出國報告（出國類別：開會）

參加 2019 歐盟水產養殖國際研討會

服務機關：台灣中油公司綠能科技研究所
姓名職稱：余宗賢 化學工程師
派赴國家/地區：德國/柏林
出國期間：民國 108 年 10 月 4 日至 10 月 14 日
報告日期：民國 108 年 11 月 12 日

摘　要

本次會議之議題幾乎包括所有水產養殖之議題，共有 56 個會議(sessions)、1039 篇摘要論文、594 篇海報(包含 94 篇之電子海報)、150 個展覽攤位、85 個參與國家、超過 2700 位參與者。

然而，因此國際研討會議題很多，故本人僅能盡可能參與和本組研究方向與未來可能研發方向相關之議題。主要參與之論文發表議題包括 Macroalgae, Climate Change, Sustainable Aquaculture Technologies, Value Addition and Marketing, Mollusc Production and Restoration, Hatchery Technologies and Practices, and Shrimp。本人就將上述之議題摘錄較重要之發表提出探討。

一、緣起與目的

2019 歐盟水產養殖研討會(Aquaculture Europe 2019)涵蓋的主題有: Climate change (氣候變遷)、Environmental and ecosystem management (環境與生態管理)、Environmental impact of aquaculture - problems coming FROM and TO aquaculture (環境衝擊-水產養殖衍生與遭受之問題)、Aquaculture on offshore structures (離岸水產養殖結構)、Recirculating aquaculture systems and closed containment systems (循環養殖系統與密閉控制系統)、Flow through and raceway systems (溢流池與迴流池系統)、Selective breeding (選擇性養殖)、Processing, co-products and value addition (高附加價值之共產物與程序)等共 38 個議題，結合水產生物科技在工業、環境、食品上的應用。

綠能所環保科技組目前研發方向與此國際研討會之討論主題契合，參加該會議有助於了解目前產業現況，與國際學者、工程師、工業專家進行交流。藉由發表研究成果及聽取與會者的簡報海報，能激發新的創意思維。

二、行程及工作摘要

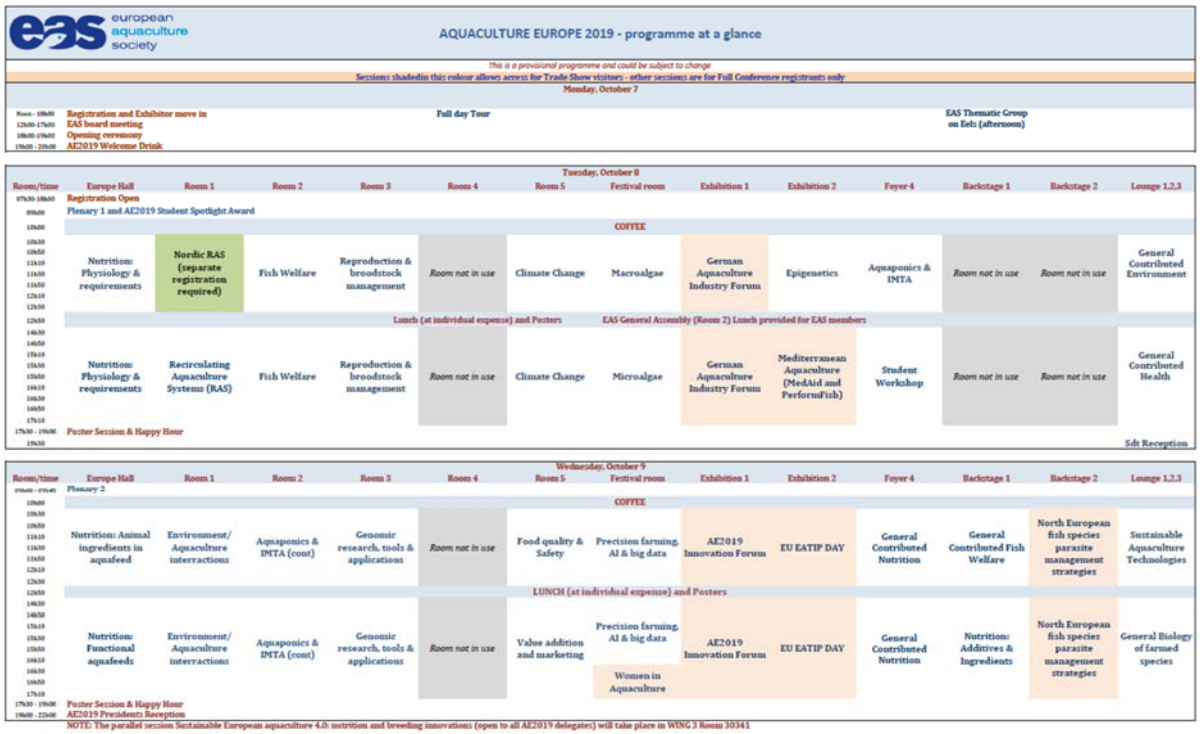
日期	到達地點	詳細工作內容
10/4	台灣→德國	啟程(高雄→德國)
10/5-6	德國	私人行程
10/7-10	德國柏林	參加 2019 Aquaculture Europe 國際研討會
10/11-12	德國柏林	私人行程
10/13-14	德國→台灣	回程(德國→桃園機場→高雄)/飛機上過夜

三、研討會內容摘要

3.1 會議簡介

本次 2019Aquaculture Europe 國際研討會是由歐洲水產養殖學會(European Aquaculture Society)主辦，舉辦時程為 2019 年 10 月 7 日至 10 月 10 日，興辦地點為英國柏林之 ESTREL 飯店會議中心。此會議除邀請多位學者專家進行專題演講外，並由世界各國學者專家共同與會進行論文口頭發表、海報發表及研究經驗交流。本次會議主要議程包括 Climate change (氣候變遷)、Environmental and ecosystem management (環境與生態管理)、Environmental impact of aquaculture - problems coming FROM and TO aquaculture (環境衝擊-水產養殖衍生與遭受之問題)、Aquaculture on offshore structures (離岸水產養殖結構)、Recirculating aquaculture systems and closed containment systems (循環養殖系統與密閉控制系統)、Flow through and raceway systems (溢流池與迴流池系統)、Selective breeding (選擇性養殖)、Processing, co-products and value addition (高附加價值之共產物與程序)等共 38 個議題。

各議題之口頭發表時間和研討室詳如下表所示，然各口頭發表之研發題目與海報發表題目則如附件一與附件二所示。



AQUACULTURE EUROPE 2019 - programme at a glance

This is a provisional programme and could be subject to change

Sessions shadedin this colour allows access for Trade Show visitors - other sessions are for Full Conference registrants only

Monday, October 7

Noon - 18h00	Registration and Exhibitor move in	Full day Tour	EAS Thematic Group on Eels (afternoon)
12h00-17h00	EAS board meeting		
18h00-19h00	Opening ceremony		
19h00 - 20h00	AE2019 Welcome Drink		

Tuesday, October 8

Room/time	Europe Hall	Room 1	Room 2	Room 3	Room 4	Room 5	Festival room	Exhibition 1	Exhibition 2	Foyer 4	Backstage 1	Backstage 2	Lounge 1,2,3
07h30-18h00	Registration Open												
09h00	Plenary 1 and AE2019 Student Spotlight Award												
10h00	COFFEE												
10h30 10h50 11h10 11h30 11h50 12h10 12h30	Nutrition: Physiology & requirements	Nordic RAS (separate registration required)	Fish Welfare	Reproduction & broodstock management	Room not in use	Climate Change	Macroalgae	German Aquaculture Industry Forum	Epigenetics	Aquaponics & IMTA	Room not in use	Room not in use	General Contributed Environment
12h50	Lunch (at individual expense) and Posters						EAS General Assembly (Room 2) Lunch provided for EAS members						
14h30 14h50 15h10 15h30 15h50 16h10 16h30 16h50 17h10	Nutrition: Physiology & requirements	Recirculating Aquaculture Systems (RAS)	Fish Welfare	Reproduction & broodstock management	Room not in use	Climate Change	Microalgae	German Aquaculture Industry Forum	Mediterranean Aquaculture (MedAid and PerformFish)	Student Workshop	Room not in use	Room not in use	General Contributed Health
17h30 - 19h00	Poster Session & Happy Hour												
19h30													5dt Reception

Wednesday, October 9

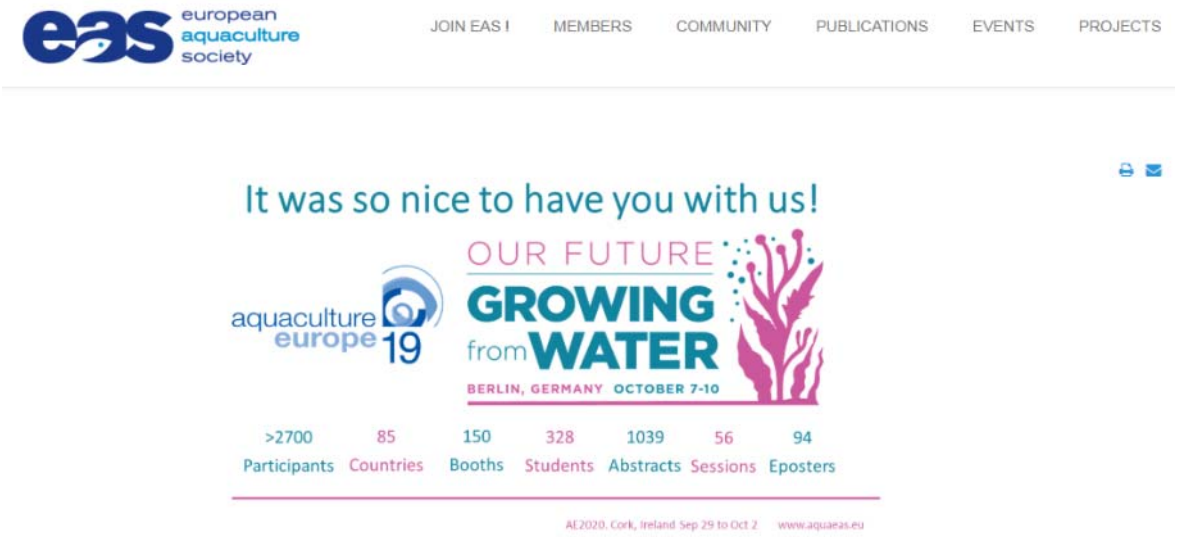
Room/time	Europe Hall	Room 1	Room 2	Room 3	Room 4	Room 5	Festival room	Exhibition 1	Exhibition 2	Foyer 4	Backstage 1	Backstage 2	Lounge 1,2,3
09h00 - 09h45	Plenary 2												
10h00	COFFEE												
10h30 10h50 11h10 11h30 11h50 12h10 12h30	Nutrition: Animal ingredients in aquafeed	Environment/ Aquaculture interractions	Aquaponics & IMTA (cont)	Genomic research, tools & applications	Room not in use	Food quality & Safety	Precision farming, AI & big data	AE2019 Innovation Forum	EU EATIP DAY	General Contributed Nutrition	General Contributed Fish Welfare	North European fish species parasite management strategies	Sustainable Aquaculture Technologies
12h50	LUNCH (at individual expense) and Posters												
14h30 14h50 15h10 15h30 15h50 16h10 16h30 16h50 17h10	Nutrition: Functional aquafeeds	Environment/ Aquaculture interractions	Aquaponics & IMTA (cont)	Genomic research, tools & applications	Room not in use	Value addition and marketing	Precision farming, AI & big data Women in Aquaculture	AE2019 Innovation Forum	EU EATIP DAY	General Contributed Nutrition	Nutrition: Additives & Ingredients	North European fish species parasite management strategies	General Biology of farmed species
17h30 - 19h00	Poster Session & Happy Hour												
19h00 - 22h00	AE2019 Presidents Reception												

NOTE: The parallel session Sustainable European aquaculture 4.0: nutrition and breeding innovations (open to all AE2019 delegates) will take place in WENG 3 Room 30341

Thursday, October 10													
Room/time	Europe Hall	Room 1	Room 2	Room 3	Room 4	Room 5	Festival room	Exhibition 1	Exhibition 2	Foyer 4	Backstage 1	Backstage 2	Lounge 1,2,3
09h00 09h20 09h40 10h00 10h20 10h40 11h00	Nutrition: Additives & Ingredients (cont)	Pathogens, diseases & treatments	Selective Breeding	Molluscs	Governance, policy, regulations & planning	Sustainable systems for large scale production - closed, offshore or both	Percid Fish	Escapes/ Interactions farmed & wild fish	Environmental & Ecosystem Management	General Topics Session	Aquaculture in Central & Eastern Europe (NACEE)	Shrimp Industry Forum	Baltic Aquaculture
11h20 11h45 12h30	Plenary 3 AE2019 Poster Awards												
12h50	LUNCH (at individual expence) and Posters												
14h30 14h50 15h10 15h30 15h50 16h10 16h30	Nutrition: Additives & Ingredients	Pathogens, diseases & treatments	Selective Breeding	Molluscs	Education, knowledge management, transfer & extension networks	Cage systems & offshore structures	Percid Fish	Laboratory aquatic models & ornamentals	Hatchery technologies & practices	General Topics Session	NACEE (cont)	Shrimp	Compounds in Lipid Transport

3.2 與會心得

本次會議之議題幾乎包括所有水產養殖之議題，共有 56 個會議(sessions)、1039 篇摘要論文、594 篇海報(包含 94 篇之電子海報)、150 個展覽攤位、85 個參與國家、超過 2700 位參與者。



然而，因此國際研討會議題很多，故本人僅能盡可能參與和本組研究方向與未來可能研發方向相關之議題。主要參與之論文發表議題包括 Macroalgae, Climate Change, Sustainable Aquaculture Technologies, Value Addition and Marketing, Mollusc Production and Restoration, Hatchery Technologies and Practices, and Shrimp。本人就將上述之議題摘錄較重要之發表提出探討。

一、Macroalgae

主題：

Brown seaweeds – A status report of offshore cultivation and expected market developments in Europe (褐藻 – 歐洲地區離岸養殖及預期市場發展之現況報告)

講者：

Diogo Raposo, Frank Neumann, Jon Funderud

摘要：

褐藻為全球水產養殖生產比例最高之海藻，主要是因為東南亞大量養殖海帶(kelp)，例如 *Saccharina japonica* (昆布 Kombu)和 *Undaria pinnifatida* (裙帶菜 Wakame)。海藻是亞洲地區非常重要的食品，但在歐洲卻非為主要食品。然而，因為海藻在烹飪和飲食的價值已經越來越受到歐洲廚師和食品產業的注意。

在歐洲養殖褐藻之最初考量是為了生物燃料，但大規模之海藻養殖場需投入大量的資金和自動化技術。而且，直到最近數年，歐洲業者才意識到褐藻可作為食品，且相較於生物燃料，食品之銷售價格又較高。在 2014 年，海藻能源解決方案公司(Seaweed Energy Solution, SES)建立了一個試驗性養殖場，主要為驗證每年收獲 100-150 公噸海藻之技術可行性；故於 2014 年之後，許多歐洲公司開始積極採用類似之養殖技術，特

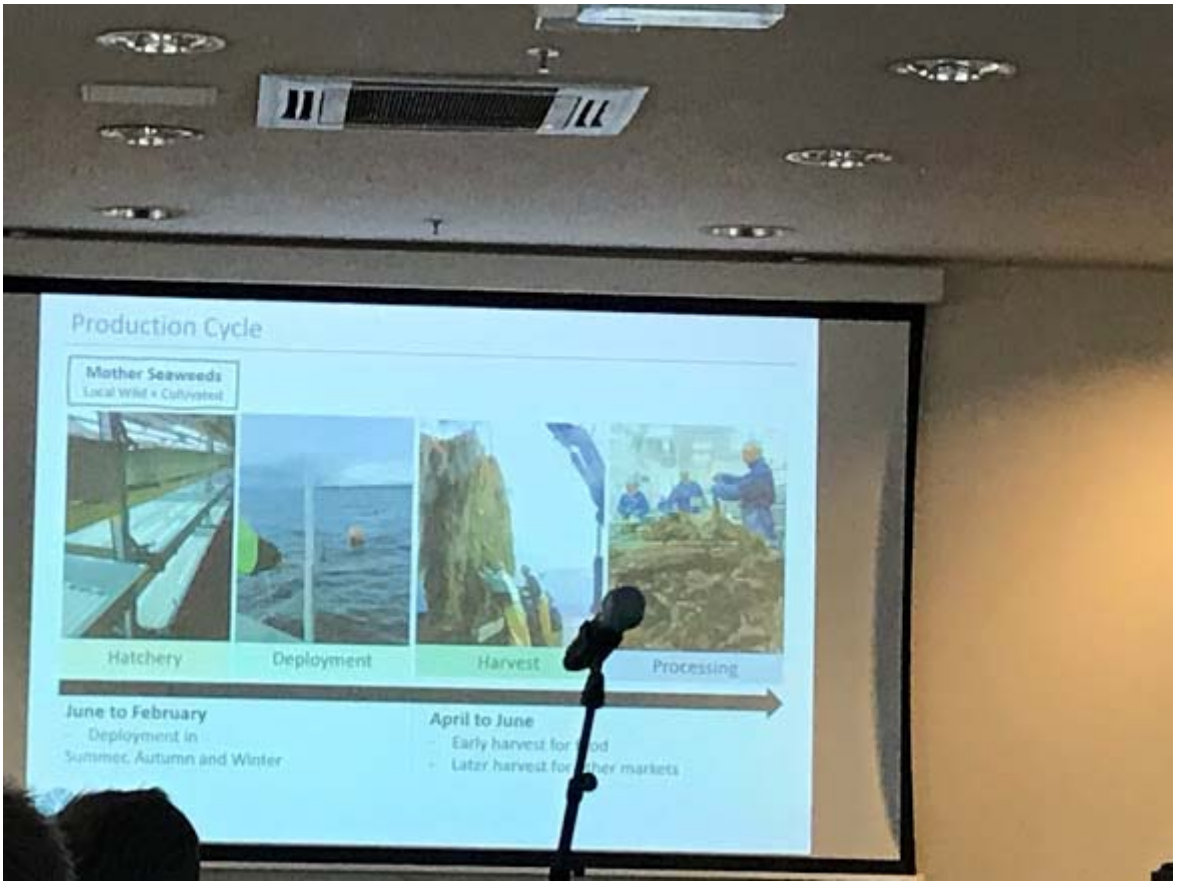
別是在挪威；挪威某一個典型之褐藻養殖場，其盈虧平衡產量為每年 200-500 公噸(取決原料銷售價格)。

褐藻對健康益處和高價化合物已經慢慢得到認可。海藻是碘的天然來源，在歐洲人缺乏碘一直是衛生部門關注的問題。海藻也是 50 種不同的礦物質和微量元素以及 Omega-3 脂肪酸的來源。因褐藻含有較多的谷氨酸(glutamate)，故可提食品的鮮味和增強的口味。

總體而言，海藻是一種高度永續且節能的食物資源，因不需使用淡水，也不需在海洋養殖場中施加化學肥料或化學品，更不會在陸地上留下任何跡象。因此，海藻作為食品成分的使用對環境有著巨大的影響。

海藻生長會吸收大量的營養物質（N，P）和 CO_2，因此可改善水質和增加生物多樣性等效益。海藻森林更是生物多樣性的增強劑，例如增加幼魚、甲殼類動物和其他魚類的庇護所和產期。

但如果持續大規模養殖海藻亦具有一些潛在威脅，例如育種和疾病所造成的基因退化。因此，目前已有許多研究專題正在探討此潛在風險，包括 GENIALG、MACROSEA、KELPPRO 和 SEABEST 等專案，並讓全球瞭解瞭藻種植的實際狀況和未來的前景。



(2)

主題：

Large-scale cultivation of seaweed in west Cork: An Irish success story (科克西部之大規模海藻養殖計畫：愛爾蘭之成功案例)

講者：

Silvia Blanco Gonzalex, Fiona Wanjiku Moejes, Julie Maguire

摘要：

海藻富含生物活性化合物(bioactive compounds)，包括抗氧化劑、可溶性膳食纖維、蛋白質、礦物質、維生素、植物化學物質和多元不飽和脂肪酸，海藻作為食物的潛力超出了日本料理的使用範圍。幾個世紀以來，海藻在愛爾蘭飲食中一直扮演著重要的角色，從果凍狀布丁中使用卡拉膠（*Chondrus crispus*），到在烘焙中使用紫紅藻（*Palmaria palmata*）。

全球有超過 95%的海藻來自海藻養殖場，中國生產大約 47%的海藻生物量。然而，歐洲海藻養殖產業仍處於起步階段，人工養殖之海藻產量<3%。儘管與全球市場相比規模較小，但歐洲擁有大西洋海岸線，不僅營養豐富，且水質清潔，其大西洋海岸線約有 3000 多種海藻，提供高庫存多樣性和高品質的生物量。

海藻可在單一養殖或整合水產養殖系統，其系統亦可在陸地上（槽池或跑道池）和海上（長繩結構）中生產。在歐洲，海帶（如 *Alaria*, *Saccharina*, *Laminaria* 等褐藻）的生

產遵循亞洲國家所使用的技術。生產技術基本原理，a.收集孢子體(sporophyte)、b.在陸地設施生產微型配子體(gametophyte)，並將受精卵(zygote)植種於繩索、c.培養受精卵發芽至特定尺寸後，再將繩索移植至開放水域、d.放置於開放水域之海上生長，直到收穫。

全球海藻生物經濟預估，至 2021 年，將迅速增加到約 176 億美元。愛爾蘭之《海洋變化策略》指出，2020 年海藻市場目標規模達到 3 000 萬歐元。然而，野生海藻便無法滿足需求，故必須轉向為人工養殖海藻。

位於愛爾蘭西南部的班特里海洋研究站有限公司（Bantry Marine Research Station Ltd, BMRS）是歐洲唯一擁有大規模海上海藻養殖場的機構之一。BMRS 以 6 公頃的場地為基礎，目前每年在班特里灣種植超過 10 噸（濕重）的翅藻(*Alaria esculenta*)。翅藻含有各種高價化合物，包括海藻黃質(fucoxanthin)和褐藻多酚(phlorotannins)。

依據 BMRS 之養殖試驗結果，發現最高翅藻收成量是在 2017 年 12 月 09 日放養，在 2018 年 5 月 28 日收成，每 1 米繩索之平均收成量為 12 公斤（濕重）。重量隨著時間的增加而增加，但葉片的長度在 5 月初可達到最大值（2.25 米），之後它們變得更寬，而不是更長。總體而言，第 2 年度的翅藻增長速度比第 1 年來得快，平均葉片更長。

而在海藻黃質之檢測分析結果方面，養殖三週後之翅藻比最後收成之含量還要來得高；此外，利用冷凍乾燥之樣品，其海藻黃質含量亦較烘箱乾燥之樣品來得高。

主題：

Perspectives for indoor seaweed (*Ulva ohnoi*) cultivation in photobioreactors (以光化反應器於室內培養海藻 *Ulva ohnoi*)

講者：

Erik Malta1, Leen Bastiaens, Kathy Elst, María del Mar Agraso Martínez

摘要：

以 75 公升之光化反應器(PBR)培養海藻(*Ulva ohnoi*)，以 f/2 作為營養源，光源為 LED 燈(150 μmol/m^2/s，16:8 L:D 週期)，初始藻種濃度為 60-70g/PBR，故溫度便為生長主要控制因子。

3 月至 7 月份之氣溫最高，平均約 16-24˚C。此週期之平均增長率為 10% d^{-1}（平均產量為 104g FW）。PBR-1）。以每支 PBR 放養 60~70 克的初始濃度，可獲得最佳生物量產量。生長主要是由室溫決定的，在最冷的月份時，其生長會受到限制。

主題：

Initial uptake capacity of ammonium in *Saccharina latissima* in an IMTA context (在 IMTA 實場環境下其糖海帶 *Saccharina latissima* 之銨攝取能力)

講者：

Erik Malta1, Leen Bastiaens, Kathy Elst, María del Mar Agraso Martínez

摘要：

挪威是世界領先的大西洋鮭魚生產國（*Saomo salar*），具挪威政府的長期目標，是希望在 2050 年將目前的產量提高四倍。然而，鮭魚生產所產生的廢棄物，已經對環境造成影響，因此需要更加注重生產的環境可持續性，包括改善資源和能源利用率。

鮭魚飼料之總氮，約有 39%會溶解至海水中，其中又以溶解性無機鹽氮（dissolved inorganic nitrogen, DIN）和銨（NH^+）為主。這多研究推估，糖海帶(*Saccharina latissimi*) 可從鮭魚養殖場之排放物中去除 5-40%DIN。

研究結果發現，*S. latissima* 可快速適應不同濃度的 NH^+，且調整並增加其攝取率。如圖 1 所示，在 50 分鐘內觀察到最大攝取率。而且，NH^+的攝取量都會隨著濃度的增加而呈現線性增加。*S. latissima* 的營養史似乎會影響其攝取量，因為氮耗盡的實驗組中，發現 NH^+的攝取速度明顯快於氮飽和控制組。

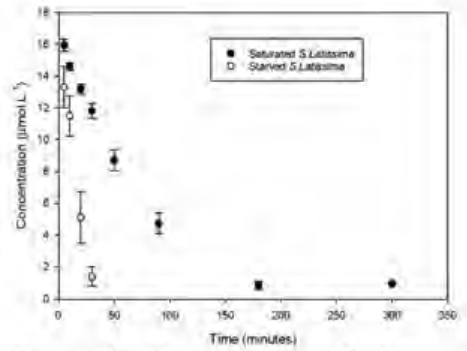

Figure 1: Time course of decrease in ammonium concentration (initially16µmol L^{-1}) in culture medium with juvenile plants of *Saccharina Latissima* for nitrate saturated and depleted plants (n=5±SD)

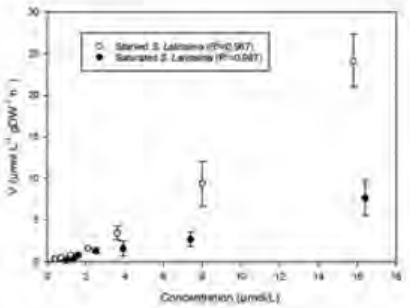

Figure 2: Ammonium uptake rates for *Saccharina Latissima* from 5 to 50 minutes related to available concentration for both nitrate saturated and depleted plants (n=5±SE, linear regression with R^2=0,987 for depleted and saturated).

(5)

主題：

Optimization of antioxidant activity in sea vegetables grown in recirculating aquaculture systems (RAS) (循環養殖系統培養海洋蔬菜之抗氧化能力最佳化探討)

講者：

Sofiia Tretiak, Jakop Schwoerbel1, Ramona Bosse, Frederike Reimold, Ina Enders, Dietmar Hoffmann, Joachim Henjes, Bela Buck, Laurie C. Hofmann

摘要：

此研究探討日長(day length)和光強度對於石蓴(Ulva sp.)生長速率、氧氣生產量和自由基清除活性之影響。此外，同時也探討鹽度、乾燥脫水、日光劑量、和紫外光等因子對於龍鬚菜(*Gracilaria vermiculophylla*)生長速率和自由基清除活性之影響。

研究結果發現，最佳抗氧化活性的條件不一定最適合生長或光合作用。例如高鹽度與脫水程度，會降低龍鬚菜之生長速率和光化系統 II 之量子效率，但抗氧化活性最高（圖 1）。

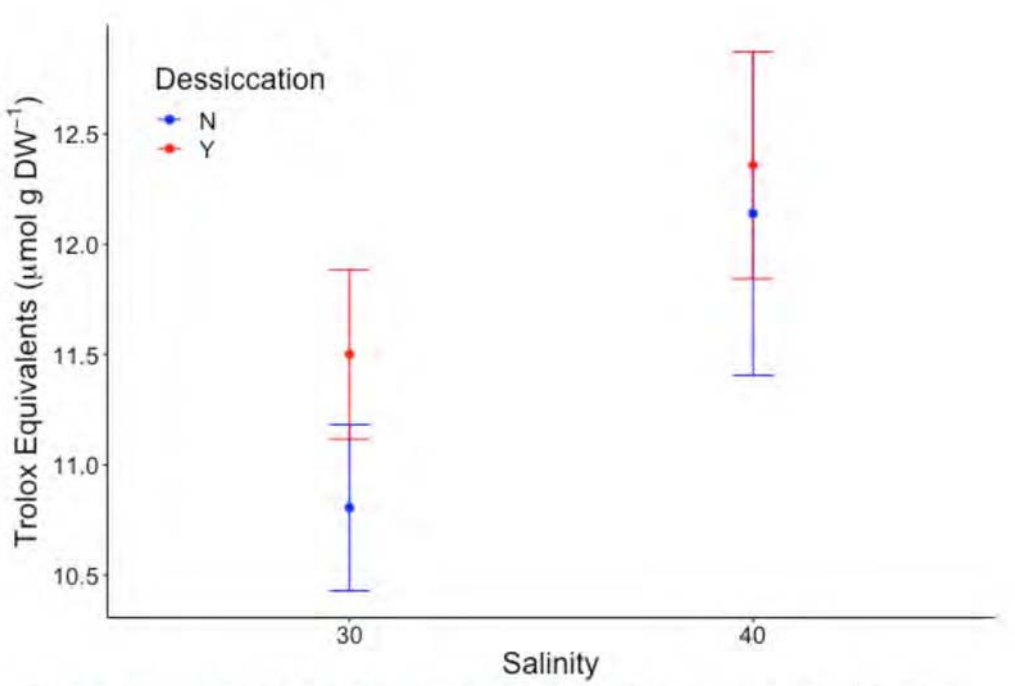

Figure 1. The mean (±SE) radical scavenging activity (as Trolox equivalents) of *Gracilaria vermiculophylla* under different salinity conditions with (Y) and without (N) exposure to desiccation.

(6)

主題：

European seaweed value chains in an international perspective (以國際觀點探討歐盟海藻價值鏈)

講者：

Sander van den Burg, Maggie Skirtun, Miriam Bernard

摘要：

目前，全球海藻產業以亞洲國家為主，中國和印尼是主要原料生產國。近年來，加工設施大多集中在中國，故印尼和智利生產的海藻大部分都以原料型式出口到中國進行進一步加工。歐洲地區，海藻大都是依賴野生捕撈，特別是在法國、愛爾蘭和挪威。杜邦(Dupont)、阿爾蓋亞(Algaia)和 FMC 等公司使用收穫的海藻生物量生產海藻酸鹽(alginates)。

近年來之研究證明，在歐洲各海域進行海藻養殖是可行的，且海藻養殖被認為是未來農業生產的重要來源。初創企業和老牌公司亦開始開發新的生產系統和機械，以便進行大規模生產和收穫，並探索新的消費品、飼料和非食品應用。對海藻的關注也反映在政策中，如荷蘭阿姆斯特丹氣候協議 (Klimaatakkoord)草案和 Noordzee 2030 草案，以及歐洲各國政府通過研究專案方式，提供資金給予研究和擴大規模生產，例如 GENIALG（www.genialgproject.eu）和 ProSeaweed（www.proseaweed.eu）。

從經濟和價值鏈的觀點，一個不可避免的問題即是，剛起步的歐洲海藻養殖部門，如何與全球主要生產者(亞洲國家)相互競爭。歐洲大規模的海藻生產，勢必要進入全球海藻供應鏈，然而其生產成本和高端產品市場銷售亦是需注意的地方。

歐洲部門目前可專注於利基市場，開發新的高價值產品和新市場。開發海藻的新標準，例如永續性和產品品質，可有別於"全球"海藻。
對分別位於荷蘭和中國的 SWOT 分析，突出了中國在海藻養殖方面的長期經驗，以及生產和加工基礎設施的可利用性。歐洲和中國海藻產業似乎相距甚遠，它們面臨著自身未來的挑戰。然而，歐洲海藻產業需克服的這些挑戰，似乎不是那麼困難。歐洲海藻產業還很年輕，且處於早期發展階段，因此擴大規模可採用高品質播種材料、降低成本的機械化和公眾的積極看法。為了實現後者，並滿足消費者和零售商的需求，該部門需要以高度的透明度證明其生產過程對環境具有正面效益。另一方面，近年中國海藻產業幾乎沒有創新作法，仍依賴勞力密集方式生產，且對於永續性和環境影響仍是一大隱憂。
根據初步分析，中國與歐洲海藻部門之間有很大的合作空間，特別是在發展永續育種、生產和捕撈方法方面。共同關注的問題是通過技術進步、改進生產過程，需要更高品質的苗木和價值鏈的透明度。

二、Climate Change

(1)

主題：

Forecasting the impact of future climate scenarios on cultured mussels growth in the Galician Rías (NW SPAIN) (預測未來氣候情境對於西班牙加利西亞下海灣區之養殖貽貝生長影響)

講者：

Isabel Fuentes-Santos, Xosé Antón Álvarez-Salgado1, Uxío Labarta1, M José Fernández-Ririz, Susan Kay, Solfrid Sætre Hjøllo

摘要：

西班牙西北地區主要養殖貝類養殖，因此當地養殖戶對未來氣候情景對生產系統的影響感到關切。ClimeFish 是一個持續進行的 H2020 專案，致力於研究氣候變化對整個歐洲淡海水養殖產業的影響。此篇研究的目的是預測未來氣候情景對加利西亞地區貝類生長的影響。
此篇研究使用 Fuentes-Santos 等人（2019 年）在觀測（2006-2015 年）下提出的動態模型類比了解貝類殼和軟組織生長，並預測了 RCP4.5 和 RCP8.5 排放情景下的氣候條件（2016-2055 年以十進位間隔計算）。
SST 預測因氣候模型而異。SST 與 POLCOMS-ESM 之預測結果得知，其目標年(2046-2055 年)之年平均氣溫幾乎沒有增加；然而，根據 CSIRO 預測結果，其目標年上升幅度約為 1℃。在 RCP8.5 情境下，在目標年逐漸增加到 1.5-2℃。MPI-ESM 預測預計夏季太陽輻照度將下降，春季和秋季的日照率將明顯增加。
圖 1 強調養殖播種時間對貝類生長的重要性。與夏季和秋季播種的貝類相比，2 月份播種的貝類達到目標重量的時間更少，而 6 月份播種的幼苗的培養長度最大。圖 2 顯示，在 POLCOMS 條件下，培養長度應略有增加，但隨著 CSIRO 和 NorESM 預測，培養長度應減小。然而，與播種時程表相比，氣候變化對貝類生長的影響很小。

此篇研究結果亦說明，氣候變化幾乎不會影響未來 30 年加利西亞的貝類生長。然而，對氣候變化對貝類水產養殖的影響進行適當分析需要解決其他因素，如種苗供應和有害藻華現象，這些因素決定了播種和收穫計畫。

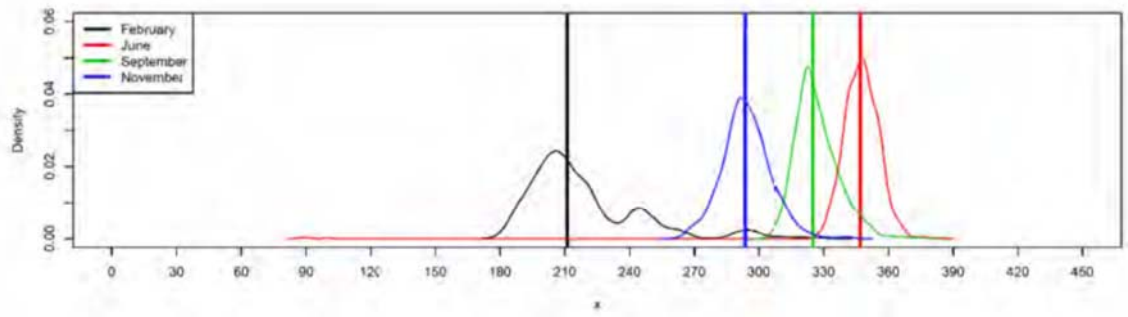

Fig. 1 Time (days) to reach the optimal flesh weight (8g) under observed environmental conditions (2006-2015) in the Ría de Ares-Betanzos. Vertical lines indicate the median.

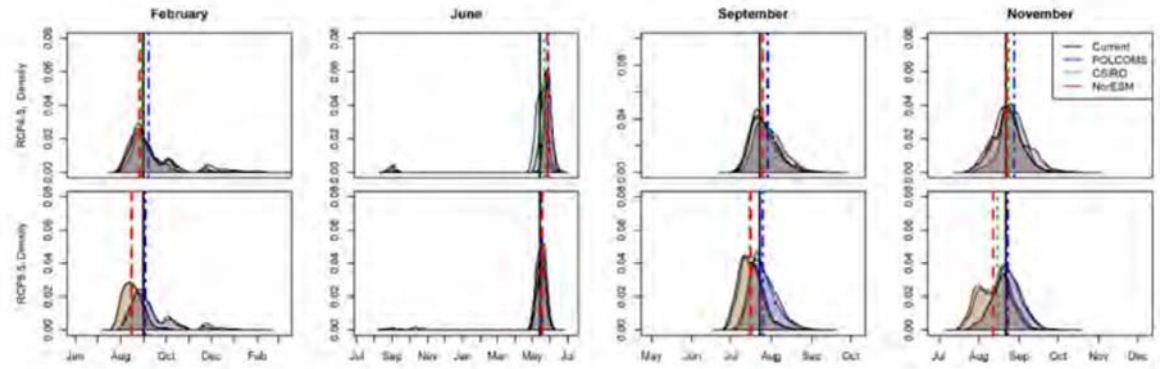

Fig. 2: Density distribution of the harvesting dates for the target size (8g flesh weight) under current (black) and RCP4.5 (top) and RCP8.5 (bottom) conditions for the three climate models in 2046-2055. Vertical lines identify the median of each distribution.

