growth performance of Senegalese sole post-larvae.

Materials and methods

Senegalese sole post-larvae with 34 days after hatching (DAH) were randomly distributed by 9 tanks with an initial density of 2650 post-larvae/m^2 and three isonitrogenous (60% crude protein) and isolipidic (17% crude lipids) diets were randomly distributed by triplicate groups of tanks. The experimental diets comprised a control (CTRL) diet based in marine protein sources (i.e. fish meal, squid meal and krill meal) and 3 % of cellulose fille , whereas two other diets were based on the control diet but replaced cellulose by 3 % *Isochrysis galbana* (ISO) or *Nannochloropsis sp.* (NANO). The experimental diets were supplied through automatic feeders set up to supply 8 meals in a 24 h period. At 45 and 65 DAH, 30 post-larvae/ tank were sampled for analyses of parameters related health status. The total length, dry weight, feed conversion ratio, relative growth rate and survival were also assessed.

Homogenates of 10 individuals were performed for the analyses of immune (i.e. lysozyme and bactericidal activities) and oxidative stress (i.e. catalase, total glutathione, lipid peroxidation and superoxide dismutase activities) related parameters.

Results

Survival, relative growth rate and feed conversion ratio were not altered by the dietary treatments at 65 DAH. However, post-larvae fed ISO presented lower dry weight compared to the other dietary treatments whereas the total length of post-larvae fed NANO dietary treatment increased compared to those fed the ISO diet.

Regarding immune status, it was observed a decrease in lysozyme levels and bactericidal activity against *T. maritimum* of whole post-larvae from 45 DAH to 65 DAH. However, Senegalese post-larvae fed NANO showed a clear tendency to increase lysozyme activity at 45 DAH. Similar to parameters related to immune status, catalase and total glutathione activities decreased from 45 to 65 DAH in whole post-larvae, whereas the opposite trend was observed for superoxide dismutase activity. Total glutathione activity decreased in post-larvae fed NANO dietary treatment at 45 DAH. However, a drop in this antioxidant tripeptide did not translate in differences regarding lipids peroxidation, which was similar among experimental groups and sampling times.

(Continued on next page)

Discussion and conclusion

Results from the present study seem to be in line to the widely known recognition of microalgae in terms of antioxidant capacity and growth promotion, which usually translates into a good welfare of farmed fish. Senegalese sole post-larvae fed experimental dietary treatments presented normal ranges for growth performance and survival. Moreover, fish fed NANO dietary treatment seem to improve their immune status at 45 DAH while maintaining an excellent growth performance and survival. According to these results, *Nannochloropsis sp.* Seems to be a promising candidate for inclusion in microdiets for Senegalese sole post-larvae.

Introduction
To maximize productivity, sustainability and fish welfare of Mediterranean aquaculture, research needs to focus on interaction between feeding and rearing condition, paving the way to a wise fish farming management. To this aim, the present study explored the effect of high and low rearing density on growth, plasma biochemistry, gut microbiome structure, humoral immunity of skin mucus and digestive enzymes activity in gilthead sea bream (*Sparus aurata*) fed low and high fishmeal (FM) and fish oil (FO) dietary leve

Materials and methods
Two isoenergetic diets with high and low FM and FO percentages, (FMFO30/15 and FMFO10/3, respectively) were tested in triplicated fish groups until reaching a final high density (HD 30kg/m^3) and low density (LD 10kg/m^3). Fish (initial body weight: 96.2g) were fed to satiation twice a day (10% overfeeding) over 97 days. At the end of the trial, growth performances, feed utilization and carcass composition were estimated. The activity of pancreatic and intestinal brush border digestive enzyme extracts (3 fish per tank) was determined as in Gisbert et al. (2018); while microbiome structure (5 fish per tank) was analysed by Next Generation Sequencing as described in Parma et al. (2016). Skin mucus (8 fish per tank) and plasma biochemistry (5 fish per tank) were analysed according to Guardiola et al. (2014) and Bonvini et al. (2018) respectively. All gained data were analysed by Two-way ANOVA followed by a Tukey's multiple comparison test. Differences among treatments were considered significant when value was lower than 0.05.

Results
No significant effect on growth (final body weight FBW, weight gain and specific growth rate SGR) were detected between high and low rearing density for both dietary treatment while fish fed FMFO30/15 displayed higher FBW, weight gain and SGR compared to FMFO10/3. Feed intake (FI) was lower in HD compared to LD (density effect P = 0.002) with more marked differences in FMFO30/15 than FMFO10/3. No significant diet effect on FI was detected. No significant effect of density on FCR was detected. Survival rate was lower at LD. No significant effect of density on skin mucus peroxidase and protease levels were found in FMFO10/3 individuals. Concerning pancreatic enzymes activity, trypsin was higher in fish fed FMFO30/15, while lipase had the opposite reaction. Activity of pepsin was significantly influenced by density which interacted with diet as well, while chymotrypsin was influenced only by density. Alkaline phosphatase and aminopeptidase in the anterior intestine brush border were reduced in FMFO10/3 compared to FMFO30/15, while maltase was lower only in FMFO10/3 reared at HD. The posterior intestine brush border alkaline phosphatase and maltase were negatively affected by FMFO10/3 while leucine alanine peptidase (LAP) was reduced at HD. Density had no significant effect on parameters analysed in plasma, while diet influenced total protein, urea and creatinine levels.

Discussion and conclusion
Rearing density did not show negative impact on growth and feed utilization at both high and low FM and FO dietary level. Similarly, density did not affect digestion condition except for trypsin, pepsin, chymotrypsin, maltase and LAP. At the end of the trial high density did not compromise fish welfare in terms of mucus enzymatic activity and plasma biochemistry. Though high vegetal dietary levels reduced growth efficienc , stocking density up to 30kg/m^3 did not show negative effects on performances, digestive capacity and animal welfare at both feed regimes. Moreover, the absence of feed intake differences between high and low density at high vegetal dietary concentration could indicate a reduced competitiveness among fish under these feeding regimes. At the light of this study, at both considered FM and FO dietary levels, fish can be reared at both 10 and 30kg/m^3 without compromising performance and health status.

Introduction

SNP arrays are enabling tools for high-resolution studies of the genetic basis of complex traits, and for incorporating genetic markers to expedite genetic gain in selective breeding programmes (Huang *et al.*, 2015). The European sea bass (*Dicentrarchus labrax*) and the gilthead sea bream (*Spaurus aurata*) are the two primary species of importance for Mediterranean aquaculture. While selective breeding programmes increasingly underpin stocky supply for this industry (Janssen *et al.*, 2015), genomic selection is not yet widespread. Genomic selection has major potential to expedite genetic gain, in particular for traits practically impossible to measure on selection candidates, such as disease resistance. Commercial-scale application of genomic selection requires relatively low-cost genome-wide genotyping platforms. Combining SNPs derived from two species onto a single SNP array can significant y reduce genotyping costs when ordering higher volumes, which would facilitate the uptake of the technology by the industry and researchers. The aim of our study was to design a combined-species, 70K SNP array for sea bass and sea bream, and to test its performance on farmed and wild populations from multiple locations throughout the Mediterranean.

Materials and Methods

For the purpose of generating a combined SNP array with extensive application, widespread sampling of both wild and farmed populations from the Mediterranean was carried out (21 populations of sea bass and 27 populations of sea bream). In total, over 500 individuals per fish species were sampled for SN discovery.

A pooled whole-genome resequencing (Pool-seq) approach was followed to maximize the number of variants detected in a cost-effective manner. DNA was extracted from ~25 individuals per population and combined in two duplicate pools. Library pools were prepared using a PCR-free protocol and sequenced using an Illumina HiSeq X (for sea bream) or Illumina HiSeq 4000 (for sea bass) technology at a minimum coverage of 50x per pool. The obtained raw sequencing reads were quality filtered and trimmed to remove adapter sequences. Cleaned paired-end reads were aligned to the European sea bass (Tine *et al.*, 2014) and the gilthead sea bream (Pauletto *et al.*, 2018)2018 genomes using BWA (Li and Durbin, 2009) England. Only uniquely mapped reads that had a MAPQ>20 were kept for analysis. Variants were called from the pools with the software Freebayes v1.20 (Garrison and Marth, 2012) if (i) at least three reads supported the alternate allele or (ii) the SNP allele frequency in the pool was above 0.05, whichever condition was met first.

From this initial list of variants, SNPs were kept if they had: a sequence coverage between 40x-100x, supporting reads on both strands, at least two reads “balanced” to each side of the variant site, and >90% of the observed/alternate alleles supported by properly paired reads. Additional filters were applied to the dataset based on SNP minor allele frequencies (MAF). SNPs with a MAF >0.45 or MAF <0.05 were removed, as they likely represent artefacts. Finally, evenly distributed SNPs were selected along the chromosomes of both sea bass and sea bream. A subset of high priority markers (e.g. SNPs annotated to genes) will be selected as candidates for inclusion in the combined-species, 70K SNP array.

(Continued on next page)

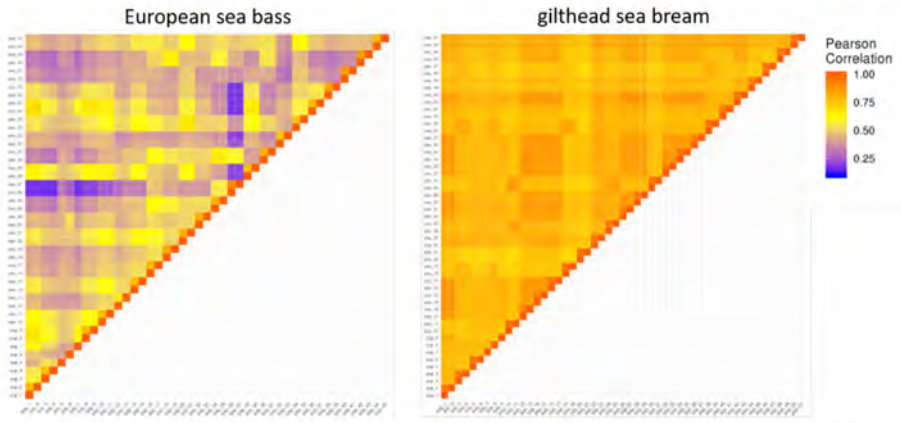

Figure 1. Pairwise correlation values of the MAFs of SNPs discovered on the sea bass and sea bream

Results and Discussion

The pooled sequencing of the diverse Mediterranean populations resulted in the discovery of 17 million SNPs for the European sea bass and 34 million SNPs in the gilthead sea bream genome.

In a preliminary analysis, Pearson correlation coefficients were calculated for the MAF of SNPs for all pairs of sea bream and sea bass populations. The results show a high correlation between technical replicates, as expected. Additionally, a higher structure was observed for the sea bass samples compared to the sea bream populations (Figure 1).

The discovered SNPs will be filtered to approximately 70K SNPs which will be used in the final combined species SNP array design. The newly developed SNP array will then be used to genotype a diverse set of wild and farmed sea bass and sea bream populations to assess its performance.