(2)

主題：

Modelling the impacts of climate change on shellfish aquaculture (模擬氣候變遷對於貝類養殖之影響)

講者：

A.M. Cubillo1, J.G. Ferreira, J. Lencart e Silva1, C.M. Kreiss, P. Kamermans, C. Saurel, J. Icely, B. Fragoso, S. Kay

摘要：

此研究建立一種模擬方法，以分析氣候變化對具有商業利益的養殖貝類物種的潛在直接（溫度和糧食供應）和間接（病原體）影響。

針對四種貝類和位置：北海的太平洋牡蠣和藍貝（荷蘭）、北海的藍貝（丹麥）和歐洲大西洋西南部海岸（葡萄牙）的地中海貝類。探討的重點在於貝類生產（生長和死亡率）影響、水質相關的環境外部因素變化、以及後端的社會經濟影響。
支援模擬工作包括：（1）多應力實驗室試驗（溫度 x 食物濃度 x 氧飽和度），主要在參數化氣候變化對雙殼體生長的直接影響;（2）降尺度之物理和生物地球化學模擬，主要利用幾個 IPCC 情境預測未來氣候變遷。
此研究亦使 FARM 模式，探討氣候變遷的直接影響，例如溫度變化對於貝類養殖之影響；另使用 ABC 模式，評估氣候變遷中宿主和病原體相互作用的影響。
根據目前氣候情況，再與 21 世紀中葉（2040-2060 年）和本世紀末（2080-2100 年）的情景進行比較。針對每一種情況，此研究都考慮的 2 種情境：（1）中度情況（IPCC RCP 4.5）;（二）極端情況（IPCC RCP 8.5）。
此研究所介紹的建模工具，主要是期望提高水產養殖部門對氣候變化潛在影響的認識，並希望水產養殖產業能預先做出適當反應，這些調適作法包括開發預警方法、創新養殖模式、基礎設施、位置選擇和商業市場。

(3)

主題：

PAN-European modelling of pacific oyster (*Crassostrea gigas*) growth in the offshore environment: Indicators, regional comparison & climate change (歐洲太平洋牡蠣在近海環境生長之模擬：指標、區域差異和氣候變遷)

講者：

Stephanie Palmer, Laurent Barillé, Pierre Gernez, Susan Kay, Stefano Ciavatta, Yoann Thomas, Philippe Glize

摘要：

海產需求逐漸增加和野生漁業捕撈量逐漸下降，因此海水養殖產業呈現上升趨勢。然而，在傳統上進行養殖的潮間帶地區，擴大貝類養殖範圍是有限的，故擴大在近海生產是一個解決辦法。因此，此研究在於探討太平洋牡蠣（*Crassostrea gigas*）養殖於歐洲和非洲西北部近海環境之生物永續性，以及評估未來氣候變遷對於太平洋牡蠣生長可能之衝擊。
透過牡蠣生長資料，此研究建立幾項產業相關指標，包括養殖至市場需求規格最少之時間、主要市場所需之規格大小和品質指標，基本市場分類為"特殊"、"良好"或"一般"。C.gigas 養殖區域需考是海水鹽度、洋流速度、溫度、和養殖區域之葉綠素範圍，此研究亦考慮兩個深度範圍：<25 公尺深度(適合小規模養殖業者)和<200 公尺深度(可供更大的規模作業投資能力業者)。
再將本世紀初期和末期之氣候預測情景之日增長圖譜轉換為指標圖（如圖 1），因此可在此區域發現了幾個"熱點"，供更詳細地研究。某些區域具有較高生長性，但空間區域較小；而有些區域，在世紀初的參考時期，具有較高生長性，但卻會受到氣候變遷的不良影響。

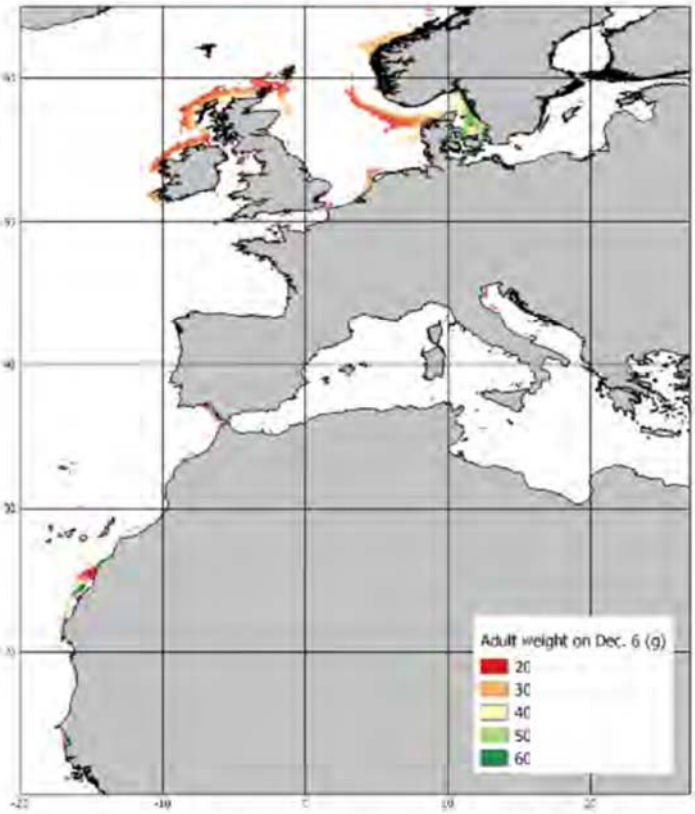

Figure 1. The model domain extent and an example of a mapped Pacific oyster growth indicator, adult weight in time for the December market, for the early-century (2000-04) reference period. Indicator maps and raw modelled growth data are also available for the two future scenarios (2090-99; RCP 4.5 and 8.5).

三、Sustainable aquaculture technologies

(1)

主題：

Tools for new and flexible approaches for aquaculture licensing and regulation (新穎且具彈性之許可和規範管理方法工具)

講者：

P. O'Donohoe*, F. Kane, J. Casserly and S. McLoughlin

摘要：

The H2020 project TAPAS (Tools for Assessment of Planning and Aquaculture Sustainability, http://tapas-h2020.eu/)，主要目的在於協助歐盟會員國能建立一套一致且有效地規範架構，以利歐洲水產養殖部門可以永續成長。因此，此篇研究在於建立一套新的策略和模式，以利水產養殖產業可永續發展。

透過協商和訪談，了解許可證制度存在的關鍵問題和瓶頸。根據收集的資料，並透過提出新的方法和創造新的工具，以改善管理和許可證制度的效率。在與利害關係人和產業界持續協商期間，對靈活的方法和工具進行實地探討，以確保這些方法的可接受性和實用性。

此研究簡要概述利害關係人投入所產出之結果，並就建立新的、靈活的水產養殖許可證和管制政策的方法和工具提出了結論性建議。

Farming warmwater fish on land in a cold country – A crazy idea or a new sustainable seafood supply chain? (在寒帶國家養殖溫水魚種：瘋狂想法，還是新的永續海產供應鏈？)

講者：

Kristina Bergman, Patrik Henriksson, Sara Hornborg, Max Troell, Malin Jonell, Friederike Ziegler

摘要：

陸地養殖溫水物種，例如吳郭魚(*Oreochromis niloricus*)、尖齒鬍鯰(*Clarias gariepinus*)、白蝦(*P. vannamei*)，構成一項瑞典的新興食物部門。

幾家小型但發展迅速的公司，自認為比傳統水產養殖更具永續性，這幾家小型公司開始在循環養殖系統（RAS）生產海鮮，其海產作為鮭魚（吳郭魚）、金槍魚（新鮮克鯰魚）、鰻魚（煙燻鯰魚）和進口蝦（白蝦）的替代品，以向有環保意識的瑞典消費者銷售。

此篇研究使用生命週期評估（LCA）方法，分析其中一家公司海鮮生產的環境壓力。LCA 廣泛應用於產品供應鏈之環境衝擊特徵化和確認改善項目，並且用於評估多項水產養殖生產系統。

此研究在瑞典養殖的吳郭魚和尖齒鬍鯰，並評估其產品供應鏈之環境壓力（如溫室氣體排放和優養化）的結果，以確定環境熱點和改進方案。

結果發現，飼料是最重要的因素，另外還有高度密養殖系統之基礎設施和維護工作。包含高密集資源之飼料成分，如動物副產品，也大大增加了環境足跡。

Ecointensification of aquaculture: innovative mortality disposal in a circular economy perspective (水產養殖生態強化：循環經濟觀點之創新死亡率處理)

講者：

Hallstein Baarset and Johan Johansen

摘要：

高密度水產養殖的主要影響包括死亡和廢棄魚類。統計資料顯示，箱網養殖之死魚損失約為 15-20%，相當於生物量的 6-9%。挪威水產養殖業者每年需耗費超過 1 億歐元之成本。

GAIN (Green Aquaculture Intensification in Europe 歐洲綠色水產養殖強化)是最近獲獎的 Horizon 2020 專案，並期望能在專案執行期間向市場提供服務和技術，為歐洲水產養殖生產的生態強化做出貢獻。資源效率、環境衝擊、和整體生產鏈的精度與價值等皆是提高海產自我生產熟練程度和區域穩定性的關鍵要素.

目前挪威水產養殖死亡率的處置方法面臨健康、安全和環境方面的挑戰，而且處理費用高昂。因此，Waister 公司評估一種現場乾燥和乾燥消毒產品運輸的死亡處理創新方法。

根據循環經濟，Waister 公司將依據歐盟和挪威的政府法規對此乾燥產品進行必要的評估。但通過乾燥和消毒產品的安全應用驗證，可能會出現進一步的應用方式，但皆需要對現行法規進行修改或修訂。

Waister 公司在挪威大西洋鮭魚生產商建立了 GAIN 示範設施，用於工業生產規模相關基材的評估、記錄和專業培訓。此示範設設為一種魚體的乾燥系統，用於處理幼鮭生產的魚體。

Waister 公司將再進一步比較現行方法和創新方法，並發現於符合政府規定下，其乾燥產品可能增加的價值及效益。

主題：

Novel banana by-products in seabass (*Dicentrarchus labrax*) diets (添加香蕉副產物於海鱸魚飼料之探討)

講者：

S. Ramírez-Bolaños, S. Díaz, N. Díaz-Padilla, A. Ventura-Castellano, R. Quirós-Pozo, L. Robaina

摘要：

加那利群島(Canary Islands)的香蕉是一個非常穩定的產業，每年約可生產 4 億噸香蕉，大約會產生 10%生質殘留物，且多數會直接堆置於香蕉園中，而造成污染的問題。Life BAQUA（LIFE 15/ENV/ES/000157）發現可從香蕉殘留物（banana pseudostem）中提取纖維，此為一項可生物降解材料，可用於包裝材料。

在香蕉纖維提取過程中，會產生一個重要的副產品：紙漿。此外，香蕉作物還產生其他重要的殘留物，如香蕉花。亦有研究表示，香蕉生質殘餘物含有大量的抗氧化劑，亦可開發作人類或動物產品。
將香蕉漿（BT）和香蕉花（BF）等兩種香蕉殘餘物添加於海鱸魚飼料中，並以等蛋白和等脂肪方式添加，以測試不同添加比例對於海鱸魚的生長情。除了生化成分、脂肪酸、消化和肝臟組織學外，亦於試驗結束時，採集生長和性能參數。
試驗結果發現，以 BT4 (表添加 4%之香蕉漿)飼料養殖 2 個月後之魚重，可較控制組之魚重增加約 23.38±1.56 克；而餵養 BF6 (表添加 6%之香蕉花)之最後魚重量約可增加 25.58±0.89 克。

主題：

Fish quality: a psychological perspective (魚肉品質：心理學的觀點)

講者：

J. Simons, C. Vierboom, M. Ley, and S.-A. Johnigk

摘要：

由已開發國家的魚類和海產購買行為文獻回顧中，了解感官、健康關注、飲食習慣、便利性、自行處理程序、價格和魚類供應等為魚類消費數量之主要決定因素。此外，產品屬性，例如原產國、生產方法、保存方法、產品創新、包裝和生態標籤，亦會影響不同產品的選擇。除購買行為外，還有永續性和消費者願付價格(willing to pay, WTP)等，亦會影響購買意願。
此研究利用形態心理學的理論框架，探討特定產品之影響。此方法是以產品為導向，確定產品滿足心理需求或動機的能力。在定性訪談和小組討論中收集對產品影響的見解，參與者在每天的直播中描述產品的含義。由於定性方法具有解釋性，因此容易產生偏差，因此透過專業心理學家團隊進行研究，以提高結果的有效性。此外，市場資料提供額外的見解，並說明減少偏頗的解釋。
2017 年 11 月和 12 月在德國進行了 10 次深入訪談和 3 次小組討論，每次有 8 至 10 人參加。鑒於產品的心理影響取決於文化環境，成果不能簡單地轉移到其他國家。
在德國，魚和魚產品的具體心理特徵因消費水準低而得到增強，每年約為 14 公斤/人，而肉類和肉製品的消費量約為 90 公斤/人/年。
魚同時具有迷人的和威脅性。此外，魚可以很容易地與假期和冒險的記憶相關聯。魚的"明亮"面與"黑暗"面形成鮮明對比。腐敗且臭掉的魚容易與中毒危險連想在一起，且會破壞魚類迷人的形象和對魚的胃口。而且，魚類可能生長的污染環境，故以魚類作為食物也會引起人類對於食魚的負面想法。魚骨也是另一個問題，可能在準備、料理和進食需要小心。訪談參與者通常會在餐廳吃新鮮的魚，因此不需要靠自己處理魚。然而，新鮮魚類僅占德國魚類總消費量的 10%左右。
魚的新鮮程度同時也是一道屏障，故高價市場額外售販已處理好的魚類產品，提供消費者選擇。

主題：

Towards improved communication in aquaculture: exploring consumers' perceptions and attitudes (改養水產養殖的溝通：探討消費者的看法與態度)

講者：

Sofia C. Franco, Sharron Kuznesof, Bruna Simões, Beth Clark and Peter Jackson

摘要：

民眾的觀念被認為是水產養殖擴張的制約因素之一，因為此觀念不僅意味著海鮮採購和消費態度，而且意味著民眾對該產業的支持與社會的認可。然而，要建立社會認可，必須先瞭解觀念、態度和基本因素，再用予改善企業、第三部門和監管機構的運作方式和與公眾互動方式。

雖然有一些研究著重於分析消費者的知識和消費習慣、對養殖或野生捕獲海產的偏好、關鍵議題的相關性、歐洲媒體報導的趨勢；然而，目前民眾對水產養殖的看法和相關的態度，例如支持或反對的看法，其研究文獻仍然很少，水產養殖產業的社會認可相關研究也是最近才開始在文獻中出現。因此，在目前有限的證據下，仍較無法去告知民眾，提升接受度或增加消費的有效策略；另外，對於應向公眾或社區傳達哪些內容以及這種參與應如何進行宣傳，存在高度不確定性。在其他角色方面，例如企業社會責任或許可證，在塑造水產養殖形象方面的作用也仍然缺乏探索。

對歐洲水產養殖的看法和態度進行系統文獻回顧，並將文獻回顧結果告知重點小組。重點小組旨在調查海產的採購和消費行為，以及公眾對水產養殖生產和產品的看法和態度；包括不同人群的英國消費者（低頻、高頻）、非消費者（一般、素食）和鄰近經營水產養殖設施的社區（年齡較大、年齡較小的社區）等共進行 6 次重點調查（每次 6-8 人）。

還與英國不同利害關係人（生產商、加工商、零售商、第三部門和監管機構;每組 3-4 人）進行一系列深入訪談，以確定民眾感知問題、溝通挑戰和途徑，以提高參與度。這項研究旨在支援制定最佳傳播作法，改善民眾對水產養殖部門的參與，以及永續的海產生產和消費。

五、Hatchery technologies and practices

主題：

Improving microdiet technology for first-feeding gilthead seabream (*Sparus aurata*) larvae (改善微粒飼料技術於第一次餵食金頭鯛)

講者：

Wilson Pinto, Sofia Engrola, Bruno Nunes, Rita Colen, André Santos, André Lopes and Luís E.C. Conceição

摘要：

金頭鯛（*Sparus aurata*）幼苗餵食方法通常是在孵化後的頭 30 天內餵食活獵物，並在第二個月完全改為餵食商業微粒飼料。儘管具有挑戰性，但開發一種在第一次餵食時提供的微粒飼料對孵化場極為有利，儘管在這個階段幼苗已經降低獵物和消化能力。

由於微粒飼料往往比活體動物接受程度低、消化性差，特別是在複雜蛋白質方面，因此在製作微粒飼料時必須考慮這些限制。

例如，透過在微粒飼料配方中加入蛋白質水解酸鹽，增強其吸引力並導引幼苗消化道進一步成熟，可以減輕這些因素。首次餵食海帶的微粒需要由小顆粒（約 100 μm）組成，表面與體積比高，導致蛋白質水解到養殖水體，致使溶出過量氮氧化物。微封裝提供了控制這些水溶性營養素溶出的可能性，提高微粒飼料攝食的營養價值。這種控制對於在第一餵食的海帶中成功導入微粒飼料似乎至關重要。

此研究目的在於開發一種微封裝原型，以減少微粒飼料中常用的一種蛋白質水解液的溶出。該原型隨後被添加到商業微粒飼料中，添加比例為 8.5 和 30%，從孵化至孵化後 34 日皆餵食此添加微封裝原型之商業飼料，並測試金頭鯛生長速率和存活率。

在海水中浸泡兩小時後，新型微封裝原型只釋放出 25%的水溶性蛋白質含量，比參考曲線（同期溶出 90%）中獲得的值低 65%。

在孵化後的 12 日，在消化道中用微粒飼料觀察到的幼苗數量比餵食活獵物的多。在這個年齡，在 CAP8.5 和 CAP30 中觀察到的幼苗體重明顯高於對照治療（圖 1）。在孵化後之 34 日，來自 CAP8.5 的幼苗比 CAP30 的幼苗大得多。前處理和對照方法之間沒有顯著差異。幼苗存活率不受微飲食的影響（約為所有實驗之 4-7%）。

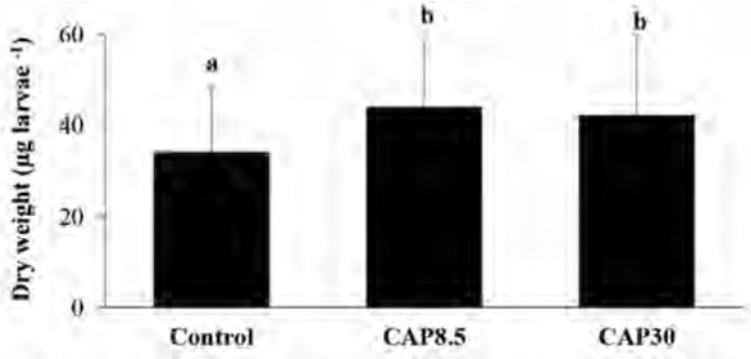

Fig. 1. Dry weight of 12 day-old seabream reared under different dietary treatments. Results are expressed as means ± standard deviation ($n = 60$).

主題：

Salinity reduction benefits european eel larvae: a review (鹽度降低對歐洲鰻魚幼苗之影響：綜合討論)

講者：

S.N. Politis, E. Syropoulou, E. Benini, S.R. Sørensen and J. Tomkiewicz

摘要：

歐洲鰻魚（*Anguilla anguilla*）是一種廣鹽性的魚種，會為繁殖(產卵)而的遷移易海中，導致歐洲鰻魚幼苗可自然存活於低滲透環境中。在此環境中，血漿滲透率必須低於環境，故歐洲鰻魚幼苗需要通過脫鹽過程以保持滲透平衡，避免滲透水損失。有趣的是，在水產養殖可透過降低鹽度來促進更佳之生長速率和存活率。因此，此研究探討少鹽度對圈養生產歐洲鰻魚幼苗的影響，以評估最佳條件飼養歐洲鰻幼苗。

在所有實驗中，當鹽度保持在 36 psu (practical salinity unit)（對照組）時，幼苗死亡率最高，這與藻海(Sargasso Sea)產卵區的鹽度相似。先前之研究結果顯示，越早和更快的將鹽度降低，其幼苗存活率越高。
降低鹽度試驗中，特別是在 0 dph (days post hatch, 孵化後日數)和 4 psu （最快降低）試驗，可降低死亡率、增加魚體面積、減少油滴利用率，提高生長效率。然而，在 3 dph 才開始減少鹽度，可能導致更高的死亡/畸形比例。因此，當鹽度緩慢降低，使得幼苗和 RAS 生物濾膜可緩慢的適應鹽度降低，故幼苗存活率增加至 50%。此外，當鹽度迅速減少時，幼苗存活率同樣得到改善，此結果與先前實驗結果一致。考量孵化場生產，這是一種更實在、更經濟的高效方法 - 減少幼苗生產對 RAS 的需求。因此，快速減少鹽度的方法可以應用於既有 RAS，且僅需設定鹽度步驟，並分別確保每個系統的水質穩定性和生物濾液的微生物平衡。
此外，劇烈之鹽度變化，其幼苗存活率與對照組實驗相似，因為它們在 36 psu 時也飼養到第 6 天；但令人驚訝的是，幼苗急劇地移動到 50%鹽度，竟能夠快速適應極端的生理變化。因此，在哪個階段或年齡應用這種急劇的變化，以抵消在前 6 dph 期間觀察到的高死亡率是後續應持續探討之問題。
此結果亦證明，可以應用大幅度降低鹽度，應用此種最經濟的鹽度降低方法，便可使幼苗產量增加 50%，而且只需要 2 個 RAS 系統控制鹽度即可。

主題：

Impact of water purification and conditioning on in vitro produced embryos and larvae of european eel (*Anguilla anguilla*) (水質純化和調理對歐洲鰻魚之外胚胎和幼苗影響)

講者：

S.R. Sørensen, E. Syropoulou, S.N. Politis, Benini, E., Hambly A.C., Tomkiewicz J.

摘要：

2012 年，水產養殖魚類產量首次超過漁業產量，目前是世界上增長最快的糧食生產部門。然而，集約式魚類養殖生產容易爆發疾病，其中以致病菌為主要原因，又以幼苗階段更容易受到集約式水產養殖的感染。
幼苗在集約化水產養殖中暴露於來自外部和內部來源的大量微生物，但其相對重要性取決於所使用的飼養技術。通過優化底層基礎、營養鹽、過濾和水力停留時間等操作條件，這可能有助於支援更有利的微生物群落，從而提高循環水產養殖系統的穩定性和養殖成功率。

研究成果得知，通過微生物處理來調節循環水養殖系統之水質，可有效提升養殖環境的穩定性，增加歐洲鰻魚的胚胎飼養成功率。

主題：

Improving automatic feeding protocols in semi-intensive pond culture of pacific white shrimp (*Litopenaeus vannamei*) (改善白蝦半集約式養殖之自動化飼料餵食協定)

講者：

João Reis, Melanie Rhodes, D. Allen Davis

摘要：

白蝦養殖的成功取決於改進飼料管理和降低工作力成本。蝦是食用多餐性的食肉動物，因為儲存食物的胃容量有限，故透過餵食多餐方式可提高白蝦養殖成效。先前研究成果發現，由每天兩次餵食轉變為多次餵食系統可提高白蝦生長率和生產量。

以先前研究成果為基礎，此研究目標是為自動餵養系統開發標準餵養協定（standard feeding protocol, SFP），以提高太平洋白蝦(*Litopenaeus vannamei*)半集約式漁塭生產中的增長率。

在第一次試驗中，在 16 個 0.1 公頃的戶外池塘進行 13 周的試驗，以 26 尾蝦/m^2 放養，並餵食 35%的蛋白質大豆優化飼料。四種餵食方式：使用自動計時器提供三種固定餵養處理，分別為 SFP130、SFP145、SFP160 提供 130、145 和 160% 的固定餵養處理，以及第四種餵食方式是使用聲學饋送系統（AQ1）。

試驗結果表示。在不同餵食方法之存活率和 FCR (feed conversion ratio, 飼料轉換率)並無明顯之統計差異。然而，增加飼料餵食量可使產量提高，又以 AQ1 聲學餵養系統之產量最高，因為 AQ1 方法投入更多的飼料量，蝦子可獲得更多的飼料量，故生產之蝦子更大隻，產量也更高。

(2)

主題：

Growth performance and survival of whiteleg shrimp *Penaeus vannamei* under varying stocking densities (不同放養密度之白蝦生長狀況和存活率)

講者：

A. Segelken-Voigt and R. Bochert

摘要：

白蝦(Penaeus vannamei)是全球養殖最多的甲殼類動物之一，不僅可戶外之漁塭養殖，也可在室內使用清水循環水養殖系統（RAS）養殖。然而，水質和放養密度是白蝦養殖最重要管理參數。

此研究探討不同白蝦放養密度，白蝦苗為第 12 天之後期蝦苗（postlarvae, PL 12）和約 2.5g 幼苗重量，評估養殖 2 週和 4 週後之生產成效。以鹽度為 20 ppt 之海水進行個別養殖試驗，每個試驗皆進行三重覆，循環水養殖系統體積為 100 L。 PL 12 放養密度分別為 6、35 和 70 尾/L，幼蝦為 300、600、900 和 1200 尾/m^2。在實驗終止時，對蝦子的長度、重量比和存活率進行比較。

後期蝦苗(PL 12)在 6 和 35 尾/L 的放養密度下，存活率較高，超過 50%，存活率僅為 30%。6 尾/L 的比生長速率（SGR）為 3.5%/天，35 和 70 尾蝦/L 為 2.8%/天。

在幼蝦放養試驗中，兩個低密度組之存活率比兩個高密度組來得高，2 個低密度組之存活率約為 90%，而 2 個高密度組約為 70%。試驗結果亦表示，低放養密度的 SGR 較高，為 3.3%/天（300 和 600 幼蝦/m^2），而 2.5%（900 和 1200 幼蝦/m^2）。

主題：

Organic and conventional marine shrimp farms in brazil: macrobenthos occurrence inside and in the outlets of the ponds (巴西之有機傳統海洋養蝦場：漁塭內部和出水部出現大型底棲性生物)

講者：

Juliana Schober Goncalves Lima and Ulfert Focken

摘要：

巴西北里奧格蘭德州(Rio Grande do Norte State, Brazil)的 Guaraira 瀉湖(Lagoon)被大量海洋養蝦場包圍，這些養殖場大都為半集約式和集約式養殖。其中一些養殖場是在 1924 年時，與前淡水湖和附近海域建立人工連接後，開始發展為海洋養魚場，而其他養殖場是最近才建立的。

雖然大眾對巴西對蝦業的生態永續性和國際市場價格的下降感到擔憂，但 Guaraira 瀉湖周圍的海洋養蝦業正在穩步增長。

2001 年，位於 Guaraira 瀉湖的一個傳統養蝦場開始發展有機養殖，將天然池塘生物群作為主要食物來源，而傳統養蝦系統則以飼料為主要食物來源。2004 年，該養殖場被認證為巴西第一個甘蔗蝦養殖場。由於放養密度較低，沒有餵食飼料，有機養殖被認為更環保，有機蝦養殖的可變成本大大降低，可以生產更大的蝦，販售更高的價格。

為了比較不同養蝦系統的池塘生態和環境影響，於 2005 年上半年進行有機養殖場和 Guaraira 瀉湖周圍的養殖蝦場，在養殖週期中進行底棲生物的調查，因底棲生物被認為是海水養殖池內外環境變化的良好指標。
底棲生物樣品的採集範圍為 100 mm，篩網尺寸為 1.0mm，且採集之生物體保存於 5% 福馬林中，供日後分析。此外，亦對採集樣本進行分類及豐富度分析。

調查結果顯示，在集約式和半集約式系統的人工飼料養蝦場中，底棲生物密度增加，而且初期之底棲生物豐富度比有機養蝦系統來得高。多毛綱動物(polychaetes)為主要之底棲生物，另亦發現甲殼類動物(crustancean)、貧毛類蠕蟲(oligochaete)和紐蟲(nemertine)。在半集式和集約式系統中，海稚蟲科(Spionidae)的多毛綱動物為主要優勢物種。只有在有機系統中，漁塭內部的生物多樣性才高於外部。
底棲生物的分析結果與土壤有機物、水中營份、氧化還原電位和土壤中的 pH 等因素相關。

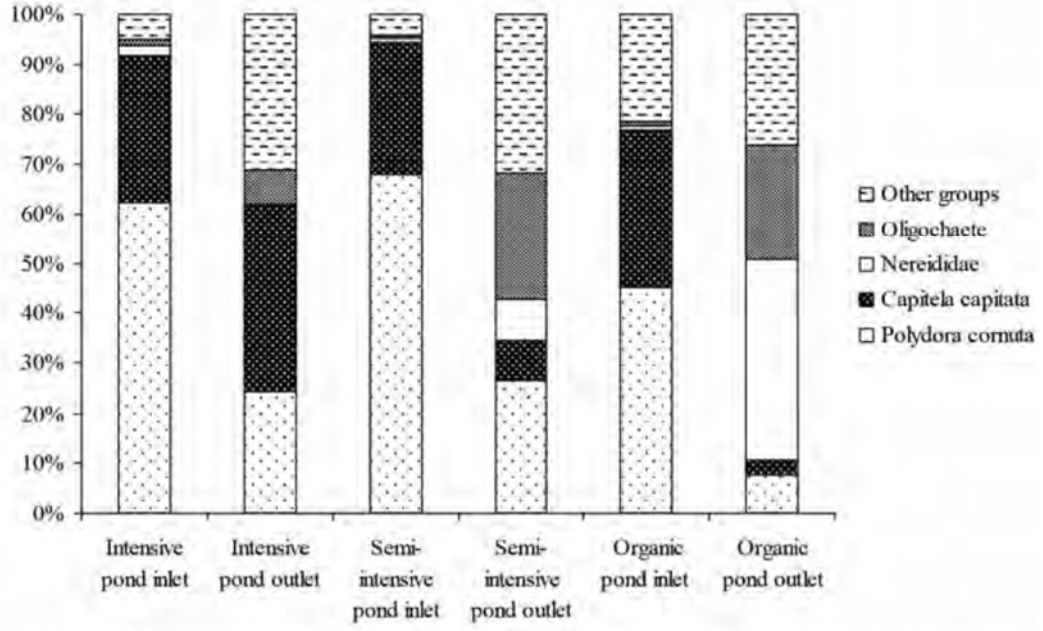

Figure 1. Occurrence (%) of dominant macrobenthos groups inside and at the outlet of the intensive, semi-intensive and organic marine shrimp ponds.

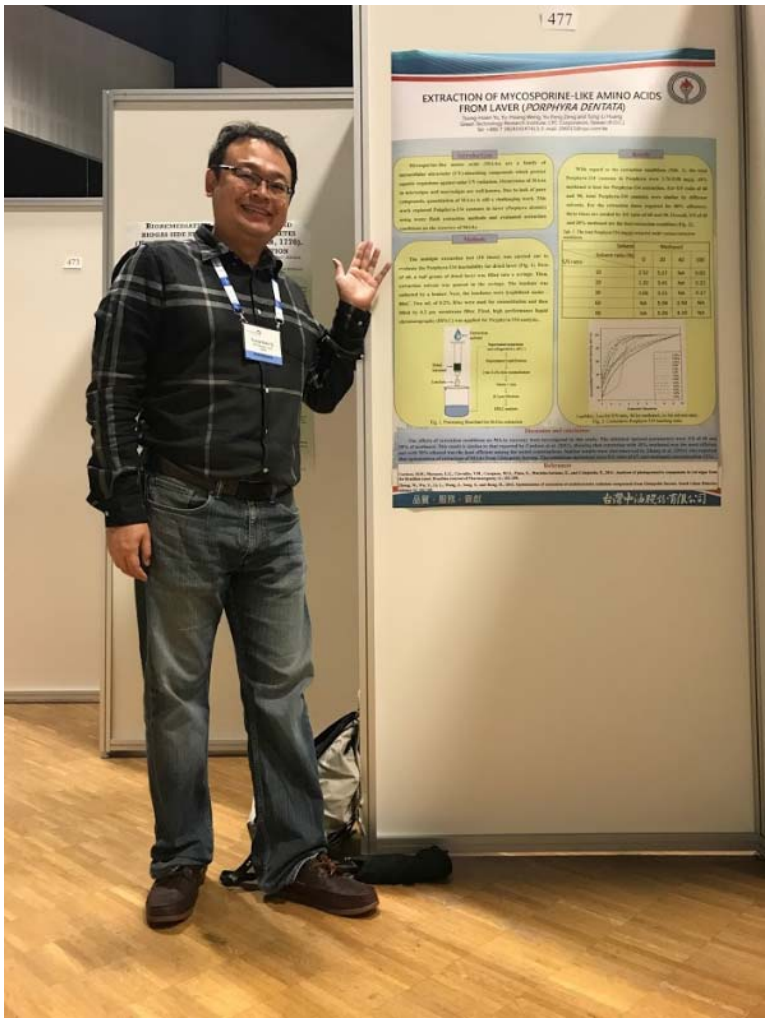
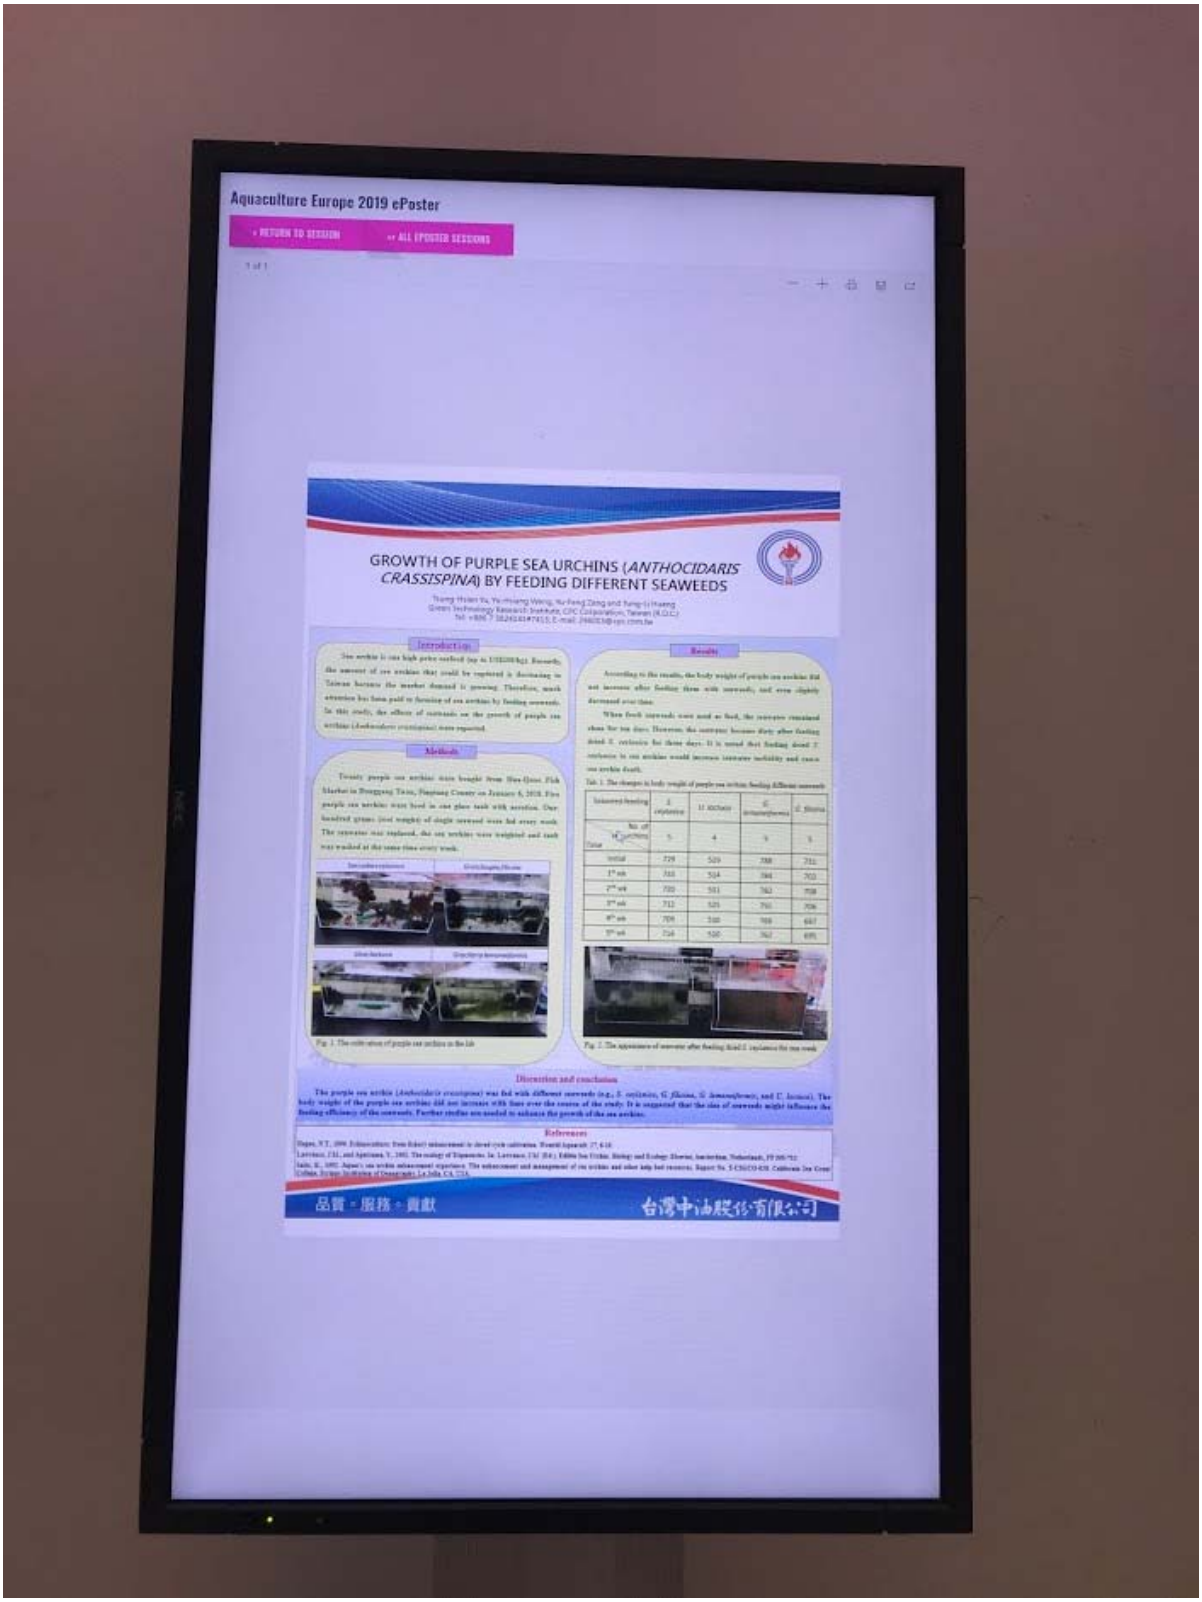
本組參與此國際研討會，共發表 2 篇海報(參與投稿證明如附件三所示)。

第一篇為「EXTRACTION OF MYCOSPORINE-LIKE AMINO ACIDS FROM LAVER *Porphyra dentata*」，此篇海報論文投搞至 Food Quality and Safety 議題類別，Poster ID 為 477。



第二篇海報論文發表為「GROWTH OF PURPLE SEA URCHINS *Anthocidaris crassispina* BY FEEDING DIFFERENT SEAWEEDS」，此篇海報論文投搞至 Seletive Breeding 議題類別，Poster ID 為 556。然因海報張貼看板僅有 500 個，故本海報論文被發表於電子海報(e-Poster)。



四、心得與建議

本次會議之議題幾乎包括所有水產養殖之議題，共有 56 個會議(sessions)、1039 篇摘要論文、594 篇海報(包含 94 篇之電子海報)、150 個展覽攤位、85 個參與國家、超過 2700 位參與者。

然而，因此國際研討會議題很多，故本人僅能盡可能參與和本組研究方向與未來可能研發方向相關之議題。主要參與之論文發表議題包括 Macroalgae, Climate Change, Sustainable Aquaculture Technologies, Value Addition and Marketing, Hatchery Technologies and Practices, and Shrimp。本人就將上述之議題摘錄較重要之發表提出探討。

目前歐洲已逐漸重視海藻，並且開始海藻養殖產業，以及海藻高值化研究。雖然，歐洲海藻產業仍無法與東南亞地區相比較，但歐洲將朝向高品質和高單價之海藻產品進行生產，以和東南亞地區之海藻有所區別。

氣候變遷對於歐洲水產養殖產業之影響有所區別，對於既有養殖物種或原本生存於當地之物種將會造成影響，例如當地養殖之貝類。然而，因氣候變暖，歐洲某些地區水溫亦慢慢變高，因此可養殖一些溫帶和亞熱帶之魚物。

另就養殖技術而言，大多傳統養殖方式皆為半集約式和集約式，高密度養殖易造成水質惡化和致病菌生長，而導致魚蝦生病死亡；因此，目前已推出許多自動化和 AI 水質監控技術，可促使水質較為穩定。

此國際研討會規模很大，許多 sessions 同時進行，故無法同時聆聽到好的發表，僅能有所取捨，挑選較適本組研發方向之 sessions 聆聽。此外，本國際研討會之發表海報數量也很多(高達 594 篇)，但海報參觀時間較短，因此無法全部細讀海報內容和有趣的海報，甚為可惜。

綜合上述，參加本次國際研討會學習到許多有趣的研究方向和內容，另亦攜回研討會摘要論文集，以及紙本海報攝影和電子海報，後續皆可再回顧研讀，或與發表者討論。

Tuesday, October 8 10.30 - 12.50 Lounge 1-3
Chair: Daniel Taylor

10.30 Festus I. Adeosun
THE FISHES OF AKOMOJE RESERVOIR DRAINAGE BASIN IN LOWER RIVER OGUN, NIGERIA: DIVERSITY AND ABUNDANCE

10.50 Ingrid Askeland Johnsen, Alison Harvey, Anne D. Sandvik, Ola Ugedal, Bjørn Ådlandsvik, Vidar Wennevik, Kevin A. Glover, Ørjan Karlsen
SALMON LICE *Lepeophtheirus salmonis* INDUCED MORTALITY OF ATLANTIC SALMON *Salmo salar* DURING POST-SMOLT MIGRATION IN NORWAY

11.10 Maggie Skirtun, Sander van den Burg, Trond Selnes
MARINE RESOURCES IN CIRCULAR CLIMATE SMART FOOD SYSTEMS: A CASE STUDY OF SEAWEED CULTIVATION IN THE NORTH SEA

11.30 Alda Miftari
ECONOMIC ISSUE AND GOOD ATTRIBUTES OF SUSTAINABLE AGRICULTURE SYSTEM WITH A FOCUS ON CAP REFORM AND WATER FRAMEWORK DIRECTIVE

11.50 Lindsay Brager, Peter Cranford, David Wong, Brent Law
CANCELLED ALTERNATIVE METHODS FOR MONITORING BENTHIC ORGANIC ENRICHMENT EFFECTS AND APPLICABILITY ACROSS A RANGE OF ENVIRONMENTAL AND AQUACULTURE CONDITIONS

12.10 Henry Peterson
WASHINGTON STATE'S POLLUTION IDENTIFICATION AND CORRECTION PROGRAM'S WORK TO PROTECT AND RESTORE SHELLFISH BEDS AND PUBLIC HEALTH

12.30 Rodrigo Roubach, F.C.M. Godoi, F.S. David, N.S. Fialho, M.R. Brande, G.W. Bueno
ENVIRONMENTAL SUSTAINABILITY INDICATORS APPLIED IN SMALL SCALE FAMILY FISH FARM AT THE ATLANTIC FOREST IN SOUTH AMERICA

CLIMATE CHANGE

Tuesday, October 8 10.30 - 17.30 Room 5
Chairs: Myron Peck, Orestis Stavrakidis

10.30 Michelle Barbosa, Caroline Schwaner, Emmanuelle Pales Espinosa, Bassem Allam
OCEAN ACIDIFICATION AND MULTIPLE STRESSORS AFFECT LARVAL BUT NOT JUVENILE STAGES OF THE EASTERN OYSTER *Crassostrea virginica*

10.50 Patrícia Anacleto, Mariana Carmona, Ana Luísa Maulvault, Vera Barbosa, Marta Santos, Pedro Pousão-Ferreira, Luísa M.P. Valente, António Marques, Rui Rosa
FISH ENERGY BUDGET OF THE ZEBRA SEABREAM *Diplodus cervinus* UNDER OCEAN WARMING AND ACIDIFICATION

11.10 I. Martins, A. Azevedo, R. Ramos, M.H. Abreu, R. Pereira, L.M.P. Valente
HOW WILL THE PRODUCTION OF AN ECONOMICALLY RELEVANT ALGA *Gracilaria* sp. VARY WITH TEMPERATURE RISE?

11.30 **António Marques**, A. L. Maulvault, Rui Rosa, Mário S. Diniz
CLIMATE CHANGE AND EMERGING CHEMICAL CONTAMINANTS IN MARINE ORGANISMS: BIOACCUMULATION, ECOTOXICOLOGY AND PUBLIC HEALTH IMPACTS

11.50 **Remigiusz Panicz**, Beata Calka, André Sobral Lopes, João Lencart e Silva, João Gomes Ferreira, Jacek Sadowski, Paulina Hofsoe-Oppermann, Slawomir Keszka, Nick Taylor, Adam Kennerley, James Guilder, Susan Kay
PATHOGEN AND BIOMASS GROWTH RISK ASSESSMENT MODEL FOR INLAND AQUACULTURE IN EASTERN EUROPE UNDER CLIMATE CHANGE

12.10 **Myron Peck**, Pauline Kamermans, Tom Doyle, Nick Taylor, Joao Ferreira
RISKS AND OPPORTUNITIES OF CLIMATE CHANGE TO EUROPEAN AQUACULTURE: ADVANCES MADE IN THE EU CERES PROJECT

12.30 **Lena Schenke**, Tamás Bardócz, Kyra Hoevenaars
CLIMATE CHANGE IMPACTS ON THE EUROPEAN ISLANDS' AQUACULTURE SECTOR

12:50 **LUNCH**

14.30 **Isabel Fuentes-Santos**, Xosé Antón Álvarez-Salgado, Uxío Labarta, Mª José Fernández-Reiriz, Susan Kay, Solfrid Saetre Hjøllo
FORECASTING THE IMPACT OF FUTURE CLIMATE SCENARIOS ON CULTURED MUSSELS GROWTH IN THE GALICIAN RÍAS (NW SPAIN)

14.50 **Alhambra Gadea Martínez Cubillo**, J.G. Ferreira, J. Lencart e Silva, C.M. Kreiss, P. Kamermans, C. Saurel, J. Icely, B. Fragoso
MODELLING THE IMPACTS OF CLIMATE CHANGE ON SHELLFISH AQUACULTURE

15.10 **Stephanie Palmer**, Laurent Barillé, Pierre Gernez, Susan Kay, Stefano Ciavatta, Yoann Thomas, Philippe Glize
PAN-EUROPEAN MODELLING OF PACIFIC OYSTER *Crassostrea gigas* GROWTH IN THE OFFSHORE ENVIRONMENT: INDICATORS, REGIONAL COMPARISON AND CLIMATE CHANGE

15.30 **Sally McGee**
THE SHELLFISH GROWERS CLIMATE COALITION: A BUSINESS PARTNERSHIP OF 100+ COMPANIES TAKING ACTION TO SECURE A LOW CARBON FUTURE FOR THE BENEFIT OF SHELLFISH AND THE ENVIRONMENTS THEY DEPEND ON

15.50 **Gergo Gyalog**, Béla Csukás, László Berzi-Nagy, Mónika Varga
IMPACT OF CLIMATE CHANGE ON CARP YIELDS IN HUNGARIAN POND AQUACULTURE

16.10 **Orestis Stavrakidis-Zachou**, Konstadia Lika, Nikos Papandroulakis
FORECASTING CLIMATE CHANGE IMPACTS ON GREEK AQUACULTURE PRODUCTION: A CLIMEFISH CASE STUDY

16.30 **Øivind Bergh**, Ingrid Johnsen, Lars Asplin, Nina Sandlund, Anne D. Sandvik, Joao G. Ferreira, Nick Taylor
CLIMATE CHANGE AND MITIGATION OF ITS IMPACTS OF NORTH EUROPEAN AQUACULTURE

16.50 **Cornelia Martina Kreiss**, Giulia Micallef, Tom Doyle, Ferit Rad, Virginia Martín, Joao Gomes Ferreira, Alhambra Cubillo, Joao Lencart e Silva, Eleni Papathanasopoulou
FUTURE PROFITABILITY OF TYPICAL FINFISH FARMS IN EUROPE

17.10 **John Icely**, A. Cubillo, M. Elliot, J. Ferreira, B. Fragoso, P. Kamermans, S. Kay, A. Kennerley, C. Kreis, A. Marques, D. Matias, M. Peck, J. Pinnegar, J. Pinnegar, H. Rambo, K. Smyth, V. Stetzenmuller, N. Taylor
POTENTIAL EFFECTS OF CLIMATE CHANGE ON OFFSHORE AQUACULTURE OF MEDITERRANEAN MUSSEL *Mytilus galloprovincialis* ON THE SW COAST OF PORTUGAL

NUTRITION: PHYSIOLOGY AND REQUIREMENTS

Tuesday, October 8 10.30 - 17.30 Europe Hall
Chair: Alessio Bonaldo, Antony Philip, Anne-Catrin Adam

10.30 **Sofia Morais**, S. Puchol, J.M. Cerdá-Reverter, A.R. Angotzi
TASTE SENSING AND GUT FEELING: POSSIBLE INVOLVEMENT OF TASTE RECEPTOR TYPE 1 FAMILY IN SEABREAM *Sparus aurata*

10.50 **David Domínguez**, Mohamed Cherkes, Ramon Fontanillas, Maria Jesus Zamorano, Marisol Izquierdo
EFFECTS OF DIFFERENT LEVELS OF VITAMINS B1, B9 AND B12 IN DIETS LOW IN FISHMEAL ON GILTHEAD SEA BREAM *Sparus aurata* FINGERLINGS

11.10 **Rui Magalhães**, F. Coutinho, I. Guerreiro, A. Couto, C. Serra, H. Peres, A. Oliva-Teles
OXIDATIVE STRESS STATUS AND MICROBIOTA OF GILTHEAD SEA BREAM *Sparus aurata* FED DIFFERENT DIETARY ARA/EPA/DHA RATIOS

11.30 **N. Gilannejad**, F.J. Moyano, G. Martínez-Rodríguez, M. Yúfera
REGULATION OF THE RHYTHMICITY OF PROTEOLYTIC DIGESTIVE FUNCTION IN GILTHEAD SEABREAM UNDER DIFFERENT DAILY FEEDING PROTOCOLS

11.50 **Serena Busti**, Luca Parma, Nicole Francesca Pelusio, Lorenzo Morsiani, Lorenzo Mariani, Marina Silvi, Maurizio Mazzoni, Francesco Dondi, Manuel Yúfera, Neda Gilannejad, Francisco Javier Moyano, Pier Paolo Gatta, Alessio Bonaldo
EFFECTS OF DIFFERENT FEEDING FREQUENCIES ON GROWTH, FEED UTILIZATION, PLASMA BIOCHEMISTRY AND DIGESTIVE CONDITIONS OF GILTHEAD SEA BREAM *Sparus aurata* FED WITH DIFFERENT FISH MEAL AND FISH OIL DIETARY LEVELS

12.10 **Sofia Engrola**, Raquel Carrilho, Rita Colen, Rita Teodósio, Jorge Dias, Cláudia Aragão
IMPROVING GILTHEAD SEABREAM *Sparus aurata* JUVENILES ADAPTABILITY TO ADVERSE CONDITIONS VIA NUTRITION

12.30 **P. Wischhusen**, M. Briens, P.A. Geraert, P. Antony Jesu Prabhu, L. Larroquet, V. Véron, S.J. Kaushik, B. Fauconneau, S. Fontagné-Dicharry
PARENTAL AND DIRECT FEEDING EFFECTS OF DIETARY SELENIUM IN RAINBOW TROUT *Oncorhynchus mykiss* FRY

12:50 **LUNCH**

14.30 **David Huyben**, Teresa Grobler, Douglas Tocher, Bente Ruyter, Brett Glencross
OPTIMISING LEVELS OF DIETARY FATTY ACIDS AND LIPIDS OF ATLANTIC SALMON UNDER NORMOXIC AND HYPOXIC CONDITIONS

14.50 **Marit A.J. Nederlof**, Ep H. Eding, Anne-Jo van Riel, Isabelle Leguen, Stephane Panserat, Patrick Prunet, Johan W. Schrama
EFFECT OF EARLY LIFE HYPOXIA AND DIET COMPOSITION ON GROWTH FEED INTAKE AND OXYGEN CONSUMPTION OF RAINBOW TROUT *Oncorhynchus mykiss* IN LATER LIFE

15.10 **Antony Jesu Prabhu Philip**, Marta Silva, May-Helen Holme, Thea Morken, Sofie Remø, Robin Ørnsrud, Pedro Araujo, Erik-Jan Lock, Rune Waagbø
IMPACT OF DIETARY ZINC LEVEL ON THE ZINC STATUS OF ATLANTIC SALMON PARR, SMOLT AND POST-SMOLT FED LOW FISH MEAL DIETS

15.30 **Claudia Figueiredo-Silva**, C. Boggino, M. Sun, Maria Mastoraki, I. Papadakis, A. Theodoridou, M. Pavlidis, S. Chatzifotis
EFFECTS OF COMPLEXED TRACE MINERALS AT DIFFERENT INCLUSION RATES IN COMMERCIAL SEA BASS *Dicentrarchus labrax* DIETS

15.50 **Nicole Francesca Pelusio**, Luca Parma, Serena Busti, Stefano Porcelli, Lorenzo Mariani, Lorenzo Morsiani, Francesco Dondi, Enric Gisbert, Maria Angeles Esteban, Federica D'Amico, Matteo Soverini, Marco Candela, Pier Paolo Gatta, Alessio Bonaldo
EFFECTS OF REARING DENSITY ON GROWTH, WELFARE INDICATORS AND DIGESTIVE CONDITIONS OF GILTHEAD SEA BREAM *Sparus aurata* FED DIFFERENT FISH MEAL AND FISH OIL DIETARY LEVELS

16.10 **Thomas Staessen**, M.C.J. Verdegem, E.H. Eding, M.A.J. Nederlof, J.W. Schrama
EFFECT OF DIETARY NON-PROTEIN ENERGY SOURCE (STARCH VS. FAT) ON TOTAL BILE ACID POOL SIZE AND COMPOSITION OF RAINBOW TROUT *Oncorhynchus mykiss*

16.30 **Karthik Masagounder**, Paulo Rema, Jorge Dias
EFFECTS OF INGREDIENT INCLUSION LEVEL AND FECES COLLECTION METHOD ON THE APPARENT NUTRIENT AND ENERGY DIGESTIBILITY OF INGREDIENTS IN NILE TILAPIA

16.50 **Caroline Candebat**, Mark Booth, Igor Pirozzi, M. Basseer Codabaccus
SULFUR AMINO ACID REQUIREMENTS AND INTERACTIONS IN JUVENILE YELLOWTAIL KINGFISH *Seriola lalandi*

17.10 **Monica B. Betancor**, Aurelio Ortega, Fernando de la Gándara, Matthew Sprague, Douglas R. Tocher, Gabriel Mourente
DEVELOPMENT OF FEEDS FOR JUVENILE ATLANTIC BLUEFIN TUNA *Thunnus thynnus* L: EFFECT OF LIPID LEVEL AND SOURCE

REPRODUCTION AND BROODSTOCK MANAGEMENT

Tuesday, October 8 10.30 - 17.30 Room 3
Chair: Constantinos Mylonas

10:30 **Yonathan Zohar**
FROM FERTILITY TO STERILITY OF FARMED FISH – HORMONES AND GENES

10.50 **Jurgen Adriaen**, Joachim Claeyé, Thomas Abeel, Wouter Meeus, Heidi Arnouts
EFFECT OF TEMPERATURE AND DIFFERENT SPAWNING AGENTS ON REPRODUCTION SUCCESS OF BURBOT IN CAPTIVITY

11.10 **Andrea Miccoli**, Ioannis Fakriadis, Irini Sigelaki, Anastasios Raftopoulos, Constantinos C. Mylonas
SPAWNING KINETICS OF GREATER AMBERJACK *Seriola dumerili* IN RESPONSE TO DIFFERENT DOSES OF GnRHa IMPLANTS

11.30 **Carlos Marrero Alemán**, Wendy González López, Sandra Ramos Júdez, Isabel Navarro, N. Duncan
ARTIFICIAL FERTILISATION IN SENEGALESE SOLE *Solea senegalensis:* INDUCTION WITH GNRHa AND DETERMINATION OF EGG QUALITY

11.50 **Michelle Grace Pinto Jørgensen**, Einar Eg Nielsen, Elin Kjørsvik, Jonna Tomkiewicz
DOSE DEPENDENT EFFECTS OF CARP PITUITARY EXTRACT ON INDUCTION OF OVARIAN DEVELOPMENT IN EUROPEAN EEL *Anguilla anguilla*

12.10 **Johanna Kottmann**, Ian A.E. Butts, Michelle G.P. Jørgensen, Peter Ravn, Jonna Tomkiewicz
EFFECTS OF EXOGENOUS GONADOTROPIN TYPE (CARP VS. SALMON PITUITARY EXTRACT) ON OFFSPRING QUALITY IN EUROPEAN EEL

12.30 **Arjan P. Palstra**, Ignacio Giménez Nebot, Pauline Jéhannet, P. Mark Lokman, William Swinkels, Leon T.N. Heinsbroek
TESTING RECOMBINANT GONADOTROPINS FOR THE PROPAGATION OF EUROPEAN EEL *Anguilla anguilla,* PRETREATED BY FEMINIZATION, SIMULATED MIGRATION AND STEROID IMPLANTS

12:50 **LUNCH**

14.30 **Javed Khan**, Alvin Setiawan, M.J. Wylie, Steve Pether, J.E. Symonds
PROGRESS IN HAPUKU *Polyprion oxygeneios* PRODUCTION FROM F1 BROODSTOCK

14.50 **Dario Vallainc**, Francesca Leggieri, Barbara Loi, Gianni Brundu, Gemma Gimenez Papiol
CANCELLED HATCHERY PRODUCTION OF FLATHEAD GREY MULLET *Mugil cephalus* JUVENILES

15.10 **Paul Engler**, Jean-Michel Le Calvez, David Guilet, Laurent Labbé, Pierre Chicoteau
IMPACTS OF A DIETARY SUPPLEMENTATION OF RAINBOW TROUT *Oncorhynchus mykiss* BROODSTOCK WITH A LOW DOSE OF DRY GRAPE EXTRACT ON THE METABOLOMIC PROFILE OF THEIR EGGS AND THE GROWTH PERFORMANCES OF THEIR OFFSPRING

15.30 **Adrien Marc**, Jarrod Guppy, Dean Jerry, Peter Mulvey, Paige Bauer, Damien Paris
EVALUATING BARRAMUNDI *Lates calcarifer* SPERM QUALITY USING HIGH THROUGHPUT ADVANCED REPRODUCTIVE TOOLS

15.50 **Francesca Bertolini**, Michelle Grace Pinto Jørgensen, Christiaan Henkel, Jonna Tomkiewicz
UNRAVELLING THE CHANGES DURING INDUCED SEXUAL MATURATION OF FEMALE EUROPEAN EEL *Anguilla anguilla* THROUGH RNA-SEQ: WHAT HAPPENS TO THE LIVER?

16.10 **Ferosekhan Shajahan**, Cathaysa Pérez-García, Serhat Turkmen, Hanlin Xu, Juan Manuel Afonso, Ramon Fontanillas, Sadasivam Kaushik, Marisol Izquierdo
INFLUENCE OF GENETIC SELECTION FOR GROWTH AND DIETARY n-3 LC-PUFA LEVELS ON REPRODUCTIVE PERFORMANCE IN GILTHEAD SEA BREAM *Sparus aurata*

16.30 **Ingun Næve**, Maren Mommens, Augustine Arukwe, Jonni J. Virtanen, Md. Enamul Hoque, Elin Kjørsvik
ESTABLISHING A NON-INVASIVE METHOD FOR SEXUAL MATURATION MONITORING IN ATLANTIC SALMON *Salmo salar* MALES AND FEMALES USING ULTRASOUND TECHNOLOGY

16.50 **Ana Pombo**, Eliana Venâncio, Pedro M. Félix, Ana C. Brito, João Sousa, Francisco Azevedo e Silva, Tomás Simões
DOES THE DIET OF A *Holothuria tubulosa* BROODSTOCK INFLUENCE VIABILITY AND LARVAL DEVELOPMENT?

17.10 **Leila Basti**, Jyoji Go, Kiyohito Nagai
EFFECTS OF MONO AND MIXED BLOOMS OF CHARMFUL ALGAE *Alexandrium, Karenia* AND *Chattonella* ON THE REPRODUCTION OF JAPANESE PEARL OYSTER *Pinctada fucata martensii*

FISH WELFARE

Tuesday, October 8 10.30 - 17.30 Room 2
Chair: MIchalis Pavlides

10.30 **Albin Gräns**, Jennifer Bowman, Per Hjelmstedt, Nicole van Nuland
CARBON DIOXIDE STUNNING OF RAINBOW TROUT *Oncorhynchus mykiss:* THE EFFECTS OF DIFFERENT SEASONAL TEMPERATURES AND THE RELIABILITY OF VISUAL INDICATORS OF CONSCIOUSNESS

10.50 **Jaume Pérez-Sánchez**, Juan Antonio Martos-Sitcha, Javier Sosa, Dailos Ramos-Valido, Francisco Javier Bravo, Cristina Carmona-Duarte, Henrique Leonel Gomes, Josep Àlvar Calduch-Giner, Enric Cabruja, Aurelio Vega, Miguel Ángel Ferrer, Manuel Lozano, Juan Antonio Montiel-Nelson, Juan Manuel Afonso
AEFishBIT: SMART DEVICE FOR TRACKING FISH BEHAVIOUR AND ACTIVITY

11.10 **Carolina Gutierrez Rabadan**, Charlotte Spreadbury, Sonia Consuegra del Olmo, Carlos Garcia de Leaniz
DEVELOPMENT AND VALIDATION OF OPERATIONAL WELFARE INDICATORS (OWI) FOR FARMED LUMPFISH *Cyclopterus lumpus* L.

11.30 **Xavier Gutierrez**, Felipe A. Briceno, Rafael Leon, Patricio Feest, Rafael Leon, Patricio Feest
LINKING FRESH WATER QUALITY AND FISH WELFARE WITH SEA WATER FEEDING PERFORMANCE IN CHILEAN SALMON FARMING: A MODELLING TOOL BASED ON SMOLT PHYSIOLOGICAL STATUS

11.50 **Mark Schumann**, Cornelius Becke, Andreas Müller-Belecke, Roland Rösch
RAINBOW TROUT WELFARE INDEX MODEL 1.0

12.10 **Jian Zhao**, Shengyu Hang, Yanci Wen, Songming Zhu, Zhangying Ye
DEEP LEARNING-BASED MONITORING OF THE LOCAL UNUSUAL BEHAVIORS FOR FISH SCHOOL IN INTENSIVE AQUACULTURE

12.30 **Jeroen Brijs**, E. Sandblom, M. Axelsson, K. Sundell, H. Sundh, A. Kiessling, C. Berg, A. Gräns
REMOTE MONITORING OF CARDIOVASCULAR PERFORMANCE TO GAUGE STRESS RESPONSES OF RAINBOW TROUT *Oncorhynchus mykiss* IN AQUACULTURE

12:50 **LUNCH**

14.30 **Alexander Jaramillo-Torres**, Torunn Forberg, Elvis Chikwati, Armin Kousha, Abdelaziz Adam Mohammed, Yanxian Li, Åshild Krogdahl, Trond M. Kortner
MICROBIOTA-RELATED INDICATORS OF GUT HEALTH IN ATLANTIC SALMON *Salmo salar*

14.50 **Jessica Petereit**, C. Hörterer, R. Pastres, L. Conceição, J. Johansen, J. Aerts, B.H. Buck
THE EFFECT OF ALTERNATIVE FEED INGREDIENTS ON GROWTH AND STRESS RESPONSE IN JUVENILE TURBOT *Scopthalmus maximus* KEPT IN RECIRCULATING AQUACULTURE SYSTEMS

15.10 **Francisco Guardiola**, Martha Reyes-Becerril, Verónica Sánchez, Carlos Angulo
YEASTS β-GLUCANS IMPACT ON IMMUNE RESPONSE IN PLASMA AND SKIN MUCUS OF PACIFIC RED SNAPPER *Lutjanus peru* CHALLENGED WITH *Aeromonas hydrophila*

15.30 **Lluis Tort**, Annais Carbajal, Felipe E. Reyes-Lopez, Oriol Tallo-Parra, Manel López-Béjar
CORTISOL IN PLASMA, SKIN MUCUS AND SCALES. A COMPARATIVE VIEW OF THE HYPOTHALAMIC-PITUITARY-INTERRENAL AXIS ACTIVITY IN DIFFERENT FISH MATRICES

15.50 **Linda Tschirren**, Nicola Rhyner, Andreas Seitz, Constanze Pietsch
GENE EXPRESSION LEVELS IN DISTINCT BRAIN AREAS OF CARPS AFTER POSITIVE AND NEGATIVE ACUTE STRESSORS

16.10 **Raminta Kazlauskaite**, Bachar Cheaib, Joshka Kaufmann, Chloe Heys, Alex Kitts, Martin Llewellyn
SALMOSIM: BUILDING ARTIFICIAL ATLANTIC SALMON *Salmo salar* GUT SYSTEM

16.30 **Luis André Barbas**, Jhenneff Feitosa, Marcelo Torres, Brenda Costa, Moisés Hamoy
EUGENOL INDUCES A SEIZURE-LIKE STATE DURING SHORT-TERM EXPOSURE IN FISH

16.50 **Maureen Ellis**, L. Dunn, M. Haskell, S. Jarvis, S. Rey, J.F. Turnbull
NOVEL USE OF QUALITATIVE BEHAVIOUR ASSESSMENT TO MONITOR WELFARE IN FARMED ATLANTIC SALMON *Salmon salar*

17.10 **Lina Weirup**, Johan Aerts, Carsten Schulz, Henrike Seibel
ASSESMENT OF CHRONIC STRESS AND WELFARE STATUS IN RAINBOW TROUT *Oncorhynchus mykiss* AT DIFFERENT STOCKING DENSITIES IN COMMERCIAL FLOW-THROUGH SYSTEMS IN GERMANY

AE2019 INDUSTRY FORUM – GERMAN FARMERS' DAY

Tuesday, October 8 10.30 - 17.30 Exhibition 1
Chair: Stefan Meyer

10.30 Bernhard Feneis
WELCOME FROM VDBA

Birgit Schmidt-Puckhaber
WELCOME FROM DLG

10.50 Birgit Schmidt-Puckhaber
PRODUCTION SYSTEMS IN EUROPE - HOW DO WE PRODUCE TOMORROW?

10.50 Bernhard Feneis,
POLITICAL AND SOCIETAL FRAMEWORK CONDITIONS - EUROPEAN AQUACULTURE PRODUCERS' PERSPECTIVE

11.20 Daniel Żarski,
TOWARD INNOVATION IN POND-BASED PRODUCTION TECHNOLOGY

11.35 Gert Füllner
CARP POND CULTURE - OUTDATED OR FUTURE TECHNOLOGY?

11.50 Martin Oberle,
COMPOSITION AND MINERALIZATION OF CARP POND SOIL

12.05 Jan Masilko
HORSEBEAN AS FEED STUFF FOR COMMON CARP - INFLUENCE ON GROWTH AND FLESH QUALITY

12.20 Andreas Müller-Belecke
INTENSIVE CARP FRY PRODUCTION - IMPROVING PERFORMANCE AND EFFICIENCY WITH STATE-OF-THE-ART FEED AND TECHNOLOGY

12.35 Szymon Łakomiak,
FROM SALMONIDS TO STURGEONS - SECOND LIFE OF OUTDATED TROUT PRODUCTION SYSTEMS

12.50 LUNCH

14.10 Werner Kloas
NEW SOLUTIONS FOR "OLD" PROBLEMS

14.10 Alexander Tautenhahn
HEALTHY FISH - STRATEGIES TO REDUCE FISH LOSSES

14.40 Thomas Wachinger
SHARING INSIGHTS FROM A BAVARIAN INDOOR-RAS FARM FOR TROPICAL SHRIMP PRODUCTION

14.55 Paul Sindilariu
RAS - FUTURE FOR SWISS AQUACULTURE?

15.10 Dominik Ewald
USE OF DIGITAL SYSTEMS IN AQUACULTURE - ARE WE READY FOR "BIG DATA"?

15.25 BREAK

15.50 Stefan Meyer
ANIMAL WELFARE AND CONSUMER ACCEPTANCE

15.50 Helmut Wedekind
SCIENCE-BASED INSIGHTS INTO ANIMAL WELFARE IN AQUACULTURE

16.10 Johannes Simons
ENJOY FISH! A GERMAN TROUT CASE STUDY ON CONSUMER ACCEPTANCE FOR FISH PRODUCTS FROM AQUACULTURE

16.30 Stefan Johnigk, Bernhard Feneis, Stefan Hofer
"FUTURE PERSPECTIVES…" - ROUND TABLE DISCUSSION

RECIRCULATING AQUACULTURE SYSTEMS (RAS)

Tuesday, October 8 14.30 - 17.30 Room 1
Chairs: Astrid Buran Holan, Carlos Octavio Letelier Gordo

14.30 Paula Rojas-Tirado, Åse Åtland, Carlos Letelier-Gordo
THE EFFECT OF DIFFERENT WATER SOURCES ON THE POTENTIAL H2S-FORMATION WITHIN RAS

14.50 Ragnhild Fossmark, Kari Attramadal, Trond Rosten, Deni Koseto, Jenny Nesje, Ingrid Bakke, Niels Jørgensen, Gema Raspati, Stein Østerhus, Olav Vadstein
MICROBIAL COMMUNITY DYNAMICS IN RECIRCULATING AQUACULTURE SYSTEMS REARING ATLANTIC SALMON PARR *Salmo salar* WITH REDUCED ORGANIC LOADING THROUGH MEMBRANE FILTRATION

15.10 Jeremiah Minich, Khattapan Jantawongsri, John Bowman, Abigail Elizur, Stewart Fielder, Rob Knight, Eric Allen
HATCHERY SYSTEM (RAS VS FT) EFFECTS ON FISH MICROBIOTA FOR ATLANTIC SALMON *Salmo salar* AND YELLOWTAIL KINGFISH *Seriola lalandi*

15.30 Felipe do Nascimento Vieira, Frederike Schmachtl, Mirko Boegner, Ana Clara C. da Silva, Vitor F. Silva, Walter Q. Seiffert, Cláudia Machado, Daniele dos Santos, Gabriela S. Ferreira
STRATEGIES FOR WATER PREPARATION IN A BIOFLOC SYSTEM: EVALUATION OF A CHEMOAUTOTROPHIC, HETEROTROPHIC AND MATURE SYSTEM FOR PACIFIC WHITE SHRIMP REARING

15.50 Desislava Bögner, Mirko Bögner, Fredericke Schmachtl, Nicolas Bill, Jörn Halfer, Kai Lorkoswki, Matthew J. Slater
DEMYSTIFYING CRITICS ABOUT HYDROGEN PEROXIDE UTILIZATION IN RECIRCULATING AQUACULTURE SYSTEMS

16.10 **Wanhe Qi**, Songming Zhu
LOW CONCENTRATION PMS/UVA-LED COMBINATION AS A POTENTIAL ALTERNATIVE DISINFECTION METHOD FOR RECIRCULATING AQUACULTURE SYSTEMS

16.30 **Angela Boley**, Wolf-Rüdiger Müller
EVALUATION OF A MEMBRANE-DENITRIFICATION REACTOR (MDR) IN A RECIRCULATION AQUACULTURE SYSTEM UNDER REAL CONDITIONS

16.50 **Jaime Orellana**, Silvia Gómez, Felipe Hurtado
BIOREMEDIATION OF ORGANIC SLUDGE FROM A MARINE RECIRCULATING AQUACULTURE SYSTEM USING THE POLYCHAETE *Abarenicola pusilla*

17.10 **Alberto Monteleone**, Shane Hunter, Simeon Deguara
AQUABIOTECH GROUP – ABT INNOVIA: EXCELLENCE THROUGH QUALITY AND INNOVATION

MICROALGAE

Tuesday, October 8 14.30 - 17.30 Festival
Chair: Kjell Inge Reitan

14.30 **Dorinde M.M. Kleinegris**, Jeroen H. de Vree, Pia Streinrücken, Hanna Böpple, Hans T. Kleivdal
THE NATIONAL ALGAEPILOT MONGSTAD: PRODUCTION OF MICROALGAE FOR AQUACULTURE

14.50 **Mariluz Bagnoud**, Alexandre Bagnoud, Cyril Mahmed, Roger Röthlisberger, Saloua Sadok
INTEGRATION OF A NEW PHOTOSYNTHETIC BIOFILM FILTER IN RECIRCULATING AQUACULTURE SYSTEMS AND DIRECT BIOMASS RECOVERY

15.10 **Robert Röllig**, Harry W. Palm, Adrian Bischoff-Lang, Hilary Jane Lewis Karlson, Malene Fog Lihme Olsen, Lars Jørgensen
MICROALGAE CULTIVATION FOR BIOREMEDIATION OF NUTRIENTS UNDER AQUAPONIC CONDITIONS

15.30 **A. Roulston**, S. Glover, J. Long, R. Roulston
COMPACT PHOTOBIOREACTORS FOR LIVE MICROALGAE PRODUCTION IN AQUACULTURE HATCHERIES AND NURSERIES

15.50 **Christos Latsos**, Pieter Oostlander, Gabrielle Verbeeke, Maria Barbosa, Rene Wijffels, Jasper van Houcke
Rhodomonas salina PRODUCTION: GOING FROM LAB TO SEMI-COMMERCIAL SCALE

16.10 **Hideaki Matsui**, Satoshi Kono, Kazuki Okita, Tomonari Kotani
THE MICROALGA *Isochrysis* AS AN ENRICHMENT DIET FOR ROTIFERS: EFFECTS OF HARVEST TIMING ON ROTIFER VITALITY AND FATTY ACID PROFILES

16.30 **Ana Viskovic**, Francisco Guardiola, Inês Alexandra Sa, Marina Machado, Filipa Fontinha, Rita Azeredo, Benjamin Costas, Ana Couto
EVALUATION OF HEALTH STATUS IN EUROPEAN SEA BASS *Dicentrarchus labrax* L. JUVENILES FED DIETS WITH PARTIAL REPLACEMENT OF FISH MEAL BY MICROALGAE MEAL

16.50 **Ifakat Tülay Çagatay**, Mehmet Özbas, Noha Sati, Hasan Emre Yilmaz
ANTIMICROBIAL ACTIVITY OF *Nannochloropsis* spp. AGAINST FISH PATHOGENS

17.10 **Joseph Penhaul Smith**, C. Beveridge, V.A. Laudicello, L. McEvoy, A.D. Hughes, J.G. Day
MICROALGAL MIXOTROPHY AS A SOURCE OF FEED FOR *Mytilus edulis* LARVAE

PERFORMFISH / MEDAID INDUSTRY FORUM

Tuesday, October 8 14.30 - 17.30 Exhibition 2
Chairs: Katerina Moutou, Bernardo Basurco

14.00 **Katerina Moutou,** Alicia Estévez
PerformFISH and **MedAID**: TWO YEARS LATER

14.20 **Leonidas Papaharisis**, Kantham Papanna, Dimitrios Chatziplis, Valia Economou, Tereza Manousaki, Costas S. Tsigenopoulos
INCREASING DISEASE RESISTANCE OF FISH FOR PARASITES THROUGH BREEDING: THE CASE OF THE EUROPEAN SEA BASS AGAINST THE MONOGENEAN *Diplectanum aequans* AND THE COPEPOD *Lernanthropus kroyeri*

Costas Tsigenopoulos
HERITABILITY ESTIMATES FOR DISEASE RESISTANCE IN EUROPEAN SEA BASS: OPEN SEA CHALLENGES TO MONOGENEAN PARASITES *Diplectanum aequansis* AND *Lernanthropus kroyeri*

14.50 **Kostas Tzokas, George Koumoundouros**
DO ALL DEFORMITIES MATTER?

15.10 **Javier Villa, Nikos Papandroulakis**
NOVEL TECHNOLOGY TO IMPROVE FEEDING MANAGEMENT

15.30 **Giovanna Marino, Dane Desnica**
KEY PERFORMANCE INDICATORS FOR EFFICIENT BENCHMARKING IN MEDITERRANEAN AQUACULTURE

15.50 **José Pérez**
SOCIAL ACCEPTABILITY AND GOVERNANCE. STAKES, CHALLENGES AND RECENT EXPERIENCES

16.10 **José L. Fernández Sánchez**
ECONOMIC FINDINGS IN PRODUCTION AND MARKETS OF MEDITERRANEAN AQUACULTURE

16.30 **María Soledad Izquierdo López**
OPEN DISCUSSION AND CONCLUSIONS

STUDENT WORKSHOP
EAS Avengers – AquaIndustry Challenges

Tuesday, October 8 14.30 - 17.30 Foyer 4
Chair: Kathrin Steinberg

14.30 Kathrin Steinberg
Welcome

14.40 Ana Nobre – SPAROS
FEEDNETICS as a tool for students and young professionals

15.00 EAS SG Travel Grant Winners - Industry and Research Experiences
Ana Costa
Kerrie Ni Dufaigh
Rodrigo Mendes
Sandra Langi
Sofiia Tretiak

15.20 Kunststoff Spranger

15.40 EAS SG National Coordinators
Status of Aquaculture, Irene Brandts (Spain)
Ivo Monteiro (Portugal)
Pauline Wischhusen (France)
Guido Bonello (Italy)
Elisavet Syropoulou (Greece)

16.05 Lourdes Reig and Rosa Flos (UPC)
How students perceive aquaculture: should we be worried? How could it be approached from the curricula?

16.25 Andrew Richardson (NC)
Issues and Problems within the Industry

16.40 Ideas and Solutions for the Industry
Group Discussions and Networking

17.20 Aideen Kearney (NC), Silvia Blanco (NC)
Outlook to Ireland for AE2020

GENERAL CONTRIBUTED HEALTH

Tuesday, October 8 14.30 - 17.30 Lounge 1-3

Chair: TBA

14.30 **Sebastian Rakers**, Lisa Jordan, Mikolaj Adamek, Dirk Scheel, Anna Becker, Marina Gebert
CELL MODELS FOR THE DEVELOPMENT OF VACCINES FOR AQUACULTURE FISH

14.50 **Kerrie Ní Dhufaigh**, Eugene Dillon, Eugene MacCarthy, Orla Slattery
BIOCHEMICAL AND PROTEOMIC CHARACTERISATION OF EXTRACELLULAR PROTEINS FROM THE PROTOZOAN PARASITE *Paramoeba perurans* REVEALED BY AN *IN VITRO* MODEL

15.10 **Dongdong Wang**, Gilbert Van Stappen, Nancy Nevejan
FOLLOWING THE INFECTION PROCESS OF VIBRIOSIS IN PACIFIC OYSTER *Crassostrea gigas* AND BLUE MUSSEL *Mytilus edulis* LARVAE USING FLUORESCENCE LABELING AND HISTOPATHOLOGY METHODS

15.30 **David Straus**, T. Meinelt, D. Liu, L.-F. Pedersen, C. Good, J. Davidson
A RETROSPECTIVE OF OUR INTERNATIONAL RESEARCH COLLABORATION ON THE USE OF PERACETIC ACID IN AQUACULTURE

15.50 **Luisa M. Vera**, Eric Leclercq, Karina Gajardo, Mathieu Castex, Hervé Migaud
DEVELOPMENT OF A PRACTICAL REPETITIVE STRESS CHALLENGE MODEL FOR SEAWATER ATLANTIC SALMON *Salmo salar*

16.10 **Uun Yanuhar,** Nico Rahman Caesar, Feri Setiawan, Muhammad Musa
IDENTIFICATION OF Chlorella sp. USING THE INTERNAL TRANSCRIBED SPACER SEQUENCE AND ITS ROLE AS INHIBITOR STRESS CAUSED BY RNA VIRAL NERVOUS NECROSIS INFECTION ON THE HUMPBACK GROUPER

WEDNESDAY, October 9

PLENARY 2

Wednesday, October 9 09.00 - 10.00 Europe Hall
Chair: Stefan Meyer

09.00 Alexander Wever
PRODUCER, TRADE AND CONSUMER – A PRESENTATION/PANEL SESSION

10:00 BREAK

NUTRITION: ANIMAL INGREDIENTS IN AQUAFEED

Wednesday, October 9 10.30 - 12.50 Europe Hall
Chair: Luisa Valente
Sponsored by

AQUASOJA

10.30 Ana Basto, Margarida R.G. Maia, Jaume Perez-Sanchez, Josep Calduch, Elisabete Matos, Luísa M.P. Valente
DEFATTED YELLOW MEALWORM *Tenebrio molitor* LARVAE MEAL: A PROMISING FISHMEAL SUBSTITUTE FOR EUROPEAN SEABASS

10.50 Constant Motte, Morgane Henry
REPLACING FISH MEAL WITH DEFATTED INSECT MEAL (YELLOW MEALWORM *Tenebrio molitor*) IMPROVES THE GROWTH AND IMMUNITY OF EUROPEAN SEABASS *Dicentrarchus labrax* L.