MICROALGAL MIXOTROPHY AS A SOURCE OF FEED FOR *Mytilus edulis* LARVAE

J. Penhaul Smith[1*], C. Beveridge[1], L. McEvoy[2], AD. Hughes[1], JG. Day[1]

[1]Scottish Association for Marine Science, Oban, Argyll, PA37 1QA, UK
[2]NAFC Marine Centre, Port Arthur, Scalloway, ZE1 0UN, UK
Corresponding author: Joe.penhaul-smith@sams.ac.uk

Mytilus edulis aquaculture represents an important section of the UK and EU economies. Current production mechanisms rely on the supply of wild larvae to be settled upon longlines and subsequently on-grown. This leaves larval collect and production of adult blue mussels reliant upon larval supply and so is one of a number of limiting factors in upscaling production. In Scotland 7000 tonnes of mussels were produced in 2015 and mussel growers aim to double production by 2020. To do so, the limiting factor of larval supply must be overcome. One method of doing this is the creation of a *M. edulis* larval hatchery. The costs associated with microalgal culture, for use as feed, in a larval hatchery are currently around 40% of total costs. As a result the creation of a larval hatchery is not economically viable (Hickman, 1992). This is due to the requirement for live microalgae, mussel larvae do not feed on dead cells. This study aims to address this limiting factor through use of mixotrophically cultured microalgae as a feed source.

Microalgae are classically considered to be photoautotrophic and are cultured in the light, in seawater with additional nitrate and phosphate. Mixotrophy is the ability of a microalga to uptake organic nutrients, such as carbon or nitrogen, in addition to, or as an alternative to, photoautotrophic fixation of carbon. This ability to be cultured mixotrophically is considered to be ubiquitous in the marine environment (Borowitzka, 2013) and has a number of advantages. Mixotrophic culture often results in greater cell numbers and dry weight, as well as an increased culture stability (Morales-Sánchez & Martinez-Rodriguez, 2015). Furthermore, dependent upon the method of culture and the carbon source utilised, the biochemical profile can be tailored to create a "designer" feed.

Over the course of three feeding trials this study takes current "industry standard" microalgal species and compares larval growth and survival to mixotrophic "designer" microalgal feeds, then subsequently optimises the diet used. The "designer" feed can be considered to be as effective as the standard benchmark feed and subsequent optimisation shows that a diet that is tailored towards the development performs the most effectively in terms of larval growth. Mixotrophic culture requires an additional organic carbon source which has a significant cost implication. Therefore using first order modelling, the economics of use of mixotrophy as an alternative to photoautotrophic culture reveals a more complex picture in terms of the optimal methods of culture. Culture optimization, a move to semi-continuous culture and alternative, low cost carbon sources potentially reveal a way forwards.

Introduction

Consumers increasingly show interest in a shift from synthetic to natural antioxidants in their food. Annual production of plants and aromatic herbs has passed 600 million tonnes per year, generating a high amount of by-products that are mostly wasted. But such discarded by-products can still be valuable source of nutrients, antioxidants and bioactive compounds that may have a positive effect on fish health and flesh quality traits. This study evaluates the potential of vegetable by-products in diets for European seabass (*Dicentrarchus labrax*). The effects of such natural antioxidants on immune system, fish growth, and fillet quality traits were evaluated.

Material and methods

Five isoproteic and isolipidic experimental diets were formulated. A commercial-based diet supplemented with a regular dose of vitamin E (100 mg/kg) was used as negative control (CTRL) and compared with a diet with a higher dose of vitamin-E (500 mg/kg) as positive control (VITE). Dried biomass from two fresh legumes and one aromatic herb (carrot, tomato and coriander, respectively) were added to the control diet at 2% resulting in three experimental diets: carrot (CA), tomato (TO) and coriander (CO). Experimental diets were fed to triplicate groups of European sea bass (initial body weight 114 ± 0.2 g) during 85 days, twice a day until apparent satiety. At the end of the trial (Day 0), growth performance, body composition, immune status and flesh quality traits (instrumental and sensory consumer panel) were evaluated. Catalase activity, total glutathione content and lipid peroxidation (TBARS) were determined as indicators of the liver oxidative stress. Fillet flesh quality traits were evaluated in terms of lipid peroxidation, muscle and skin colour, and flesh texture immediately after sampling the fish (Day 0) and after storing the whole fish in ice for 8 days (Day 8). Fish from day 0 were evaluated by a sensory consumer panel of 60 naïve consumers in order to assess the sensorial properties of fillets, using a classic 9-point hedonic scale (like extremely-dislike extremely).

Results and discussion

All diets were well accepted by fish that doubled their initial size reaching a final body weight between 237 and 248 g without significant differences among treatments. The specific growth rate (0.89 ± 0.06), feed conversion ratio (1.3) and whole body composition of fish remained unaffected by the experimental diets. Tissue lipid level was similar among diets, but the viscerosomatic index (VSI) of fish fed TO was significantly higher than those fed the CO diet (7.1 vs 5.7). Innate immune status of fish, determined by plasma lysozyme, peroxidase and ACH50 activities, as well as the adaptive immunity evaluated by total immunoglobulin M (IgM) content, were not significantly affected by the diets. Likewise, total red and white blood cell number, haematocrit and haemoglobin concentration were similar among treatments.

The antiperoxidative activity of catalase in the liver did not differ among treatments, but total glutathione levels were significantly higher in CTRL compared to CA fed fish. Moreover, fish fed the TO diet displayed significantly higher rates of lipid peroxidation in the liver than those fed the positive control (VITE). But the muscle lipid peroxidation was similar among all fish, irrespectively of the experimental diet or the storage time.

The experimental diets did not affect skin color. However, muscle color showed a significantly higher yellowness (b*) in fish from CTRL compared to those fed with TO, CA and CO. Muscle chroma (C*) values were significantly higher in CTRL, compared to CO, but hue angle (h*) was significantly lower in CTRL, in comparison to CA. Storage time impacted both skin and muscle colour: b* and C* significantly decreased in both tissues whereas h* increased. In muscle there was also an increase in the lightness (L*) values after 8 days of storage in ice.

(Continued on next page)

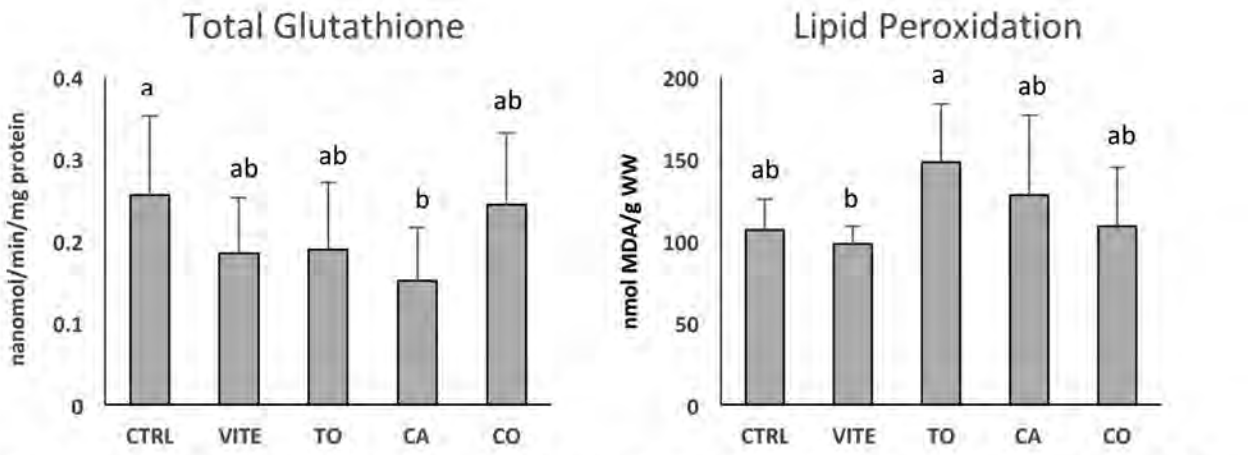

Figure 1 – Total glutathione (nmol/min/mg protein) and lipid peroxidation (TBARS, nmol MDA/g) in *D. labrax* liver after sampling (Day 0). Different letters indicate statistical differences ($P < 0.05$). Values are presented as mean ± SD. N= 12 per dietary treatment.

The fillets from fish fed CO showed significantly higher gumminess values compared to those fed TO. Storage in ice significantly affected all textural parameters: a decrease in hardness, adhesiveness, cohesiveness, gumminess and chewiness was observed whereas springiness and resilience increased. However, by the end of the experiment, the sensory consumer panel could not perceive any significant differences in fillets overall liking, as all samples were positively evaluated in terms of visual attractiveness, odour, texture, taste, juiciness and colour.

Conclusions

The natural antioxidants evaluated in this study did not affect European sea bass growth performance, immunological status or muscle lipid peroxidation, even though liver oxidative stress seems to be affected with higher lipid peroxidation caused by TO conversely to an antioxidant effect (i.e. increase of glutathione concentration) caused by CA. The supplementation of diets with a higher vitamin E level (500 mg/kg) does not seem to have any impact on the parameters evaluated. The sensory consumer panel could not perceive significant differences in global acceptance of fillets among dietary treatments.

sinem.zeytin@awi.de

Introduction

In the CAMAFAN project (Characterization and industrial Application of Marennine as Aquaculture Feed Additive and Nutraceuticals), we are focusing on developing industrial application of the marine diatom *Haslea ostrearia* and maximizing its blue-green pigment marennine for possible uses in aquaculture. This blue-green pigment is divided in two forms: the intracellular mareninne (IMn) and the extracellular mareninne (EMn) (Neuville and Daste, 1978). Apart from the widely known colouring capabilities, recent research has shown that this pigment has antibacterial, antiviral, antiproliferative and antioxidant (Pouvreau et. al., 2018) properties as well. Considering the optimization of the culturing protocols of *Haslea ostrearia* for marennine production, we conducted series of experiments focusing on important parameters e.g. light spectra, nutrients N:P ratio, photoperiod and salinity. These parameters have great influence and impact on the overall yield of this blue-green pigment production. By achieving these improvements, we have been producing blue water (culture medium enriched with EMn) to be applied on some parallel experiments that test the applicability of the pigment in improving health and overall quality of marine aquaculture species. In addition, no information in literature about the process of maintenance and storage of marennine has been found. Thus, a new set of experiments are currently in progress to identify the best/right conditions for marennine to be stored for long-term without any loss of concentration, quality or biological effect.

Material and methods

We have grown *H. ostrearia* cultures using North Sea water F/2 medium in a total volume of 2000 mL per flask, in a climate-controlled room at 18°C with aeration and CO_2 supply to maintain pH between 7.8 and 8.2. The photoperiod was kept at 16:8 light/dark. The different light treatments were obtained by using LED lights of different spectra, warm light with emission peaks of 450 nm and around 600 nm, and blue LED with emission peak around 450 nm. We choose blue and warm light based on literature on the effect of different light spectra on *Haslea* and based on our experience. Apart from spectra, we also tested intensity, from 80 to 200 µmol photons*m^{-2}*s^{-1}. Additionally, we have tested different light/dark photoperiods to determine their impact on marennine production. To test the effect of different salinities, we prepared North Sea water F/2 media with different degrees of salinity: 15, 20, 25 and 28 psu. The influence of light quality on marennine production by cultures of *H. ostrearia* was investigated in the laboratory. In the first series of experiments in the laboratory, a clone of *H. ostrearia* was cultured under light of different colors (white, blue, green, yellow, and red) and at two irradiances ('low' and 'high', 20 and 100 µmol photons m^{-2} s^{-1}, respectively).