11.10 Mónica Costa, Benjamin Costas, Marina Machado, Carla Teixeira, Sergio Fernández-Boo, Tiago Sá, Sónia Batista, Alexandra Marques, Fernando Miranda, Luísa M.P. Valente
ANCHOVY AND GIANT SQUID HYDROLYSATES CAN ENHANCE GROWTH AND THE IMMUNE RESPONSE OF EUROPEAN SEABASS *Dicentharcus labrax* FED VEGETABLE BASED-DIETS

11.30 Luisa Valente, Inês Campos, Elisabete Matos
LOCALLY PROCESSED LAND ANIMAL BY-PRODUCTS AS POTENTIAL CANDIDATES TO REPLACE FISHMEAL AND FISH OIL IN PRACTICAL DIETS FOR EUROPEAN SEABASS

11.50 Elisabete Matos, Inês Campos, Luísa M.P. Valente, Pedro Marques, Fausto Freire
LIFE-CYCLE ASSESSMENT OF ANIMAL FEED INGREDIENTS: POULTRY FAT, POULTRY BY-PRODUCT MEAL AND HYDROLYZED FEATHER MEAL

12.10 Jessica Jaxion-Harm
EFFECTS OF DIETARY PHOSPHOLIPIDS ON EARLY STAGE ATLANTIC SALMON *Salmo salar* PERFORMANCE: A COMPARISON AMONGST PHOSPHOLIPID SOURCES

12.30 Gabriella Do Vale Pereira, Felipe Soares, Ana Margarida Fernandes, Tome Silva, Bruna Silva, Jorge Dias, Bela Buck, Johan Johansen, Luis Eugenio Castanheira Conceicao
ASSESSMENT OF SUSTAINABLE AQUAFEED FORMULATIONS USING TWO APPROACHES: GROWTH TRIAL AND A DYNAMIC NUTRIENT-BASED MATHEMATICAL MODEL

FOOD QUALITY AND SAFETY

Wednesday, October 9 10.30 - 12.50 Room 5
Chair: Johannes Pucher

10.30 Valeska Weymann
EFFICIENT GUIDE TO PRODUCERS FOR GOOD AQUACULTURE PRACTICES AT ALL STAGES OF PRODUCTION

10.50 Miguel Angel Pardo, Andrea Gustinelli, Monica Caffara, Maria Letizia Fioravanti, Kurt Buchmann, Santiago Pascual, George Rigos, Csaba Székely, Diana Sandor, Gabor Cech
A EUROPEAN SURVEY ON ZOONOTIC HELMINTHS REVEALS A NEGLIGIBLE RISK OF INFECTION FROM FARMED FISH TO HUMANS

11.10 Andrew D. Younger, Robson V. de Sousa, Mickael Teixeira Alves, Carlos Campos
AN INVESTIGATION OF HOW THE CLASSIFICATION STATUS OF SHELLFISH PRODUCTION AREAS MAY BE AFFECTED BY THE NUMBER OF *Escherichia coli* RESULTS ASSESSED

11.30 Christian Schlechtriem
INVESTIGATIONS ON NATURE AND LEVEL OF RESIDUES IN FARMED FISH AS PART OF THE EUROPEAN PESTICIDE REGULATION

11.50 Johannes Pucher, K. EL Arbani, E. Strauch
MICROBIAL COMMUNITIES IN BIOFLOC SYSTEMS FOR WHITELEG SHRIMP *Litopenaeus vannamei*

12.10 Y.D. Ahongo, T. Kerneis, L. Goardon, L. Labbé, J. Bugeon, P-Y. Rescan, F. Lefèvre
FLESH QUALITY RECOVERY IN FEMALE RAINBOW TROUT *Oncorhynchus mykiss* AFTER EGG PRODUCTION

12.30 Olajumoke Omosowone, Sunday Olatoye
BIOACTIVITY OF GARLIC *Allium sativum* AGAINST *Dermestes maculatus* ON SMOKE-DRIED AFRICAN CATFISH *Clarias gariepinus*

SUSTAINABLE AQUACULTURE TECHNOLOGIES

Wednesday, October 9 10.30 - 12.50 Lounge 1-3
Chair: Alexander Brinker

10.30 Pauline O'Donohoe, Frank Kane, Joanne Casserly, Sean McLoughlin
TOOLS FOR NEW AND FLEXIBLE APPROACHES FOR AQUACULTURE LICENSING AND REGULATION

10.50 Kristina Bergman, Patrik Henriksson, Sara Hornborg, Max Troell, Malin Jonell, Friederike Ziegler
FARMING WARMWATER FISH ON LAND IN A COLD COUNTRY – A CRAZY IDEA OR A NEW SUSTAINABLE SEAFOOD SUPPLY CHAIN?

11.10 Hallstein Baarset, Johan Johansen
ECOINTENSIFICATION OF AQUACULTURE: INNOVATIVE MORTALITY DISPOSAL IN A CIRCULAR ECONOMY PERSPECTIVE

11.30 **Rui Rocha**, Sílvia Pires, Diogo Martins, Andreia Rodrigues, Pearl Ofoegbu, Vitória Pereira, Ana Costa, Amadeu Soares
COCKLES HARVESTING, TRANSPORT AND PACKAGING: HOW TO IMPROVE THE QUALITY OF PRODUCT IN CONSUMERS TABLE

11.50 **Anneliese Ernst**, Patrick Maurer, Uwe Waller
SOURCES AND SINKS OF BACTERIA IN RECIRCULATING AQUACULTURE SYSTEMS (RAS)

12.10 **Thomas Adams**, Dmitry Aleynik, Andrew Dale, Max Holloway, Keith Davidson
CHOOSING THE BEST LOCATIONS FOR SALMON AQUACULTURE SITES: INSIGHTS FROM BIOPHYSICAL MODELS AND THE MOVE TO MORE EXPOSED SITES

12.30 **Langley Gace**
THE CRITICAL SUCCESS FACTORS OF AN OPEN OCEAN FARMING OPERATION

GENERAL CONTRIBUTED FISH WELFARE

Wednesday, October 9 10.30 - 12.50 Backstage 1
Chair: Lina Weirup

10.30 **Joan Martorell-Ribera**, Mareen Nipkow, Torsten Viergutz, Christian Plinski, Tom Goldammer, Ulrike Gimsa, Alexander Rebl
STRESS HORMONES EVOKE CHARACTERISTIC EXPRESSION PROFILES IN SALMONID HEAD KIDNEY CELLS UNDER IMMUNE STIMULATION

10.50 **Constanze Pietsch**, Andreas Seitz, Nicola Rhyner, Marcel Arter, Linda Tschirren
NEW INSIGHTS INTO THE APPETITE GENE REGULATION IN COMMON CARP *Cyprinus carpio*

11.10 **Asa Johannesen**, Pascal Klebert, Øystein Patursson
THE EFFECT OF WAVES ON VERTICAL DISTRIBUTION OF SALMON IN AN EXPOSED SALMON CAGE

11.30 **Susana M.F. Ferreira**, Ana F. Ruas, Adriana G. Gaveta, Sílvia C. Gonçalves
ASSESSMENT OF FEED DOSES TO BE ADMINISTERED TO *Garra rufa* (HECKEL, 1843) UNDER AN ICHTHYOTHERAPY REGIMEN

11.50 **M. Carla Piazzon**, Fernando Naya-Català, Josep A. Calduch-Giner, Paula Simó-Mirabet, Amparo Picard-Sánchez, Ariadna Sitjà-Bobadilla, Jaume Pérez-Sánchez
SEX, AGE AND BACTERIA: HOW THE INTESTINAL MICROBIOTA IS MODULATED IN A PROTANDROUS HERMAPHRODITE FARMED FISH

12.10 **Josip Barisic**, Brian Quinn, S. Cannon
BLOOD BIOCHEMISTRY DURING SEAWATER TRANSFER: INVESTIGATION INTO THE CAUSES OF FAILED FISH SYNDROME IN RAINBOW TROUT *Oncorhynchus mykiss*

12.30 **Erik Sandblom**, Henrik Seth, Brankica Djordjevic, Lars Niklasson, Henrik Sundh, Bo Algers, Lotta Berg, Torbjörn Lundh, Michael Axelsson, Jeffrey Lines, Snuttan Sundell, Albin Gräns, Anders Kiessling
STUNNING OF ARCTIC CHAR *Salvelinus alpinus* WITH CARBON DIOXIDE AND ELECTRIC FIELD EXPOSURE: PHYSIOLOGICAL MECHANISMS OF ACTION AND WELFARE IMPLICATIONS

PRECISION FARMING, AI AND BIG DATA

Wednesday, October 9 10.30 - 16.30 Festival
Chair: Martin Fore

10.30 **Mohammadmehdi Saberioon**, Petr Cisar, Laurent Labbé, Pavel Soucek, Pablo Pelissier
APPLICATION OF HYPERSPECTRAL IMAGERY TO DISCRIMINATE DIFFERENT DIETS OF LIVE RAINBOW TROUT *Oncorhynchus mykiss*

10.50 **Dinara Bekkozhayeva**, Mohammadmehdi Saberioon, Petr Cisar
INDIVIDUAL PHOTO-IDENTIFICATION OF FISH WITH VISIBLE SKIN PATTERNS (SUMATRA BARB *Puntigrus tetrazona)* USING COMPUTER VISION

11.10 **Petr Cisar**, Mohammadmehdi Saberioon, Dinara Bekkozhayeva, Rudolf Schraml
COMPUTER VISION BASED FISH INDIVIDUAL IDENTIFICATION AS AN ALTERNATIVE TO FISH TAGGING

11.30 **Christian Schellewald**, A. Stahl, O. Markovic, M. Markovic, I. Hammerset, E. Moen, H. Trengereid, L.M. Sunde
TOWARDS AN INDIVIDUAL CHARACTERISATION OF FARMED SALMON

11.50 **Joao G. Ferreira**, Nick Taylor, Alhambra Cubillo, Joao Lencart e Silva, Roberto Pastres, Øivind Bergh, Nicola McPherson, James Guilder
THE ABC MODEL – A PARADIGM SHIFT IN INTEGRATED CARRYING CAPACITY MODELLING

12.10 **Stepan Papacek**, Petr Cisar, Karel Petera
CFD SIMULATION OF FLUID FLOW AND RTD ANALYSIS FOR AQUACULTURE SYSTEMS: WITH AND WITHOUT FISH

12.30 **Fearghal O'Donncha**, Scott C. James
A MACHINE-LEARNING-BASED APPROACH TO FORECAST HARMFUL ALGAL BLOOMS

12:50 **LUNCH**

14.30 **René Alvestad**, Kristian H. Liland, Ingrid Måge, Chris Noble, Bjørn-Steinar Sæther
CHARACTERISTICS AND QUALITY OF PRODUCTION DATA IN AN ATLANTIC SALMON *Salmo salar* L. PRODUCER'S LEGACY DATABASE

14.50 **Petter Olsen**
SHOULD THE AQUACULTURE INDUSTRY USE BLOCKCHAIN TECHNOLOGY FOR DATA RECORDING?

15.10 **Jon Grant**, R. Filgueira, M. Burke, C. Stockwell, E. Milos, L. Torgo, F. Donncha
FISH FARM SENSORS AND THE INTERNET OF THINGS

15.30 **Vagelis Chalkiadakis**, George Livanos, Michalis Zervakis, Konstantia Moirogiorgou, Nikos Papandroulakis
AN AUTONOMOUS UNDERWATER VEHICLE FOR AUTOMATED INSPECTION OF AQUACULTURE NET PEN CAGES

15.50 **Eleni Kelasidi**, Biao Su, Martin Føre, Kevin Frank, Walter Caharija, Christian Schellewald, Leif Magne Sunde
AUTONOMOUS UNDERWATER ROBOTS FOR SAFER AND MORE EFFICIENT OPERATIONS IN FISH FARMS

16.10 **Maxime Lafont**, Ambre Vallauri, Samuel Dupont, Charlotte Dupont
DIGITIZATION OF AQUACULTURE: REAL-TIME MONITORING AND PREDICTION FOR A SUSTAINABLE FUTURE

ENVIRONMENT / AQUACULTURE INTERACTIONS – FROM AND TO AQUACULTURE

Wednesday, October 9 10.30 - 17.30 Room 1
Chair: Shawn Robinson

10.30 **Christopher Naas**, Werner Kloas
META-ANALYSIS OF GROWTH PERFORMANCE OF FRESHWATER FISHES UNDER SALINE ENVIRONMENTS IN AQUACULTURE

10.50 **Renée K. Bechmann**, Maj Arnberg, Emily Lyng, Stig Westerlund, Shaw Bamber, Alessio Gomiero, Thorleifur Agustsson, Alfhild Kringstad, Les Burridge
SENSITIVITY OF NORTHERN SHRIMP *Pandalus borealis* TO COMMERCIAL FORMULATIONS USED AS ANTI-PARASITIC DRUGS

15.30 **Simon Goddek**, Alyssa Joyce, Oliver Koerner, Karel Keesman
A FULLY INTEGRATED SIMULATION MODEL OF MULTI-LOOP AQUAPONICS: PUTTING THEORY INTO PRACTICE

15.50 **Edson Panana**, B. Delaide, P. Bleyaert, S. Teerlinck
ORGANIC REDUCTION AND NUTRIENT RECOVERY PERFORMANCES OF PIKEPERCH *Sander lucioperca* SLUDGE AEROBIC DIGESTION AND LETTUCE GROWTH PERFORMANCE IN ITS EFFLUENTS

16.10 **U. Knaus**, H.-D. D. Hübner, H.W. Palm
AQUAPONICS (S.L.) PRODUCTION OF SPEARMINT *Mentha spicata* AND BASIL *Ocimum basilicum* WITH BIOHUMIN AND AFRICAN CATFISH *Clarias gariepinus*

16.30 **Gilles Stouvenakers**, Sébastien Massart, M. Haïssam Jijakli
AQUAPONIC WATER SUPPRESSIVENESS ON *Pyhtium aphanidermatum* ROOT ROT IN LETTUCE AND ITS ORIGIN

16.50 **Sarah Milliken**, Benz Kotzen, Ranka Junge, Morris Villarroel, Tjasa Griessler Bulc
AQU@TEACH: INNOVATIVE EDUCATIONAL TOOLS TO PROMOTE LEARNING AMONG EUROPEAN STUDENTS USING AQUAPONICS

17.10 **Luigi Petrocchi Jasinski**, G. Galliano, L. Rossi
TOWARDS SUSTAINABLE AWARENESS: IMPLEMENTATION OF AN AQUAPONIC CODE OF PRACTICE

AE2019 INNOVATION FORUM

Wednesday, October 9 10.30 - 17.30 Exhibition 1
Chair: Stefan Meyer

Aquaculture development requires upscaling production systems and developing new solutions for producing more to supply a growing market with healthy products. EAS wants to promote and support start-ups and emerging business models in the aquaculture sector, by matching ideas to those that can push the development of new companies and new products. With all the new knowledge presented at our events, we have a wealth of possibility for innovation and value creation to help develop the sector.

This is the EAS Aquaculture Europe Innovation Forum and its inaugural event will take place during our AE21019 event in Berlin on Wednesday, October 9th. In partnership with Hatch Blue and the German Startups Association, the day will be made up of introductory speakers and then pitches from 12 new companies that wish to seek further investment to develop. Speakers include Olaf Birkner on "raising awareness for your start-up"; "What an investor looks for in a start-up" from Viggo Halseth, Chief Innovation Officer, Nutreco and the "European Innovation Council: a one-stop-shop to high-potential innovators" from Sigi GRUBER, Head of the Healthy Oceans & Seas Unit, in the Directorate General for Research and Innovation at the European Commission. A teaser on 'lessons learned' will be provided by Rob van de Ven, Landing Aquaculture, The Netherlands and former EAS Student Group chair.

10.30 Short introduction and welcome messages from our partners:
"Dynamic AgriTech Eco-System - Focus: Marine and Aquaculture",
Dominik Ewald, German Startups Association
Wayne Murphy, COO and co-founder HATCH Aquaculture Accelerator
Session I TECHNOLOGY Chair Stefan Meyer
10.40 "How to get yourself noticed - Raising awareness for your start-up"
Olaf Birkner - Tech founder and advisor digital marketing and innovations
11.00 Introduction of panellists that will judge the pitches of this session
Dominik Ewald – Monitorfish, Angela Schultz-Zehden – Sustainable Projects
Lucille Bonnet – High-Tech Gründerfonds and Margriet Drouillon – Gent University

11.10 Microbia Environnement – Early warning for Harmful Algal Blooms (HABs)
11.20 Networking Break
11.30 Umitron – Data services (IoT, remote sensing, AI…)
11.40 Tellspec – Fish quality control and fraud
11.50 onCyt – Real time monitoring of micro-organisms
12.10 Teaser: Rob van de Ven - Landing Aquaculture
12.20 Watergenics – Sensors for dissolved oxygen and nutrients
12.30 Inalve – Concentrated microalgal production
12.40 Wrap-up of session. Lunch break (on your own). One-to-one meetings.
Session II: PRODUCTION Chair Bjorn Myrseth
14.10 "What an investor looks for in a start-up"
Viggo Halseth, Chief Innovation Officer Nutreco
14.30 Session II Introduction of panellists that will judge the pitches of this session
Viggo Halseth – Nutreco, Robin Shields – Scottish Aquaculture Innovation
Harald Sveier - Lerøy Seafood Group and Johan Verreth – EAS Past President
14.40 SEAentia – Land based production of meagre
14.50 SEADUCER – Production equipment for oysters
15.10 Arbiom – Feed protein source from wood
15.20 Genetirate – selective breeding services (HATCH)

15.30 Univiv (HATCH)
15.40 Networking Break
15.50 Dynaspace – algae detection by state-of-the-art satellite remote sensing (HATCH)
16.00 NSS - Nitrogen Sensing Solutions – multiparametric sensor for water analysis (HATCH)
16.20 Aquaculture Health Lab – Rapid diagnostics
16.30 Tunatech – Blue biofouling bioresources
16.40 Panel deliberations
16.40 "European Innovation Council: a one-stop-shop to high-potential innovators"
Sieglinde Gruber, European Commission DG R&I
16.55 Session chairs wrap up and announce the winners of the AE2019 Innovation Forum
17.30 AE2019 Happy Hour in Exhibition Area

EU EATIP DAY – LOW IMPACT – HIGH OUTPUT
Promoting food security and new value chains in aquaculture

Wednesday, October 9 10.30 - 17.30 Exhibition 2
Chair: Sigi Gruber, Alexandra Neyts

Aquaculture in Europe provides safe food of the highest quality and nutritional value, across a wide range of products adapted to consumer preferences and lifestyles. European policies and strategies recognise its potential as a full-fledged sector of the blue bioeconomy and as an essential approach to acquiring global food and nutrition security. Future-proofing our food systems in terms of sustainability, resilience and competitiveness, calls for strengthening circularity and resource efficiency.

According to the report "Food from the Oceans"[1], the biggest potential for increasing seafood production is through mariculture, especially at lower levels in the ocean food chain. In addition, the production of shellfish, algae and other low-trophic organisms contributes to carbon sequestration and eutrophication mitigation. It is therefore important to consider their suitability to produce food and feed, as well as other high value compounds for use in cosmetics, personal care, pigments, etc. Other ways of supporting the circular bio-economy are the use of waste from one aquatic species as feed for another, and the introduction of alternative feed ingredients from insects, unicellular organisms, fungi, wood and other terrestrial plants.

As a joint effort, the Healthy Oceans & Seas Unit of the European Commission, Directorate General Research and Innovation (DG RTD), and the European Aquaculture Technology and Innovation Platform (EATiP) are setting focus on the impact of European research for the benefit of aquaculture development within Europe as well as worldwide. Through three consecutive sessions, they present some major outcomes of technology and innovation efforts that contribute to tackle the bottlenecks and opportunities in aquaculture towards the overall goal of ensuring food and nutrition security. Pitching the latest results from EU funded projects will be followed up by industry-driven panel discussions.

AQUAEXCEL[2020] is a key aquaculture research project funded by the EU, which integrates leading European aquaculture research facilities that work towards bringing aquaculture research in Europe to a new level. The latest industry-relevant outputs will be presented and discussed at an interactive brokerage session, creating a forum for engagement and exchange between aquaculture researchers and potential industry beneficiaries of these innovative aquaculture outcomes.

10:30 SESSION 1: Setting the scene – How can European research and innovation stimulate sustainability and competitiveness of the aquaculture sector?
Policy context and stakeholders' engagement driving food security and new value chains in aquaculture. Incl. introductory talks by the European Commission and EATiP.

11:25 SESSION 2 – Low trophic production technologies and new feed resources
New findings, future bottlenecks and opportunities on sustainable production of novel food, feed and added value products from alternative low-trophic resources.

14:10 SESSION 3 – Efficient management systems to optimize sustainability and competitiveness
Sustainable, resilient, climate friendly and competitive practices through eco-intensification, intelligent management and new systems for the production of low-trophic species.

NORTH EUROPEAN FISH SPECIES PARASITE MANAGEMENT STRATEGIES

Wednesday, October 9 10.30 - 17.30 Backstage 2
Chair: Emma Bello Gomez

Disease prevention and management are essential for the sustainability of the European aquaculture industry. The diversity of species and farming practices throughout Europe involves a significant number of threats related to a large variety of pathogens that hamper production and require specific preventive and curative practices and tools ensuring a high level of biosecurity of aquaculture production and related seafood products. Among other disease-related threats, parasites and related infections can cause significant damages to farmed fish species and can result in poor growth performance, impaired welfare, and high mortality rates with significant consequences in terms of production and economic performance.

Over the last four years, the EU-funded project **ParaFishControl** (634429) has been working to develop innovative solutions and tools for the prevention, control and mitigation of the most harmful parasitic species affecting the main European farmed fish species, namely: Atlantic salmon, rainbow trout, turbot, gilthead seabream, European sea bass and common carp.

The **"North European Fish Parasite Management Strategies in Aquaculture Farms" workshop** will focus on the parasites which have been most damaging for fresh water and marine farmed species in North Europe (salmon, carp and trout) - *Lepeophtheirus salmonis*, *Tetracapsuloides bryosalmonae*, *Sphaerospora molnari*, *Ichthyophthirius multifiliis*, *Paramoeba perurans* and *Saprolegnia parasitica* as well as zoonotic helminths. During the workshop, industry representatives will provide an overview of the most prevalent issues related to parasitic diseases in North European aquaculture farms. **ParaFishControl** partners will then present the **new tools and techniques** developed within the project to **diagnose, prevent and treat** these diseases. The workshop will provide attendees with new knowledge to better manage their farms, and greatly reduce population loss in a cost-effective way.

More information about the event and full programme of the ParaFishControl workshop will be available online at: https://bit.ly/2IwQw3J

AE2019 INNOVATION FORUM - (1 TO 1 MEETINGS)

Wednesday, October 9 10.30 - 17.30 Backstage 3
Chair: Stefan Meyer

GENERAL CONTRIBUTED NUTRITION

Wednesday, October 9 10.30 - 17.30 Foyer 4
Chair: Andrew Richardson

10.30 **Barbara Rossi**, Maria Angéles Esteban, José María García-Beltrán, Alberto Cuesta, Andrea Piva, Ester Grilli
ANTIOXIDANT EFFECT OF THYMOL AND SORBIC ACID IN FISH HEPATOCYTES*IN VITRO*

10.50 **Florence Perera**, Bjørn Grønevik, Mette Sørensen, Ørjan Hagen
THE EFFECT OF TOTAL REPLACEMENT OF FISH OIL WITH RAPESEED OIL ON GROWTH, BODY COMPOSITION AND GUT HEALTH OF JUVEILE LUMPFISH *Cyclopterus lumpus*

11.10 **Kamil Mert Eryalçin**, Marisol Izquierdo
VITAMIN AND MINERAL COMPOSITIONS OF THE ROTIFER *Brachionus plicatilis* (MÜLLER, 1786) CULTURED WITH DIFFERENT FEEDS

11.30 **Erik Höglund**
ANTI-INFLAMMATORY FEEDS AND TRYPTOPHAN METABOLIC PATHWAYS TO STRESS RESILIENCE IN FISH

11.50 **Susana M.F. Ferreira**, Gonçalo Branco, Pedro M. Santos, Andreia Raposo, Ana Pombo
EFFECTS OF VEGETABLE DIETS ON THE GROWTH, GAMETOGENIC AND OFFSPRING DEVELOPMENT OF THE SEA URCHIN *Paracentrotus lividus* (LAMARCK, 1816)

12.10 **Monica B. Betancor**, Alexa MacEwan, Matthew Sprague, Daniel Montero, Fernando Norambuena, Olga Sayanova, Lihua Han, Johnathan Napier, Marisol Izquierdo, Douglas R. Tocher
FEASIBILITY OF AN OIL DERIVED FROM A GM-OILSEED CROP AS A SUBSTITUTE FOR FISH OIL IN FEEDS FOR EUROPEAN SEA BASS *Dicentrarchus labrax*

12.30 **Zainal Abdin Muchlisin**, Abdullah A. Muhammadar, Nur Fadli, Kartini Eriani, Irma Dewiyanti, Mahfud Mahfud
APPLICATION OF PROBIOTIC AND PAPAIN ENZYME IN THE DIET OF TROPICAL SHORTFIN EEL *Anguilla bicolor*

12.50 **LUNCH**

14.30 **Xiaoting Zheng**, Adam F. Feyaerts, Patrick Van Dijck, Peter Bossier
EVALUATION OF THE ANTI-VIBRIO ACTIVITY OF ESSENTIAL OILS AND THEIR COMPONENTS IN GNOTOBIOTIC ARTEMIA TEST SYSTEM

14.50 **Sjo Zwart**, Frank Ruyseveldt
EVALUATING THE EFFECT OF DIFFERENT FEED PHOSPHATES ON BLOOD PARAMETERS, CORPSE ANALYSIS, INTESTINAL HISTOLOGY AND GROWTH RATE OF KOI CARP *Cyprinus carpio*

15.10 **Amal Biswas**, Fumiaki Takakuwa, Shinichi Yamada, Akihisa Matsuda, Hiroki Kihara, Jonas Miller, Josh Silverman, Renee Saville, Allan LeBlanc, Hideki Tanaka
METHANOTROPH *Methylococcus capsulatus* MEAL AS AN ALTERNATIVE PROTEIN SOURCE FOR YELLOWTAIL *Seriola quinqueradiata*

GENOMIC RESEARCH, TOOLS AND APPLICATIONS

Wednesday, October 9 10.30 - 17.30 Room 3
Chairs: Klaus Kohlmann, Ross Houston

10.30 **Yang Jin**, Rolf Erik Olsen, Thomas Nelson Harvey, Mari-Ann Østensen, Keshuai Li, Nina Santi, Olav Vadstein, Jon Olav Vik, Simen Rød Sandve, Yngvar Olsen
DOMESTICATION-ASSOCIATED LIPID METABOLISM REGULATION IN ATLANTIC SALMON

10.50 **Manu K. Gundappa**, A.C. Bertolotti, R.M. Layer, M.D. Gallagher, C.M. Hollenbeck, T. Nome, S.R. Sandve, D. Robledo, R.D. Houston, I.A. Johnston, S. Lien, D.J. Macqueen
THE STRUCTURAL VARIATION LANDSCAPE IN ATLANTIC SALMON AND IT'S POTENTIAL CONTRIBUTION TO DISEASE RESISTANCE

11.10 **Nicholas Robinson**, Luqman Aslam, Diego Robledo, Ross Houston, Hooman Moghadam, Borghild Hillestad, Matthew Kent, Matthew Baranski, Aleksei Krasnov, Solomon Boison
QTL AND EQTL FOR SALMONID ALPHAVIRUS VIRAL LOAD IN ATLANTIC SALMON – IMPLICATIONS FOR PANCREAS DISEASE RESISTANCE AND TOLERANCE

11.30 **Muhammad Luqman Aslam**, S.A. Boison, C. Jacq, O.J. Hansen, V. Puvanendran, A. Mortensen, P. Sae-Lim
GENETICS OF LICE EATING ABILITY IN LUMPFISH *Cyclopterus lumpus* USING ddRAD SEQUENCING

11.50 **Jan Pawlowski**, Kristina Cermakova, Tristan Cordier
MONITOR THE ENVIRONMENTAL IMPACTS THROUGH ARTIFICIAL INTELLIGENCE APPLIED TO METAGENOMICS

12.10 **Emilie Cardona**, Jérôme Montfort, Hugues Parinello, Laurent Journot, Julien Bobe, Sandrine Skiba-Cassy
CIRCULATING MICRORNA IN PLASMA AND OVARIAN FLUID AS POTENTIAL NON INVASIVE BIOMARKERS OF NUTRITION AND REPRODUCTION OF FEMALE RAINBOW TROUT *Oncorhynchus mykiss*

12.30 **Fabio Sarais**, Henrike Rebl, Marieke Verleih, Bernd Köllner, Alexander Rebl, Tom Goldammer
MOLECULAR CHARACTERIZATION OF THE NKIRAS PROTEIN FAMILY IN RAINBOW TROUT *Oncorhynchus mykiss*

12.50 **LUNCH**

14.30 **Mikhail Ozerov**, Anti Vasemägi, Riho Gross
DECIPHERING THE GENOME OF THE RIVER MONSTER – THE EUROPEAN CATFISH *Silurus glanis*

14.50 **Daniel Zarski**, Aurelie Le Cam, Joanna Nynca, Christophe Klopp, Slawomir Ciesielski, Jerome Montfort, Pascal Fontaine, Andrzej Ciereszko, Julien Bobe
TRANSCRIPTOMIC PROFILING OF EGGS OF PIKEPERCH *Sander lucioperca* REVEALS NOVEL EGG-QUALITY-ASSOCIATED TRANSCRIPTS

15.10 **Carolina Peñaloza**, Tereza Manousaki, Rafaella Franch, Alexandros Tsakogiannis, Anna Sonesson, Luca Bargelloni, Costas Tsigenopoulos, Ross Houston
DEVELOPMENT OF A COMBINED SPECIES SNP ARRAY FOR THE EUROPEAN SEA BASS AND THE GILTHEAD SEA BREAM

15.30 **Anna K. Sonesson,** Siri Storteig Horn, Theo Meuwissen, Aleksei Krasnov, Borghild Hillestad, Hooman Moghadam, Bente Ruyter
GENOMICS OF OMEGA-3 FATTY ACID CONTENTS IN ATLANTIC SALMON

15.50 **Luca Bargelloni**, Marianna Pauletto, Serena Ferraresso, Massimiliano Babbucci, Giuseppe Radaelli, Lisa Maccatrozzo, Daniela Bertotto
MUSCLE TRANSCRIPTOME RESPONSE TO FASTING-REFEDING IN FAST-GROWING COMPARED TO AGE- OR SIZE-MATCHED SLOW GROWING INDIVIDUALS IN THE GILDHEAD SEA BREAM

16.10 **Tom L. Jenkins**, Charlie D. Ellis, Carly L. Daniels, Eduarda M. Santos, Jamie R. Stevens
DETERMINING THE HERITABILITY OF GROWTH TRAITS IN CULTURED EUROPEAN LOBSTERS USING GENOMICS

16.30 **Inés González-Castellano**, Chiara Manfrin, Alberto Pallavicini, Ana M. González-Tizón, Andrés Martínez-Lage
NOVEL INSIGHTS INTO SEX-RELATED GENES IN THE COMMON LITTORAL SHRIMP *Palaemon serratus* BY GONADAL TRANSCRIPTOMIC ANALYSIS

16.50 **Jeremiah Minich**, Eric Allen, Rob Knight
CONSIDERATIONS FOR MICROBIOME RESEARCH IN AQUACULTURE: OVERCOMING CHALLENGES WITH LOW BIOMASS ENVIRONMENTS, REDUCING COSTS, ADDRESSSING TECHNICAL NOISE, AND META-ANLAYSES

17.10 **Julien Nguinkal**, Lidia de los Ríos-Pérez, Nadine Schäfer, Frieder Hadlich, Marcus Stüecken, Olaf Wolkenhauer, Ronald M. Brunner, Alexander Rebl, Marieke Verleih, Dörte Wittenburg, Tom Goldammer
THE DRAFT GENOME OF PIKEPERCH *Sander lucioperca*

VALUE ADDITION AND MARKETING

Wednesday, October 9 14.30 - 17.30 Room 5
Chairs: Marija Banovic, Johannes Simons

14.30 **Johan Johansen**, Lars Svenningsson, Hallstein Baarset
ECOINTENSIFICATION OF AQUACULTURE: CAPTURE AND VALORISATION OF SLUDGE FROM AQUACULTURE WASTEWATER

14.50 **Andreas Müller-Belecke**, Nicolas Borchert, Rafael Valbuena, Adam Erdös
FISHMEAL FROM ENSILAGED FRESHWATER FISH PROCESSING BY-PRODUCTS IN A RAINBOW TROUT DIET: GROWTH PERFORMANCE, PRODUCT QUALITY AND ENVIRONMENTAL IMPACT

15.10 **Sara Ramírez-Bolaños**, S. Díaz, N. Díaz-Padilla, A. Ventura-Castellano, R. Quirós-Pozo, L. Robaina
NOVEL BANANA BY-PRODUCTS IN SEABASS *Dicentrarchus labrax* DIETS

15.30 **Jose Luis Fernández Sánchez**, Jose Manuel Fernández Polanco, Ignacio Llorente García, Elisa Baraibar Diez, Maria Dolores Odriozola Zamanillo, Manuel Luna García, Ladislao Luna Sotorrio
THE EFFECT OF PRICE AND PRODUCTION CHANGES ON FIRMS' PROFITABILITY AND RISK: A SIMULATION WITH EUROPEAN PRODUCERS OF CULTURED SEA BASS AND SEA BREAM

15.50 **Guilherme Wolff Bueno**, Maicon R. Brande, Naor Silveira Fialho, Elisa M. Godoy, Pablo Gallardo Ojeda, Rodrigo Roubach
FINANCIAL RISK EVALUATION OF COMMERCIAL PRODUCTION OF NILE TILAPIA *Oreochromis niloticus* IN NET-CAGES, SÃO PAULO, BRAZIL

16.10 **Marija Banovic**, Machiel Reinders, Anna Claret, Luis Guerrero, Athanasios Krystallis
WHAT SEPARATES WINNERS FROM LOSERS? EVIDENCE FROM A CROSS-COUNTRY INVESTIGATION ON CONSUMER ACCEPTANCE OF NEW AQUACULTURE PRODUCTS

16.30 **Johannes Simons**, Carl Vierboom, Michael Ley, Stefan Johnigk

16.50 **Sofia C. Franco**, Sharron Kuznesof, Bruna Simões, Beth Clark, Peter Jackson
TOWARDS IMPROVED COMMUNICATION IN AQUACULTURE: EXPLORING CONSUMERS' PERCEPTIONS AND ATTITUDES

17.10 **Johannes Simons**, Carl Vierboom, Michael Ley, Stefan Johnigk
CHALLENGES OF CONSUMER ORIENTED COMMUNICATION ABOUT SCIENTIFICALLY BASED SUSTAINABILITY STANDARDS FOR AQUACULTURE

FUNCTIONAL AQUAFEEDS

Wednesday, October 9 14.30 - 17.30 Europe Hall

Chair: Pedro Gomez Requeni

Sponsored by Biomar

14.30 **Jie Wang**, Peng Lei, Amr A.A. Gamil, Leidy Lagos, Yang Yue, Kristin Schirmer, Liv Torunn Mydland, Margareth Øverland, Åshild Krogdahl, Trond M. Kortner
RAINBOW TROUT *Oncorhynchus mykiss* INTESTINAL EPITHELIAL CELLS AS A MODEL FOR STUDING GUT IMMUNE FUNCTION AND EFFECTS OF FEED ADDITIVES

14.50 **Carmen Tatiana Kalinowski**, L.E. Robaina, L. Larroquet, V. Veron, S. Kaushik, S. Fontagné-Dicharry
INFLUENCE OF DIETARY ASTAXANTHIN ON THE OXIDATIVE STRESS RESPONSE CAUSED BY EPISODIC HYPEROXIA IN RAINBOW TROUT

15.10 **Paul J. Midtlyng**
ANTI-INFLAMMATORY EFFECTS OF BETA-1,3/1,6 GLUCAN SUPPLEMENTED FEED IN ATLANTIC SALMON *Salmo salar*

15.30 **Nicola Tallarico**, Christophe Bodenreider, Geoff Horst
POSITIVE EFFECTS OF SUPPLEMENTING ALGAL 1,3-BETA GLUCAN ON THE SURVIVAL OF ATLANTIC SALMON *Salmo salar* IN CHALLENGE CONDITIONS

15.50 **Yanxian Li**, Leonardo Bruni, Alexander Jaramillo-Torres, Trond Kortner, Elvis Chikwati, Ikram Belghit, Erik-Jan Lock, Åshild Krogdahl
GUT HEALTH AND MICROBIOTA IN POST-SMOLT ATLANTIC SALMON *Salmo salar* FED LARVAE MEAL FROM BLACK SOLDIER FLY *Hermetia illucens*

16.10 **Nafsika Karakatsouli**, Kostas Domalis, Socratis Panopoulos, Antonio Coli, Constantina Anastasiadou, Maria Rati, Spyros Bantounas, Alkisti Batzina
INVESTIGATION OF EARLY INTRODUCTION OF DRY FEED ON GILTHEAD SEABREAM *Sparus aurata* LARVAL DEVELOPMENT AND GROWTH PERFORMANCE AFTER METAMORPHOSIS

16.30 **Delano Dias Schleder**, Priscila Costa Rezende, Felipe Nascimento Vieira
COMBINATIONS OF BROWN SEAWEEDS AS FEED ADDITIVES IMPROVED THERMAL SHOCK RESISTANCE OF PACIFIC WHITE SHRIMP POST-LARVAE REARED IN BIOFLOC SYSTEM

16.50 **Ricardo Pereira**, Luísa Valente, Sónia Batista
ANTIOXIDANT AND IMMUNE-MODULATORY POTENTIAL OF MARINE ALGAE IN DIETS FOR EUROPEAN SEABASS

17.10 **Leong-Seng Lim**, Rossita Shapawi, Gunzo Kawamura
AMINO ACIDS AS FEEDING STIMULANT IN THE DEVELOPMENT OF SOYBEAN-BASED DIET FOR JUVENILE GROUPER *Epinephelus fuscoguttatus*

GENERAL BIOLOGY OF FARMED SPECIES

Wednesday, October 9 14.30 - 17.30 Lounge 1-3

Chair: Ivo Monteiro

14.30 **Orestis Stavrakidis-Zachou**, Konstadia Lika, Jorge Alarcon, Abdulaziz M. Al-Suwailem, Nikos Papandroulakis
BIOLOGICAL PERFORMANCE OF MEAGRE *Argyrosomus regius* UNDER HIGH TEMPERATURE

14.50 **Dieter Steinhagen**, M. Adamek, M. Dietrich, F. Teitge, M. Ganter, I. Baumann, V. Jung-Schroers, V. Piackova, G. Gela, M. Kocour, A. Ciereszko, D. Steinhagen
THE MULTIFUNCTIONAL GILL – THE ACHILLES' HEEL OF FISH HEALTH?

15.10 **Smaragda Tsairidou**, A. Hamilton, D. Robledo, J. Bron, R.D. Houston
OPTIMISING GENOMIC SELECTION WITH LOW DENSITY MARKERS IN FARMED ATLANTIC SALMON

15.30 **Benan Gulzari**, Kasper Janssen, Hans Komen
IDENTIFICATION OF FACTORS EXPLAINING THE GROW-OUT PERFORMANCE OF EUROPEAN SEABASS *Dicentrarchus labrax* AND GILTHEAD SEABREAM *Sparus aurata* IN THE MEDITERRANEAN

15.50 **Sergio Vela-Avitúa**, Ingunn Thorland, Vasileios Bakopoulos, Kantham Papanna, Arkadios Dimitroglou, Leonidas Papaharisis, Bruno Guinand
ADVANCED SELECTIVE BREEDING FOR DISEASE RESISTANCE IN EUROPEAN SEA BASS *Dicentrarchus labrax*

16.10 **Laureana Rebordinos**, Aglaya Garcia-Angulo, Emilio García, Silvia Portela-Bens, María Esther Rodríguez, Belen Molina, Manuel Alejandro Merlo, Marco Anaya, Alberto Arias, Ismael Cross
CONSTRUCTION ON AN INTEGRATED GENETIC MAP OF BENEFIT TO THE *Solea senegalensis* AQUACULTURE

16.30 **Carlos Andrade**, Natacha Nogueira, Mariana Martins
MONITORING IMPACTS OF MACROPLASTICS IN MADEIRA ISLAND'S OFFSHORE FISH FARM OF *Sparus aurata*

16.50 **Maria Mastoraki**, Lydia Katsika, Efthimia Antonopoulou, Laura Gasco, Stavros Chatzifotis
THE EFFECT OF FISHMEAL SUBSTITUTION WITH THREE DIFFERENT INSECT MEALS ON GROWTH PERFORMANCE, NUTRIENT UTILIZATION AND DIGESTIBILITY OF GILTHEAD SEA BREAM *Sparus aurata*

NUTRITION: ADDITIVES AND INGREDIENTS - CONTINUED

Wednesday, October 9 14.30 - 17.30 Backstage 1
Chair: Katerina Kosoulaki, Kiron Viswanath

BD # 356 **Luca Grosso**, Alessandra Fian*chini*, Stefano Cataudella, Michele Scardi, Arnold Rakaj
EFFECTS OF DIFFERENT DIETS ON THREE SIZE CLASSES OF SEA URCHIN *Paracentrotus lividus*

14.30 **Marialena Kokkali,** Francisco J. Barba, Francisco J. Marti-Quija, Dorinde Kleinegris, Katerina Kousoulaki
RELEASE OF PHENOLICS AND OTHER ANTIOXIDANTS FROM MICROALGAE *Phaeodactylum tricornutum* AND *Tetraselmis chuii* FOLLOWING BEAD MILLING

14.50 **Alessandra Roncarati**, Marina C.T. Meligrana, G. Enrico Magi, Francesca Mariotti
RAINBOW TROUT *Oncorhynchus mykiss* GROWING TRIAL USING DIETS WITH DIFFERENT DOSAGES OF THE SAME ADDITIVE

15.10 **Maria Angéles Esteban**, Barbara Rossi, José María García-Beltrán, Alberto Cuesta, Andrea Piva, Ester Grilli
DOSE-EFFECT RESPONSE OF A BLEND OF ORGANIC ACID AND NATURE-IDENTICAL COMPOUNDS ON GILTHEAD SEABREAM *Sparus aurata* L.

15.30 **Roel Maas**, Marc Verdegem, Yueming Dersjiant-Li, Johan Schrama
IMPACT OF NSP LEVEL AND ENZYMES (PHYTASE AND XYLANSE) ON NUTRIENT UTILIZATION, GROWTH PERFORMANCE IN NILE TILAPIA *Oreochromis niloticus*

15.50 **Frederik Kaiser**, Carsten Schulz
EFFECTS OF RAPESEED PROTEIN PRODUCTS SUPPLEMENTED WITH GLUCOSINOLATES AND PHYTIC ACID ON THE GROWTH PERFORMANCE OF RAINBOW TROUTS *Oncorhynchus mykiss*

HOW DIET COMPOSITION AND ENVIRONMENTAL FACTORS AFFECT THE UPTAKE AND METABOLISM OF ASTAXANTHIN IN ATLANTIC SALMON *Salmo salar*

SUSTAINABLE EUROPEAN AQUACULTURE 4.0: NUTRITION AND BREEDING INNOVATIONS

Wednesday, October 9 14.30 - 17.50 Room 30341, Wing 3, Estrel Hotel
Chair: Antti Kuse

Session: Sustainable European aquaculture 4.0: nutrition and breeding innovations

In recent years, advancements in enabling technologies have led to completely novel innovations that are now being implemented within the aquaculture industry. This session presents the latest developments in the interacting fields of digital information technology, genomics and circular economy applied in fish feeding, nutrition and selective breeding. They together produce more sustainable aquaculture practices and more robust, healthy, nutritious and resource-efficient farmed fish. The results originate from three Horizon 2020 EU-projects, AquaIMPACT, FutureEUAqua and iFishIENCi, funded under the topic 'Sustainable European Aquaculture 4.0: Nutrition and Breeding Innovations'. In these complementary projects, researchers and companies together develop more sustainable aquaculture corresponding to the UN's Sustainable Development Goals.

14.30 Antti Kause
AquaIMPACT – GENOMIC AND NUTRITIONAL INNOVATIONS FOR GENETICALLY SUPERIOR FARMED FISH

14.50 Lars Ebbesson, Dominique Durand, Tamás Bardócz
iFishIENCi: INTELLIGENT FISH FEEDING THROUGH INTEGRATION OF ENABLING TECHNOLOGIES AND CIRCULAR PRINCIPLES

15.10 Åsa Maria Espmark
FutureEUAqua – FUTURE GROWTH IN SUSTAINABLE, RESILIENT AND CLIMATE FRIENDLY ORGANIC AND CONVENTIONAL EUROPEAN AQUACULTURE

15.30 Giuseppe Lembo, Pierluigi Carbonara, Sebastien Alfonso, Walter Zupa, Maria Teresa Spedicato
THE ROLE OF INTERNET OF THINGS FOR HEALTHY FISH AND ENVIRONMENT IN THE EUROPEAN AQUACULTURE

15.50 Franck Le Gall, Ahmed Abid, Philippe Cousin, Elisa Ravagan
MODELLING DATA IN THE CONTEXT OF AQUACULTURE

16.10 Steven Prescott, Tamas Bardocz
iFishIENCi: WILL INCREASED EFFICIENCY THROUGH THE USE OF BREAKTHROUGH INNOVATIONS AND PRINCIPLES OF CIRCULAR ECONOMY TRANSLATE INTO IMPROVED SUSTSAINABILITY FOR EUROPEAN AQUACULTURE?

16.30 Elena Mente, K. Kousoulaki, N. Vlahos, A. Vasilaki, E. Antonopoulou, A. Jokumsen, P. Lembo, I. Nengas
FEED AND NUTRITION IN ORGANIC AQUACULTURE

16.50 Daniel Montero, S. Torrecillas, D.R. Tocher, M. Vandeputte, R. Fontanillas, G. Rosenlund, P. Haffray, B. Ruyter, A. Sonesson, J. Bastiaansen, A. Kause
DEVELOPMENT OF FISH FEEDS AND FEEDING STRATEGIES FOR GENETICALLY SUPERIOR FISH FROM BREEDING PROGRAMMES

17.10 John Bastiaansen
THE IMPACT OF GENOMIC SELECTION IN COMMERCIAL BREEDING PROGRAMMES FOR FOUR IMPORTANT SPECIES IN EUROPEAN AQUACULTURE

17.30 Anne Kettunen, Marie Lillehammer
POWER CALCULATIONS FOR OPTIMISATION OF THE EXPERIMENTAL DESIGN TO DETECT G X E: SALMON EXPERIMENTS IN FutureEUAqua

WOMEN IN AQUACULTURE

Wednesday, October 9 16.30 - 17.30 Festival
Chair: Alistair Lane

Jointly organised by EAS and The Fish Site, the Women in Aquaculture session will offer firsthand insights into how women can overcome perceived gender-related obstacles and build thriving careers right across the aquaculture sector. Panellists will discuss key issues related to the benefits of diversity in the workforce and ways to ensure that aquaculture organisations pursue recruitment policies that allow talented people, regardless of gender, to succeed.

SESSION HOSTS
Synnøve Hellund, NOFIMA AND EATIP
Rob Fletcher, The Fish Site

PANEL MEMBERS
Lara Barazi, Kephalonian Fisheries
Ole Christiansen, BIOMAR
Ben Hadfield, MOWI Scotland
Matthijs Metselaar, Benchmark Animal Health
Birgit Schmidt-Puckhaber, German Agriculture Society
Selina Stead, University of Stirling

ENVIRONMENTAL AND ECOSYSTEM MANAGEMENT

Thursday, October 10 09.00 - 11.20 Exhibition 2
Chair: Oyvind Berg

09.00 **Pierre Gernez**, Laura Zoffoli, Thomas Lacour, Virginie Raimbault, Véronique Séchet, Victor Martinez Vicente, Tristan Harmel
HIGH RESOLUTION SATELLITE REMOTE SENSING OF RED TIDES IN SHELLFISH FARMING COASTAL WATERS

09.20 **Roberto Pastres**, Suzanne B. Bricker, Bela H. Buck, Luis Conceição, Joao Gomes Ferreira, Jon Grant, Johan Johansen, David C. Little, Carmen Sotelo, Chang Bo Zhu
TOWARDS THE ECOLOGICAL INTENSIFICATION OF EUROPEAN AQUACULTURE: THE GAIN PROJECT

09.40 **Maren Lyngsgaard**, Per Dolmer, Daniel Taylor, Bent Vismann
BLUE BIOMASS – A WAY FORWARD FOR MITIGATION MUSSELS

10.00 **Ellen Sofie Grefsrud**, Terje Svåsand, Lasse Berg Andersen
RISK ASSESSMENT OF NORWEGIAN SALMON FARMING – A NEW APPROACH

10.20 **Marcos Carvajalino Fernández**, N.B. Keeley, I. Fer, B.A. Law, R.J. Bannister
IMPACT OF BOTTOM SUBSTRATE TYPE ON THE RESUSPENSION OF ATLANTIC SALMON *Salmo salar* FAECAL MATERIAL

10.40 **Thorsten Stoeck**, Thomas A. Wilding, Tristan Cordier, Jan Pawlowski, Verena Dully, Larissa Frühe, Marc Coulson
ESTABLISHING BENTHIC ECOLOGICAL STATUS AROUND SALMON AQUACULTURE CAGES USING DNA-BASED ENVIRONMENTAL MONITORING

11.00 **Øivind Bergh**, Alexander Christian Beck, Guldborg Søvik, Erik Olsen, Trude H. Thangstad, Genoveva Gonzalez-Mirelis, Fabio Grati, Luca Bolognini
SPATIAL CONFLICTS OF COASTAL FISHERIES WITH LARGE SCALE SALMONID AQUACULTURE IN A NORWEGIAN FJORD ENVIRONMENT ANALYZED BY GIS AND STAKEHOLDER SURVEYS

SUSTAINABLE SYSTEMS FOR LARGE SCALE PRODUCTION - CLOSED, OFFSHORE OR BOTH

Thursday, October 10 09.00 - 11.20 Room 5
Chairs: Asa Espmark, Hans Bjelland

09.00 **David Kristiansen**, Biao Su, Stefan Vilsen, Per C. Endresen, Carina Norvik, Zsolt Volent
DESIGN CONSIDERATIONS AND RESEARCH CHALLENGES FOR CLOSED FISH CAGES IN CURRENTS AND WAVES

09.20 **Sharada Navada**, Frédéric Gaumet, Olav Vadstein, Claudia Spanu, Øyvind Mikkelsen, Jelena Kolarevic
IMPROVING SALINITY ADAPTATION IN NITRIFYING BIOREACTORS BY SEAWATER PRIMING

09.40 **Enrique Pino Martinez**, Pablo Balseiro Vigo, Markus Braanaas, Valentina Tronci, Cindy Pedrosa, Naouel Gharbi, Sigurd Handeland, Tom Nilsen
INFLUENCE OF WATER TEMPERATURE AND FEEDING REGIME ON THE INCIDENCE OF EARLY SEXUAL MATURATION IN ATLANTIC SALMON *Salmo salar* L. POSTSMOLTS DURING THE FRESHWATER STAGE

10.00 **Khurram Shahzad**, Harald Takle, Karl F. Ottem, Magnus Stendal, Kevin T. Stiller, Yuriy Marchenko, Jelena Kolarevic
CFD MODELING OF SEMI-CLOSED CONTAINMENT FLOATING SYSTEM WITH FLEXIBLE WALLS EFFECT OF INLET ORIENTATION ANGLE ON THE FLOW FIELD HYDRODYNAMICS

10.20 **Christopher Good**, Travis May, Curtis Crouse, John Davidson, Natalie Redman, Megan Murray, Anna DiCocco, Brian Vinci, Steven Summerfelt, Lars Ebbesson, Sigurd Handeland, Tom Ole Nilsen, Sigurd Stefansson, Bendik Fyhn Terjesen, Frode Mathisen, Åsa Maria Espmark
DETERMINING THE IMPACT OF PHOTOPERIOD, FEEDING REGIME, AND PLOIDY ON ATLANTIC SALMON *Salmo salar* POST-SMOLT HEALTH, GROWTH PERFORMANCE, AND MATURATION IN FRESHWATER RECIRCULATION AQUACULTURE SYSTEMS

10.40 **John Davidson**, Steven Summerfelt, Brian Vinci, Kevin Schrader, Christopher Good
EVALUATING THE FEASIBILITY OF INCOPORATING MEMBRANE BIOLOGICAL REACTORS WITHIN RAS: EFECTS ON WATER USE, WATER QUALITY, AND RAINBOW TROUT *Oncorhynchus mykiss* PERFORMANCE

11.00 **Uwe Waller**, Klaus Kimmerle, Sabine Boehmer, Uwe Köhler
SUSTAINABLE AQUACULTURE OF ATLANTIC SALMON *Salmo salar* ON BOARD A LARGE SAIL SHIP

BALTIC AQUACULTURE

Thursday, October 10 09.00 - 11.20 Lounge 1-3
Chair: Mathis von Ahnen

09.00 **Monika Normant-Saremba**, Hanna Ladkowska, Halina Kendzierska, Barbara Dmochowska, Katarzyna Smolarz
FROM LARVAE TO PLATE – AN EXPERIMENTAL LAND-BASED RAS CULTURE OF *Litopeanaeus vannamei* IN POLAND

09.20 **Xiaoyu Huang**, Carlos Letelier-Gordo
NITROGEN REMOVAL FROM A SALT-WATER RECIRCULATING AQUACULTURE SYSTEM (RAS) USING A STEP FED BATCH REACTOR (SFBR) OPERATED UNDER EXTERNAL AND INTERNAL CARBON SOURCES

09.40 **Jouni Vielma**, Gunno Renman, Agnieszka Renman, Jani Pulkkinen
PHOSPHORUS REMOVAL FROM RECIRCULATING AQUACULTURE SYSTEMS (RAS) EFFLUENT BY REACTIVE COLUMN FILTERS

10.00 **Sanni Aalto**, Jani T. Pulkkinen, Suvi Suurnäkki, Jouni Vielma, Marja Tiirola
AUTO- AND HETEROTROPHIC NITROGEN REMOVAL IN WOODCHIP REACTORS TREATING RECIRCULATING AQUACULTURE SYSTEM EFFLUENTS

10.20 **Suvi Suurnäkki**, Jani Pulkkinen, Marja Tiirola, Sanni Aalto
GEOSMIN PRODUCERS AND MICROBIAL COMMUNITY COMPOSITION IN COMMERCIAL RECIRCULATING AQUACULTURE FARMS

10.40 **Anniina Runtuvuori**, Heidi Kunttu, Gabriel Almeida, Elina Laanto, Kati Mäkelä, Mathias Middelboe, Lotta-Riina Sundberg
ISOLATION AND CHARACTERIZATION OF NEW *Flavobacterium columnare* AND ITS BACTERIOPHAGES FROM FISH FARMS

11.00 **Miriam von Thenen**, M. Maar, H.S. Hansen, K.S. Schiele
A GIS SUITABILITY ANALYSIS FOR SELECTING MUSSEL FARM SITES IN THE SOUTH-WESTERN BALTIC SEA

GOVERNANCE, POLICY, REGULATIONS AND STRATEGIC PLANNING

Thursday, October 10 09.00 - 11.20 Room 4
Chair: John Bostock

09.00 **Qingyin Wang**
CANCELLED SOME CONSIDERATIONS ON THE SUSTAINABLE DEVELOPMENT OF AQUACULTURE – CHALLENGES, CONSTRAINTS AND PROSPECTS

09.20 **Keith Jeffery**, Stephen Mangi, Heather Conejo-Watt, Angela Muench, Kieran Hyder
INTEGRATION OF FISHERIES AND AQUACULTURE INTO A MORE HOLISTIC SEAFOOD PRODUCTION SYSTEM

09.40 **Øivind Bergh**
CONSTRAINTS AGAINST GLOBAL DEVELOPMENT OF AQUACULTURE: COMPETITION FOR SPACE, RESOURCES AND SOCIETAL COMMITMENT

10.00 **Jenny Weitzman**, Ramon Filgueira, Jon Grant
TOWARDS AN ECOSYSTEM APPROACH TO AQUACULTURE: DEVELOPING A HOLISTIC FRAMEWORK FOR CARRYING CAPACITY OF SALMON AQUACULTURE IN CANADA

10.20 **Trevor Telfer**, Hanne Kaas, Anne Lise Middelboe, Lynne Falconer, Pauline O'Donohoe
AN 'AQUACULTURE SUSTAINABLITY TOOLBOX' FOR FLEXIBLE LICENSING AND REGULATION OF AQUACULTURE IN EUROPE

10.40 **Gudrun Olafsdottir**, David Cook, Shraddha Mehta, Ingunn Yr Gudbrandsdottir, Maitri Thakur, Sigurdur G. Bogason
GOVERNANCE AND PERCEIVED POWER IN THE SALMON VALUE CHAIN

11.00 **Tim Knöpfel**, Bernhard Brümmer, Stephan Wessels
EFFICIENCY OF RAINBOW TROUT PRODUCTION IN NORTH-WEST GERMANY

ESCAPES / INTERACTION OF FARMED AND WILD FISH

Thursday, October 10 09.00 - 11.20 Exhibition 1
Chair: Kjetil Hindar

09.00 **Sten Karlsson**, Tonje Aronsen, Geir Bolstad, Ola H. Diserud, Ingerid J. Hagen, Kjetil Hindar
ESTIMATING GENETIC INTROGRESSION OF FARMED SALMON – P(WILD); METHODOLOGY, ACHIEVEMENTS AND PROSPECTS

09.20 **Ola H. Diserud**, Kjetil Hindar, Sten Karlsson, Kevin A. Glover, Øystein Skaala
ESCAPED FARM SALMON AFFECT THE GENETICS OF WILD SALMON *Salmo salar* POPULATIONS ALL ALONG THE NORWEGIAN COAST

09.40 **Tony Farrell**, Yangfan Zhang, Mark Polinski, Phillip Morrison, Colin Brauner, Kyle Garver
THE IMPACT OF A PISCINE ORTHOREOVIRUS (PRV) INFECTION ON THE RESPIRATORY PERFORMANCE AND CAPACITY OF ATLANTIC SALMON AND SOCKEYE SALMON IN BRITISH COLUMBIA, CANADA

10.00 **Monica F. Solberg**, Grethe Robertsen, Line E. Sundt-Hansen, Kjetil Hindar, Kevin A. Glover
DOMESTICATION LEADS TO INCREASED PREDATION SUSCEPTIBILITY

10.20 **Marie Lillehammer**
FITNESS EFFECTS OF INTROGRESSION OF ESCAPED FARMED SALMON INTO WILD POPULATIONS

10.40 **Kevin A. Glover**, Monica Solberg
CRYPTIC INTROGRESSION: WILL PLASTICITY AND NATURAL SELECTION MASK THE EFFECTS OF GENE-FLOW FROM DOMESTICATED ESCAPEES ON NATURAL POPULATIONS?

11.00 **Øystein Skaala**, Francois Besnier, Reidar Bordstrøm, Bjorn Barlaup, Anne Sørvik, Eirik Normann, Britt Østebø, Michael Hansen, Kevin Glover
A LONG-TERM STUDY OF DOMESTICATED AND WILD ATLANTIC SALMON IN THE RIVER GUDDALSELVA

EUROSHRIMP INDUSTRY FORUM

Thursday, October 10 09.00 - 11.20 Exhibition 2

Chairs: Gregor Jaehne, Stefan Meyer

INFORMAL MEETING FOR ALL SHRIMP ENTHUSIASTS

Meet and greet. We offer the opportunity to meet each other without any program constraints and discuss the topics that interest you the most.

WORKSHOP OPENING

Dr. Matthew Slater, Head of Aquaculture Research Group at the Alfred Wegener Institute, Helmholtz Centre for Polar and Marine Research (AWI)

STAKEHOLDER SURVEY "RECIRCULATION AQUACULTURE SYSTEMS – POSITIONS OF THE ORGANIC FOOD SECTOR

Dr. Stefan Bergleitner, Naturland e.V.

DIVERSIFICATION OF GLOBAL SHRIMP FARMING THROUGH TRANSPARENCY – THE NEW ASC METRICS METHODOLOGY

Kathrin Steinberg, Aquaculture Stewardship Council (ASC)

THE DEVELOPMENT OF INEXPENSIVE SALT MIXTURES FOR INLAND INTENSIVE SHRIMP *Litopenaeus vannamei* FARMING

Dr. Andrew Ray, Kentucky State University, College of Agriculture, Communities and the Environment, School of Aquaculture and Aquatic Sciences

FIGHTING AND AVOIDING VIBRIO IN INTENSIVE CULTURE OF *Litopenaeus vannamei*: OVERVIEW OF RESEARCH DONE AT CREVETEC FARM

Eric De Muylder, CreveTec

PRODUCTION OF POSTLARVAE *Litopenaeus vannamei* IN EUROPE

Nicola Scalise, EcoShrimp

EXPERIENCES FROM A NEW SHRIMP RESEARCH FACILITY IN LITHUANIA

Nerijus Nika, Kleipeda Science and Technology Park

NATIONAL PILOT PLATFORMS CONECTING THE SHRIMP SECTOR IN VIETNAM, THAILAND AND BANGLASDESH

David Basset, European-Asian Technology and Innovation Platform (EURASTIP)

APPLICATION OF THAILAND TO GET POSITIVE LISTED AS A COUNTRY TO EXPORT LIVE SHRIMP INTO THE EU

Dr. Patrick Sorgeloos, Ghent University, Department of Animal Production

SUPPORT LETTER AND WORKSHOP CLOSING

Dr. Matthew Slater, Head of Aquaculture Research Group at the Alfred Wegener Institute, Helmholtz Centre for Polar and Marine Research (AWI)

NUTRITION: ADDITIVES AND INGREDIENTS - CONTINUED

Thursday, October 10 09.00 - 16.50 Europe Hall
Chair: Katerina Kosoulaki, Kiron Viswanath

09.00 **Antigoni Vasilaki**, Katerina Kousoulaki, Tor Andreas Samuelsen, Giorgos Pyrenis, Dimitra Kogiannou, Kriton Grigorakis, Eleni Fountoulaki, Elena Mente, Ioannis Nengas
EFFECTS OF NOVEL INGREDIENTS ON GROWTH PERFORMANCE IN EUROPEAN SEA BASS *Dicentrarchus labrax*

09.20 **Sandrine Skiba**, Christine Burel, Thierry Kerneis, Laurent Labbé, Frédéric Terrier, Geneviève Corraze, Nadège Richard, Yann Marchand, Mathilde Dupont-Nivet
SUPLEMENTING AQUAFEEDS WITH NEW ALTERNATIVE INGREDIENTS: A PROMISING SOLUTION TO IMPROVE PLANT-BASED DIET EFFICIENCY IN RAINBOW TROUT

09.40 **Pabodha Weththasinghe**, Leidy Lagos, Jon Øvrum Hansen, Liv Torunn Mydland, Margareth Øverland
THE EFFECT OF DIETARY BLACK SOLDIER FLY LARVAE *Hermetia illucens* MEAL AND PASTE ON GROWTH PERFORMANCES AND IMMUNE PARAMETERS IN ATLANTIC SALMON *Salmo salar*

10.00 **Mette Sørensen**, Katerina Kousoulaki, Dorinde Kleinegris, Chris Andre Johnsen, Anjana M. Palihawadana, Marialena Kokkali, Viswanath Kiron
WHOLE OR BROKEN CELLS OF *Phaeodactylum tricornutum* AND *Tetraselmis chuii* FED TO ATLANTIC SALMON *Salmo salar*

10.20 **Ricardo Pereira**, Luísa Valente, Mónica Costa, Luís Baião, Sónia Batista, Sergio Fernández-Boo, Benjamín Costas, Luís Cunha, Rui Lima
EXPLORING THE BENEFITS OF NATURAL ANTIOXIDANTS IN DIETS FOR EUROPEAN SEABASS UNDER A CIRCULAR ECONOMY CONTEXT

10.40 **Tiziana Bongiorno**, Andrea Di Biase, Mauro Vasconi, Vittorio M. Moretti, A. Lopez, Aldo Tava, Domenico Carminati, Giuliana D'Imporzano, Marina Montedoro, Fabrizio Adani, Gabriel F. Acién Fernández, Javier F. Alarcón, Katia Parati
GROWTH PERFORMANCE AND QUALITY TRAITS OF SIBERIAN STURGEON *A. baerii* JUVENILES FED DIETS INCLUDING *Nannochloropsis gaditana* AND *Scenedesmus almeriensis* MICROALGAE MEAL

11:20 **BREAK**

11:45 **PLENARY 3 – POSTER AWARDS – LUNCH**

14.30 **M. Ferreira**, P. Campelos, M.L. Nunes, V. Barbosa, M. Barata, A. Marques, L. Ribeiro, P. Pousão-Ferreira, J. Dias, S. Sousa, V.F. Domingues, L.M.P. Valente
BIO-FORTIFICATION OF GILTHEAD SEABREAM *Sparus aurata* WITH DIETS CONTAINING ALGAE AND SELENISED YEAST

14.50 **Marta Carvalho**, Ramón Fontanillas, Grethe Rosenlund, Daniel Montero, Marisol Izquierdo
THE COMBINATION OF POULTRY AND ALGAE OILS AS REPLACERS OF FISH OIL IN DIETS FOR GILTHEAD SEA BREAM *Sparus aurata* FINGERLINGS

15.10 **Ana Catarina Matias**, Marisa Barata, Ravi Luna Araujo, Jorge Dias, Pedro Pousão-Ferreira
TAURINE MODULATES PROTEIN TURNOVER IN SEVERAL TISSUES OF MEAGRE JUVENILES FED WITH PLANT-BASED DIETS

15.30 **David San Martin**, Bruno Iñarra, Mikel Orive, Alicia Estevez, Joan Nazzaro, Ricard Fenollosa, José Miguel Martínez, Anna-Maria De Smet, Jaime Zufía
BREWERS' SPENT YEAST AND GRAIN AS ALTERNATIVE INGREDIENTS FOR AQUACULTURE FEED

15.50 **Ivan Viegas**, Mariana Palma, Francisca Silva-Brito, Emanuel Silva, João Rito, Paulo Rema, Elisabeth Plagnes-Juan, Stéphane Panserat, Leonardo Magnoni
METABOLIC UTILIZATION OF DIETARY GLYCEROL BY RAINBOW TROUT *Oncorhynchus mykiss:* A MULTI-TRIAL EVALUATION

SELECTIVE BREEDING

Thursday, October 10 09.00 - 16.50 Room 2
Chairs: Christos Palaikostas, Marc Vandeputte

09.00 **Hugues de Verdal**, Marc Vandeputte, François Allal, Mathieu Besson, Wagdy Mekkawy, Dirk-Jan de Koning, John A.H. Benzie
ARE GENETICS AND GENOMICS HELPFUL TO IMPROVE FEED EFFICIENCY IN NILE TILAPIA *Oreochromis niloticus?*

09.20 **Hanne Dvergedal**, Jørgen Ødegård, Margareth Øverland, Liv Torunn Mydland, Gunnar Klemetsdal
NOVEL INDICATOR TRAITS FOR FEED EFFICIENCY IN ATLANTIC SALMON *Salmo salar*

09.40 **Marc Vandeputte**, Clémence Fraslin, Pierrick Haffray, Anastasia Bestin, François Allal, Martin Prchal, Martin Kocour, Mathilde Dupont-Nivet
HOW TO GENETICALLY INCREASE FILLET YIELD IN FISH: RELEVANT GENETIC PARAMETERS AND METHODS FOR THE ESTIMATION OF GENETIC GAIN

10.00 **Martin Prchal**, Martin Kocour, Marc Vandeputte, Antti Kause, Alain Vergnet, Jinfeng Zhao, David Gela, Lucie Genestout, Anastasia Bestin, Pierrick Haffray, Jérôme Bugeon
MORPHOLOGICAL PREDICTORS OF SLAUGHTER YIELDS USING 3D DIGITIZER AND THEIR UTILIZATION IN COMMON CARP BREEDING PROGRAM

10.20 **Anne Kettunen**, Hooi Ling Khaw, Dennis Brandborg Nielsen, Borghild Hillestad, Hooman Moghadam
SLAUGHTER QUALITY OF ATLANTIC SALMON *Salmo salar* USING COMPUTERIZED TOMOGRAPHY

10.40 **Samuel Bekele Mengistu**, Han A. Mulder, John A.H. Benzie, Hans Komen
GENETIC PARAMETERS FOR RESILIENCE BASED ON FLUCTUATIONS IN BODY WEIGHT IN NILE TILAPIA GROWN IN AERATED AND NON-AERATED PONDS

11.00 **Clemence Fraslin**, A. Bestin, N. Dechamp, J. D'Ambrosio, F. Krieg, E. Belmonte, C. Poncet, P. Hocde, P. Haffray, Y. Guiguen, F. Phocas, E. Quillet
GWAS REVEALS SEVERAL GENOMIC REGIONS GOVERNING SPONTANEOUS XX-MALENESS IN RAINBOW TROUT

11:20 **BREAK**

11:45 **PLENARY 3 – POSTER AWARDS – LUNCH**

14.30 **Luca Bargelloni**, Oronzo Tassiello, Ludovica Montanucci, Massimiliano Babbucci, Serena Ferraresso, Paolo Carnier
EXPLORING MACHINE LEARNING METHODS FOR GENOMIC PREDICTION OF DISEASE RESISTANCE AND BODY LENGTH IN THE GILTHEAD SEA BREAM

14.50 **Christos Palaiokostas**, Henrik Jeuthe, Dirk-Jan Koning
IMPLEMENTATION OF LOW COVERAGE GENOTYPE BY SEQUENCING IN THE SELECTIVE BREEDING PROGRAM OF ARCTIC CHARR *Salvelinus alpinus* IN SWEDEN

15.10 **Binyam Dagnachew**, Solomon Antwi Boison, Matt Baranski
IMPUTATION AND GENOMIC PREDICTION ACCURACIES FOR SEA LICE RESISTANCE IN ATLANTIC SALMON

15.30 **Rama Bangera**, Sergio Vela-Avitua, Marie Lillehammer, Marcela Salazar, Morten Rye, Edna Constanza Erazo, Andres Suarez, James Cock, Nicholas Robinson
GENOMIC SELECTION TO IMPROVE WHITE SPOT SYNDROME VIRUS (WSSV) RESISTANCE IN A *Litopenaeus vannamei* BREEDING PROGRAM

15.50 **Alejandro Gutierrez**, Jane Symonds, Nick King, Konstanze Steiner, Tim Bean, Ross Houston
POTENTIAL OF GENOMIC SELECTION FOR THE IMPROVEMENT OF PACIFIC OYSTER RESISTANCE TO OSTREID HERPESVIRUS (OSHV-1)

16.10 **Sara Faggion**, Daniela Bertotto, Massimiliano Babbucci, Giulia Dalla Rovere, Rafaella Franch, Mauro Bovolenta, Stanislas Laureau, Francesco Pascoli, Anna Toffan, Luca Bargelloni, Paolo Carnier
GENETIC AND GENOMIC PARAMETERS FOR VNN RESISTANCE, BODY WEIGHT AND CORTISOL CONCENTRATION IN EUROPEAN SEA BASS *Dicentrarchus labrax* L.

MOLLUSC PRODUCTION AND RESTORATION

Thursday, October 10 09.00 - 16.50 Room 3
Chair: Camille Saurel

09.00 **Pernille Nielsen,** Camille Saurel, Pedro S. Freitas, Pascal Barreau, Lene Friis Moller, Jens Kjerulf Petersen
IS THERE A NEED FOR FLAT OYSTER Ostrea edulis RESTORATION IN DENMARK?

09.20 **Linda Tonk**, Pauline Kamermans, Remment ter Hofstede, Tony van der Hiele, Tjeerd Bouma, Tom van der Have, Karin Didderen
FLAT OYSTER *Ostrea edulis* RESTORATION IN OFFSHORE WIND PARKS: AN OPPORTUNITY FOR INNOVATION OF SCOUR PROTECTION

09.40 **Susanne Vogeler**, Xiaoxu Li, Garry H. Wikfors, Stefano Carboni, Alyssa Joyce
N-METHYL-D-ASPARTATE RECEPTOR AND NITRIC OXIDE PATHWAYS AS POTENTIAL REGULATORS OF LARVAL METAMORPHOSIS IN BIVALVE SPECIES: INVESTIGATION OF NEW PATHWAYS FOR COMMERCIAL HATCHERY APPLICATIONS

10.00 **Kristina Arranz**, Iñaki Urrutxurtu, Irrintzi Ibarrola, Miren Bego Urrutia, Daniel Prieto, Enrique Navarro
SEED CONDITION AND DIETARY N CONTENT AFFECTS C/N HOMEOSTASIS IN TISSUES OF JUVENILE CLAMS *Ruditapes philippinarum*

10.20 **Eva Hartog**, Tony van der Hiele, Jouke Heringa, Niels Wagenaar, Jacob Capelle
COPING WITH THE INVASIVE JAPANESE OYSTER DRILL *Ocinebrellus inornatus* ON OYSTER CULTURE PLOTS

10.40 **Kati Michalek**, David Vendrami, Michaël Bekaert, Joanna Wilson, David Green, Thomas Wilding, Kim Last, Joseph Hoffman
SPECIES COMPOSITION, INTROGRESSION AND SHELL PLASTICITY IN FARMED *Mytilus* spp. ON THE WEST COAST OF SCOTLAND

11:20 **BREAK**

11:45 **PLENARY 3 – POSTER AWARDS – LUNCH**

14.30 **Ramón Filgueira**, Leah Strople, Tore Strohmeier, Samuel Rastrick, Øivind Strand
MUSSELS OR TUNICATES: THAT IS THE QUESTION. EVALUATING EFFICIENT AND SUSTAINABLE RESOURCE USE BY LOW-TROPHIC SPECIES IN AQUACULTURE SETTINGS

14.50 **Anna-Lucia Buer**, Lukas Ritzenhofena, Marie Maarb, Gerald Schernewskia
PRODUCTION POTENTIAL OF BLUE MUSSEL *Mytilus* spp. FARMING ALONG THE SALINITY GRADIENT OF THE GERMAN BALTIC SEA

15.10 **M. Maar**, A. Holbach, K. Timmermann, D. Taylor
SPATIAL MODELLING OF BLUE MUSSEL FARM PRODUCTION POTENTIAL IN THE WESTERN BALTIC SEA

15.30 **Daniel Taylor**, Camille Saurel, Pernille Nielsen, Finn Bak, Niels-Peter Nielsen, Jens Kjerulf Petersen
OPTIMIZING PRODUCTION OF MITIGATION MUSSELS

15.50 **Gerald Schernewski**, Rene Friedland
ZEBRA-MUSSEL (DREISSENA) CULTIVATION IN BALTIC COASTAL WATERS – AN OPTION FOR BLUE GROWTH AND WATER POLICY IMPLEMENTATION?

16.10 **Lars Kjerulf Petersen**, Nardine Stybel
LOCAL ACCEPTANCE OF MUSSEL CULTIVATION IN THE BALTIC SEA

16.30 **Andrew van der Schatte Olivier**, S.K. Malham, L. Le Vay, M. Christie, J. Wilson, S. Allender, S. Schmidlin, J. Brewin, L. Jones
POTENTIAL FOR USING MUSSEL FARMING *Mytilus edulis* IN NUTRIENT REMEDIATION IN ESTUARIES OF THE UNITED KINGDOM

PERCID FISH

Thursday, October 10 09.00 - 16.50 Festival
Chair: Daniel Zarski

09.00 Carole Rougeot
REVIEW ON SEX DETERMINATION PROCESS, ALL-FEMALE PRODUCTION AND GROWTH PERFORMANCES IN EURASIAN PERCH *Perca fluviatilis*

09.20 Marcus Stüeken, Tobias Rapp, Fabian Schäfer, Daniel Zarski, Ralf Bochert, Werner Kloas
THE EFFECT OF LIGHT SPECTRUM ON GONADAL DEVELOPMENT IN PIKEPERCH *Sander lucioperca* (L., 1758)

09.40 Oleksandr Malinovskyi, Lukáš Veselý, Miroslav Blecha, Jiří Kříšřan, Tomáš Policar
THE SUBSTRATE SELECTION AND SPAWNING BEHAVIOR OF PIKEPERCH *Sander lucioperca* L. BROODSTOCK UNDER POND CONDITIONS

10.00 Leila El Mohajer, Sirine Selmi, Pascal Fontaine, Sylvain Milla
THE SEARCH FOR THE MATURATIONS INDUCING STEROID (MIS) IN EURASIAN PERCH *Perca fluviatilis*

10.20 Uros Ljubobratovic, Ferenc Demeny, Geza Peter, Oleksandr Malinovskyi, Maciej Kwiatkowski, Andras Ronyai, Akos Horvath
THE EFFECT OF DIFFERENT HORMONAL INDUCTION STRATEGIES ON PIKEPERCH *Sander lucioperca* L. GAMETE QUALITY OBTAINED AFTER OUT-OF-SEASON ARTIFICIAL REPRODUCTION

10.40 Daniel Zarski, Gergely Bernath, Imen Ben Ammar, Sebastien Baeckelandt, Zoltan Bokor, Pascal Fontaine, Akos Horvath, Patrick Kestemont, Syaghalirwa N.M. Mandiki
REPEATED HORMONAL INDUCTION OF SPERMIATION AFFECTS STRESS BUT NOT IMMUNE RESPONSE IN PIKEPERCH *Sander lucioperca*

11.00 Gergely Bernáth, Levente Várkonyi, Ferenc Fodor, Tamás Koltai, Ádám Bodnár, József Molnár, Levente Zete Láng, Tibor Izsák, Árpád Ferincz, Ádám Staszny, Béla Urbányi, Zsolt Szári, Zoltán Bokor
THE METHODICAL IMPROVEMENT OF SPERM CRYOPRESERVATION IN VOLGA PIKEPERCH S*ander volgensis*

11:20 BREAK

11:45 PLENARY 3 – POSTER AWARDS – LUNCH

14.30 Edson Panana, S. Teerlinck
EFFECT OF PHOTOPERIOD ON PIKEPERCH *Sander lucioperca* LARVAE PERFORMANCE IN RECIRCULATING AQUACULTURE SYSTEMS

14.50 Aiman Imentai, Christoph Steinbach, Carlos Yanes-Roca, Tomas Policar
EFFECT OF FEEDING STRATEGY WITH ROTIFERS *Brachionus plicatilis* ON PIKEPERCH *Sander lucioperca* LARVAL PERFOMANCE

15.10 Katarzyna Palinska-Zarska, Piotr Niewiadomski, Jaroslaw Król, Daniel Zarski
NUTRITIONALLY CHALLENGED EURASIAN PERCH LARVAE *Perca fluviatilis* SHEDS LIGHT ON ADAPTABILITY OF FISH TO COMPOUND DIET

15.30 **Sandra Langi**, Edson Panana, Ceder Alloo, Gilbert Van Stappen, Wouter Meeus
REPLACEMENT OF FISH MEAL USING ALTERNATIVE PROTEIN SOURCE IN FEEDS FOR PIKEPERCH *Sander lucioperca* DURING GROW OUT PHASE

15.50 **Stefan Heidemann**, Marcus Stüeken, Ralf Bochert, Tobias Rapp
THE EFFECT OF LIGHT COLOUR ON PERFORMANCE PARAMETER OF JUVENILE PIKEPERCH *Sander lucioperca*

16.10 **Tobias Rapp**, Moritz Tielmann, Ralf Bochert, Marcus Stüeken
FEEDING MANAGEMENT OF JUVENILE PIKEPERCH *Sander lucioperca* UNDER PRODUCTION CONDITIONS

16.30 **Alain Pasquet**, Marielle Thomas, Yannick Ledoré, Lucas Schaeffer, Sarah Nahon, Joël Aubin, Christophe Jaeger, Aurélie Wilfart, Alain Benard, Thomas Lecocq
ICTHYODIVERSITY AS A DRIVING FORCE TO PROMOTE NEW AGRO-ECOLOGICAL APPROACH FOR *Sander lucioperca* REARING

AQUACULTURE IN CENTRAL AND EASTERN EUROPE

Thursday, October 10 09.00 - 16.50 Backstage 1
Chair: Laszlo Varadi

09.00 **Gennady G. Matishov**, Elena N. Ponomareva, Marina N. Sorokina
PRESENT BIOTECHNOLOGY OF AQUACULTURE OF SOUTH RUSSIA

09.20 **Koushik Roy**, Mario Precanica, Petr Dvorak, Jaroslav Vrba, Sadasivam J. Kaushik, Jan Mraz
IS THERE A EUTROPHICATION CONCERN IN SUPPLEMENTARY FEED BASED COMMON CARP FARMING?