Results

We have identified that marennine production is increased when using white LED's at 200 *µmol* m^{-2} s^{-1} (when compared with lower intensity blue or white light) (Figure 1). The effect of photoperiod in the production of the blue-green pigment indicated that its concentration is higher in groups cultured under 12/12 light/dark conditions then 18/6 and 20/4 light/dark treatments (Figure 2). There were noticeable separations in terms of marennine concentration between 18/6, 20/4 and 12/12 already after 10 days of cultivation period. Results in experiments on oysters and storage availability of marennine are still pending. Our expectation is that the process of maintenance and storage of mareninne being currently developed will be implemented as a new and standardized method in industry.

Discussion and conclusion

It should be possible to scale-up these positive findings to the industrial scale for indoor marennine production. We aim to present the preliminary data of this set of experiments at the conference where the best set of parameters to obtain the most efficiency production of marennine from *H. ostrearia* as well as the effects of this molecule on oyster health, growth and in the process of maintenance and storage.

Introduction

Marine algae are natural sources of several bioactive molecules that can have health promoting benefits. Both macro and microalgae have demonstrated high potential in stimulating antioxidant defences, and can also have an immune-modulatory effect on fish. The aqua feed industry can take advantage of such properties of marine algae potentially improving the defences of farmed fish against reactive oxygen species (ROS) and consequentially preventing the occurrence of peroxidative damage. This study selected one microalgae (*Nannochloropsis sp*.), one macroalgae (*Gracilaria sp.)* and a blend of both to include in diets for European sea bass (*Dicentrarchus labrax*) juveniles.

Materials and methods

Three practical isoproteic (53%) and isoenergetic (22 kJ/g) experimental diets were formulated with 8 % *Gracilaria sp.* (GRA), 8% *Nannochloropsis sp.* (NAN) and a blend of 4% *Gracilaria sp.* and 4% *Nannochloropsis sp.* (NANGRA) to partially replace fish meal. An algae-free diet was used as control (CTRL). Extruded diets were fed to triplicate groups of European sea bass (initial body weight 29.7 ± 3.5 g) during 140 days, three times a day until apparent satiety. At the end of the trial, growth performance and feed efficiency were evaluated. Humoral non-specific immune parameters (lysozyme, peroxidase and the alternative complement pathway (ACH50) activity and antiperoxidative activities (catalase, glutathione-peroxidase and glutathione S-transferase activities) were determined in liver. In terms of non-enzymatic parameters, total glutathione content, as well as lipid peroxidation using the TBARS method for malondialdehyde (MDA) formation were also measured in liver.

Results

By the end of the experiment, fish tripled their initial size, reaching a final body weight between 78 and 81g, without significant differences among treatments. Specific growth rate (0.9) and feed conversion ratio (1.6) remained unaffected by the experimental diets. The viscerosomatic index did not vary among treatments, but the hepatosomatic index of fish fed the CTRL diet was significantly higher compared to those fed the GR diet.

Humoral lysozyme and peroxidase activities did not show significant differences among dietary treatments, but the ACH50 activity was significantly lower in fish fed NANG compared to those fed the CTRL diet.

Catalase and glutathione s-transferase activities in the liver did not vary among treatments. Glutathione-peroxidase was significantly lower in fish fed NANGRA compared to those either fed the CTRL or GRA diets, whereas total glutathione content was significantly lower in fish fed NANGRA than in those fed the CTRL. Liver lipid peroxidation values were significantly higher in fish fed NAN when compared to those fed the CT (Figure 1).

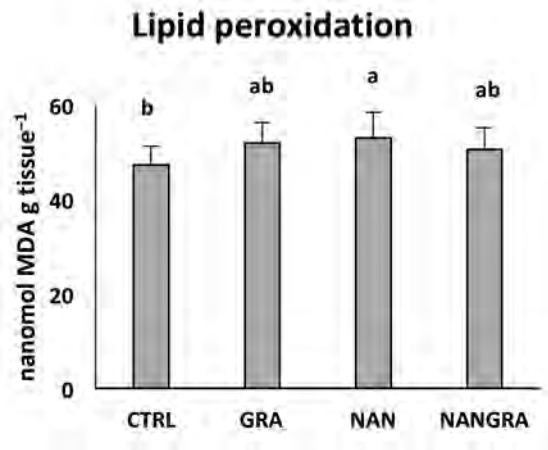

Figure 1 - Values are means + standard deviation: n = 12. Means in columns without a common superscript letter differ significantly (P<0.05).

(Continued on next page)

Conclusions

The experimental diets evaluated in this study did not affect fish growth or feeding efficienc , so both algae can be considered good alternative sources to fish meal in diets for European sea bass. Results from ACH50 showed that fish fed with the NANGRA displayed significantly lower values when compared to those fed with CTRL. This result suggests that this blend of algae may have provided antibacterial protection, but this will require further confirmation by submitting fish to a challenge trial.

The NANGRA diet induced both significantly lower glutathione content and glutathione peroxidase activity compared to the CTRL diet, but did not result in any differences in fish lipid peroxidation

Glutathione peroxidase acts in association with total glutathione and catalyses the conversion of hydrogen peroxide, therefore avoiding lipid peroxidation. The obtained results suggest that the antioxidants provided by the dietary algae blend seem to lessen the need for endogenous biosynthesis of glutathione and glutathione peroxidase. In terms of future perspectives, a growth trial with a pro-oxidant and/or bacterial challenge might provide further insight on the beneficial properties of the selected algae in European sea bass diets.

Introduction

High substitution of fish oil (FO) by vegetable oils (VO) in aquafeeds is still a challenge for marine fish. VOs have low content of *n-3* LC-PUFA such as EPA and DHA, and instead, they are rich in fatty acids (FA) such as ALA and LA. High VO feeding leads to increased hepatic fat accumulation in gilthead sea bream (*Sparus aurata*) and other fish species, increasing the risk of steatosis. Different studies in fish have provided evidence of the effect of broodstock nutrition on the lipid metabolism of the progeny (e.g., Izquierdo et al., 2015; Turkmen et al., 2017). In higher vertebrates, enriching maternal diet with ALA prevented fatty liver in the offspring (Hollander et al., 2014) by decreasing both SCD1 and FADS2 gene expression (Leikin-Frenkel et al., 2017). We used a 'control' and an 'ALA-rich' diet to study the effect of parent's nutrition on the promoter methylation and gene expression of *fads2* and *scd1a* in *S. aurata* offspring.

Materials and Methods

Two broodstock diets were used with a similar composition but a 19-fold difference in ALA content. ARA, EPA and DHA were kept similar to avoid confounding effects. The diet for juvenile offspring was a low FM (5%) and low FO (3%) diet. The genomic database of gilthead sea bream (http://nutrigroup-iats.org/seabreamdb) was used to obtain the gene sequences of *fads2* and *scd1a*. *In silico* analysis included predictions for gene structure, core promoter, transcription factor binding sites (TFBS), and CpG islands. DNA methylation was examined by bisulfite conversion and pyrosequencing. The pattern of CpG methylation of the *fads2* promoter was confirmed in a group of fish subjected to normoxia or moderate hypoxia. Gene expression was assessed by qPCR.

Results

The gene organization of *fads2* and *scd1a* was conserved respect to other vertebrates. Key TFBS were conserved in proximal promoters of both genes, including PUFA response regions. Methylation within key TFBS in *fads2* proximal promoter were unaffected by parent's diet or oxygen availability. CpGs within a regulatory SREBP site were particularly hypomethylated. Conversely, ALA enrichment of parent's diet increased methylation in the distal promoter of *scd1a*, mainly in CpGs associated with specificity protein 1 (SP1) and hepatic nuclear factor-4alpha (HNF4α) binding sites. DNA methylation at these sites (mostly CpG7) correlated inversely with *scd1a* expression of the offspring (Fig. 1). Liver fat content suggested that this might favor less fat storage in offspring. This would be more important under lipogenic conditions, as we found that the highest transcriptional response occurred for *scd1a* when fis fed on deficient or low n-3 LC-PUFA diets, exhibiting signs of hepatic fat accumulation.

Discussion and conclusions

CpG sites at regulatory regions in the proximal promoter of *fads2* are insensitive to the ALA content of parent's diet in 7 months old juveniles if nutritionally challenged with a low *n-3* LC-PUFA diet. Conversely, methylation of different CpGs, neighboring key regulatory sites (SP1 and HNF4α) of the *scd1a* promoter, is susceptible to ALA enrichment of parent's diet and correlates with offspring *scd1a* gene expression. These TFs have been related in other animals with SCD1 regulation (Mar-Heyming et al., 2008; Mauvoisin et al., 2010). These epigenetic changes may favor a more controlled upregulation of *scd1a*, and ameliorate hepatic fat accumulation, in fish fed with high levels of VO. This study provides the first evidence of epigenetic programing of a gene involved in lipid metabolism in a marine fish through broodstock nutrition. Further studies are needed to understand the true adaptive (or practical) value of *scd1a* epigenetic programing in marine fish

(Continued on next page)

THE EFFECT OF TOTAL REPLACEMENT OF FISH OIL WITH RAPESEED OIL ON GROWTH, BODY COMPOSITION AND GUT HEALTH OF JUVEILE LUMPFISH (*Cyclopterus lumpus*)

Florence Perera, Bjørn Grønevik, Mette Sørensen & Ørjan Hagen

Faculty of Biosciences and Aquaculture, Nord University, N-8049, Bodø, Norway
*E-mail: florence. .perera@nord.no

Introduction

Commercial production of lumpfish has grown rapidly since 2012 and has reached 30 million fish in 2017 (Norwegian Directorate of Fisheries, 2018), making lumpfish the second largest aquaculture species in Norway. The boost in lumpfish production is due to their grazing efficiency on sea lice at low temperatures (Nytrø et al. 2014) combined with a relatively uncomplicated and short production period. They are introduced to salmon farms already four months post hatching. However as a new species, the lumpfish farming industry is facing several knowledge gaps that need to be overcome. One of these areas that needs more focus includes the tolerance to plant feed ingredients. Hence, the present experiment aimed to investigate the lumpfish performance when they were fed rapeseed oil replacing 0 – 100% of the fish oi

Material and methods

Four iso-nitrogenous and iso-energetic diets were formulated to contain 54% crude protein and 13% crude lipid (on dry matter weight). The control diet and three experimental diets were based on soy and pea protein concentrate in 1:1 ratio replacing 50% of the fishmeal (FM) as the main protein source. Diets were varying only in their alternative lipid source, rapeseed oil (RO) replacing FO at 25% (RO25), 50% (RO50) and 100% (RO100). The experiment was carried out in triplicates at Mørkvedbukta research station, Nord University (Bodø, Norway) and juvenile lumpfish were obtained from a commercial hatchery (Mørkvedbukta AS, Norway). In August 2017 approximately 2400 of juveniles with a mean weight of 4 g were randomly allocate into twelve 500 L circular tanks with continues feeding and dimmed light setting according to best commercial practice. Biometrical data (weight, total length and height) of all fish was recorded at prior to and at the end of the experiment. In addition, samples for chemical composition (whole fish), fatty acids and gut histology was taken to study the dietary effects on growth, chemical profile and digestive health of the juvenile lumpfish

Results and Discussion

Body weight of fish increase of approximately six fold within 42 days and there was no mortality during the experimental period indicating that the fish were in good health. The overall growth was similar among groups, except for the fish that had been fed on RO100% that was significantly lower compared to other groups ($p<0.05$). Other Analysis mentioned are currently being carried out and will be presented.