09.40 **Eva Kerepeczki**, Péter Palásti, G. Gyalog
ECOSYSTEM SERVICES PROVIDED BY FRESHWATER FISHPONDS

10.00 **Szilvia Keszte**, Kata Tóth-Ihász, Réka Balogh, Árpád Ferincz, Ádám Stasznyi, Vilmos Józsa, Béla Urbányi, Balázs Kovács
MOLECULAR GENETIC DIVERSITY OF HUNGARIAN SILVER PRUSSIAN CARP *Carassius auratus gibelio* POPULATIONS BASED ON MITOCHONDRIAL D-LOOP SEQUENCES

10.20 **Béla Urbányi**, Balázs Kriszt, Sándor Szoboszlay, Judit Háhn, László Friedrich, Gábor Jónás, Gergely Bernáth, Zsolt Csenki-Bakos, Zsolt Czimmerer, Péter Palotás, Katalin Rákóczi, Zsófia Tarnai-Király, Brigitta Nyiro-Fekete, Gábor Bordós, László Zanathy, Adrienn Micsinai
INTRODUCTION OF THE ENVIRONMENT AND FOOD SAFETY RISKS OF POND FISH PRODUCTION – CAN CARP CONSUMERS BE SATISFIED?

10.40 **Alexandre Tahar**, Alan Kennedy, Ronan Cooney, Sarah Naughton, Emer O'Neill, Siobhan Kavanagh, Andy Fogarty, Neil Rowan, Eoghan Clifford
SUPPORTING THE SUSTAINABLE DEVELOPMENT OF THE IRISH FRESHWATER AQUACULTURE INDUSTRY

11.00 **Edouard Royer**, Daniele Brigolin, Roberto Pastres
IMPLEMENTING PRECISION FISH FARMING ON A RAINBOW TROUT FARM: A DATA ASSIMILATION APPROACH

PATHOGENS, DISEASES AND TREATMENT

Thursday, October 10 09.00 - 16.50 Room 1
Chairs: Giorgos Rigos, Egdar Brun

09.00 **Gabriel Arriagada**
THE ROLE OF EPIDEMIOLOGY IN THE SURVEILLANCE AND CONTROL OF PREVALENT FISH DISEASES – THE CASE OF SEA LICE IN FARMED SALMONIDS IN CHILE

09.20 **Tülay Akayli**, Ozgur Canak, Remziye Eda Yardimci, Cigdem Urku, Dilek Okmen
ENTEROBACTER INFECTIONS OF CULTURED RAINBOW TROUT *Oncorhynchus mykiss*

09.40 **Trina Galloway**, Jacob Seilø Torgersen, Jørgen Ødegård, Tim Martin Knudsen
ROBUST SALMON SKIN – IS THERE A GENETIC COMPONENT?

10.00 **Carolina Barroso**, J.V. Neves, P.N.S. Rodrigues
THE MULTIPLE FUNCTIONS OF PISCIDINS IN THE EUROPEAN SEA BASS *Dicentrarchus labrax*

10.20 **Mikolaj Adamek**, Marek Matras, Andy Dowson, Verena Jung-Schroers, Veronika Piackova, David Gela, Martin Kocour, Jerzy Adamek, Rafal Kaminski, Michal Reichert, Dieter Steinhagen
COMPREHENSIVE APPROACH TO DEVELOPMENT OF COMMON CARP STRAINS RESISTANT TO DISEASES CAUSED BY INFECTIONS WITH CYHV-3, CEV AND SVCV

10.40 **Jose Gallardo**, Carolina Figueroa, Pamela Veloso, Lenin Espin, Debora Torrealba, Juan Manuel Afonso, Carlos Soto, Drian Dixon, Pablo Conejeros
FAMILIAR VARIATION EXPLAINS REDUCED PROTECTION OF COMMERCIAL VACCINES AGAINST BACTERIAL PATHOGENS IN ATLANTIC SALMON

11.00 **Lluis Tort**, Felipe E. Reyes-López, Xiaohong Liu, Ali R. Khansari, Mariana Teles, Gonzalo Martínez, Juan M. Mancera
VACCINES INDUCE A SIGNIFICANT IMMUNE RESPONSE BUT NOT A ROBUST NEUROENDOCRINE REACTION IN BRAIN AND PITUITARY TISSUES OF SEABREAM *Sparus aurata*

11:20 **BREAK**

11:45 **PLENARY 3 – POSTER AWARDS – LUNCH**

14.30 **Paul J. Midtlyng**
NUCLEIC ACID VACCINES ARE EFFECTIVE FOR CONTROL OF VIRAL INFECTIONS AND DISEASE IN SALMONID AQUACULTURE

14.50 **Hans Petter Kleppen**, Eirik Baardsen, Juan J.J. Martinez, Ingrid S. Larsen, Cyril Frantzen
USE OF BACTERIOPHAGES TO CONTROL *Yersinia ruckeri* IN SALMON FARMING

15.10 **Hector Abelardo Ocampo**, Andres Vasavilbazo-Saucedo, Norma Alamaraz-Abarca
ANTIVIRAL EFFECTS IN *L. vannamei* OF FEED ADDITIVE OF MICROENCAPSULATED PHENOLIC EXTRACTS OF *M. umbellata*

15.30 **Parini Manuela**, Matteo Calligaris, Alessio Paoli
1-MONOGLYCERIDES OF SHORT- AND MEDIUM-CHAIN FATTY ACIDS PROVED TO BE EFFECTIVE IN DECREASING THE MORTALITY CAUSED BY *Flavobacterium psychrophilum* AND IN REDUCING THE ANTIBIOTIC TREATMENTS IN RAINBOW TROUT *Oncorhynchus mykiss,* WITH FAVORABLE ECONOMIC RETURN FOR THE FISH PRODUCERS

15.50 **Dibo Liu**, Thomas Meinelt, David L. Straus, Petra Bartschat
TOXICITY OF PERACETIC ACID (PAA) PRODUCTS: IMPACT OF WATER QUALITY, PRODUCT COMPOSITION AND FISH SPECIES

16.10 **Dimitra Kogiannou**, Chrysanthi Nikoloudaki, Antigoni Vasilaki, Giorgos Pyrenis, Ioannis Nengas, George Rigos
PHARMACOKINETIC COMPARISON OF DIFFERENT DOSING STRATEGIES OF IN-FEED ADMINISTERED PRAZIQUANTEL IN GREATER AMBERJACK *Seriola dumerili*

16.30 **Claudia Tschesche**, Michaël Bekaert, James E. Bron, Armin Sturm
DELTAMETHRIN RESISTANCE IN SALMON LICE: MITOCHONDRIAL AND NUCLEAR SINGLE NUCLEOTIDE MARKERS

GENERAL TOPICS SESSION

Thursday, October 10 09.00 - 16.50 Foyer 4
Chair: TBA

09.00 **Diogo Thomaz**
THE POTENTIAL OF ARTIFICIAL INTELLIGENCE TO SUPPORT AQUACULTURE FARM MANAGERS: PRELIMINARY RESULTS OF THE APPLICATION OF MACHINE LEARNING ALGORITHMS FOR THE EARLY PREDICTION OF BATCH PERFORMANCE

09.20 **Mohamad Fadjar**, Sri Andayani, Chung-Hun Liu, Jefri Anjaini
EFFECTS OF SQUID *Loligo* sp. INK EXTRACT TO WHITE SHRIMP *Litopeneus vannamei* CypA GENE POLYMORPHISM IN WHITE FECES SYNDROME (WFS) CASE

09.40 **Michael Besmer**, Frederik Hammes, Konstanze Schiessi
MONITORING SHORT-TERM MICROBIOLOGICAL DYNAMICS WITH FULLY AUTOMATED ONLINE FLOW CYTOMETRY IN REALTIME

10.00 **Rayaprolu Srinivas**
EFFECT OF ORGANIC ACIDS IN GROWTH, SURVIVAL AND CONTROLLING CONTINUOUS MORTALITIES OF *Litopenaeus vannamei* CULTURE AT KATTUKALAVA, WEST GODAVARI DISTRICT, ANDHRA PRADESH, INDIA

10.20 **Majid Mohammad Nejad**, Hajimohammad Shirmohammadli
CHANGES IN PROTEIN, FAT, ASH AND DRY MATTER IN DIFFERENT WEIGHTS OF COMMON CARP

10.40 **Inmaculada González Cabrera**, Elena Proietti, Ricardo Haroun Tabraue
THE DEVELOPMENT OF AQUACULTURE IN THE CANARY ISLANDS: NEW PERSPECTIVES AFTER THE PUBLICATION OF THE “PROAC” AND THE “NEW CANARY AUTONOMY STATUTE”

11.00 **Nyiko C. Mabasa,** Clifford L.W. Jones, Mark Laing
SOLVING THE PROBLEM OF SALT ACCUMULATION IN RECYCLED BREWERY EFFLUENT THROUGH THE INTEGRATION OF WATER TREATMENT, AGRICULTURE AND AQUACULTURE

11:30 PLENARY 3 – POSTER AWARDS – LUNCH

14.30 Mohammad Sayyadbourani, Mohammad Pourkazemi, Alireza Valipour, Seied Reza Seied Mortezaei
MONOCULTURE OF PIKEPERCH *Sander lucioperca* IN INTENSIVE SYSTEM OF IRAN

14.50 Olarinke Victoria Adeniyi, Faith Omowumi Dosunmu
GROWTH RESPONSE AND BLOOD INDICES OF AFRICAN SHARPTOOTH CATFISH *Clarias gariepinus* TO DIETS FORTIFIED WITH WILD LETTUCE *Latuca virosa* LEAF EXTRACT

15.10 Javad Daghigh Roohi, Abdolhossein Dalimi, Mohammad Pourkazemi, Mohaddes Ghasemi, Shokoofeh Shamsi
MOLECULAR AND PHYLOGENETIC ANALYSIS OF *Dactylogyrus spp.* PARASITES IN CULTIVATED SILVER CARP *Hypophthalmichthys molitrix* AND BIG HEAD CARP *Hypophthalmichthys nobilis* IN IRAN

15.30 Yenitze Fimbres Acedo, Mauricio Emerenciano, Masato Endo, Kevin Fitzsimmons, Rodolfo Garza, Rosalia Servin, Francisco Magallon
TILAPIA PRODUCTION WITH BIOFLOC TECHNOLOGY IN THREE DIFFERENT TROPHIC CONDITIONS

15.50 Yenitze Fimbres Acedo, Mauricio Emerenciano, Kevin Fitzsimmons, Masato Endo, Rodolfo Garza, Rosalia Servin, Francisco Magallon
HYDROPONIC CULTURE IN NFT USING EFFLUENTS FROM BIOFLOC TECHNOLOGY IN THREE DIFFERENT TROPHIC CONDITIONS

PLENARY 3 AND POSTER AWARDS

Thursday, October 10 11.45 - 12.50 Europe Hall
Chair: Stefan Meyer

11.45 Dina Dziuba
MANAGING RISKS IN A CHANGING ENVIRONMENT

CAGE SYSTEMS AND OFFSHORE STRUCTURES

Thursday, October 10 14.30 - 16.50 Room 5
Chairs: Bela Buck, Hans Bjelland

14.30 Heidi M. Føre, P.C. Endresen, Grim Eidnes, Morten Bondø, Carina Norvik, Andrei Tsarau, David Kristiansen, David Kristiansen, Hans V. Bjelland
HYDRODYNAMIC LOADS ON EXPOSED FISH FARMS

14.50 Kevin Heasman, Malcolm Smeaton, Nicholas Scott, Bela H. Buck
THE INFLUENCE OF STRUCTURE ORIENTATION TO WATER CURRENTS AND WAVES AND THE EFFECT OF WATER DEPTH ON STRUCTURAL STRESS AND SHELLFISH RETENTION IN EXPOSED OCEAN ENVIRONMENTS

15.10 Ajie B.K. Pribadi, Luca Donatini, Evert Lataire
MUSSEL CULTIVATION IN THE BELGIAN NORTH SEA

15.30 **Maximilian Felix Schupp**, Gesche Krause, Vincent Onyango, Bela H. Buck
MULTI-USE POTENTIAL OF MARINE AQUACULTURE WITHIN OFFSHORE WIND FARMS IN THE GERMAN BIGHT: A SWOT ANALYSIS

15.50 **Laurent Barillé**, Stéphanie Palmer, Pierre Gernez, Yoann Thomas, Stefan Simis, Philippe Glize
SATELLITE-MAPPED BIOLOGICAL POTENTIAL FOR MOVING PACIFIC OYSTER AQUACULTURE OFFSHORE

16.10 **Mark Capron**, Michael Chambers, Jim Stewart, Kelly Lucas, Zach Moscicki, Corey Sullivan, Stacy Krueger-Hadfield
RESTORATIVE AQUACULTURE WITH OFFSHORE STRUCTURES

16.30 **Nina Bloecher**, Kevin Frank, Lionel Eisenhauer, Morten Bondø, Oliver Floerl
THE IMPACTS OF BIOFOULING CONTROL MEASURES ON FISH HEALTH AND INFRASTRUCTURE, AND HOW TO MITIGATE THEM

HATCHERY TECHNOLOGIES AND PRACTICES

Thursday, October 10 14.30 - 16.50 Exhibition 2
Chair: Ignacio Fernandez Monzon

14.30 **Barbara Loi**, Francesca Leggieri, Gemma Giménez Papiol, Dario Vallainc
GROWTH RATE AND SURVIVAL IN JUVENILES OF GREY MULLET *Mugil cephalus* REARED UNDER THREE SALINITY LEVELS

14.50 **Vincenzo Alessandro Laudicella**, Christine Beveridge, Stefano Carboni, John Day, Mary K. Doherty, Elaine Mitchel, Michele Stanley, Phil D. Whitfield, Adam D. Hughes
LIPIDOMICS: SPOT ON LIPID METABOLISM DURING NURSERY PRODUCTION OF JUVENILE BLUE MUSSELS *Mytilus edulis* L. REARED UNDER DIFFERENT DIET REGIMES

15.10 **Wilson Pinto**, Sofia Engrola, Bruno Nunes, Rita Colen, André Santos, André Lopes, Luís E.C. Conceição
IMPROVING MICRODIET TECHNOLOGY FOR FIRST-FEEDING GILTHEAD SEABREAM *Sparus aurata* LARVAE

15.30 **Jan Giebichenstein**, Julia Giebichenstein, Christopher Heiduk, Björn Ronge, Casten Schulz
BALLAN WRASSE *Labrus bergylta* LARVAL REARING, A COMPARATIVE STUDY OF DIFFERENT FEEDING REGIMES AND MICRO DIETS BASED ON THE COPEPOD *Acartia tonsa* AS START FEED

15.50 **Sebastian Nikitas Politis**, E. Syropoulou, E. Benini, S.R. Sørensen, I.A.E. Butts, J.J. Miest, D. Mazurais, A. Servili, J.-L. Zambonino-Infante, J. Tomkiewicz
SALINITY REDUCTION BENEFITS EUROPEAN EEL LARVAE: AN OVERVIEW

16.10 **Sune Riis Sørensen**, E. Syropoulou, S.N. Politis, E. Benini, A.C. Hambly, J. Tomkiewicz
IMPACT OF WATER PURIFICATION AND CONDITIONING ON *IN VITRO* PRODUCED EMBRYOS AND LARVAE OF EUROPEAN EEL *Anguilla anguilla*

16.30 **Stefan Spreitzenbarth**, Andrew Jeffs
ARTIFICAL WORLD – NEW INSIGHTS ON OCTOPUS EGG REARING AND LARVAL FEEDING BEHAVIOUR

LABORATORY AQUATIC MODELS AND ORNAMENTALS

Thursday, October 10 14.30 - 16.50 Exhibition 1
Chair: Julien Bobe

14.30 **Julien Bobe**, Caroline Cheung, Thaovi Nguyen, Stephanie Gay, Amelie Patinote, Emilie Cardona, Violette Thermes
WHAT MAKES A FISH EGG ABLE TO BE FERTILIZED AND SUBSEQUENTLY DEVELOP INTO AN EMBRYO: NEW INSIGHTS FROM CRISPR/CAS9 GENOME EDITING IN MODEL SPECIES

14.50 **Laia Ribas**, J. Moraleda-Prados, M. Caballero-Huertas, S. Joly, N. Roher
ZEBRAFISH AND LPS, MODEL TOOLS FOR DECIPHERING EPIGENETIC CHANGES DURING SEX DIFFERENTIATION

15.10 **J. Min**, Rob Knight, Barbara Nowak, Todd Michael, Eric Allen
DEVELOPMENT OF A *Scrombidae* MODEL MARINE FISH FOR DISEASE ECOLOGY, PACIFIC CHUB MACKEREL

15.30 **Ana P.L. Costa**, Igor S. Bernardo, Davide A.M. Silva, Andreia C.M. Rodrigues, Catarina R. Marques, Amadeu M.V.M. Soares, Rui J.M. Rocha
TESTING DIFFERENT PROTOTYPE DIETS FOR CORAL AQUACULTURE

15.50 **Guro Løkka**, Alexander Jaramillo-Torres, Karina Gajardo, Jorge Arturo Vargas-Abúndez, Elvis Chikwati, Elin Valen, Trond M. Kortner, Åshild Krogdahl
ADULT ZEBRAFISH AS MODEL ANIMAL FOR THE EVALUATION OF POSSIBLE HEALTH EFFECTS OF SEAWEEDS IN THE DIET

16.10 **Boris Gomelsky**, Jeffrey Warner, Noel Novelo, Alexander Kramer, Brandylyn Thomas
INHERITANCE AND EXPRESSION OF RED-EYE KOI MUTATION IN KOI *Cyprinus carpio* × GOLDFISH *Carassius auratus* HYBRIDS

16.30 **Antonia Theodoridi**, Michail Pavlidis, Luisa Dalla Valle, Aleka Tsalafouta
BEHAVIORAL DIFFERENCES IN COPING STYLES BETWEEN WILD-TYPE AND GR-KNOCKOUT ZEBRAFISH GENERATED WITH THE CRISPR/CAS9 TECHNOLOGY

SHRIMP

Thursday, October 10 14.30 - 16.50 Exhibition 2
Chair: Matt Slater

14.30 **Joao Reis**, Melanie Rhodes, D. Allen Davis
IMPROVING AUTOMATIC FEEDING PROTOCOLS IN SEMI-INTENSIVE POND CULTURE OF PACIFIC WHITE SHRIMP *Litopenaeus vannamei*

14.50 **Alexandra Segelken-Voigt**, Ralf Bochert
GROWTH PERFORMANCE AND SURVIVAL OF WHITELEG SHRIMP *Penaeus vannamei* UNDER VARYING STOCKING DENSITIES

15.10 **Gerardo Rodríguez-Quiroz**, Arturo Polanco-Torres, Píndaro Álvarez-Rúiz
EARTHWORM VERMICOMPOST TO ENHANCE SHRIMP WHITE SHRIMP *Litopenaeus vannamei* GROWTH AND INHIBIT AHPND DISEASE IN A EXPERIMENTAL CULTURE

15.30 **Eran Hadas**, Asaf Elkayam, David Hazut
MOLTING CAN BE A MAJOR CAUSE OF MORTALITY IN INTENSIVE SYSTEMS (RAS) FOR SHRIMP *Litopenaeus vannamei* CULTURE

15.50 **Yustian Rovi Alfiansah**, Sonja Peters, Jens Harder, Christiane Hassenrück, Astrid Gärdes
STRUCTURE AND CO-OCCURRENCE PATTERNS OF BACTERIAL COMMUNITIES ASSOCIATED WITH WHITE FAECES DISEASE OUTBREAKS IN THE PACIFIC SHRIMP *Litopenaeus vannamei*

16.10 **Vikash Kumar**, Peter Bossier, Kartik Baruah
PIRABVP TOXIN MEDIATES *IN VIVO* PATHOGENICITY OF *Vibrio parahaeolyticus* AHPND STRAIN: ROLE OF NOVEL PLANT-BASED HSP70 INDUCING COMPOUND IN PROTECTION AGAINST AHPND STRAIN IN SHRIMP SPECIES

16.30 **Ulfert Focken**, Juliana Schober Goncalves Lima
ORGANIC AND CONVENTIONAL MARINE SHRIMP FARMS IN BRAZIL: MACROBENTHOS OCCURRENCE INSIDE AND IN THE OUTLETS OF THE PONDS

NACEE PANEL – AQUACULTURE IN CENTRAL AND EASTERN EUROPE

Thursday, October 10 14.30 - 16.50 Backstage 1
Chair: Laszlo Varadi

Concept
The Central and Eastern European (CEE) region of Europe has certain specific features that make this region a special aquaculture region in Europe, which is sometimes called “pond region” or “carp region”. There are however other specificities as well why we may consider this region a special aquaculture region of Europe. For example, the fish consumption of several countries in the region is among the lowest in Europe. The CEE region includes both EU and non-EU countries and this “interface” character also creates challenges and opportunities in aquaculture development. In spite of the gradual social and economic development in the CEE region, aquaculture development is often constrained by limited resources, not only in terms of money, but, for example, in terms of language knowledge and international collaboration. This is well indicated by the low number of participants in international events from CEE countries and relatively low number of publications in international journals. Only few CEE institutions and organisations are members of project consortia. Multi-stakeholder cooperation is also rather weak in the CEE region where strong producers’ associations exist only in few countries. One of the main NACEE objectives is to bridge the gap that still exists between Eastern and Western Europe in the field of aquaculture. The proposed session could contribute to alleviate the situation and facilitate the improvement of collaboration between East and West.

Moderator: Peter Lengyel, General Secretary of NACEE

14:30 **Laszlo Varadi, Zsigmond Jeney**
CEE IN THE EUROPEAN AQUACULTURE SCENE

14:50 **Vitaliy Bekh, Nikolay Barulin, Peter Lengyel**
AQUACULTURE IN CENTRAL AND EASTERN EUROPE: CONSTRAINTS AND OPPORTUNITIES

15:10 **OPEN DISCUSSION**

15:50 **CONCLUDING REMARKS**

EDUCATION, KNOWLEDGE MANAGEMENT, TRANSFER AND EXTENSION NETWORKS

Thursday, October 10 14.30 - 16.50 Room 4
Chair: Georgia Bayliss-Brown

14.30 **Kay Lwin Tun**, Kevin Fitzsimmons, Hillary Egna, Hendrik Stolz, Uwe Scholz, Peter Buri
DEVELOPMENT OF BSC AND MSC FISHERIES AND AQUACULTURE DEGREE PROGRAMS IN MYANMAR

14.50 **Lourdes Reig**, Rosa Flos, Eva Vallejos, Felipe Reyes
PERCEPTION ABOUT AQUACULTURE AMONG UNDERGRADUATE STUDENTS; INFLUENCE OF PERSONAL PROFILE AND PSYCHOGRAPHIC MODULATORS

15.10 **Natacha Nogueira**, Lydia Png, Carlos Andrade
PUBLIC PERCEPTIONS OF AQUACULTURE IN ATLANTIC ISLANDS: IS THERE ROOM FOR MSP?

15.30 **Yik Sung Yeong**, Happy Nursyam, Quoc Phu Truong, Min Pau Tan, Najiah Musa, Siti Azizah Mohd Nor, Mieke Eggermont, David Bassette, Marieke Reuver, Patrick Sorgeloos
THE ASEAN FISHERIES EDUCATION NETWORK; ESTABLISHMENT, EXPANSION AND EXTENSION

15.50 **Marieke Reuver**, Jane Maher, John Bostock, Yeong Yik Sung
ENHANCING EUROPE-ASIA COOPERATION IN AQUACULTURE EDUCATION – ACHIEVEMENTS OF THE EU HORIZON2020 PROJECT - EURASTIP

16.10 **Joseph Molnar**, Isaac Omiat, Moureen Matuha, John Walakira, Gertrude Atukunda, Theodora Hyuha, James Bukenya
SUSTAINING A MOBILE APPLICATION FOR FISH FARMERS IN UGANDA: POLICY CONTRADICTIONS, TECHNICAL CAPABILITIES, AND USER NEEDS

16.30 **John Bostock**, Martyn Haines, John Birger Stav, Marieke Reuver
PROFESSIONAL AQUACULTURE – SUPPORTING SKILLS AND CAREER DEVELOPMENT IN EUROPEAN AQUACULTURE

COMPOUNDS IN LIPID TRANSPORT

Thursday, October 10 14.30 - 16.50 Lounge 1-3
Chair: Ashild Krogdahl

14.30 **Åshild Krogdahl**, Anne Kristine Grostøl Hansen, Elvis Chikwati, Michael H. Penn, Aleksei Krasnov, Ingemar Björkhem, Trond M. Kortner
NUTRIENTS INVOLVED IN DIGESTION AND TRANSPORT OF LIPID ACROSS THE INTESTINAL MUCOSA OF ATLANTIC SALMON *Salmo salar* L.– PART 1: AN OVERVIEW

14.50 **Elvis Chikwati**, Paul Midtlyng, Trond M. Kortner, Jie Wang, Yanxian Li, Weiwen Zhou, Guro Løkka, Alexander Jaramillo-Torres, Åshild Krogdahl
NUTRIENTS INVOLVED IN DIGESTION AND TRANSPORT OF LIPID ACROSS THE INTESTINAL MUCOSA OF ATLANTIC SALMON – PART 2: LIPID MALABSORPTION IN SIX, NORWEGIAN ATLANTIC SALMON *Salmo salar* L FARMS

15.10 **Trond M. Kortner**, Anne Kristine G Hansen, Elvis Chikwati, Aleksei Krasnov, Ingemar Björkhem, Åshild Krogdahl
NUTRIENTS INVOLVED IN DIGESTION AND TRANSPORT OF LIPID ACROSS THE INTESTINAL MUCOSA OF ATLANTIC SALMON *Salmo salar* L. – PART 3: EFFECTS OF DIETARY CHOLESTEROL, PHOSPHOLIPIDS AND BILE SALTS ON INTESTINAL LIPID METABOLISM

15.30 **Anne Kristine G. Hansen**, Trond M. Kortner, Elvis Chikwati, Hans J. Grav, Ingemar Björkhem, Vegard Denstadli, Åshild Krogdahl
NUTRIENTS INVOLVED IN DIGESTION AND TRANSPORT OF LIPID ACROSS THE INTESTINAL MUCOSA OF ATLANTIC SALMON *Salmo salar* L.– PART 4: EFFECTS OF DIETARY PHOSPHATIDYLCHOLINE AND CHOLINE ON INTESTINAL LIPID METABOLISM

CLIMATE CHANGE POSTERS

Board #

0 **John Icely,** A Cubillo, M Elliot, J Ferreira, B Fragoso, P Kamermans, S Kay, A Kennerley, C Kreis, A Marques, D Matias, M Peck, J Pinnegar, H Rambo, K Smyth, V Stetzenm?Iler, N Taylor, N Taylor, X Álvarez-Salgado, N Norte, I Fuentes-Santos, D Brigolin, M Ballesteros, R Chapela, M Fernández-Reiriz, U Labarta, F Pranovi, J Santiago
COMPARISON BETWEEN THE RESULTS FROM THE EU H2020 CERES AND CLIMEFISH PROJECTS ON THE POTENTIAL EFFECTS OF CLIMATE CHANGE FOR AQUACULTURE OF MEDITERRANEAN MUSSEL (*Mytilus galloprovincialis*)

1 **M. Virginia Martín**, B.C. Felipe, A. Misol, S. Jerez, F.J. Santamaría, E. Almansa
COMBINED EFFECT OF INCREASING TEMPERATURE AND FEED RESTRICTION IN GILTHEAD SEABREAM *Sparus aurata* JUVENILES

2 **Ingrid A. Johnsen**
FJORD BASIN WATER EXCHANGE IN SILL NORWEGIAN FJORDS

3 **Elisabeth Ytteborg**, Bruce McAdam, Trevor Telfer, Solfrid Sætre Hjøllo, Øystein Hermansen, Lynne Falconer
POTENTIAL IMPACT OF WARMING SEA WATER TEMPERATURES ON ATLANTIC SALMON *Salmo salar* FARMING IN NORWAY

4 **Natacha Nogueira**, João Canning-Clode, Mafalda Freitas, Sonia Gueroun, Jamileh Javidpour
TRIALS WITH JELLYFISH SPECIES: IMPROVEMENTS ON THE BIOLOGY OF THE SPECIES AND REARING TECHNOLOGY

5 **Elke Burgstaller**, Janneke Aelen, Douglas Tenison-Collins, Eddie A.M. Bokkers
GREENHOUSE GAS ASSESSMENT OF ATLANTIC SALMON *Salmo salar* AQUACULTURE ON CERTIFIED (ASC) FARMS

6 **Thuy Pham**, Charlotte Weber, Ragnhildur Friðriksdóttir, Jónas Viðarsson, Sigurður Örn Ragnarsson, Petter Olsen, Tarub Bahri, Elisabeth Ytteborg, Alan Baudron, Michaela Aschan
GUIDELINES ON DEVELOPING CLIMATE ADAPTATION PLAN FOR FISHERIES AND AQUACULTURE SECTORS: CO-CREATION APPROACH

7 **Richard Heal**, Joseph Nagoli, M. Mahfujul Haque, Arifuzzaman Syed, Charles Tyler, David Bass
USING FARMERS EXPERIENCES TO STUDY THE EFFECT OF POND PRACTICE ON DISEASE IN POLYCULTURE OF NILE TILAPIA IN BANGLADESH

8 **Balázs Kovács**, Dóra Kánainé Sipos, Réka Balogh, Csaba Guti, Kata Ihász, Szilvia Keszte, Béla Urbányi
MICROSATELLITE SET FOR PARENTAGE ANALYSES OF AFRICAN CATFISH, *Clarias gariepinus* (BURCHELL, 1822)

9 **Rui J. M. Rocha,** D. B. Freitas, J. G. Fonseca, I. B. Oliveira, C. M. Barroso, S. Galante-Oliveira
HIGH PERFORMANCE OF *Venerupis corrugata* LARVAL CULTURE UNDER PROJECTED ACIDIFICATION AND WARMING SCENARIOS UNVEILS THE SPECIES RESILIENCE TO FUTURE CLIMATE CHANGE

ENVIRONMENTAL AND ECOSYSTEM MANAGEMENT POSTERS

Board #

10 **Andreas Müller-Belecke**, Cornelius Becke, Mark Schumann, Roland Rösch
EVALUATION AND COMBINATION OF MEANINGFUL PARAMETERS TO ACCESS FISH WELFARE IN RAS CULTURED PIKEPERCH *Sander lucioperca*

11 **Tae Young Ahn**
ACUTE TOXICITY AND BIOACCUMULATION IN EELS *Anguilla japonica* BY EXPOSURE OF WATERBORNE CADMIUM

12 **Nuria García Bueno**, Arnaldo Marin
BIOFILM AS TOOL TO EVALUATE ORGANIC AND CHEMICAL DISPERSION FROM MARINE FISH FARMS

13 **Nuria García Bueno**, Arnaldo Marin
STUDY OF SEDIMENT ALONG AN ENVIRONMENTAL GRADIENT TO EVALUATE THE IMPACT OF MARINE FISH FARMS

14 **Øivind Bergh**, Henning Wehde, Vidar S. Lien
CORDINET AND COPERNICUS MARINE – ON THE USE OF EARTH OBSERVATION DATA FOR MARINE ENVIRONMENTAL MONITORING

15 **Lydia Png-Gonzalez**, Patrício Ramalhosa, Soledad Álvarez, Ignacio Gestoso, João Canning-Clode, Natacha Nogueira
ASSESSMENT OF FOULING COMMUNITIES ON OFFSHORE AQUACULTURE STRUCTURES IN MADEIRA (EASTERN ATLANTIC)

16 **Nicola Rhyner**, Constanze Pietsch
USING MICROSATELLITE MARKERS TO ASSESS POST-STOCKING SURVIVAL OF HATCHERY-REARED ATLANTIC TROUT *Salmo trutta* L. IN TRIBUTARIES OF A PREALPINE LAKE

17 **Fatema Al-Fatle Ali Abdulhur**, Erika Edvine Meleg, Katalin Ihasz, Tamas Molnar, Balázs Kovács, Istvan Lehoczky
CONSERVATION OF NATIVE CYPRINID SPECIES IN HUNGARY – PRELIMINARY RESULTS ON THE GENETIC VARIABILITY OF CRUCIAN CARP *Carassius carassius* (L., 1758) AND TENCH *Tinca tinca* (L., 1758) POPULATIONS AND STOCKS

18 **Lynne Falconer**, Akpojotor Ekpeki, Reed Ozretich, Trevor C. Telfer
SPATIAL FRAMEWORK FOR SITE SELECTION AND REGULATION OF FRESHWATER CAGE AQUACULTURE IN EUROPE

19 **Olaf Kattenpoel Oude Heerink**, Paul J. Van den Brink, Douglas Tenison-Colli
ENVIRONMENTAL IMPACT ASSESSMENT: THE IMPACT OF COPPER ANTIFOULANTS AND SEA LICE THERAPEUTANTS ON THE BENTHIC SPECIES BIODIVERSITY SURROUNDING ASC-CERTIFIED NORWEGIAN SALMON FARMS

20 **Elisa Ravagnan**, Anna Nora Tassetti, Gianna Fabi
BUILDING KNOWLEDGE FOR A SUSTAINABLE AQUACULTURE INDUSTRY: THE DECISION-SUPPORT TOOL SEAGRID

21 **Amita Saxena**, Sagar Kuvaskar
GENERATION OF THEMATIC MAP OF MACROPHYTE AND INTERPRETING ITS EFFECT ON ICHTYOFAUNA IN BHIMTAL AND NAUKUCHIATAL LAKE

22 **Naor S. Fialho**, G.W. Bueno, F.S. David, E.M. Godoy, D.C. Proença, M.R. Brande, W.C. Valenti
APPLICATION OF ENVIRONMENTAL SUSTAINABILITY INDICATORS AND INDICES IN TWO NILE TILAPIA *Oreochromis niloticus* NET-CAGE CULTURES

23 **Ghada El Serafy**, Anna Spinosa, Antoine Mangin, Adelio Silva, Simon van Dam, Danny Pape, Rafa Company Peris, Eleni Geropanagioti
HIGH RESOLUTION COPERNICUS-BASED INFORMATION SERVICES AT SEA FOR AQUACULTURE

24 **Sang-Eun Nam**, Jae-Sung Rhee
MEASUREMENT OF MICROBEADS PERSISTENCY IN THE RADIAL CANAL AND TUBE FOOT OF ECHINODERMS

25 **Mastooreh Doustdar**, Mahmoud Ramin, Arezoo Vahabnejad
EVALUATION OF BIOACCUMULATION FACTOR (BAF) OF SOME METALLIC ELEMENTS IN ARAS RIVER FISH, EAST AZERBAIJAN PROVINCE, IRAN

26 **P. Yuvarajan**
NUTRIENT DISCHARGE FROM SHRIMP POND AND IT'S MANAGEMENT BY ADVANCED TECHNOLOGY

27 **R. Balaji**, P. Yuvarajan, R. Velmurugan, B. Ramji
EFFECT OF MANGROVE DEFORESTATION AND ITS CONSERVATION

28 **J. John Kirubakaran**, P. Yuvarajan, D. Arun kumar, P. Seenivasan
INTEGRATED MULTITROPHIC AQUACULTURE SYSTEM PAVES SUSTAINABLE WAY TO MITIGATE THE BIOEFFLUENT

29 **J. Maniselvam**, R. Balaji, R. Velmurugan, P. Yuvarajan
IMPACTS OF BOTTOM TRAWLING ON MARINE ECOSYSTEM

30 **Wahyudin**, Tamiji Yamamoto
A PROPOSAL TO INCREASE CARRYING CAPACITY OF HIROSHIMA BAY ECOSYSTEM TO INCREASE OYSTER CULTURE PRODUCTION WITH SIMULTANEOUS MAINTAINING THE SPECIES DIVERSITY

31 **Keshia Naidoo Govender**, Francois Lampen
THE EFFICACY OF VARIOUS FILTER MEDIA IN REMOVING COPPER FROM TREATED SEAWATER

32 **Bayode Omobepade**, Olarewaju Omoju, Hauwa Nuhu, Oluwatobi Olaniyi, Olumide Akande, Kemisola Odeyemi
MODELLING SUITABILITY OF ERO RESERVOIR AND ITS ENVIRONS FOR AQUACULTURE IN EKITI STATE, NIGERIA

33 **Ademola Michael Akinsorotan**, J.O. Jimoh, J.O. Oyewumi
BEHAVIOURAL AND MORPHOLOGICAL ASSESSMENT OF PARAQUAT TOXICITY ON JUVENILES OF NILE TILAPIA *Oreochromis niloticus*

34 **Almut Gerhardt**
REAL-TIME AUTOMATED QUALITY CONTROL OF OEGANISMS HEALTH AND WATER QUALITY IN AQUACULTURE

ENVIRONMENT / AQUACULTURE INTERACTIONS - FROM AND TO AQUACULTURE POSTERS

Board #

40 **Yadong Zhang**, Songming Zhu, Zhangying Ye
EFFECTS OF DIFFERENT LIGHT COLORS ON THE GROWTH PERFORMANCE OF LARGEMOUTH BASS *Micropterus salmoides* IN A RECIRCULATING AQUACULTURE SYSTEM

41 **Sang-Gyu Park**, Jinxin Zhou, Shuchuang Dong, Qiao Li, Takero Yoshida, Daisuke Kitazawa
THE NEIGHBORING FLOW FIELD OF STOCKED FISH CAGE: LABORATORY EXPERIMENT AND FIELD SURVEY

42 **Ismail Berat Çantas**, Onder Yildirim
DETERMINATION OF CARRYING CAPACITY IN INLAND WATERS AND VARIOUS MODELS

43 **Rebecca J. Weeks**, Thomas P. Adams, Kenneth D. Black, Kevin Black, Adam D. Hughes
NEWDEPOMOD – A MODELLING TOOL FOR BENTHIC IMPACT PREDICTION BENEATH MARINE CAGE FISH FARMS

44 **Shuchuang Dong**, Hongxia Gao, Sang-Gyu Park, Jinxin Zhou, Qiao Li, Takero Yoshida, Daisuke Kitazawa
SIMPLE ANALYSIS OF THE CARRYING CAPACITY OF AQUACULTURE IN A SEMI-CLOSED SEA AREA

45 **Najat El Moutchpu**, Lisa Wickliffe, Barry King, Jennica Hawkins, Trevor Carpenter, James A. Morris, Jr.
SITING GUIDELINES, MONITORING STANDARDS, AND ENVIRONMENTAL MODELS FOR COASTAL FINFISH AQUACULTURE

46 **M. Hartnett**, Mab Sayeed, F. O'Donncha, T. Doyle, R. Atan, S. Nash
DEVELOPMENT OF A HYDRODYNAMIC PARTICLE TRANSPORT MODEL TO STUDY JELLYFISH INTERACTIONS WITH FISH FARMS

47 **Irene Brandts Busom**, Asta Tvarijonaviciute, Lorena Franco-Martínez, Camila Barría, Manuel A. Martins, Maria L. Pereira, Lluís Tort, Miguel Oliveira, Mariana Teles
EFFECTS OF PLASTIC NANOPARTICLES ON *Dicentrarchus labrax*

48 **Assel Baishulakova**, Dmitry Malashenkov, Yersultan Mirasbekov, Veronika Dashkova, Almira Zhantuyakova, Kuanysh Sarkytbayev, Thomas A. Davidson, Ivan A. Vorobjev, Erik Jeppesen, Natasha S. Barteneva
MESOCOSM EXPERIMENTS AS A TOOL FOR CYANOBACTERIAL BLOOMS DYNAMICS RESEARCH

49 **B. Ramji**, P. Yuvarajan, R. Velmurugan, R. Balaji
ROLE OF ANTIBIOTICS IN SHRIMP FARMING

50 **S.M. Vahid Farabi**, S.R. Sayyed Mortezaei
SURVEY OF WATER QUALITY AROUND RAINBOW TROUT *Oncorhynchus mykiss* CAGES IN THE SOUTHERN CASPIAN SEA

51 **Saioa Ramos**, Maite Cidad, Susana Etxebarria, Manolis Tsapakis, Anastasia Tsiola, Lohitzune Larrinaga, Miguel Angel Cuevas, Liesbet Vranken, Michiel De Baw
LIFE AQUAPEF: EFFECTIVE IMPLEMENTATION OF THE PRODUCT ENVIRONMENTAL FOOTPRINT IN THE MEDITERRANEAN AQUACULTURE SECTOR

POSTERS

52 **Yeon Gyu Lee**, Da Un Jeong, Jeong Won Kang, Yang Ho Choi
EFFECT OF FISH FARM CONVERTED FROM RED LAVER FARM ON SEDIMENT GEOCHEMISTRY AND BENTHIC FORAMINIFERAL ASSEMBLAGE OF HWATEDO, SOUTH KOREA

53 **Yang-Ho Choi**, Mi-Jin Lee, Seong-Jin Park, Young-Sang Suh, Yeon-Gyu Lee
THE ENVIRONMENTAL EFFECTS OF WATER MOVEMENT ON THE ABALONE MARINE AQUACULTURE AREA

54 **Xiaoming Yu,** Lei Chen, Leiming Yin, Maolin Wang, Hongquan Li, Yaqi Wang
EFFECTS OF TEMPERATURE AND BODY LENGTH ON THE SWIMMING PERFORMANCE AND OXYGEN CONSUMPTION IN RAINBOW TROUT *Oncorhynchus mykiss*

CAGE SYSTEMS AND OFFSHORE STRUCTURES POSTERS

Board #

55 **Maryam Behgozin**, Aboulghasem Roohi
FACTORS DETERMINING THE CONDITIONS OF THE MARINE AQUACULTURE (CAGE CULTURE) DEVELOPMENT IN THE SOUTHERN CASPIAN SEA

56 **Taeho Kim**
COMPARISON OF SURVIVAL AND GROWTH RATES OF ABALONE *Haliotis discus hannai* IN THE DISCHARGE AND INTAKE CHANNELS OF IN POWER PLANT

57 **Pascal Klebert**, Biao Su
TURBULENCE AND FLOW FIELD ALTERATION IN THE WAKE OF AQUACULTURE SEA CAGE

58 **Asbjørn Bergheim**, Martin Gausen, Nils Hovden, Henrik Grundvig, Carlo Barth
SALMON CAGES SUPPLIED FRESHWATER FOR CONTROL OF SEA LICE

59 **Bijoy Kumar Ghosh**
HYDRAULIC IMPACT ON FISH MIGRATION IN SARIAKANDHI FISH PASS OF BANGLADESH

60 **John Icely**, S. Cristina, B. Fragoso, G. Moore
REAL TIME MONITORING OF ENVIRONMENTAL CONDITIONS FOR THE MANAGEMENT OF OFFSHORE AQUACULTURE AT SAGRES, SW PORTUGAL

AQUAPONICS AND IMTA POSTERS

Board #

65 **Stepan Papacek**, Radek Filip, Karel Petera
NUMERICAL SIMULATION OF THE MACROALGAE MOVEMENT WITHIN IMTA-RAS SYSTEMS

66 **Ingrid Masaló**, Samuel Machado, Patricia Jimenez de Riedder, Joan Oca
EFFECT OF DENSITY AND PHOTOPERIOD IN *Ulva ohnoi* PHOTOINHIBITION CULTURED WITH ARTIFICIAL ILLUMINATION

67 **Joanne Casserly**, Frank Kane
IMPAQT – AN INTELLIGENT MANAGEMENT SYSTEM FOR INTEGRATED MULTI-TROPHIC AQUACULTURE

68 **Kati Michalek**, Adrian Macleod, Arlene Ditchfield, Michele Stanley
TOWARDS AN INTELLIGENT MANAGEMENT SYSTEM FOR INTEGRATED MULTI-TROPHIC AQUACULTURE (IMPAQT)

69 **Sofia C. Franco**, Pamela Katic, Maria Sharmina, Luca Panzone
DEVELOPMENT OF A BIOECONOMIC MODEL TO VALUE ECOSYSTEM SERVICES IN INTEGRATED MULTI-TROPHIC AQUACULTURE SYSTEMS

70 **Young Dae Kim**, Yun Kyung Shin
A STUDY ON POLY-CULTURE OF SEA SQUIRT *Halocynthia roretzi* AND SEA CUCUMBER *Apostichopus japonicus* UNDER A HANGING CULTURE SYSTEM

71 **Ingrid Masaló**, Joan Oca, José Pintado, Patricia Ruiz, Patricia Jimenez de Ridder, Stepan Papacek, Javier Cremades
"ULVAPRO" COORDINATED PROJECT: OBJECTIVES AND PRELIMINARY RESULTS OF SUBPROJECT 2 "LIGHT MANAGEMENT STRATEGIES TO MAXIMIZE *Ulva* PRODUCTIVITY IN IMTA-RAS SYSTEMS AND PROMOTE EFFECTS INDUCED BY MICROBIOTA"

72 **Ellen Schagerström**, Klara Bladin, Kristina Sundell
ASSESSING THE POTENTIAL OF THE COLD WATER SEA CUCUMBER SPECIES *Parastichopus tremulus* FOR USE IN CIRCULAR AQUACULTURE

73 **Marta Castilla Gavilan**, Vincent Turpin, Bruno Cognie, Priscilla Decottignies
INTEGRATED MULTI-TROPHIC AQUACULTURE ASSAY: BIOREMEDIATION POTENTIAL OF *Palmaria palmata* ASSOCIATED TO REARED OYSTERS AND SEA URCHINS

74 **Francisco Veiga Machado**, H. Quental-Ferreira, C. Cardoso, M.E. Cunha
LEVELS OF BIOACTIVE COMPOUNDS IN *Ulva* spp. GROWN IN DIFFERENT INTEGRATED SYSTEMS

75 **Evanthia Chatzoglou**, Magdalene Karavoulia, Christina Zantioti, Kassandra Koussouli, Nefeli Tsaoussi, Anastasia Christofi, Panorea Kechagia, Joel Aubin, Helen Miliou
INTEGRATED CULTIVATION OF EUROPEAN SEA BASS *Dicentrarchus labrax* AND *Ulva* sp. IN RECIRCULATING AQUACULTURE SYSTEMS WITH TWO DIFFERENT DIETS

76 **José Pintado**, Patricia Ruiz, Ingrid Masaló, Joan Oca, Patricia Jiménez, Javier Cremades
"ULVAPRO" PROJECT: SHEDDING LIGHT ON THE ULVA HOLOBIONT: THE ROLE OF LIGHT IN QUORUM SENSING AND IN MICROBIAL INTERACTIONS WITH IMPLICATION IN IMTA-RAS

77 **María Galindo Ponce**, Jessica Ratcliff, Mark Johnson
UNDERSTANDING INTEGRATED MULTI-TROPHIC AQUACULTURE (IMTA) WITH ULVA SPP: DEVELOPING A BIOFILTER IN A RECIRCULATING AQUACULTURE SYSTEM (RAS)

78 **Vlastimil Stejskal**, Simona Paolaci, Marcel A.K. Jansen, Damien Toner
A NEW CONCEPT IN MULTITROPHIC AQUACULTURE; FARM CULTURED EURASIAN PERCH *Perca fluviatilis,* RAINBOW TROUT *Onchorhynchus mykiis,* COMMON DUCKWEED *Lemna minor* AND GIBBOUS DUCKWEED *Lemna gibba*

79 **Cedomir Stevcic**, Katja Pulkkinen, Juhani Pirhonen
THE USE OF BIOLOGICAL TRAPS FOR WATER TREATMENT IN RECIRCULATING AQUACULTURE SYSTEMS (RAS)

80 **Jeong-Dae Kim**, Dong-Hoon Lee, Seong-Ryul Lim, Dal-Young Kim, Jin-Young Kim
EFFECT OF DIETARY MONOBASIC POTASSIUM PHOSPHATE (MKP) ON GROWTH OF FAR EASTERN CATFISH *Silurus asotus* AND LEAFY VEGETABLES IN HBFT (HYBRID BFT) AQUAPONIC SYSTEM

81 **Jeong-Dae Kim**, Dong-Hoon Lee, Seong-Ryul Lim, Dal-Young Kim, Jin-Young Kim
EFFECT OF LOW PH AQUAPONICS USING MIXED MICROORGANISMS ON WATER QUALITY AND BLOOD CHARACTERISTICS OF FAR EASTERN CATFISH *Silurus asotus*

82 **Uliana Aleksandrova**, Tatiana S. Gridina, Konstantin D. Matishov, Anton A. Kuzov
THE AGROBIOTECHNOLOGY ECOLOGICALLY CLEAN PRODUCTS WITH THE USE OF NEW TECHNOLOGIES IN RAS

83 **Gundula Proksch**, Alex Ianchenko
CITYFOOD: ASSESSING AQUAPONICS WITHIN THE URBAN FOOD-WATER-ENERGY NEXUS

84 **Gundula Proksch**, Alex Ianchenko
BUILDING-INTEGRATED AQUAPONICS: ARCHITECTURAL DESIGN CONSIDERATIONS FOR FUTURE FARMS

85 **Gundula Proksch**, Alex Ianchenko
GLOBAL AQUAPONIC PRACTITIONER SURVEY: PRELIMINARY FINDINGS AND TRENDS

86 **Evangelia Tsoumalakou**, Eleni Mente, Nikolaos Katsoulas, Konstantinos A. Kormas, Panagiotis Berillis, Nikolaos Vlahos, Panagiotis Kapsis, Paraskevi Stathopoulou, Efi Levizou
NUTRIENT INPUT IN A SMALL SCALE AQUAPONIC SYSTEM: EFFECT ON LETTUCE FUNCTIONAL RESPONSES AND TILAPIA GROWTH

88 **Isabela Pinheiro**, Ramon Carneiro, Matheus Rocha, Angela Kugelmeier, Claudia Machado, Felipe Vieira, Walter Seiffert
AQUAPONIC PRODUCTION OF *Salicornia ambigua* AND PACIFIC WHITE SHRIMP IN BIOFLOC SYSTEM UNDER DIFFERENT SALINITIES

89 **Sara Crappé**, Saskia Buysens
THE OPPORTUNITIES OF PRODUCING FRUITY VEGETABLES IN AN AQUAPONIC SYSTEM ON COMMERCIAL SCALE

90 **Maryam Shafahi**
HOW AQUAPONICS CAN HELP URBAN AGRICULTURE

91 **J. Pasch**, U. Knaus, H.W. Palm
GROWTH OF MOROCCAN MINT *Mentha spicata* IN THREE HYDROPONIC SUBSYSTEMS (DRF, RAFT, NFT) UNDER DECOUPLED AQUAPONIC PRODUCTION OF *C. gariepinus*

92 **Anneliese Brüggmann**
EFFECT OF INSECT-, BLOOD-, AND FEATHER MEAL IN FISH FEED ON THE EXCREMENTS OF TWO FISH SPECIES AND THEIR EVALUATION FOR THEIR APPLICATION IN AQUACULTURE SYSTEMS

94 **Maria Celia Portella**, Ricardo Dutra, Sara Pinho, Jesaias Costa
STATE-OF-ART OF AQUAPONICS PRODUCTION IN BRAZIL

95 **Laura Silva**, Ricardo Dutra, Sara Pinho, Jesaias Costa, Maria Celia Portella
MAIN DIFFICULTIES FACED BY AQUAPONICS PRACTITIONERS IN BRAZIL

96 **Jesaias Costa**, Bruna Peppe, Luis Caetano, Sara Pinho, Laura Silva, Maria Célia Portella
PLANT SALE PRICE AND PRODUCTION PROFILE AS TOOLS TO IDENTIFY PLANTS WITH POTENTIAL FOR AQUAPONICS SYSTEM IN URBAN AREAS, CASE OF STUDY: JABOTICABAL, BRAZIL

97 **Veronika Tumová**, Lukáš Kalous
DOES AQUAPONICS WORK IN PRACTICE OR IS IT JUST A VIRTUAL INDUSTRY? STATUS OF COMMERCIAL AQUAPONICS IN THE CZECH REPUBLIC

98 **Wenceslao Valenzuela-Quinonez**, Cesar Luque-Gamez, Adolfo Dagoberto Armenta-Bogorquez, Ely Sara Lopez-Alvarez, Nadia Vázquez-Montoya, Mariel López-Espinoza
EFFECT OF DIFFERENT CONCENTRATIONS OF NITRATE IN THE PRODUCTION OF TOMATO *Solanum lycopersicum cv Grape* AND SHRIMP *Penaeus vannamei* IN LOW SALINITY WATER

99 **Erik Malta,** Blanca Partida, María del Mar Agraso Martínez, Hugo Ferreira, Sofia Gamito, Maria Emilia Cunha
TOWARDS A STANDARD MODEL FOR LAND-BASED IMTA: CASE STUDIES FROM EARTHEN PONDS IN SPAIN AND PORTUGAL

100 **Anna Soler Vila,** J.J. Ratcliff, M.D. Edwards
PROJECT INTEGRATE. CULTIVATION OF SEA SPAGUETTI *Himanthalia elongata*

101 **Jessica Ratcliff,** Bertrand Jacquemin
IMTA IN THE ATLANTIC AREA: DEFINITION, BEST-PRACTICE, STATUS AND NEEDS

SUSTAINABLE SYSTEMS FOR LARGE SCALE PRODUCTION - CLOSED, OFFSHORE OR BOTH POSTERS

Board #

105 **Bjarne Kvæstad**, Torfinn Solvang, Andreas Hagemann, Haiqing Wang, Kjell Inge Reitan, Arne Malzahn
ADVANCES IN POLYCHAETE CULTIVATION TECHNOLOGY – AN INDOOR SPACE EFFICIENT CULTIVATION SYSTEM

106 **Bibiana G. Crespo**, Sara Calabrese, Åse Åtland, T. Rosten, J.E. Jensen, Trine Dale
MICROALGAE DYNAMICS IN A CLOSED FARMING SYSTEM IN THE SEA FOR ATLANTIC SALMON

107 **Å.M. Espmark**, J. Kolarevic, L.H. Johansen, S. Handeland, S. Stefansson, T.O. Nilsen
CtrlAQUA SFI – CONTRIBUTION TO FUTURE AQUACULTURE

108 **Md. Mehedi Alam**, Mohammad Mahfujul Haque
ASSESSING THE MAJOR CONSTRAINTS OF INTERNATIONAL AQUACULTURE CERTIFICATION FOR EXPORT FISH FROM BANGLADESH

109 **Philippa Bayford**, J. Webb, J. Alexander, S. Ward, L. LeVay, S. Malham
DEVELOPMENT OF OFFSHORE BIVALVE SHELLFISH PRODUCTION IN THE EASTERN IRISH SEA

NUTRITION: PHYSIOLOGY AND REQUIREMENTS POSTERS

Board #

115 **Daniel Matulic**, Maria Blažina, Andrea Budiša, Slavica Colak, Renata Baric, Silvia Križanac, Lav Bavcevic, Tea Tomljanovic
FATTY ACID PROFILE OF MUSCLE TISSUE OF MEAGRE *Argyrosomus regius* FED DIETS CONTAINING DIFFERENT LEVELS OF FISH OIL

116 **Le Thien Thuat Phan**, Julia Mas, Karthix Masagounder, Johan W. Schrama
EFFECT OF DIETARY MACRONUTRIENT VARIATION ON ENERGY UTILISATION EFFICIENCY IN SNAKEHEAD *Channa striata*

117 **Ana Pombo**, Natacha Moreira, Rui Ganhão, Andreia Raposo, Pedro M. Santos, Susana S.M. Ferreira, Carla Tecelão, Marta Neves, Teresa Baptista, Sílvia C. Gonçalves, Maria M. Gil
GONAD YIELD AND NUTRITIONAL QUALITY OF WILD AND ENHANCED SEA URCHIN *Paracentrotus lividus* (LAMARCK, 1816)

118 **Irene García Meilán**, Ángeles Gallardo Romero
REGULATION OF DIGESTIVE AND ABSORPTIVE PROCESSES IN TWO MEDITERRANEAN FISH: GILTHEAD SEA BREAM AND SEA BASS

119 **Folasade Elesho**, J.A.J. Verreth, D.A.H. Sutter, S. Kröckel, J.W. Schrama
QUANTIFYING METHIONINE REQUIREMENT OF AFRICAN CATFISH *Clarias gariepinus* USING A PLANT-BASED DIET

120 **Aires Oliva-Teles**, Catarina Basto-Silva, Paula Enes, Sara Balbuena-Pecino, Encarnación Capilla, Inês Guerreiro
EFFECT OF PROTEIN SOURCE AND PROTEIN/CARBOHYDRATE RATIO ON APPETITE REGULATION IN GILTHEAD SEABREAM *Sparus aurata*

121 **Manuel Yúfera**, T. Silva, N. Gilannejad, G. Martínez-Rodríguez, I. Rønnestad, L. Conceição
SIMULATING THE EFFECT OF FEEDING TIME AND FREQUENCY ON GUT TRANSIT AND DIGESTIBILITY IN GILTHEAD SEABREAM AND SENEGALESE SOLE JUVENILES

122 **Renata Goncalves**, Ivar Lund, Manuel Gesto, Peter Vilhelm Skov
NUTRITIONAL REQUIREMENTS OF EUROPEAN LOBSTER *Homarus gammarus* L.: EFFECT OF PROTEIN, LIPID, AND CARBOHYDRATE DIET CONTENT ON METABOLIC POSTPRANDIAL RESPONSE

123 **Gehad Eisa**, Fathy Mohamed, Ramadan El-Banna, Ahmed El-Ashram
EFFECT OF MAGNETIZED WATER ON THE GROWTH PERFORMANCE AND OXIDATIVE STATUS OF EGYPTIAN NILE TILAPIA

124 **Ana Pombo**, Ana Gomes, Sílvia Lourenço, Pedro M. Santos, Andreia Raposo, Beatriz Cunha, Susana M.F. Ferreira
SEA URCHIN LARVAE DEVELOPMENT WITH DIFFERENT MICROALGAE DIETS: IMPACTS IN GROWTH AND SETTLEMENT

125 **Marie-Teresa Grobler**, D. Huyben, R. Smullen, M. Leaver, B. Glencross
POSTPRANDIAL PLASMA-FREE AMINO ACID RESPONSE TO BRANCHED-CHAIN AMINO ACID SUPPLEMENTATION IN ATLANTIC SALMON *Salmo salar*

126 **Luca Parma**, Nicole Francesca Pelusio, Serena Busti, Matteo Zerlotin, Lorenzo Mariani, Lorenzo Morsiani, Francesco Dondi, Federica D'Amico, Matteo Soverini, Marco Candela, Manuel Yúfera, Neda Gilannejad, Francisco Javier Moyano, Pier Paolo Gatta, Alessio Bonaldo
INTERACTION BETWEEN DIETARY COMPOSITION AND SEASONAL TEMPERATURE CHANGES IN GILTHEAD SEA BREAM *Sparus aurata:* EFFECTS ON GROWTH, FAT DEPOSITION, PLASMA BIOCHEMISTRY, DIGESTIVE ENZYME ACTIVITY AND GUT BACTERIAL COMMUNITY

127 **Renato Barbosa Ferraz**, Ana Lúcia Salaro, Rodrigo Ozório, Oscar Monroig, Luis Filipe Castro
EFFECTS OF DIFFERENT SOURCE AND LEVELS OF OIL ON LIPID METABOLISM RELATED GENE EXPRESSION IN JUVENILE TAMBAQUI *Colossoma macropomum*

128 **Weiwen Zhou**, Trond Kortner, Elvis Chikwati, Kristin Hamre, Gerd Berge, Ingrid Lein, Øystein Sæle, Katerina Kousoulaki, Åshild Krogdahl
EFFECTS OF VARIATION IN DIET MACRONUTRIENT COMPOSITION ON GUT FUNCTION IN LUMPFISH *Cyclopterus lumpus*

129 **Ignacio Fernández**, Cristina Tomás-Almenar, Ana Larrán
VITAMIN K IN FISH NUTRITION: AN INTEGRATIVE UPDATE OF FUNCTIONS AND REQUIREMENTS

130 **Manuel Alejandro Marrero Arteaga**, M.B Betancor, A. Galindo, Ó. Monroig, M. Herrera, D. Garrido, J.A. Pérez, I. Giráldez, C. Rodríguez
INFLUENCE OF DIETARY LIPIDS AND ENVIRONMENTAL SALINITY ON THE ω3 LC-PUFA BIOSYNTHESIS CAPACITY OF *Solea senegalensis*

131 **Cláudia Aragão**, Rita Colen, Nadège Richard, Rita Teodósio, Wilson Pinto, Laura Ribeiro, Juan Fuentes, Ivar Rønnestad, William Koven, Luís E.C. Conceição, Jorge Dias
DIETARY TAURINE INCLUSION IN HIGH PLANT BASED-DIETS HAS POSITIVE EFFECTS ON SENEGALESE SOLE *Solea senegalensis* PERFORMANCE

132 **G.D.P. Konnert**, E. Martin, W.J.J. Gerrits, S.W.S. Gussekloo, K. Masagounder, J. Mas-Muñoz, J.W. Schrama
PROTEIN DEPOSITION IN NILE TILAPIA *Oreochromis niloticus:* THE INTERPLAY BETWEEN DAILY PROTEIN AND ENERGY INTAKE

133 **Yiyen Tseng**, David Domínguez, U. Sivagurunathan, Kamil Mert Eryalçin, C.M. Hernández-Cruz, P. Eckhard Witten, Marisol Izquierdo
EFFECT OF THE DIETARY SUPPLEMENTATION OF ZINC ON GROWTH, SURVIVAL AND BONE DEVELOPMENT IN GILTHEAD SEA BREAM LARVAE

134 **Lawrence Nwanna**, C.S. Olaniyi
VALINE REQUIREMENT OF AFRICAN CATFISH *Clarias gariepinus* JUVENILES

135 **Christiana Kounna**, Eleni Fountoulaki, Helen Miliou, Stavros Chatzifotis
GASTRIC EVACUATION, STOMACH DIGESTA MOISTURE AND CARCASS PROXIMATE COMPOSITION OF MEAGRE *Argyrosomus regius* FED DIETS WITH DIFFERENT DIETARY LIPID LEVEL

136 **U. Sivagurunathan**, D. Dominguez, Yiyen Tseng, Kamil Mert Eryalçin, J. Roo, C. Boglione, M. Izquierdo
EFFECT OF DIETARY VITAMIN D3 IN GROWTH, SURVIVAL AND SKELETAL DEVELOPMENT OF GILTHEAD SEA BREAM LARVAE *Sparus aurata*

137 **Mónica B. Betancor**, Aurelio Ortega, Fernando de la Gándar, Matthew Sprague, Douglas R. Tocher, Gabriel Mourente
TAURINE METABOLISM IN ATLANTIC BLUEFIN TUNA *Thunnus thynnus* L. LARVAE AND EFFECTS OF INCLUSION LEVEL VIA ROTIFER *B. rotundiformis*

POSTERS

138 **David Dominguez**, U. Sivagurunathan, Pedro Castro, Lidia Robaina, Maria Jesus Zamorano, Ramon Fontanillas, Marisol Izquierdo
LEVELS OF VITAMIN A, D AND K IN DIETS HIGH IN PLANT BASED FEEDSTUFFS FOR GILTHEAD SEA BREAM *Sparus aurata* FINGERLINGS

139 **Igo G. Guimarães**, Ludmila L.C. Menezes, Janaína G.A. Santos, Delma MC Pádua, Vânia M.V. Machado, Cristielle N. Souto
BONE MINERALIZATION PATTERN DIFFERENTLY AFFECT PHOSPHORUS REQUIREMENT IN TAMBAQUI *Colossoma macropomum*

140 **Raja S.N. Janjua**, Shafaq Fatima, Sehar Munawar
JOURNEY FROM INTRODUCTION TILL LOCAL PRODUCTION OF SOY-BASED FLOATING EXTRUDED AQUAFEED IN PAKISTAN; A REVOLUTION IN AQUACULTURE INDUSTRY

141 **N.G. Acosta**, A. Afonso, R. Dorta-Guerra, J.A. Pérez, M.J. Pérez, A. Lorenzo, A. Bolaños, C. Rodríguez
EFFECTS OF DIETARY FISH OIL SUBSTITUTION BY *Echium* OIL ON ENTEROCYTE AND HEPATOCYTE LIPID METABOLISM OF EUROPEAN SEA BASS *Dicentrarchus labrax* (LINNAEUS, 1758)

142 **Mariana Palma**, Ludgero C. Tavares, João Rito, Luís F. Henriques, João G. Silva, Paulo Rema, Rodrigo Ozório, Miguel A. Pardal, Leonardo J. Magnoni, Ivan Viegas
EFFECTS OF DIETARY GLYCEROL SUPPLEMENTATION ON LIVER AND MUSCLE METABOLOME: COMPARATIVE STUDY IN EUROPEAN SEABASS AND RAINBOW TROUT

143 **Ludgero Tavares**, M. Palma, E. Silva, F. Silva-Brito, R. Ozório, L.J. Magnoni, I. Viegas
TOWARDS A SEMI-AUTOMATED NMR-BASED METABOLIC PROFILE OF FISH PLASMA: RESPONSE TO GLYCEROL-SUPPLEMENTED DIETS IN SEABASS

144 **P. Presa**, M. Martínez, M. Palacios
INGESTION RATE AND NUTRITIONAL REQUIREMENTS OF JUVENILE RED SEA URCHIN *Loxechinus albus* FROM THE XII CHILEAN REGION

145 **N. Gilannejad**, I. Rønnestad, F. Lai, A.E. Olderbakk-Jordal, A.P. Gottlieb Almeida, G. Martínez-Rodríguez, F.J. Moyano, M. Yúfera
INFLUENCE OF DIFFERENT DAILY FEEDING PROTOCOLS ON REGULATION OF CCK HORMONE AND PANCREATIC PROTEASES ACTIVITY IN SENEGALESE SOLE JUVENILES

146 **N. Gilannejad**, G. Blanco-Rivas, A.P. Gottlieb Almeida, J.M. Mancera, M. Yúfera, G. Martínez-Rodríguez, J.A. Martos-Sitcha, N. Gilannejad
GROWTH PERFORMANCE AND CIRCADIAN RHYTHM OF DIGESTIVE FUNCTION IN GILTHEAD SEABREAM JUVENILES WITH DIFFERENT DAILY FEEDING FREQUENCIES

DEALING WITH STRESS IN OCTOPUSES

GENOMIC RESEARCH, TOOLS AND APPLICATIONS POSTERS

Board #

290 **Tom Goldammer**, Julien Nguinkal, Lidia de los Ríos-Pérez, Nadine Schäfer, Frieder Hadlich, Marcus Stüecken, Olaf Wolkenhauer, Ronald M. Brunner, Alexander Rebl, Marieke Verleih, Dörte Wittenburg
GENOMIC TOOLS FOR THE AQUACULTURE OF PIKEPERCH *Sander lucioperca* L., 1758

291 **Ki Taek Cho**
COMPARISON OF EXPRESSION LEVEL OF GLUCOCORTICOID RECEPTOR (GCR) GENE IN ORIENTAL WEATHERFISH *Misgurnus anguillicaudatus* ACCORDING TO REARING DENSITY

293 **Ligia Panasiak**, Lukasz Leonowicz, Joanna Grudniewska, Tomasz Zalewski, Stefan Dobosz, Konrad Ocalewicz
INDUCTION OF TRIPLOID DEVELOPMENT IN THE EUROPEAN GRAYLING *Thymallus thymallus*

294 **Sang Yoon Lee**, Hwa Jin Lee, Yi Kyung Kim
FUNCTIONAL CLASSIFICATION AND EXPRESSION PATTERN ANALYSIS OF MEMBRANE PROTEIN GENES PRESENT IN IONOCYTES OF SKIN INCLUDING LATERAL LINE IN BRACKISH WATER EXPOSURE OF RAINBOW TROUT *Oncorhynchus mykiss*

295 **Miguel Angel Pardo**, Ane del Rio, Elisa Jimenez
A NOVEL AND RAPID METHOD FOR THE IDENTIFICATION OF EUROPEAN MUSSEL SPECIES BASED ON REAL TIME PCR MELTING CURVE ANALYSIS

296 **Silvia Garcia-Ballesteros**, J. Fernández, B. Villanueva
BENEFITS FROM WITHIN-FAMILY GENOMIC EVALUATION IN AQUACULTURE SCHEMES WITH SMALL FAMILY SIZES

297 **Aleksandra A. Krasilnikova**
EFFECT OF RATE OF FREEZING ON THE SPERM OF STURGEON

298 **Babak Najafpour**, João C.R. Cardoso, Adelino V.M. Canário, Deborah M. Power
EVOLUTION OF THE COMPLEMENT SYSTEM IN FISH

299 **Lisen Li**, João C.R. Cardoso, Liliana Anjos, Ana Patricia Mateus, Adelino V.M. Canário, Deborah M Power
LYSOZYME GENE FAMILY EVOLUTION AND FUNCTION DURING EARLY FISH DEVELOPMENT

300 **Delphine Lallias**, M. Boussaha, M. Bernard, A. Peigné, C. Ciobotaru, N. Dechamp, M. Dupont-Nivet, E. Quillet
IN-DEPTH GENOMIC CHARACTERIZATION OF A UNIQUE COLLECTION OF RAINBOW TROUT ISOGENIC LINES

301 **Israel Guerrero Cózar**, Jose Córdoba, Pedro Seoane, M. Gonzalo Claros, Ricardo Zerolo, Manuel Manchado
IDENTIFICATION OF SNP MARKERS ASSOCIATED TO SOMATIC GROWTH IN THE FLATFISH SENEGALESE SOLE *Solea senagalensis*

302 **Costas S. Tsigenopoulos**, Alexandros Tsakogiannis, Tereza Manousaki, Anamarija Vrbatovic, Zeljka Trumbic, Jerko Hrabar, Ivana Buselic-Garber, John Taggart, Paola Beraldo, Georgios Rigos, Ariadna Sitja-Bobadilla, Ivona Mladineo
STUDYING GENETIC DIVERSITY IN PARASITES WITH HIGH IMPACT ON THE MEDITERRANEAN AQUACULTURE INDUSTRY USING MODERN GENOMIC APPROACHES: THE CASE OF *Ceratothoa oestroides* AND *Sparicotyle chrysophrii*

303 **Costas S. Tsigenopoulos**, Marianna Pauletto, Serena Ferraresso, Tereza Manousaki, Jon B. Kristoffersen, Alexandros Tsakogiannis, Luca Bargelloni
IMPROVING THE GILTHEAD SEABREAM AND EUROPEAN SEABASS GENOMES USING OXFORD NANOPORE TECHNOLOGY

304 **Dileepa Sripal Liyanage**, Welivitiye Kankanamge Malithi Omeka, Jehee Lee
MOLECULAR INSIGHTS AND IMMUNE RESPONSES OF BIG-BELLY SEAHORSE *Hippocampus abdominalis* SYNDECAN-2

305 **Welivitiye Kankanamge Malithi Omeka**, Dileepa Sripal Liyanage, Jehee Lee
MOLECULAR, TRANSCRIPTIONAL AND FUNCTIONAL PROFILING OF TWO GLUTAREDOXINS FROM BIG-BELLY SEAHORSE *Hippocampus abdominalis*

306 **Srinith Walawedurage**, Jehee Lee
BIOINFORMATIC ANALYSIS AND IMMUNE-STIMULATED TRANSCRIPTIONAL ANALYSIS OF THE IFP35 COUNTERPART FROM ROCK BREAM *Oplegnathus fasciatus*

307 **Neranjan Tharuka**, Jehee Lee
FUNCTIONAL CHARACTERIZATION, ANTIVIRAL CAPACITY AND TRANSCRIPTIONAL BEHAVIOUR OF IRF6 IN *Hippocamus abdominalis*

308 **Satia Costa Bomfim**, Pedro L. de Castro, Jawahar G. Patil, André Luiz Julien Ferraz, Ricardo P. Ribeiro
CRYOPRESERVATION OF FISH EMBRYOS: THE USE OF MELATONIN AS AN INHIBITOR OF THE APOPTOTIC PROCESS

309 **Carolina Moraleda**, Diego Robledo, Alejandro Gutiérrez, Jorge Del Pozo, José Manuel Yáñez, Ross Houston
IDENTIFICATION OF FUNCTIONAL GENES RELATED TO HOST RESISTANCE TO *Piscirickettsia salmonis* IN ATLANTIC SALMON *Salmo salar* USING RNA-SEQ

310 **Márcia S.N. Galvão**, J.R. Monteiro, F.S. Fonseca, H.L.A. Marques, A.W.S. Hilsdorf
MOLECULAR APPROACHES FOR THE GENETIC MANAGEMENT OF OYSTERS ALONG THE SOUTH COAST OF BRAZIL

311 **Aurelie Gueho**, Hélène Rime, Emmanuelle Com, Régis Lavigne, Blandine Guevel, Jérôme Montfort, Chrales Pineau, Julien Bobe
FUNCTIONAL AND PROTEOMIC CHARACTERISATION OF SALMONID COELOMIC FLUID

312 **Daniel J. Macqueen**, Sigbjørn Lien, The AQUA-FAANG Consortium
ADVANCING EUROPEAN AQUACULTURE BY GENOME FUNCTIONAL ANNOTATION: 'AQUA-FAANG'

313 **Derrick Kwame Odei**, Stefano Peruzzi, Ørjan Hagen, Jorge M.O. Fernandes
LIVER TRANSCRIPTOME OF JUVENILE DIPLOID AND TRIPLOID ATLANTIC SALMON *Salmo salar* L.

314 **Jenna Alexander**, Shelagh Malham, Lewis Le Vay, Julie Webb, Philippa Bayford, David Fidler, James McDonald
THE USE OF MOLECULAR TOOLS TO IDENTIFY MARINE BIVALVE LARVAE IN ENVIRONMENTAL SAMPLES

315 **P. Presa**, A. Pita, N.R. Matusse, M. Pérez
MOLECULAR IDENTIFICATION OF A NEW GROUPER SPECIES *Polyprion* spp. FROM SOUTH AFRICA

316 **María Fernández Míguez**, M. Pérez, P. Presa, Ø.J. Hansen, H. Tveiten, A. Mortensen, V. Puvanendran
GENE EXPRESSION ANALYSIS AS AN INDICATOR OF EGG QUALITY IN ATLANTIC COD *Gadus morhua*

317 **Lidia de los Ríos Pérez,** Ronald M. Brunner, Marieke Verleih, Alexander Rebl, Julien A. Nguinkal, Nadine Schäfer, Tom Goldammer, Marcus Stüeken, Dörte Wittenburg
STUDY OF GENOMIC VARIATION WITH WHOLE GENOME SEQUENCING IN PIKEPERCH *Sander lucioperca*

318 **Ólöf Dóra Bartels** Jónsdóttir, Simo Maduna, Albert Kjartan Dagbjartarson Imsland, Snorre Hagen
CYCLOPTERUS-STR: DEVELOPMENT AND VALIDATION OF A GENOME- AND TRANSCRIPTOME-DERIVED MICROSATELLITE DATABASE OF *Cyclopterus lumpus*

LABORATORY AQUATIC MODELS AND ORNAMENTALS POSTERS

Board #

320 **Sanja Babić**, Polonca Trebše, Maja Galić, Natalija Topić-Popović, Ivancica Strunjak-Perović, Rozelindra Čož-Rakovac
ZEBRAFISH EMBRYOTOXICITY OF OLIVE OIL MILL WASTEWATER AND CONSIDERATION OF IT'S RENEWABLE POTENTIAL

321 **Oki Hayasaka**, Yutaka Takeuchi, Akinobu Honda, Estefany García-Cruz, Yoji Yamamoto, Jyunji Kawakami, Motonobu Chikata, Kazuhiro Shiozaki, Kazushiro Anraku, Tomonari Kotani
IRRADIATION USING MIDDLE- TO LONG-WAVELENGTH LIGHT INDUCES OVEREXPRESSTION OF GSDF AND MALE-SPECIFIC GONADAL DIFFERENTIATION IN GENETIC FEMALE MEDAKA *Oryzias latipes*

322 **Mikolaj Adamek**, Krzysztof Rakus, Veronika Breitkopf, Joao Monteiro, Piotr Podlasz, Miriam Mojzesz, Niedharsan Pooranachandran, Magdalena Widziolek-Pooranachandran, Sebastian Rakers, Keith Way, Magdalena Chadzinska, Bernd Lepenies, Dieter Steinhagen
USE OF ZEBRAFISH MODEL IN STUDIES OF VIRAL INFECTIONS AFFECTING CULTURED FISH SPECIES

323 **Yagmur Kaya**, George Franz, Philipp Ciba, Bianka Grunow
FISH CELL CULTURES AS A ROBUST TEST SYSTEM IN AQUACULTURE RESEARCH

324 **Ana P.L. Costa**, Andreia C.M. Rodrigues, Davide A.M. Silva, Catarina R. Marques, Amadeu M.V.M. Soares, Rui J.M. Rocha
DO TROPICAL CORALS GET STRESSED DUE TO SHIPPING?

325 **Andreia C.M. Rodrigues**, Jamen Mussa, Davide A.M. Silva, Ana P.L. Costa, Amadeu M.V.M. Soares, Andreia C.M. Rodrigues, Rui J.M. Rocha
CORAL AQUACULTURE: THE INFLUENCE OF COLONY ORIGIN IN THE PERFORMANCE OF CULTURED FRAGMENTS IN DIFFERENT ARTIFICIAL LIGHT CONDITIONS

326 **Davide Silva**, Jamen Mussa, Ana Costa, Andreia Rodrigues, Amadeu Soares, Rui Rocha
Sinularia flexibilis AQUACULTURE: DOES LIGHT MATTER?