AGE- AND SEASON-MEDIATED CHANGES IN DNA METHYLATION AND EXPRESSION PATTERNS OF SIRTUINS IN GILTHEAD SEA BREAM *Sparus aurata*

Paula Simó-Mirabet*, Erick Perera, Josep Alvar Calduch-Giner, Jaume Pérez-Sánchez

Nutrigenomics and Fish Growth Endocrinology Group, Institute of Aquaculture Torre de la Sal, IATS-CSIC, 12595 Ribera de Cabanes s/n, CastelloÏn, Spain
E-mail: paula.simo@csic.es

Introduction

Sirtuins (SIRTs) are a conserved family of enzymes that couple protein deacetylation of histone and non-histone substrates with the energy status of the cell via the cellular NAD^+/NADH ratio. This protein family has been largely conserved through evolution, and the SIRT counterparts of higher vertebrates have been identified and molecularly characterized in gilthead sea bream (Simó-Mirabet et al., 2017). Transcriptional studies have also revealed a ubiquitous *sirt* gene expression that is tissue-specific for each *sirt* and highly dependent on feed intake and growth potentiality (Simó-Mirabet et al., 2017, 2018). This agrees with an epigenetic role of SIRT related with developmental, differentiation and genome environment interactions. Nevertheless, there are few studies assessing the DNA methylation pattern of SIRT promoters, and the aim of this study was to determine if changes of *sirt* gene expression in liver and white skeletal muscle of one- and three-year old fish during winter and summer are due, at least in part, to changes in DNA methylation of *sirt* promoters. The study also included the gene expression profiling of markers of oxidative metabolism (*cs, cpt1a, pgc1a*) and mitochondrial respiration uncoupling (*ucp1, ucp3*).

Materials and methods

The exon-intron organization of the seven gilthead seabream *sirts* was determined by blat searches in our genomic gilthead sea bream database (http://nutrigroup-iats.org/seabreamdb). This i*n silico* analysis included predictions of transcription start sites (TSS), core promoter regions, transcription factor binding sites (TFBS) and CpG islands (CGIs). For transcriptional and DNA methylation assays, tissue portions of liver and white skeletal muscle were processed for RNA and DNA extraction in fish of two class of age (+1, +3) at two different times (winter, February 2018; summer, June 2018). DNA methylation was examined by bisulfite conversion and pyrosequencing of CGIs close to TSS of *sirt1* (22 CpG sites) and *sirt3* (4 CpG sites). Gene expression patterns of *sirt1-7* in addition to that of *cs*, *cpt1a, pgc1α*, *ucp1,* and *ucp3* were analyzed by a PCR-array designed for the simultaneous gene expression profiling of all genes in the analyzed tissues.

Results

The number and length of exons-introns are highly conserved for each *sirt* variant through the evolution, despite of the variable length of introns across species (humans/sea bream/zebrafish) (Fig. 1A). Clear CGIs were only found at the 5'-flanking region of *sirt1* and *sirt3* (Fig. 1B). The analyzed CpG sites of *sirt3* remained highly hypomethylated regardless of age, season and tissue. By contrast, the methylation level of the 22 analyzed CpG sites of *sirt1* varied with age in skeletal muscle. Thus, in comparison to age +3, young fish (+1) sampled in summer, but not in winter, showed a two-fold increase in the methylation level of CpG sites close to TSS, reaching values close to 4% in the first four CpG sites. This feature was accompanied by a decreased expression of *sirt1,* which reduced the difference of expression between fish of the age class +1 and +3 when comparisons are made in summer. This was especially evident at the position CpG3, as it was evidenced by correlation analysis of *sirt1* gene expression and methylation level (Pearson Correlation Coefficient = -0.7; P = 0.007) (Fig.1D). Intriguingly, skeletal muscle also appeared more responsive than liver to changes in *sirt* gene expression with a statistically significant interaction of age and season for *sirt1*, *4, 5* and *7*, which was extensive to *cs* and *cpt1a*. This was reinforced by discriminant analysis (PLS-DA), which identified *cs, cpt1a* and *ucp1* as the most important variable loads in liver, whereas *sirts* contribute to better discriminate the energy status of skeletal muscle.

Discussion and conclusions

The presence of CGIs close to TSS did not match well with the level of *sirt* gene expression (*sirt5*>*sirt2*>*sirt1*>*sirt 3/4/6/7*). However, the overall hypomethylation of *sirt1* and *sirt3* CGIs would provide a transcriptionally permissive state that ensures their basal expression in relation with their central role in mitochondrial and intermediary metabolism. Moreover, methylation changes at specific CpG positions of *sirt1* promoter were tissue-specific (e.g. skeletal muscle) in response to a particular energy situation (e.g. summer). These results corroborate the high value of *sirts* as energy sensors through life cycle. This is the first study analyzing the DNA methylation at CpG islands located at the promoter region of *sirts* genes in a marine fish, and provide new insights into *sirt* regulation as key markers of energy status.

DEVELOPMENT OF A LOW-POWER UNDERWATER RFID-ENABLED DATA ACQUISITION SYSTEM TO CLASSIFY FISH BEHAVIOUR

Caroline Peres*, Brendan O'Flynn

Tyndall National Institute, University College Cork, Cork, Ireland
E-mail: caroline.peres@tyndall.ie

Introduction

The need to maintain health and welfare of livestock is necessary to ensure seafood product quality, minimize the impact on the environment and optimize the production system. The most common method of measuring stress in fish – which is a common welfare indicator –is blood sampling (Huntingford et al. 2006). This can itself cause stress, altering the results of the measurements. This problem can potentially be solved by using biotelemetry: the remote measurement of physiological, behavioural and environmental variables (Cooke et al. 2004). This is accomplished by equipping the animal with an electronic tag which contains a sensor and a transmitter that sends the measurements wirelessly to a receiver for analysis.

Objective

This work proposes a system that combines Accelerometry and data analytics to measure and classify fish behaviour to identify stress. The miniaturized tag transmits back the measurements via magnetic induction, and could potentially be used with PIT tag readers to monitor and evaluate fish health continuously and in real time

Background

Behavioural parameters such as detailed activity, movement, locomotion, and body pose are usually measured with an Inertial Measurement Units (IMU), usually comprised of a tri-axial accelerometer, and optionally a magnetometer and a gyroscope (Brown et al. 2013). It can be used to classify animal behaviour and patterns (Shepard et al. 2008), such as fish swimming modes, feeding and escape behaviours, spawning, post-tagging and handling behaviours. It can also provide estimates of swimming speed, tail-beat frequency and size-at-age and energy expenditure (Broell 2016)”genre”:”Thesis” ,”source”:”dalspace.library.dal.ca”,”abstract”:”Recent advancements in tracking technology have increased the ability to unravel key parameters affecting behaviour patterns among marine animals where direct observations are scarce. Within the suite of biologging techniques, tri-axial accelerometers are particularly promising for providing data that can link physiological and ecological processes in the context of movement. The objective of my thesis research was to determine how the analysis of accelerometer data can provide reliable and complex information on fish locomotion and behaviour that are relevant for advancing the informed management of commercially and recreationally valued fish. To reach this objective, a high-frequency accelerometer data logger was developed. Based on a series of controlled-environment and field experiments using this technology, a library of automated signal-processing algorithms was developed that relate acceleration signals to rates of activity, swimming speed, size-at-time and behavioural states in a variety of fish species. The algorithms are efficient in extracting behavioural states (feeding, escape, swimming. The main limitations of an accelerometer electronic tag are: its size and power consumption, as it requires battery for continuous measurement and logging; the method of attachment of the tag to the fish, which can be invasive; and data recovery, as wireless transmissions consume more power and archiving data inside the tag requires it to be retrieved.

As the recapturing event to recover data is a stressor for the fish, the ideal solution would transmit the measurements wirelessly and in real time. Propagating signals in water pose some challenges, especially in shallow water. Acoustic, optical and radio-frequency all have downsides, such as attenuation, fading, multipath propagation, Doppler effects and variable channel characteristics (Gussen et al. 2016)particularly in the sea, has ignited the development of many technological advances in the domains of environmental monitoring, oil and gas exploration, warfare, among others. In all these domains, underwater wireless communications play an important role, where the technologies available rely on radiofrequency, optical, and acoustic transmissions. This paper surveys key features inherent to these communication technologies, putting into perspective their technical aspects, current research challenges, and to-be-explored potential.”,”DOI”:”10.14209/jcis.2016.22”,”ISSN”:”19806604, 19806604”,”note”:”00018”,”journalAbbreviation”:”JCIS”,”language”:”en”,”author”:[{“family”:”Gussen”,”given”:”Camila M. G.”},{“family”:”Diniz”,”given”:”Paulo S. R.”},{“family”:”Campos”,”given”:”Marcello L. R.”},{“family”:”Martins”,”given”:”Wallace A.”},{“family”:”Costa”,”given”:”Felipe M.”},{“family”:”Gois”,”given”:”Jonathan N.”}],”issued”:{“date-parts”:[[“2016”]]}}],”schema”:”https://github.com/citation-style-language/schema/raw/master/csl-citation.json”} . This makes the deployment of these technologies challenging.

(Continued on next page)

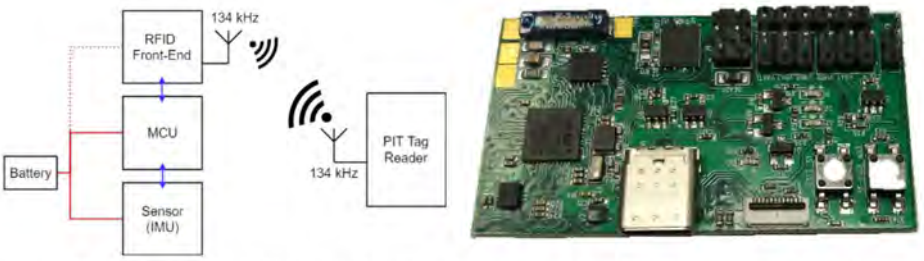

Figure 1: (a) Block diagram of proposed system and (b) photo of evaluation board

System Design

The solution proposed consists of a device with an accelerometer, microprocessor and RFID front-end with coil antenna. To test this, an evaluation board was developed, measuring 3 cm x 5 cm, with additional components for testing. The final solution is planned to be a third of the current size.

Low-frequency RFID was chosen due to its immunity to some adverse effects that other communication methods exhibit underwater, such as multipath propagation. The coil antenna can harvest energy from the field generated by the reader, powering up the tag. An added benefit is the compatibility of the system with existing PIT tag readers already used in aquaculture.

The evaluation board is currently being tested and results will be presented at the conference.

Future Work

The next steps consist of miniaturizing the system and developing the data analytics algorithm. The algorithm will use methods from machine learning to analyse the data gathered from the accelerometer to classify the fish s behaviour and identify states of stress.

Acknowledgments: This work is part of the IMPAQT project (presenting at booth 15). This project has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No 774109.

Introduction

In recent years has increased the use of humans probiotics such as lactic acid bacteria in the culture of fish of interest. These probiotics strains reduce stress in larval phases and protection against pathogenic microorganisms such as *Vibrio parahaemolyticus*, *Aeromonas*, *Vibrio harveyi* (Fečkaninová *et al.*, 2017). However others bacterial strains have been identified in fish such as *Shewanella putrefaciens* Pdp11. It´s a strain isolated by our research group from gilthead seabream and after numerous studies, it has been described as probiotic of aquatic species such as senegalese sole (*Solea senegalensis*) and gilthead seabream (*Sparus aurata*)(Tapia-Paniagua *et al.*, 2012). The present study analyzes the pathogenic inhibitory capacity of lactic acid bacteria and its effect on the probiotic Pdp11 in comparison with other strains of *S. putrefaciens* described as pathogenic for other cultured fish (Esteve, Merchán and Alcaide, 2017)damage of the mouth, extensive skin discoloration, exophthalmia, ascites and bad odour. The S. putrefaciens group was recovered from freshwater samples taken at the L'Albufera system, along autumn-winter 2015. Its counts significantly increased in freshwater parallel to hypoxia and temperature rising. Shewanellae strains were identified as S. putrefaciens and S. xiamenensis by 16S rRNA gene sequencing. These isolates recovered from sick eels or freshwater were virulent for European eel by IP challenge (LD50 106 CFU g-1 body weight.

Materials and Methods

The inhibition test has been made using pathogenic strains (*Shewanella putrefaciens* SH12, SH4, SH6, SH16, SH19), the probiotic strain Pdp11 and probiotics lactic acid strains (*Bifidobacterium lactis* Bb12, *Enterococcus faecium* Tehobak, *Lactobacillus johnsonii* La1, *Lactobacillus casei* Shirota).

The double layer inhibition methodology used is an adaptation of Dopazo et al. (1988) to the growth conditions of acid lactic bacteria, Pdp11 and pathogenic. From 3-6 colonies were inoculated into 10 ml of MRS/ TSBs broth and incubated at 23 ° C. The bacterial culture was adjusted to a concentration of 10^5 cfu / ml for acid lactic strains and 10^4 cfu / ml for Pdp11 and pathogenic strains. The lactic acid bacteria cultured in the first layer and incubated for 18 hours at 23 ° C. The pathogenic strains and Pdp11 were tested in second layer inoculated with 1 ml of TSBs (supplemented withs NaCl). The results of the double layer were observed after 24 hours of incubation at 23 º C and were considered the result is positive in the presence of inhibition halo.

Cepas ensayadas	Pdp11	SH12	SH4	SH6	SH16	SH19
Bifidobacterium lactis Bb12	++++	+	++	+	++	++
Enterococcus faecium Tehobak	++++	+	++++	+++	+	+
Lactobacillus johnsonii La1	++++	++	++	++	+	++
Lactobacillus casei Shirota	++++	++	+++	+	+	++

(Continued on next page)

Results

Table 1. Inhibition halos produced by the lactic acid strains tested on the pathogenic strains SH12, SH4, SH6, SH16, SH19 and the probiotic strain Pdp11 in the double-layer agar technique. The radius of the halo corresponds to: ≤1 mm (+); 1 mm <1.5 mm (++); 1.5mm <2 mm (+++), ≥2 mm(++++).

Discussion and conclusion

The lactic acid present in extracellular products are important in the inhibition assay, and to demonstrated this composition the ECPs were neutralized and used in the inhibition of the SH strains and it was evidenced that the inhibition was lower. Previous studies with lactic acid strains show that different concentrations of lactic acid produced by probiotics such as *Pediococcus acidilactici* induced the production of quorum quenching by the inhibition of homoserine lactone (Kiymaci *et al.*, 2018). This would indicate that the production of acids is an important element in the inhibition of pathogenic strains.

In base on the results about the higher susceptibility howed by Pdp11, other analysis were carried to check molecular difference between probiotics and pathogenic strains. In previous studies, 21 genes have been identified in the SH pathogenic strains absent in the Pdp11 probiotic. One gene encoding for two-component regulatory system (SO_4623) and others two genes (Sbal195_4327, Sput200_4303) codify for histidine kinases, which are intermediates in phosphotransfer pathways. In *Shewanella oneidensis* those genes functions are essential in responses to changes in acidic environments (Leaphart *et al.*, 2006).

Although the production of lactic acid is a relevant factor in the inhibition of pathogenic strains, it is important not to forget the influence of other elements that are part of the ECPs as the bacteriocins

Introduction

The wreckfish *Polyprion americanus* is a promising aquaculture species with late sexual maturation, around the ten years of life (Wakefield et al. 2013), and no sexual dimorphism, involving the use of techniques such as cannulation or ultrasound imagery in the management of the captive broodstocks. However these techniques requires specialized training of the technical staff, and requires an advanced gonadal development of the animal to acquire clear results. The expression levels of Foxl2 gene during gonadal development has been studied extensively in vertebrates as sexual marker due to its female-specific expression profile (Bertho et al., 2016). Foxl2 is one of the earliest sexually dimorphic genes during ovarian development, regulating the activity of Cyp19 aromatase, which converts androgens into estrogens (Guiguen et al. 2010). Foxl2 expression is no restricted to the gonads, being also detected in other tissues like pituitary, brain, spleen, liver, eyes and gills (Wang et al. 2012). In the present study we have identified the Foxl2 sequences in wreckfish and its expression levels has been measured in branchial and gonadal tissues from wild and cultured wreckfish in order to evaluate its suitability as sexual marker in this species.

Material and methods

Thirty five wreckfish caught by commercial vessels and twenty four captive fishes from two stocks located in Galicia(NW Spain) were used in the present study. In all cases, branchial and gonadal samples were obtained (by cannulation in the live animals from the broodstocks) and preserved on ethanol and RNAlater at 4ºC for 24 hours and then transferred to -80ºC storage. Total genomic DNA was extracted from ethanol-preserved tissues using the FENOSALT method (Pérez and Presa, 2011). A 655 bp sequence was amplified using the primer pair f*oxl2F/R* designed by Alam *et al* (2008) to amplify *Epinephelus merra*forkhead transcription factor L2 (Foxl2).The Foxl2 amplicons were cloned using the pGEM-T Easy Vector System II (Promega). The cloned sequences were checked with Chromas Lite software (Technelsyum) and aligned using BioEdit Sequence Alignment Editor Software.Their homology with other teleost species obtained from GenBank, was compared using the BLAST software. The RNA from 30 gonadal and 27 branchial genetic samples were extracted individually with Trizol, and 1↑ g of total RNA from each sample was reverse transcribed to cDNA using a NZY First-Strand cDNA Synthesis Kit (NZYTech)PamFox148F and PamFox68R primers were used for perform the qPCR reactions. Differences in gene expressions between both sexes and both tissues analyzed were determined with one-way analysis of variance (ANOVA) following by Tukey´s HSD test

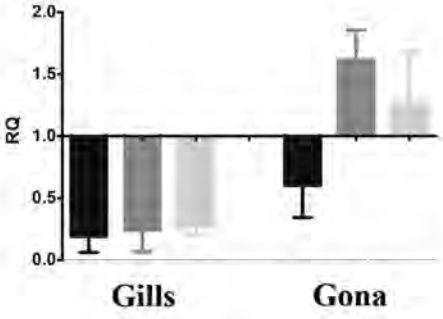

Fig. 1 Relative expression levels of Foxl2 for males (black bars), females (grey) and undetermined (light grey)

(Continued on next page)

Results

The application of these primers for the qPCR experiments was successful for both tissues (Fig.1). The relative expression of Foxl*2* were significantly higher in gonads than in gills ($p<0.001$), and differs between sexes ($p=0.042$) showing their maximum values on females followed by undetermined individuals (those which a sex cannot be assigned by macroscopic examination), while it is under expressed in males (fig.3). For the branchial tissue, all groups shows under expression comparing with the reference sample with no difference between sexes ($p=0.780$)

Discussion and conclusion

The amplificati n of Foxl2 was achieved successfully on both tissues analyzed. Our data in gonadal samples shows significant difference between sexes for the presence of Foxl2, detecting the highest levels on gonadal samples from females of the live broodstocks, over the 90 cm. of total length. The studies on wild populations shows that this size correlates with the age of first maturation, at the 10 years old in the southwestern Atlantic groups (Peres et al. 2003) and at 7 years in the Ionian Sea (Carbonara et al. 2003).The males showed a low expression profile regardless of its maturation status, as it has been recorded in most of vertebrates (Bertho et al. 2016). Five of the wild wreckfish sampled could not be sexed macroscopically due to its low gonadal development, however, their levels Foxl2 leads us to classify two of them as potential females, and as males the remaining three animals. On the branchial tissue, all samples shows a low level of expression with no differences between males, females nor undetermined individuals. Our conclusion is that Foxl2 is a suitable marker for determining the sex of the wreckfish starting from gonadal tissues samples, avoiding the traditionally used histological protocols. However, in other more accessible tissues such as the gills, the search for an appropriate marker is still required.

Introduction

In bivalve populations reared either under controlled laboratory conditions or under environmental conditions, inter-individual growth rates attain an outstandingly high variability (Gaffney and Scott, 1984; Brown, 1988, Tamayo et al., 2011, 2014). This variation indicates the existence of endogenously determined differences in the physiological capacity of individuals to acquire and metabolize food energy. Sibling specimens (families) constitute an excellent biological material to test the genetic basis of such dissimilarities. The present study was designed to identify the physiological parameters responsible for a) intra-familiar and b) inter-familiar differences in the growth potential of the clam *Ruditapes decussatus*.

Materials and methods

Four different families (F1, F2, F3 and F4) from the same cohort of the clam *Ruditapes decussatus* were produced simultaneously. The larvae resulting from each crossing were reared in separate water tanks, maintained under identical temperature and feeding conditions. After 4 months, individuals from the four families were divided into four different categories representing differences in growth capacity: larger than 8 mm (L), between 5 and 8 mm (M), between 2 and 5 mm (S), between 1 and 2 mm (SS), and a group under 1 mm in size. Samples of different size-categories from each family were selected to determine the main parameters underlying the energy balance of individuals: i) routine oxygen consumption (VO_2:$mlO_2 \cdot h^{-1}$) and ii) clearance rate (CR: $L \cdot h^{-1}$), which represent the main parameters of energy loss and gain, respectively. Experimental values of physiological parameters (Y: VO_2or CR) obtained in individuals from different size-categories in each family were used to calculate intra-familiar allometric relationship between physiological parameters and body weight (W) expressed as $Y = a\ W^b$.

Intra-family differences. Recorded mass-exponents in the intra-family allometric

Table I: Allometric relationship obtained for the individual weight, following the expression $Y = a \cdot LW^b$. A: oxygen consumption; B: clearance rate.

A	Family	n	a (±SD)	b (±SD)	R^2	p	F
	1	16	-4.741 (±0.125)	1.033 (±0.065)	0.948	< 0.0001	253.766
	2	17	-5.130 (±0.179)	1.201 (±0.092)	0.919	< 0.0001	170.380
	3	18	-4.837 (±0.097)	1.083 (±0.048)	0.969	< 0.0001	503.931
	4	16	-4.880 (±0.087)	1.184 (±0.048)	0.978	< 0.0001	613.575
B	Family	n	a (±SD)	b (±SD)	R^2	p	F
	1	16	-3.729 (±0.106)	1.033 (±0.054)	0.967	< 0.0001	414.245

	3	20	-3.748 (±0.106)	1.083 (±0.050)	0.958	< 0.0001	413.726
	4	16	-3.086 (±0.106)	1.184 (±0.057)	0.926	< 0.0001	175.089

relationships for VO_2 and CR were close to 1 (with the exception of 0.753 obtained for

(Continued on next page)

Results

All the intra-family allometric relationships of VO_2 and CR showed high statistical significance (see Table I). Regarding the oxygen consumption, the analysis of covariance (ANCOVA) disclosed no significant differences ($F=1.5096$; $df=3, 59$; $p>0.05$) amongst the mass exponents (slopes, b) of the four families. Thus, a common slope ($b_c=1.124\pm0.034$) was calculated. Concerning the elevations (a), significative differences were observed between the second and the forth families (F2vs. F4: $q=4.3689$; $df=3, 35$; $p<0.05$). As regards the clearance rate, statistically significant differences were obtained for the comparison amongst slopes ($F=6.3891$; $df=3,61$; $p<0.05$) and the Tuckey test revealed that the F4 family had a significantly lower mass exponent for CR than the other families (F1 vs. F4:$q=5.5127$; $df=3, 61$; $p<0.05$; F2 vs. F4: $q=4.5706$; $df=3, 61$; $p<0.05$; F3 vs. F4: $q= 4.5268$;$df=3, 61$; $p<0.05$).

Discussion and conclusion

Intra-family differences. Recorded mass-exponents in the intra-family allometric relationships for VO_2 and CR were close to 1 (with the exception of 0.753 obtained for

the CR in F4). This indicates that both measurements follow an isometric relationship with body size. Besides, intra-family mass exponents for VO_2 and CR were not significantly different between them. This result contrasts with the literature that systematically shows lower mass-exponents for CR than for metabolic rate (e.g., Ibarrola *et al.*, 2012).The equivalency of scaling-exponents indicates that the capability to acquire energy (CR) is not comparatively diminished more than the metabolic expenditure (VO_2) with rising body size; thus, in mass-specific terms, the energy balance is virtually independent of body-size. Therefore, individual siblings with faster growth-rates are those in which clearance rate appears to be less constrained by rising body-size.

Inter-family differences. Recorded significant differences in the elevation of intra-family allometries of VO_2 with body size between F2 and F4 families indicate the existence of significant inter-family differences in the metabolic efficiency of individuals: the mass-specific oxygen consumptions of the individuals belonging to the F2 family are lower than those from F4. In addition to metabolic differences, the results of the F4 family show a significantly lower mass-exponent for CR ($b=0.753\pm0.057$) than for metabolic rate ($b=1.184\pm0.048$), denoting the existence of inter-family differences in the constraining effect that increasing body-size imposes to the filtering activit .

Introduction

Producers and researchers have been trying to improve the production of bivalve mollusc spat for many years. Difficulties in the culture of bivalve molluscs are mainly associated with the settlement and metamorphosis processes. Bivalve larvae must develop competence and recognize appropriate exogenous morphogenetic cues to settle and metamorphose (Degnan and Morse, 1995).

The molecular mechanisms underlying the metamorphosis of larvae are not well understood although several inducers have been identified (Boettcher and Targett 1998; Pires et al. 2000). Competent molluscan larvae from different species can be induced to settle and metamorphose using analogues of natural inducers such as γ-aminobutyric acid (GABA) (Bryan and Qian 1998; Rahmani and Ueharai 2001; García-Lavandeira et al. 2005; Alfaro et al. 2011; Mesías-Gansbiller et al. 2008, 2013) and the catecholamine L-DOPA (Coon et al. 1985; Estupinan and Waite 1988; Pires et al. 2000; Dobretsov and Qian, 2003). In this study we examined the effect of several inducers on the larval metamorphosis of the clam *Ruditapes philippinarum* (Adams & Reeve 1850).

Materials and methods

Two experiments of induction of the metamorphosis at laboratory scale have been developed following the protocols previously described in García-Lavandeira et al. (2005) and Mesías-Gansbiller et al. (2013). Competent larvae of *R. phillipinarum*, supplied by the CIMA of Ribadeo, were treated with several neuroactive compounds: GABA, the catecholamines epinephrine and norepinephrine, L-DOPA, IBMX, serotonin and acetylcholine. To determine the optimum concentration of the possible inductor, three different concentrations were used: 10^{-4}M, 10^{-5}M and 10^{-6}M and the exposure time to the inducers was 72h. Experiments were performed in triplicate in Petri dishes of 90mm, for each one of the concentrations mentioned above at a density of 4 larvae/ml. Each experiment included a control with FSW with no potential inductor. Metamorphosis has been monitored with a Nikon SMZ-2T microscope. The percentage metamorphosis was calculated as 100 (total number of larvae metamorphosed/total number larvae). A larva was considered to have undergone metamorphosis when it lost its velum and was using its foot to crawl. Results were analysed by means of SPSS 20.0. Percentages of both metamorphosis and mortality were analysed by ANOVA. The results were considered to be significantly di ferent when $p<0.05$.

Results and discussion

After 72h, maximum percentages of settlement were induced by 10^{-4}M acetylcholine and serotonin. Exposure to 10^{-5}M and 10^{-6}M acetylcholine and serotonin also induced significant levels of metamorphosis in *R. philippinarum.* In contrast, GABA, epinephrine, norepinephrine, L-DOPA and IBMX failed to increase the metamorphosis rates comparing to the control larvae. In both experiments, the proportion of larvae that successfully exceeded metamorphosis in control, in the absence of inducers, was also very high, around 80%. Even in these conditions it could be observed that acetylcholine and serotonin in the three concentrations tested were effective inducers of the metamorphosis, increasing the percentage of success significantly to values close to 100%. Urrutia et al. (2004) previously reported that acetylcholine and serotonin induced larval metamorphosis of *R. philippinarum* larvae. Furthermore, García-Lavandeira et al. (2005) identified GABA and epinephrine as active inducers of metamorphosis of in two clam species *V. pullastra* and *R. philippinarum*. However, the percentages of metamorphosis were very low compared with those obtained in the present study. Differences in the efficacy of various chemicals in inducing metamorphosis may be due to several factors, such as species differences, larval age and qualitative differences among batches of cultures of the same species, resulting in a different degree of larval competence and responsiveness to chemical inducers.

Mortality of *R. philippinarum* larvae was not affected by acetylcholine, serotonin and other inducers except by the highest concentrations of L-DOPA which increased the percentage of mortalities.

Introduction

The use of new technologies for individual and non-invasive monitoring of farmed fish is becoming an urgent demand of the aquaculture industry (Føre et al., 2018). This offers the possibility of the measurement of a range of variables that are directly or indirectly related with metabolic condition, health and welfare status (Metcalfe et al., 2016; Neethirajan et al., 2017). The solution proposed within the AQUAEXCEL^{2020} EU project is a smart device named AEFishBIT, developed and validated to provide reliable and simultaneous measurements of physical activity and respiratory frequency. The device is attached in the operculum using a fairly invasive procedure, and initial testing has been conducted in gilthead sea bream and European sea bass, the two most important farmed fish of Mediterranean aquaculture

Materials and methods

The AEFishBIT is a tri-axial accelerometer for recording and processing acceleration data from x-, y- and z-axes. Records of operculum breathing (z-axis acceleration) served as a direct measurement of respiratory frequency, whereas estimation of fish activity was derived from the x- and y-axis signals. The device also includes a passive RFID tagging device for rapid identification. The final weight of the full packaged device is less than 1 g in air. The autonomy of the system in stand-alone mode is 6 h of continuous data recording with different programmable time schedules.

Algorithms to convert accelerometer measurements in physical activity and respiratory frequency (breaths/s) have been validated with exercised juveniles in a 10-L swim tunnel respirometer (Loligo® Systems). Fish were submitted to controlled speeds from 1 body-length per second (BL/s) until exhaustion by 0.5 BL/s increase steps, with measurements of O_2 consumption rates (MO_2). AEFishBIT was programmed for 2-min time window at different intervals. Examples of use: 2 min each 15 min for 2 days; 2 min each 60 min for 8 days; 2 min each 180 min for 24 days.

Measurements in free-swimming fish have been conducted in juveniles and adult fish for tracking the effects of a number of biotic and abiotic factors (age, season, stocking density, oxygen concentration, disease progression, etc).

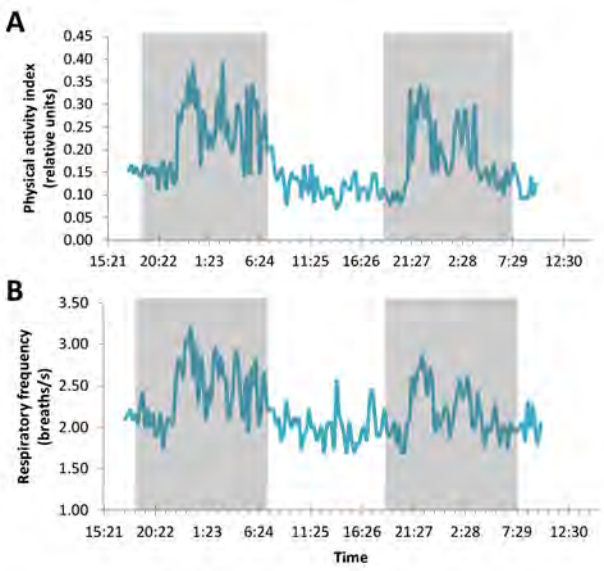

Fig.1. Activity pattern of a "nocturnal" sea bream measured with AEFishBIT, with different behaviour in the light (7:00-19:00 h, white area) and dark (grey area) phases. **(A)** On-board measurements of physical activity index. **(B)** On-board measures of respiratory frequency.

(Continued on next page)

Results

The close parallelism between the inferred respiratory frequency and MO_2 highly validates the use of the proposed algorithm to infer respiratory frequency in exercised sea bream and sea bass (1-4 BL/s speed range). Likewise, the physical activity index increased exponentially rather than linearly with the increase of swimming speed, as the total jerk magnitude only reflects fish-related accelerations. Regarding fish species differences, it is important to note that, at the same swimming speed, MO_2 and the calculated respiratory frequency were consistently higher in sea bream than in sea bass.

AEFishBIT measurements in free-swimming fish evidenced different chronotypes for a given fish population, termed as "diurnal", "nocturnal" or "arrhythmic" on the basis of the moment of the day when the maximum activity pattern (light phase, dark phase or undifferentiated, respectively) is achieved (Fig.1). AEFishBIT measurements also offer the possibility to discriminate different personality traits when fish are challenged with aquaculture stressors (e.g. hypoxia, stocking density).

Discussion and conclusions

The present work represents the proof of concept of a miniaturized device for individual fish phenotyping of metabolic condition and welfare. The different behavior patterns of free-swimming fish can be associated with a better performance or differences in stress and disease resilience. These monitored features also evoke changes in season, age, development or nutritional condition, remaining to establish the involvement of genetic and epigenetic factors on the measured parameters. This opens new research opportunities for the individual fish phenotyping of productive traits through the production cycle, but also for selective breeding in combination with other now promising *omics* approaches (e.g transcriptomics, methylomics, metabolomics, microbiomics).

Introduction

Aquaculture is the fastest growing food production sector in the world and plays a key role in human nutrition. In framework of this increasing intensification in aquaculture and expanding world population, which is expected to rise to 9.8 billion by 2050, rendering aquaculture practices more sustainable is a huge challenge. This implies that the global food production needs to increase by 25-70 % by 2050, whereby the global aquaculture production needs to increase to 109 million tons in 2030 (Ahmed et al., 2018; FAO, 2018).

Aquaculture production is depending on a variety of environmental as well as managementbased factors such as climate, water availability, space, etc. Hereby, feed, in particular fishmeal, represents a high cost for the farmer and is not sustainable as wild fish stocks are under threat and long distance transport to the aquaculture farm is in most cases needed. Subsequently, aquaculture feed producing companies as well as research institutes are urged to find alternative ingredients for fishmeal (Kobayashi et al., 2015). Most of these alternatives consist of plant-based ingredients, whereby these alternative protein sources often lead to a decreased digestion rate, health and welfare of the fish across species (Booman et al., 2018; Pelletier et al., 2018). Studies have demonstrated a reduced digestibility for turbot (*Scophthalmus maximus)*, when fishmeal protein was replaced with plant and insect protein (Burel et al., 2000; Fournier et al., 2004; Kroeckel et al., 2012). In our study, we investigated the effect of alternative feed formulation on growth characteristics, feed utilization and stress response in juvenile turbot.

Material and Methods

Experiments were conducted with juvenile turbot in a recirculating aquaculture system (RAS) at the Alfred Wegener Institute (Bremerhaven, Germany) between April and August 2019. Fish were kept at standardized conditions (16 °C, 90-100 % oxygen saturation, salinity of 32 ppt, pH of 7.7) in 700 L tanks (1 m² bottom area). Hereby, a total of 50 fish (initial weight of 20.0 ± 0.6 g and standard length of 8.0 ± 0.1 cm were housed per tank.

Four experimental diets (Sparos Ltd, Olhão, Portugal) were tested with five replicate tanks: (i) control [CTRL] consisting of > 50 % fish meal; (ii) no processed animal protein (NOPAP) consisting of approx. 35 % fish meal and 5 % insects and algae; (iii) processed animal protein (PAP) consisting of 35 % fish meal, no algae and some animal proteins (poultry meal); and (iv) MIX consisting of 25 % fish meal and a mix from plant, algae, animal and insect ingredients. In addition, an identical number of treatments was included, whereby each of the above mentioned diets were spiked with cortisol (CORT), as a positive control for stress.

Fish were fed twice a day *ad libitum* with extruded pellets for 6 days a week. Every four weeks, six fish per tank were weighted, measured, and sampled for blood, soft fin ra , and otoliths.

(Continued on next page)

Preliminary Results and Discussion

Preliminary data indicate that fish provided with cortisol-spiked feed eat less than non-stressed fish and have a slower growth curve, indicative for the negative effect of long-term elevated cortisol levels on fish performance. It was further observed that the intake of MIX is less compared to other diets, while control fish showed no difference in feed intake between the more plant-based diets.

No significant differences at the end of the trail between control diet and plant-based diet could result in a reduction of costs for the farmer. The stressed induced fish (with cortisol-spiked food) show that stressed fish feeds less and therefore shows a depressed length increament compared to the non-stressed food. This could be due to the fact that indicators for stress in farms need to be identified in more detail to increase growth.

MITIGATING EFFECTS OF EUTROPHICATION USING MUSSEL FARMING: STATUS ON CURRENT RESEARCH AND FUTURE CHALLENGES

J.K. Petersen*, P. Nielsen, D. Taylor and C. Saurel

Technical University of Denmark, DTU Aqua, Danish Shellfish Centre, Øroddevej 80, 7900 Nykøbing Mors, Denmark
Email: jekjp@aqua.dtu.dk

Introduction

Ecosystem services provided by marine bivalves in relation to nutrient extraction from the coastal environment have gained increased attention provided the adverse effects of excess nutrient loading from human activities, such as agriculture, finfis aquaculture and sewage discharge. In combination with the increasing expenses of further reducing nutrient input from land or the difficulti s with nutrient emission from off-coast or off-shore finfis aquaculture mitigation in the receiving water body has become an attractive alternative to ordinary abatement measures. Nutrient extraction using shellfish farming is further attractive as it can boost blue economy in countries with little activity within the area.

Results and discussion

A number of national, e.g. the Danish MuMiPro project (http://www.mumipro.dk), and EU funded projects, like EU BONUS OPTIMUS (http://www.bonus-optimus.eu) and EU Interreg Baltic Blue Growth are currently developing the scientific background for implementing mussel farming as a tool for mitigating effects of eutrophication. The projects encompass various topics like development of culture practice in regions with adverse conditions for mussel farming, e.g. low salinity, environmental impact of mussel farming, mussel farming and coastal zone management and social acceptance. All topics of relevance for implementing mussel farming as a mitigation tool.

Here we report on recent achievements across disciplines within optimization of mussel production in terms of biomass at lowest possible costs, effects of mussel farming in terms of nutrient regeneration and particle depletion, processing and use of mussels for other purposes than human consumption. The results are put in a context of ecosystem services provided by mussel farming and how these can be rewarded by nutrient emitters or government agencies.

WASHINGTON STATE'S POLLUTION IDENTIFICATION AND CORRECTION PROGRAM'S WORK TO PROTECT AND RESTORE SHELLFISH BEDS AND PUBLIC HEALTH

H. Peterson*

Washington Department of Health, National Estuary Program, PO Box 47624, Olympia, WA 98504-7824 (USA), Email: Henry.peterson@doh.wa.gov

Introduction

Puget Sound, located on the Pacific Northwest of the continental United States (specifically Washington state), has 1,332 miles of shoreline. The Puget Sound watershed is home to twenty federally recognized treaty tribes, 12 counties, over four million people, a mixture of rural and urban areas (including Seattle and Tacoma), agricultural and dairy farms, and shellfish. Subsistence, recreational, and commercial harvesters take advantage of the region's vast availability of wild and farmed shellfish. Washington's commercial shellfish industry generates over $150 million every year from the harvest of clams, geoduck, mussels, and oysters.

To protect this resource, state agencies, the Environmental Protection Agency (EPA), tribes, county governments, academics, industry leaders, and citizens work together. Due to Washington's rainy climate, resource practitioners consider the whole watershed for management and planning decisions as the rain transports any fecal waste into streams that flow into to shellfish growing areas. Specificall , the Washington State Department of Health and county governments test freshwater and marine water for concentrations of fecal coliform to protect the public from waterborne illnesses. Counties use a methodology called Pollution Identification and Correction (PIC) to find and fix pollution hot spots. To correct and prevent high concentrations of fecal coliform, state agencies and local governments work with farmers, wastewater treatment plants, and pet and onsite septic system owners. Farms are a source of fecal waste from cows, chickens, pigs, and other livestock and from the land application of manure as a fertilizer. Onsite septic systems can contribute fecal waste if they are not routinely inspected and maintained or properly designed.

Materials and Methods

My study design aimed to understand challenges and barriers that PIC programs face and how Washington State agencies can improve oversight and build capacity for these programs. To complete this, I collected and reviewed previous, current, and planned work related to PIC programs around the Puget Sound. Additionally, I interviewed the practitioners from the twelve Puget Sound counties over a two month period. We discussed water quality sampling, education and outreach programs, enforcement protocols, inter-agency coordination, sustainable funding, and more. After the interviews, I transcribed the interview to analyze the responses.

Results

Results highlighted areas for future work to improve the stability and certainty of consistent funding sources, improving citizen trust and understanding of the importance to restore and protect marine water quality, and foster communication and knowledge sharing between programs. The programs highlighted their need for Washington State to improve access to laboratory services, define regulatory backstopping responsibilities and expectations, and provide continual political and moral support to programs for continued success.

Discussion and Conclusion

It is clear the PIC approach to improving water quality is widely effective, but there are structural differences between programs that lead to varied outcomes and impacts that improve marine water quality. Counties with effective program are recognized and trusted by citizens, utilize and communicate with partners, adapt their messaging to meet their audiences' values, and more. Effective programs dedicate resources to build working relationships with farmers, to educate home owners about maintenance of their septic system, and to establish cross county and international working groups. Over the last decade, PIC programs have improved water quality around Puget Sound leading to an increase in approximately 6000 acres of shellfish bed viable for a mix of commercial, recreational, and subsistence harvest. As a result of this work, state and county agencies will continue coordination to find sources of poor water quality and find ways to fix them. This work is done to protect public health, preserve property values, and improve water quality.

A SURVEY TO IDENTIFY OPERATIONAL WELFARE INDICATORS (OWIs) IN FARMED EUROPEAN SEA BASS *Dicentrarchus labrax* AND GILTHEAD SEA BREAM *Sparus aurata*

Introduction

Welfare of farmed fish is a key aspect of sustainable and ethical aquaculture. At European level, the EU Commission has recently published studies on welfare of farmed fish and has reported on fish welfare during transport and at slaughter to the EU Council and Parliament (SANTE, 2017; SCAR FISH, 2018; COM 87 final (2018). The European Aquaculture Advisory Council has adopted in 2017 the position paper 'Farmed Fish Welfare During Slaughter in the European Union' and in June 2019 has provided a new recommendation for optimising fish welfare at slaughter (AAC, 2019). Producers' Associations, certification bodies and NGOs are searching for suitable operational welfare indicators (OWIs) for measuring the welfare status of farmed fish and improving standard and welfare friendly practices.

The PerformFISH consortium (http://performfish.eu/) is working on welfare of European sea bass and gilthead sea bream and is validating a set of OWIs and a welfare scoring system specifically designed for sea bass and sea bream, in collaboration with fish Producers' Associations and Mediterranean aquaculture companies. This paper presents the results of the PerformFISH *Fish Welfare Survey* for the selection of most suitable OWIs for sea bass and sea bream aquaculture.

Materials and Methods

The PerformFISH consortium has adopted in 2017 a first set of Welfare key performance indicators actually in use by 20 farm companies participating in the benchmarking of performances of sea bass and sea bream across the Mediterranean area. The welfare indicators are: i) total fish mortalities; ii-iii) fish mortalities after 3 and 10 days after transport and stocking; iv) vaccinated fish by disease; v-vi) number of antiparasitic and antibiotic treatments; vii) fish feed intake; viii) fish stocking density; ix) number of oxygen depletion persistence days

The *Fish Welfare Survey* was designed to identify additional OWIs for sea bass and sea bream to be used during grow-out farming in sea cages and land-based tanks, transport and at slaughter. The set of OWIs was chosen following an analysis and systematization of knowledge on welfare of sea bass and sea bream available in literature. About four hundred scientific publications were consulted, together with OIE and EU recommendations, EFSA opinions, Technical guidelines and Codes of conduct (FAO, FEAP), Benchmarking systems (GAPI, GSSI), Certification schemes (RSPCA, ASC, Global GAP, BAP GAA, FOS, Organic), Welfare Handbook for Atlantic salmon (Noble et al., 2018) and expert judgments. The approaches to assess animal welfare in terrestrial livestock production (e.g. Welfare Quality; AWIN) have been further considered.

The PerformFISH consortium (Scientific partners, Producers' Associations, Industry) participating in the *Fish Welfare Survey* is requested to score the suitability of OWIs on the basis of the following indicator's attributes: informative, reliable, cost and labour effective, repeatable, comparable and easy to apply.

Results

The 48 OWIs included in the survey cover 9 different areas of fish welfare: health, growth, behavior, housing, transport, harvest, stunning/slaughter, staff training and compliance with recommendations (OIE and EU). The overall set of OWIs includes a 46% of animal-based indicators and a 54% of indirect indicators related to environment and husbandry management and practices. The 47% of OWIs are quantitative indicators providing numerical values for welfare scoring and 53% are qualitative indicators reporting on the use of best management practices during farming, transport and slaughter. Although most OWIs proposed in PerformFISH survey are included in aquaculture certification schemes, only few quantitative indicators are available for farmed sea bass and sea bream.

(Continued on next page)

Discussion and conclusion

Although the general aspects of health and the welfare of farmed fish are well known by farm managers, a set of suitable OWIs for analyze welfare status of sea bass and sea bream is still missing and reference values for most of quantitative indicators are completely lacking. A Welfare Scoring System based on OWIs can thus improve the measurement and certification of fish welfare status. The set of OWIs will be a simple and friendly tool for farmers and health managers to measure fish welfare, helping them to find room for improvement in husbandry practices. Welfare indicators will be further used to inform retailers, consumers, NGOs and policy makers on welfare-friendly farming practices and standards in use in marine fish farming secto .

Acknowledgments

The study has received funding from the European Union's Horizon 2020 research and innovation program under Grant Agreements No 727610 (PerformFISH). Introduction

Aquaponics (AP) is considered an innovative and sustainable source of food due to the high production and low environmental impact. However, these features are hardly known by the consumers which consider low environmental impact in food production a principal factor of choice. The main objective of the project is to develop a system able: to define and ensure the quality of AP products; to provide to the final consumer a comprehensive, clear and instant explanation of the various aspects and parameters that make an AP product a product of quality. This type of solution has never been made in Europe so far.

Development of the project

Adopting AP certification, allow the registration at Network of European Commercial Aquaponic Producers (NECAP).

Step 1 - put in writing CP. Every producer interested in being part of NECAP and commercializing, beyond their logo and label's product, with our logo (described in Step 3) must respect our values summarised in the following guideline.

Sustainability indicators

- **More than 50% of energy must to come from renewable sources.**
- **Less than 40% of water can be replace during whole cycle**. Modern RAS alone have a high degree of water reuse, i.e. 95–99%, Dalsgaard et al. (2013).
- **At least 75% of total Nitrogen and 70% of total Phosphorous retains by fishes and plants**.
- **Floating systems (RAFT) should be prefer to Media-Filled Beds Systems (MFBS)** which is more impacting due to the large use of inert material to sustain vegetables, Forchino et al. (2017).
- **Product Carbon-footprint and water footprint must be calculated.** Our producers must calculate them with software that they can freely choose.
- In order to **circular economy**, our project encourage the use of recycle materials and the recycle of any waste for the realizations of the system (ex: the reuse of abandoned greenhouses or manufactured) or use biodegradable materials.
- **Waste.** Use **solid waste** to obtain compost which can be used to fertilize plants instead of chemical fertilizers; cleanse **water waste** with a natural technique named phytoremediation.
- **To prefer local fish or seedling.**

Fish welfare indicators

- **Oxygen dissolved (DO) at least 8mg L^{-1}.** Although in literature is common to found suggested values ranging between 4-6mg L^{-1}, Yildiz et al. (2017).
- **Temperature (T) 18-30°C.**
- **pH at last 6 and not higher than 7.5.**
- **Ammonia (NH_3) at least 1mg L^{-1}.**
- **Nitrite (NO_2^-) at most 1mg L^{-1}.** High levels of Nitrite leads to the oxidation of Fe^{2+} in haemoglobin with a reduction in the transport of oxygen by blood cells, Yildiz et al. (2017).
- **Nitrate (NO_3^-) 5-150mg L^{-1}.** Concentrations higher than 300mg L^{-1} cause toxic lesions for fish, Yildiz et al. (2017).

Moreover, producers must give guarantees of taking under control the traceability and safety of food products. With respect to **traceability guarantees** we consider necessary maintaining an upgraded supplier list and monitoring data production and store (described in Step 2). The adoption of disinfection plants such as UV light (Elumai et al., 2017) or other sterilization tools (such as ozone) and biosecurity measures (like GMP) will be considered **guarantees** of **food safety**.

(Continued on next page)

Step 2- Creation of "Network of European Commercial Aquaponics Producers" (NECAP), a web platform in which producers upload production data. Data from NECAP are also used as link for smart labelling. Before yearly audit control body could be require data from NECAP in order to verify the accuracy of the information. NECAP could be integrated with digital tools, such as Ponics® app (https://ponics.it/) to upload data real time or could be uploaded manually.

Step 3- Creation of app for consumers, which is available for free download and allow to consumer to know products and provides a direct contact with producers. Eco-labelling has become increasingly popular a means of encouraging more sustainable consumer choices, Madin et al. (2015). In our project too, sustainability will be communicated through smart-label with QR code containing all information about product. In addition to the legal information which accompany food products, in certified product label will be a logo with the slogan "SUSTAINABILITY ON HAND", associated to a QR code. The QR code can be scan by consumer's devices, giving back a lot of additional information about the products.

Introduction

The effects of climate change are already being widely observed in fisheries and aquaculture in Europe and will continue to have major implications on these sectors. The impacts of climate change on the seafood production sector will vary significantl , from negative to positive effects and both in its form and severity. In order to maintain responsible, sustainable and profitable seafood production under future climate change, development of adaptation plans or strategies is becoming increasingly important (FAO, 2015). The adaptation to climate change aiming at making Europe more climate-resilient was included in the EU strategy in 2013. The goal of sustainable fishery and aquaculture is also mentioned under the new Common Fisheries Policy (European Commission, 2016). This ambition is challenged by a range of climate-induced uncertainties.

National Action Plans (NAP) are currently under development in most European countries. To date, 23 European countries have adopted national adaptation strategies; whereas eight are reported to be in the process of development. However, these NAPs are mainly focused on transport, cities, and agriculture. Fisheries and/or aquaculture are not included in these plans.

This paper aims to develop a guideline on making Climate Adaptation Plan (CAP) within the fishing and aquaculture industry. To our knowledge, there are no such guidelines available today. The paper therefore is exploratory. We illustrate the guideline with an application to the two case studies built in the EU H2020 ClimeFish project.

Literature review on climate adaptation plans for fisheries and aquaculture sector

The analytical framework of CAP guideline is based on the three following documents: (1) The most comprehensive assessment of climate change undertaken by the IPCC, particularly the synthetic report of Climate Change (2014): Impacts, Adaptation, and Vulnerability (IPCC, 2014); (2) The work done by FAO on assessing climate change vulnerability in fisheries and aquaculture. Available methodologies and their relevance for the sector (Brugère, C., & De Young, C. 2015); (3) Sustainability and sustainable development framework introduced by Circular Ecology.

A vulnerability assessment is considered an important step in adaptation planning for climate change. Existing frameworks for conducting vulnerability assessments have been provided by authors such as FAO (2015), Johnson et al. (2016) and Grafton (2010), and in all cases, the process includes estimating sensitivity, exposure and adaptive capacity to yield vulnerability of a species, community, country or other entity under assessment. The ClimeFish CAP guidelines follows these existing frameworks by estimating these factors to weigh the climate-related vulnerability of all key components of the production system.

Discussion and conclusion

Communicating with stakeholders is an important component of the decision making process to increase a general acceptance of management decisions. The fact that each of stakeholders has different interests, agendas and roles in the process. They differ in their sense of urgency of the problem, their approach to the problem, their language and knowledge levels, and their rationality regarding potential solutions. Participation of stakeholders in decision making process is advocated for following reasons. First, both individuals and society are enriched through the encouragement of social and individual learning. Second, multiple views would help improves understanding of the issues and selection of the appropriate solutions. Third, the success of policy implementation is promoted by the encouragement of collaborative relationships. Thus, in order to involve the stakeholders in an efficient way, it is necessary to define rules of engagement, promote a shared vision and the planning to achieve it, extended peer review process.

EFFECT OF DIETARY MACRONUTRIENT VARIATION ON ENERGY UTILISATION EFFICIENCY IN SNAKEHEAD (*Channa striata*)

L.T.T. Phan[1*], J. Mas[2], K. Masagounder[3] & J.W. Schrama[1]

Introduction

Fish energy demands for maintenance and growth has been assessed using the factorial approach on a digestible basis (Glencross and Bermudes, 2012). In such an approach, the efficiency of digestible energy utilisation for growth (k_{gDE}) is the slope of the regression between retained energy (RE) and digestible energy (DE) intake with assumption that the feed composition does not affect k_{gDE}. However, the various k_{gDE} values in barramundi (Glencross *et al.*, 2017), Nile tilapia (Schrama *et al.*, 2012) and rainbow trout (Rodehutscord and Pfeffer, 1999)</style><style face="italic" font="default" size="100%">Oncorhynchus mykiss</style></title><secondary-title>Aquaculture</secondary-title></titles><periodical><full-title>Aquaculture</full-title></periodical><pages>95-107</pages><volume>179</volume><number>1</number><keywords><keyword>Rainbow trout</keyword><keyword>Digestible energy</keyword><keyword>Partition</keyword><keyword>Maintenance requirement</keyword><keyword>Energy utilisation</keyword><keyword>Multiple regression</keyword></keywords><dates><year>1999</year></dates><isbn>0044-8486</isbn><urls><related-urls><url><style face="underline" font="default" size="100%">http://www.sciencedirect.com/science/article/pii/S0044848699001556</style></url></related-urls></urls><electronic-resource-num><style face="underline" font="default" size="100%">https://doi.org/10.1016/S0044-8486(99 fed various macronutrient profiles reflects the effect of the dietary macronutrient profile on k_{gDE}. This effect maintains to be validated for other fish species. This study therefore aimed to investigate effect of dietary macronutrient variation on energy utilisation efficiency in snakehead *i.e.*, a carnivore).

Materials and methods

A total of 2400 snakehead (mean weight 29.1g) were fed a total of four diets, which were formulated based on a 2×2 factorial design with 2 dCP-to-dLipid ratios (7:1 and 2:1) and 2 dCP-to-dstarch ratios (3:1 and 1:1) with the gross energy ranging 18.4 – 21.3kJ.g^{-1}DM, and applied at 2 feeding levels to have a 2×2×2 factorial design with a total of 8 treatments in triplicate. This design aimed to achieve the large contrast in digested energy intake among the 4 diets. This was conducted to run regression analysis of retained energy (*i.e.*, growth response) as a function of digestible energy intake. The experiment includes a total of twenty four 500-l tanks (100 fish/tank)

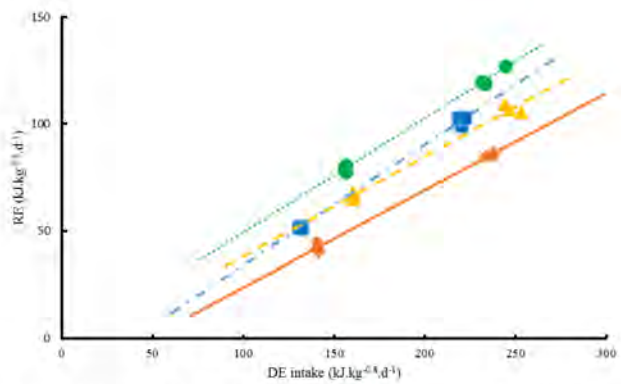

Fig 1. Relationship between retained energy and digestible energy intake for snakehead (■ Diet 1: RE= -22.3 (SE 2.55) + 0.56 (SE 0.01) DE (R^2=0.99), ♦ Diet 2: RE= -21.6 (SE 2.90) + 0.45 (SE 0.01) DE (R^2= 0.99), • Diet 3: RE= -3.8 (SE 2.80) + 0.53 (SE 0.01) DE (R^2= 0.99), ▲ Diet 4: RE= -8.1 (SE 5.80) + 0.46 (SE 0.03) DE (R^2=0.99)).

(Continued on next page)

Results

At both feeding levels, snakehead fed the carbohydrate-rich diet had the lowest feed efficiency while the highest value was found in fish fed the lipid-rich diet (Table I). By conducting regression between retained energy and digestible energy, the k_{gDE} was determined in a range from 45% to 56% with the highest value found in the protein-rich diet and the lowest value found in the carbohydrate-rich diet (Fig 1).

Discussion and conclusion