327 **Sofia Engrola**, Maria Morais, Jorge Dias, Rita Colen, Carmen Navarro-Guillén, Manuel Sardinha
ASSESSING OPTIMAL DIET FORMULATION TO HIGH QUALITY CLOWN ANEMONEFISH *Amphiprion ocellaris* JUVENILES

328 **Sang Yoon Lee**, Hwa Jin Lee
MOLECULAR CLONING, CHARACTERIZATION AND EXPRESSION OF OPSIN1 SUBFAMILY GENES FROM MUD LOACH (*Misgurnus mizolepis*)

SHRIMP POSTERS

Board #

330 **Alexandra Segelken-Voigt**, Ralf Bochert
THE EFFECT OF TWO DIFFERENT FEEDS ON GROWTH, SURVIVIAL AND CARAPACE COLOR IN WHITELEG SHRIMP *Penaeus vannamei*

331 **Jaehyeong Shin**, Kyeong-Jun Lee
DIETARY UTILIZATION OF MEALWORM AND BLACK SOLDIER FLY FOR PACIFIC WHITE SHRIMP *Litopenaeus vannamei*

332 **Chorong Lee**, Soohwan Kim, Ji Eun Kim, Sung Hun Kim, Jae Won Kim, Jong Su Eun, Kyeong-Jun Lee
DIETARY SUPPLEMENTATIONS OF Bacillus PROBIOTIC IMPROVE DIGESTIBILITY, INNATE IMMUNITY, WATER QUALITY AND GROWTH PERFORMANCE OF PACIFIC WHITE SHRIMP *Litopenaeus vannamei*

333 **Chorong Lee**, Ji Eun Kim, Hayun Jo, Sung Hun Kim, Jae Won Kim, Jong Su Eun, Kyeong-Jun Lee
DIETARY SUPPLEMENTATIONS OF *Bacillus* spp. IMPROVES INNATE IMMUNITY, GROWTH PERFORMANCE AND DISEASE RESISTANCE OF PACIFIC WHITE SHRIMP *Litopenaeus vannamei* AGAINST WHITE SPOT SYNDROME VIRUS AND ACUTE HEPATOPANCREATIC NECROSIS DISEASE

334 **André Barreto**, Wilson Pinto, Adriana Laranjeira, Renata Serradeiro, Luis Conceição, Benjamín Costas
MICRODIETS SUPPLEMENTED WITH NUTRITIONAL ADDITIVES AS A TOOL TO IMPROVE IMMUNE CONDITION AND ENHANCE GROWTH PERFORMANCES OF WHITE-LEG SHRIMP *Penaeus vannamei* POST LARVAE

335 **Neaz Al Hasan**, Mohammad Mahfujul Haque
WSSV RISK FACTORS OF SHRIMP FARMING IN BANGLADESH: STATISTICAL MODEL-BASED ASSESSMENT

336 **Andrew Ray**, Leo Fleckenstein, Jill Fisk, Thomas Tierney
THE DEVELOPMENT OF INEXPENSIVE SALT MIXTURES FOR INLAND, INTENSIVE SHRIMP *Litopenaeus vannamei* FARMING

PERCID FISH POSTERS

Board #

340 **Christopher Naas**, Werner Kloas, Andreas Müller-Belecke
INDIVIDUAL GROWTH PERFORMANCE OF JUVENILE PIKE PERCH *Sander lucioperca* UNDER SALINE CONDITIONS IN RECIRCULATING AQUACULTURE SYSTEMS (RAS)

341 **Andreas Müller-Belecke**, Steffen Zienert
MARKETING OPTIONS ASIDE FOOD FISH PRODUCTION – APPLICABILITY OF RAS DERIVED PIKEPERCH *Sander lucioperca* AS STOCKING MATERIAL FOR OPEN WATER BODIES

342 **Piotr Hliwa**, Jaroslaw Król, Slawomir Krejszeff, Malgorzata Wozniak, Sergiusz J. Czesny, Agnieszka Stabinska, Daniel Zarski
EFFECT OF VARIOUS COMMERCIAL FEEDS ON GROWTH RATE AND VERTEBRAL COLUMN ANOMALIES IN EURASIAN PERCH *Perca fluviatilis* JUVENILES

343 **Ana Gavrilovic**, Steven Van Gorder, Jurica Jug-Dujakovic
INHIBITION OF GONADAL DEVELOPMENT OF YELLOW PERCH *Perca flavescens* GROWN AT CONSTANT TEMPERATURE AND PROLONGED PHOTOPERIOD

344 **Jiri Kristan**, Oleksandr Malinovskyi, Jitka Kolárová, Josef Velíšek, Alžbeta Stará, Azin Mohagheghi Samarin, Tomáš Policar
THE EFFECT OF OZONE ON WATER QUALITY AND PIKEPERCH *Sander lucioperca* PERFORMANCE IN RECIRCULATING AQUACULTURE SYSTEM

346 **Türker Bodur**
LAND-MARK BASED MORPHOMETRIC DISCRIMINATION OF NATIVE AND INTRODUCED PIKE-PERCH *Sander lucioperca* L. POPULATIONS IN EURASIA

347 **Gregory J. Fischer**
OPTIMIZING WALLEYE *Sander vitreus* AND HYBRID WALLEYE *S. vitreus* × *S. canadense* TANK STOCKING DENSITY AND PERFORMANCE IN A TRADITIONAL RECIRCULATING AQUACULTURE SYSTEM (RAS) FOR COMMERCIAL FOOD FISH PRODUCTION

348 **Tatyana Gebauer,** Radek Gebauer, Vlastimil Stejskal, Jan Kouril, Thomas Korytár
POPULATION-SPECIFIC IMMUNE RESPONSE OF *Perca fluviatilis* TOWARDS *Aeromonas hydrophila*: PILOT STUDY

MEDITERRANEAN AQUACULTURE

Board #

350 **Mado Kotsiri**, Efthimia Cotou, Eleni Fountoulaki, Konstantinos Charalabous
EFFECTS OF HEAT-TREATED SOY AND SUNFLOWER FLOUR FOR FISH MEAL SUBSTITUTION ON ENERGY RESERVES AND ANTIOXIDANT AND DIGESTIVE ENZYMES IN THE GILTHEAD SEA BREAM *Sparus aurata*

351 **Viviana Pasquini**, Ambra Angelica Giglioli, Marco Secci, Pierantonio Addis
THE EFFECT OF LIGHT ON THE CHOICE OF FOOD OF REARED SEA URCHIN *Paracentrotus lividus* IN LAND-BASED SYSTEMS

352 **Ana Nobre**, Filipe Soares, Luís Conceição, Tomé Silva, João Henriques, Manuel Sardinha, Renata Serradeiro
CUSTOMIZED FEEDING TABLES FOR PRECISION FARMING: DEMONSTRATION FOR GILTHEAD SEABREAM

353 **Josefina Blasco**, J. Fernàndez-Borràs, M. Perelló, S. Yu, A. Sánchez-Moya, J. Gutiérrez
A PRACTICAL SWIMMING ACTIVITY FOR THE EUROPEAN SEA BASS CULTURE *Dicentrarchus labrax:* EFFECT ON GROWTH AND METABOLISM

354 **Arjan P. Palstra**, Pablo Arechavala-Lopez, Ana Roque
ACCELEROMETRY OF SEABREAM IN A SEACAGE: EFFECTS OF FLOW CONDITIONING ON ACTIVITY PATTERNS, GROWTH AND ROBUSTNESS

355 **Katerina Moutou**, Andreas Tsipourlianos, Themistoklis Giannoulis, Deborah M. Power, Zissis Mamuris
MICROSATELLITE ANALYSIS OF *Dicentrarchus labrax* AND *Sparus aurata* POPULATIONS OF MEDITERRANEAN FISH FARMS

356 **Luca Grosso,** Alessandra Fianchini, Stefano Cataudella, Michele Scardi, Arnold Rakaj
EFFECTS OF DIFFERENT DIETS ON THREE SIZE CLASSES OF SEA URCHIN *Paracentrotus lividus*

AQUACULTURE IN CENTRAL AND EASTERN EUROPE POSTERS

Board #

360 **Midory Esmeralda Vigueras Velázquez**, Jose Carbajal Hernández, Luis Pastor Sánchez Fernández, Margarita Hernández Martínez
WATER QUALITY INDICATOR FOR AQUACULTURE IN INTENSIVE CULTURE USING A FUZZY ANALYTICAL HIERARCHY PROCESS

361 **Edilmar Cortes-Jacinto**, Juan C. Pérez-Rodríguez, Laura S. López-Greco, Jaime Gómez-Gutiérrez
SPERMATOPHORE PRODUCTION AND SPERM QUALITY OF THE RIVER PRAWN *Macrobrachium americanum* (BATE, 1869) FED WITH DIFFERENT DIETS

362 **José Luis Vázquez-Burgos**
NON-IONIZED AMMONIA ASSESSMENT MODEL IN *Chirostoma estor estor* INTENSIVE CULTURE USING ARTIFICIAL NEURAL NETWORKS

363 **James Oso**, Ayodeji Aluko
ASSESSMENT OF ABUNDANCE AND DISTRIBUTION OF FISH SPECIES IN SOME DAMS IN EKITI STATE, NIGERIA

364 **Richard Heal**, Joseph Nagoli, M. Mahfujul Haque, Arifuzzaman Syed, Charles Tyler, David Bass
USING FARMERS EXPERIENCES TO COMPARE TILAPIA FARMING IN BANGLADESH AND MALAWI: UNDERSTANDING GROWTH POTENTIAL

365 **Ákos Horváth**, Milán Fehér, Gyula Kovács, Uroš Ljubobratovic, Máté Havasi, Csaba Székely, László Stündl, István Szucs, Miklós Bercsényi, Béla Urbányi
GOODFISH – A PROJECT FOR THE DEVELOPMENT OF POND AQUACULTURE IN HUNGARY

366 **Albena Merdzhanova**, Veselina Panayotova, Diana D. Dobreva, Katya Peycheva, Lubomir Makedonski, Elitsa Petrova-Pavlova
ANNUAL CHANGES IN DIETARY BIOACTIVE LIPIDS IN AQUACULTURE MUSSELS *Mytilus galloprovincialis* FROM BULGARIA

367 **Panagiotis Efstathiou**, Evaggelia Kouskouni, Andreas Efstathiou, Paraskevi Karlovasiti, Zacharoula Manolidou
USE OF COPPER ALLOY MESH IN MEDITERRANEAN MARINE AQUACULTURE

369 **Atle Foss**, Felipe Briceno, Albert Imsland, Xavier Gutierrez
THE EFFECT OF DENSITY ON GROWTH IN RED CUSK EEL *Genypterus chilensis* – A NEW SPECIES FOR CHILEAN LAND-BASED AQUACULTURE

370 **Victoria Tarus,** Judy Amadiva, Hillary Egna
ASSESSMENT OF WOMEN'S PARTICIPATION IN AQUACULTURE POST-ECONOMIC STIMULUS PROGRAM IN KENYA

PATHOGENS, DISEASES AND TREATMENT POSTERS

Board #

374 **Sven Ostermann,** Ruth Tamara Montero, Tobias Kroniger, Dörte Becher, Bernd Köllner
BACTERIAL OUTER MEMBRANE VESICLES OF Aeromonas salmonicida INDUCE A PRO INFLAMMATORY IMMUNE RESPONSE IN VITRO AND IN VIVO

375 **George Rigos**, Morgane Henry, Chrysa Nikoloudaki, Giorgos Pyrenis, Dimitra Kogiannou, Oswaldo Palenzuela
Enteromyxum leei TREATMENT TRIAL IN SHARPSNOUT SEA BREAM *Diplodus puntazzo* USING PHYTOBIOTICS

376 **Verena Jung-Schroers**, Arne Jung, Julia Bauer, Felix Teitge, Dieter Steinhagen
DEVELOPMENT OF ANTIBIOTIC RESISTANCES IN BACTERIA ISOLATED FROM ORNAMENTAL FISH AND FISH FOR FOOD PRODUCTION BETWEEN 2005 AND 2017

377 **Verena Jung-Schroers**, Mikolaj Adamek, Angela Boley, Julia Bauer, Anna Korshun, Felix Teitge, Dieter Steinhagen
INFLUENCE OF A NANOFILTRATION - REACTOR ON THE BACTERIAL MICROFLORA AND ON *Ichthyophthirus multifiliis* THERONTS IN RECIRCULATING AQUACULTURE SYSTEMS

378 **Aikaterini Papadopoulou**, Aikaterini Papadopoulou, Stamatia Natoudi, Theodoros Karatzinos, Vasiliki Mavrogianni, Panagiota Panagiotaki, Eleni Golomazou
EFFECT OF DISINFECTION WITH NATURAL SUBSTANCES ON HATCHING OF GILTHEAD SEABREAM EGGS

379 **Teresa Baptista**, A. Correia, M.V. Freitas, A. Pombo, T. Mouga, C. Afonso
ANTIBACTERIAL ACTIVITY OF RED SEAWEED *Gracilaria gracilis*

380 **Carolina Figueroa**, B. Morales, P. Veloso, C. Soto, L. Mercado, J.A. Gallardo
COHABITATION CHALLENGE REVEALS LOW EFFICACY OF A COMMERCIAL VACCINE AGAINST *Piscirickettsia salmonis* IN ATLANTIC SALMON

381 **Olivia Pérez**, Silvana Tapia, Helena Martin, Pedro Seaone, Gonzalo Claros, Mari Carmen Balebona, Miguel Angel Moriñigo
EVALUATION OF LACTIC ACID BACTERIA EFECT ON THE PROBIOTIC *Shewanella putrefaciens* PDP11 AND PATHOGENIC STRAINS

382 **Angel Hernández Contreras**, G.I. Mita, R. Álvarez, M.D. Hernández
EFFECT OF INCREASING DOSES OF *Nannochloropsis gaditana* ON THE IMMUNE SYSTEM OF GILTHEAD SEABREAM *Sparus aurata*

383 **Olivia Pérez Gómez**, Daniel Enrique Di Zeo, Álvaro Polonio, Alejandro Pérez-García, Miguel Ángel Moriñigo, María Carmen Balebona
EXPRESSION OF *Photobacterium damselae* subsp. *piscicida* IMMUNOGENIC PROTEINS AND *IN VITRO* EFFECTS ON IMMUNE GENE EXPRESSION OF *Solea senegalensis* HEAD KIDNEY CELLS

384 **Iman Abumourad**, Marwa Gamal, Al-Zahraa Karam El Deen, Hussein Abd El Kareem, Ola Gomaa
SCREENING OF BIOSORPTION CAPACITY OF MACROPOROUS FUNGAL BIOMASS OF *Trichoderma viride* FOR LEAD REMOVAL: A PROPOSED BIOREMEDIATION IN AQUACULTURE

385 **Uun Yanuhar**, Nico Rahman Caesar, Feri Setiawan, Muhammad Musa
IDENTIFICATION OF *Chlorella* sp. USING THE INTERNAL TRANSCRIBED SPACER SEQUENCE AND ITS ROLE AS INHIBITOR STRESS CAUSED BY RNA VIRAL NERVOUS NECROSIS INFECTION ON THE HUMPBACK GROUPER

386 **Hanan Tageldin**, Esam Rizkalla, Ali Hassan, Reda Rezk
CLIMATIC FACTORS AND SERUM STEROID HORMONES IN NILE CATFISH *Clarias gariepinus*

387 **Francisco Guardiola**, Yulema Valero, María Ruíz, Rosa León, Elena Chaves-Pozo, Carmen González-Fernández, M. Ángeles Esteban, Constanza Cárdenas, Fanny Guzmán, Alberto Cuesta
ANTIVIRAL ROLE OF THE ANTIMICROBIAL PEPTIDE NK-LYSIN AND ITS POTENTIAL APPLICATION IN AQUACULTURE

388 **Hashem Al-Gharabally**, A. Saheb, S. El-Dakour
ß-GLUCANS, SODIUM ALGINATE AND THYROXINE HELP IN ENHANCED SURVIVAL RATE, STRESS TOLERANCE AND IMMUNITY IN BLUEFIN BREAM *Sparidentax hasta* LARVAE

389 **Aires Oliva-Teles**, Rafaela A. Santos, Maria J. Saavedra, Paula Enes, Cláudia R. Serra
FISH-GUT *Bacillus* spp. AS POWERFUL ANTAGONISTS OF BACTERIAL AQUACULTURE FISH DISEASES

390 **Julieta Moraes**, Fernando C. Ramos-Espinoza, Victor A. Cueva-Quiroz, Jefferson Yunis-Aguinaga, Nicoli P. Mello, Norquis C. Álvarez-Rubio, Julieta R. E. Moraes
EFFICACY OF THE ADDITION OF TWO ADJUVANTS TO AN INACTIVATED VACCINE AGAINST *Streptococcus agalactiae* AND THEIR EFFECT OVER HEMATOLOGICAL PARAMETERS IN NILE TILAPIA FINGERLINGS

391 **Philip N. Just**, Matthew J. Slater, Tom Goldammer, Bernd Köllner
FEEDING REGIMES FOR AN OPTIMAL UPTAKE TO OBTAIN HERD IMMUNITY IN RAINBOW TROUT *Oncorhynchus mykiss*

392 **Chamilani Nikapitiya**, H.P.S.U. Chandrarathna, Jehee Lee, Mahanama De Zoysa
GROWTH INHIBITION EFFECT OF *Edwardsiella tarda* BY LYTIC PHAGE ETP-1 ALONE AND ITS COMBINED EFFECT WITH AMPICILLIN

393 **N. Mahadevi**
INDIAN ALMOND TREE *Terminalia catappa* (LINN.) AS HERBAL BIOMEDICINE IN AQUACULTURE

394 **Danijel Mejdandžić**, Slavica Čolak, Toni Ševanja, Matko Kolega, Renata Barić, Bosiljka Mustać, Bruna Petani, Ivan Župan, Tomislav Šarić
MATE FINDING OF *Ceratothoa oestroides* IN FISH FARMING CONDITIONS

395 **Dennis Kallert**, Marcus Zielasko, Christina Loy, Felix Teitge, Gregor Schmidt, Verena Jung-Schroers, Dieter Steinhagen, Helmut Wedekind
TRANSMISSION INTERRUPTION OF THE CILIATE *Ichthyophthirius multifiliis* AS AN ALTERNATIVE, NON-THERAPEUTIC CONTROL METHOD

396 **Mette S.W. Breiland**, Sigurd Hytterød, Saima Nasrin Mohammad, Malene Soleng, Lill-Heidi Johansen, Lisbeth Rørmark, Lars-Flemming Pedersen, Carlo C. Lazado
PERACETIC ACID AND ITS ANTI-PARASITIC ACTIVITY AGAINST *Paramoeba perurans,* THE CAUSATIVE AGENT OF AMOEBIC GILL DISEASE (AGD)

397 **Felix Teitge**, Verena Jung-Schroers, Christina Loy, Dennis Kallert, Marcus Zilasko, Gregor Schmidt, Helmut Wedekind, Dieter Steinhagen
FIGHTING THE PARASITIC CHALLENGE IN MODERN FISH FARMS: ALTERNATIVE REDUCTION STRATEGIES AGAINST *Ichthyopthirius multifiliis*

398 **Lyu jin Jun**, Joon bum Jeong
QRT-PCR ANALYSIS OF *PARVICAPSULA* sp. IN DIFFERENT ORGANS FROM EMACIATED OLIVE FLOUNDER *Paralichthys olivaceus* IN KOREA

399 **Claudia Tschesche**, Michaël Bekaert, James E. Bron, Armin Sturm
THE CARBOXYLESTERASE FAMILY IN SALMON LICE AND THEIR ROLE IN DELTAMETHRIN RESISTANCE

400 **Gabriel Arriagada**, Sandra Marín, Marcela Lara, Alicia Gallardo, Cristian Gallardo-Escárate
IDENTIFICATION OF SUCCESS FACTORS FOR ANTIPARASITIC TREATMENTS AGAINST THE SALMON LOUSE *Caligus rogercresseyi* IN CHILE THROUGH AN EXPERT PANEL

401 **Anna S. Båtnes**, J.A.Å. Vatn, M.A. Solstad, L.F. Bjørnstad, E. Børset, J.S. Tyssedal, Ø. Sture, M. Ludvigsen, Ø. Evensen, D. Altin, C. Miljeteig
LIGHT RESPONSES OF SALMON LOUSE *Lepeophtheirus salmonis* COPEPODITES

402 **Natalia Salamanca de Nieves**, M. López-Sanmartín, M. Moreira, J.R. López, M. Barata, P. Pousão-Ferreira, F. Soares
MOLECULAR IDENTIFICATION OF *Photobacterium damselae* subsp. *piscida* ASSOCIATED WITH PASTEURELLOSIS IN MEAGRE

403 **Tevfik Tansel Tanrikul**, Ezgi Dinçtürk
SPREAD OF A NEW DISEASE AGENT FOR RAINBOW TROUT *Oncorhynchus mykiss* IN TURKEY: STRAWBERRY DISEASE

404 **Robert Potts**, Ross Houston, Tim Bean, Alejandro Gutierrez

Argyrosomus regius IN THE MEDITERRANEAN AQUACULTURE: IS IT A SILENT CARRIER AND CONTAMINANT SPECIES FOR THE TWO GRAM POSITIVE BACTERIAL TYPES NAMELY MYCOBACTERIUM AND NOCARDIA? WHAT ARE THE IMPLICATIONS TO MARINE FARMING?

414 **Sarithaa Sellaththurai**, S.N. Shanaka Kateepe Arachchige, Thiunuwan Priyathilaka Thanthrige, Jehee Lee
GENOMIC CHARACTERIZATION AND EXPRESSION LEVEL ANALYSIS OF MALECTIN FROM BIG BELLY SEAHORSE *Hippocampus abdominalis*

415 **Kasun Madusanka Rajamanthrilage**, Jehee Lee
IDENTIFICATION, MOLECULAR AND FUNCTIONAL CHARACTERIZATION OF GLUTAREDOXIN-1 FROM BLACK ROCKFISH *Sebastes schlegelii*

416 **S.N. Shanaka Kateepe Arachchige**, Thanthrige Thiunuwan Priyathilaka, Jehee Lee
ROCKFISH *Sebastes schlegelii* MYD88 MOLECULAR IDENTIFICATION AND FUNCTIONAL ANALYSIS

417 **Gayashani Sandamalika**, Anushka Vidurangi Samaraweera, Jehee Lee
THE INVOLVEMENT OF C- LECTIN A AND F- LECTIN IN THE IMMUNE SYSTEM OF REDLIP MULLET *Liza haematochelia;* GENOMIC, MOLECULAR AND TRANSCRIPTIONAL FEATURES UPON IMMUNE STIMULANTS

418 **Anushka Vidurangi Samaraweera**, Thiunuwan Priyathilaka Thanthrige, Jehee Lee
MOLECULAR IDENTIFICATION, BIOCHEMICAL CHARACTERIZATION AND ITS INNATE IMMUNE RESPONSES OF PEROXIREDOXIN 4 (HaPrx4) IN BIG BELLY SEAHORSE *Hippocampus abdominalis*

419 **Jaewon Kim**, D.S. Liyanage, W.M. GayashaniSandamalika, Jehee Lee
MOLECULAR CHARATERIZATION OF OMEGA AND KAPPA CLASS GLUTATHIONE S-TRANSFERASE FROM REDLIP MULLET *Liza haematocheilus* AND ENZYME KINETICS, OPTIMUM CONDITIONS

420 **Rosa Allshire**, Johanna Baily, Ola Wands, Rhona Robertson, Manfred Weidmann
UNRAVELLING THE PATHOGENESIS OF SALMON GILL POXVIRUS IN FRESHWATER ATLANTIC SALMON

421 **Hager Metwally**
THE USE OF COMET ASSAY TO DETECT DNA DAMAGE IN TILAPIA ERYTHROCYTES TREATED WITH MALATHION

422 **Javad Daghigh Roohi**, Abdolhossein Dalimi, Mohammad Pourkazemi, Mohaddes Ghasemi, Shokoofeh Shamsi
MOLECULAR AND PHYLOGENETIC ANALYSIS OF *Dactylogyrus* spp. PARASITES IN CULTIVATED SILVER CARP *Hypophthalmichthys molitrix* AND BIG HEAD CARP *Hypophthalmichthys nobilis* IN IRAN

423 **Juan L. Barja**, Susana Prado, Esteban Blanco, José G. Olveira
Vibrio bivalvicida, A REAL THREAT FOR *Ostrea edulis;* THE NEED FOR RESEARCH ON THE DYNAMIC OF PATHOGENS IN HATCHERY

424 **Ane V. Nytrø**, Bengt Finstad, Rolf E. Olsen
INFESTATION PRESSURE OF SALMON LICE *Lepeophtheirus salmonis* ON RETURNING ATLANTIC SALMON *Salmo salar* IN CENTRAL NORWAY

425 **Francisco A. Guardiola**, Yulema Valero, Laura Cervera, Elena Chaves-Pozo, M. Ángeles Esteban, Jimena Cortés, Felipe Ramírez-Cepeda, Luis Mercado, Alberto Cuesta
PRESENCE OF CD8+ LYMPHOCYTES IS MODIFIED IN EUROPEAN SEA BASS IMMUNE TISSUES UPON NODAVIRUS INFECTION

426 **Teresa Baptista**, P. Pires, R. Passos, I. Ferreira, M. Simões, P. Santos, M. Machado, B. Costas
DIFFERENTIAL IMMUNE RESPONSES IN GILTHEAD SEABREAM AND MEAGRE JUVENILES INFECTED WITH *Photobacterium damselae* subsp. *piscicida*

427 **Daniel Paredes**, Carmela Rebaza, Ricardo Oliva
PATHOLOGY ASSOCIATED WITH *Pseudomonas* sp. IN *Pseudoplatystoma fasciatum*

POSTERS

428 **Mahanama De Zoysa**, Thiloma Liyanage, Chamilani Nikapitiya
EXPRESSION PROFILES OF MIR-462 AND 734 IN ZEBRAFISH LARVAE UPON *Aeromonas hydrophila* AND *Edwardsiella piscicida* EXPOSURE

429 **Marcelino Herrara,** M. Lopez-Sanmartin, J. R. Lopez
MOLECULAR CHARACTERIZATION OF *Vibrio harveyi* STRAINS ASSOCIATED TO DISEASE IN REARED GREY MULLET *Mugil cephalus*

430 **Robert Durborow**, Stephen Atkinson
DEVELOPING A CLINICAL DATABASE, MOBILE APPLICATION (APP), AND LEARNING GAMES FOR FISH DISEASE DIAGNOSTICS

431 **Mikolaj Adamek**, Ferenc Baska, Darius Nienius, Vladimir Radosavljevic, Snježana Zrnčić, Dragan Brnić, Dražen Oraić, Dieter Steinhagen
WIDE DISTRIBUTION OF CARP EDEMA VIRUS IN EUROPE IS CONFIRMED BY RECENT DETECTIONS IN HUNGARY, CROATIA, SERBIA AND LITHUANIA

432 **Gabriel Arriagada**, Christopher Hamilton-West, Omid Nekouei, Claudia Foerster, Andrea Müller, Marcela Lara, Cristian Gallardo-Escárate
Caligus rogercresseyi INFESTATION IS ASSOCIATED WITH *Piscirickettsia salmonis*-ATTRIBUTED MORTALITIES IN FARMED SALMONIDS IN CHILE

433 **Roy Rosen**, Barbara Doupovec, Ines Taschl, Michele Muccio, Nitzan Unger
MYCOTOXINS – A WORLDWIDE THREAT FOR THE BLUE REVOLUTION?

434 **Susana M.F. Ferreira**, Daniela S. Eiras-Novo
ASEXUAL REPRODUCTION OF SEA ANEMONES FOR ORNAMENTAL PURPOSES

435 **Mateusz Rawski**, Joanna Kowalska, Zuzanna Mikolajczak, Bartosz Kieronczyk, Jan Mazurkiewicz, Silvia Nogales-Mérida, Agata Józefiak, Damian Józefiak
THE USE OF FULL-FAT SUPERWORM *Zophobas morio* MEAL IN GUPPY *Poecilia reticulata* NUTRITION

436 **Ana Luísa Patrício Silva**, L. Cícero, Apl Costa, Acm Rodrigues, D. Silva, Amvm Soares, Rjm Rocha
EFFECTS OF MICROPLASTICS TO THE CORAL *Zoanthus sociatus* MIGHT BE DRIVEN BY POLYMER TYPE IN SHORT-TERM EXPOSURE SCENARIOS

437 **Eirini Schoina**, Helen Miliou, George-John Nychas
EVALUATION OF THE BIOFILM FORMATION ON STAINLESS STEEL SURFACES IN A MARINE RECIRCULATED AQUACULTURE SYSTEM

438 **Fotini Kokou**, Itzhak Mizrahi, Avner Cnaani
EXPLORING EUROPEAN SEABASS GUT MICROBIOME AND ITS RESILIENCE TO IN-FEED ANTIBIOTICS

439 **Yi-Feng Li**, Xiao Liang, You-Ting Zhu, João C.R. Cardoso, Deborah M. Power, Jin-Long Yang
THYROID HORMONE RECEPTORS A NEW PLAYER IN LARVAL METAMORPHOSIS OF THE HARD-SHELLED MUSSEL

440 **Nicole Verdile**, Rolando Pasquariello, Marco Scolari, Giulia Scirè, Tiziana A.L. Brevini, Fulvio Gandolfi
QUANTITATIVE CHARACTERIZATION OF THE RAINBOW TROUT *Oncorhynchus mykiss* INTESTINAL EPITHELIUM IN RESPONSE TO DIET CHANGES DURING THE FIRST YEAR OF DEVELOPMENT

441 **Jennifer Catherine Nascimento Schulze**, Tim Bean, Chantelle Hooper, Matthew Sanders, Robert P. Ellis
NATIVE FLAT OYSTER RESISTANCE TOWARDS *Bonamia ostreae:* A HOLISTIC APPROACH COMBINING OMICS AND PHYSIOLOGY

442 **Ignacio Fernández**, Ana Larrán, Luis Laguna, Pedro Cárdaba, Jose Mateos, Cristina Tomás-Almenar
SKELETOGENESIS OF TENCH *Tinca tinca* REARED IN EXTENSIVE AQUACULTURE: TOWARDS HIGH QUALITY PRODUCTION STANDARDS

443 **Henrik Sundh**, Giedre Asmonaite, Noomi Asker, Bethanie Carney Almroth
EFFECTS OF DIETARY MICROPLASTIC (100-400 µm) EXPOSURE ON INTESTINAL PHYSIOLOGY OF RAINBOW TROUT *Oncorhychus mykiss*

444 **Hadiseh Dadras**, A. Golpour, B. Dzyuba, J. Kristan, T. Policar
TESTIS DEVELOPMENT AND ULTRASTRUCTURAL FEATURES OF SPERMATOGENESIS IN BURBOT *Lota lota*

445 **Mel V. Boo**, Kum C. Hiong, Celine Y.L. Choo, Shit F. Chew, Yuen K. Ip
LIGHT-ENHANCED SHELL FORMATION IN THE FLUTED GIANT CLAM *Tridacna squamosa* INVOLVES LIGHT-DEPENDENT EXPRESSION OF NA+-DEPENDENT SECONDARY ACTIVE TRANSPORTERS IN ITS CTENIDIUM

446 **Olubunmi Agbebi**, Kikelomo Fakunle, Odunayo Oyaleke, Chukwuemeka Amadi, Grace Akinyemi, Timothy Sanni
PHENOTYPIC CHARACTERIZATION AND GENETIC VARIATION OF NILE TILAPIA *Oreochromis niloticus* FROM WILD AND CULTURE POPULATIONS

447 **Irom Okey**
EFFICACY OF *Ocimum gratissimum* (BASAL SCENT LEAF) POWDER AS ANAESTHETIC AND ITS EFFECT ON THE HAEMATOLOGY OF *Clarias gariepinus* JUVENILES

448 **Mirela Cretu**, Lorena Dediu, Victor Cristea, Angelica Docan, Raluca Cristina Andrei, Anca Nicoleta Cordeli
EFFECT OF STARVATION AND RE-FEEDING WITH DIFFERENT DIETARY PROTEIN LEVEL ON SOME HEMATOLOGICAL PARAMETERS OF JUVENILE RAINBOW TROUT *Oncorhynchus mykiss* (WALBAUM, 1792)

449 **Marian Tiberiu Coada**, Victor Cristea
THE INFLUENCE OF GROWING TANK SIZE ON PADDLEFISH *Polydon spathula* (WALBAUM, 1792)

450 **Antonio Luna-González**, Darío Israel García-Medel, Luis Alfredo Ortega-Clemente, Ruth Escamilla-Montes, Jesús Arturo Fierro-Coronado
THE ADDITION OF PROBIOTIC *Bacillus licheniformis* BCR 4-3 IN THE REARING WATER AND FEED ENHANCES SURVIVAL AND IMMUNE RESPONSE OF *Litopenaeus vannamei* CHALLENGED WITH *Vibrio parahaemolyticus*, THE CAUSATIVE AGENT OF AHPND

451 **Yanran Cao**, Anne Stene, Beate Julie Thu, Anne Synnøve Røsvik
IDENTIFICATION OF EPITOPES TARGETED BY IMMUNE RESPONSE AGAINST SALMON PANCREAS DISEASE VIRUS IN NORWEGIAN SALMON AQUACULTURE

452 **Thilina Duminda Weerasinghe Kasthuri Arachchige,** J. C. Harasgama, R. K. Madhusanka, Qiang Wan, Jehee Lee
CHARACTERISATION OF INTERLEUKIN-11 OF REDLIP MULLET Liza haematocheila AND ITS REGULATORY FUNCTIONS ON STAT3 TRANSCRIPTION FACTOR

453 **Ruth Tamara Montero,** Sven Ostermann, Tobias Kroniger, Fabio Sarais, Philip Just, Matt Slater, Alexander Rebl, Tom Goldammer, Dörte Becher, Bernd Köllner
MODULAR ORAL APPLICABLE MULTI-VACCINE (MOMV) – PRINCIPLE SOLUTIONS TOWARDS A BETTER VACCINATION IN AQUACULTURE

454 **Ruth Tamara Montero,** Sven Ostermann, Tobias Kroniger, Dörte Becher, Bernd Köllner
BACTERIAL OUTER MEMBRANE VESICLES (MOMV)- TARGET AND CARRIER FOR FISH ORAL VACCINATION AND CHARACTERIZATION OF THE SYSTEMIC AND MUCOSAL INNATE AND ADAPTIVE IMMUNE RESPONSE

FOOD QUALITY AND SAFETY POSTERS

Board #

455 **Arllon Dias**, Gabriel Ferreira, Nyelle Façanha, Ed Marcos Silva, Gabriel Silva
USE OF STINGRAYS OF THE GENUS *Potamotrygon* (GARMAN, 1877) (POTAMOTRYGONIDAE, MYLIOBATIFORMES), FOR ELABORATION OF NEW PRODUCTS AND EVALUATION OF THE POTENTIAL PRESERVATIVE OF SPICE *Eryngium foetidum* L.

QUANTIFYING GENETIC AND ECOLOGICAL EFFECTS OF ESCAPED FARMED SALMON ON WILD SALMON

491 **Francis Mmanda**, Deogratias Mulokozi, Jan Lindberg, Anna Hallden, Matern Mtolera, Rukia Kitula, Torbjorn Lundh
FISH FARMING IN TANZANIA AND THE AVAILABILITY AND NUTRITIVE VALUE OF LOCAL FEED INGREDIENTS

492 **Jakob Gaehrken**, Jens Tetens, Stephan Wessels
NUTRITION MEETS GENETICS: GROWTH COMPARISON OF EIGHT RAINBOW TROUT *Oncorhynchus mykiss* STRAINS DEPENDING ON PROTEIN SOURCE OF THREE DIFFERENT EXPERIMENTAL DIETS

ePosters
a first for Aquaculture Europe!

For the first time, AE2019 will feature *ePosters.*
***ePosters* will be available to AE2019 delegates through:**
- the AE2019 Meeting Assistant application
- online at the AE2019 web site
- visioning on site

All of the posters below are only accessed through the *ePoster* methods. *There will not be hard copies of the posters available to view.*

RECIRCULATING AQUACULTURE SYSTEMS (RAS)
ePOSTERS

Board #

500 **Omoniyi Popoola**, Samuel Oguntade, Temitayo Oyesiji, Olajumoke Ajibola
BIOCHEMICAL ANALYSIS OF SERUM FROM AFRICAN CATFISH *Clarias gariepinus* RAISED IN BIOFLOC SYSTEMS

501 **Petra Lindholm-Lehto**, Jani T. Pulkkinen, Tapio Kiuru, Juha Koskela, Jouni Vielma
WATER QUALITY IN A RECIRCULATING AQUACULTURE SYSTEM WITH PASSIVE DENITRIFICATION RAISING RAINBOW TROUT *Oncorhynchus mykiss*

502 **Jan Klein**, Andrea Schüch, Adrian Bischoff-Lang, Harry Wilhelm Palm
UTILIZATION OF EFFLUENT STREAMS FROM RECIRCULATING AQUACULTURE SYSTEMS BY VERMIFILTRATION

503 **Jani Pulkkinen**, Sanni Aalto, Suvi Suurnäkki, Jouni Vielma, Marja Tiirola
BACTERIAL COMMUNITIES OF DIFFERENT BIOFILMS IN FRESHWATER AND SYNTHETIC SALT WATER RECIRCULATING AQUACULTURE SYSTEMS

504 **E. Murari**, J.L. Rodríguez
ONGROWING OF SOLE *Solea senegalensis* SUBJECTED TO THREE FEEDING PATTERS IN A RECIRCULATION SYSTEM

505 **Balázs Kucska**, Béla Csukás, Mónika Varga
IMPLEMENTATION OF PROGRAMMABLE STRUCTURES FOR MODEL BASED ANALYSIS OF RECIRCULATING AQUACULTURE SYSTEMS

506 **Tobias Rapp**, Ralf Bochert, Frederik Buhrke, Tim Gottschalk
EFFECT OF FOUR DIFFERENT COMMERCIAL FEEDS ON GROWTH PERFORMANCE AND SURVIVAL OF EUROPEAN PERCH *Perca fluviatilis* IN RECIRCULATING AQUAQUALTURE SYSTEM

507 **Sudip Dutta**, V.K. Tewari
DESIGN AND DEVELOPMENT OF RECIRCULATING LIFE-SUPPORT SYSTEM AS AN AMENDED LIVE FISH ROAD TRANSPORTATION FACILITY

508 **Henrik Mortensen**
NEW HEX-X LINE DRUMFILTERS FOR WARM SALTWATER APPLICATIONS AND END PIPE SOLUTIONS

509 **Kukka Kujala**, Jani Pulkkinen, Jouni Vielma
COMBINING PHOSPHORUS REMOVAL BY ORGANIC FLOCCULANTS WITH WOODCHIP DENITRIFICATION IN RECIRCULATION AQUACULTURE SYSTEM (RAS)

510 **Pedro Gomez-Requeni**, Kim Schøn Ekmann, Kyla Meagan Zatti
IMPROVEMENT OF FAECES STABILITY THROUGH DIETARY MANIPULATION IN STARTER FEEDS FOR SEABASS *D. labrax* AND SEABREAM *S. aurata* REARED IN RECIRCULATION SYSTEMS

511 **Aikaterini Spiliotopoulou**, Richard Martin, Henrik R. Andersen
OZONATION OF SEMI-CLOSED AQUATIC SYSTEMS

512 **Mirko Bögner**, Kai Lorkowski, Desislava Bögner, Fynn Wilsdorf, Gregor Jähne, Matt Slater
AMMONIUM REMOVAL BY ION EXCHANGER - EFFECTS ON WATER PARAMETERS, MICROBIAL COMMUNITY AND SEA BASS *Dicentrarchus labrax* IN A MARINE RECIRCULATING AQUACULTURE SYSTEM

513 **Wilson Wasielesky**, Lucas Genésio Silveira, Victor Torres, Luis Poersch, Dariano Krummenauer
REDUCTION OF STOCKING DENSITY THROUGH PARTIAL HARVEST: EFFECTS ON COMPENSATORY GROWTH AND PRODUCTION PARAMETERS OF *Litopenaeus vannamei* REARED IN BIOFLOC SYSTEM

514 **Karin Schiefenhövel**, Melanie Schiffer-Harms, Joachim Henjes
DEVELOPMENT OF A NOVEL, LAND-BASED AQUACULTURE PROCESS FOR THE PRODUCTION OF MARINE SPONGE *Chondrosia reniformis* AND THE PHARMACOLOGICAL USE OF SPONGE COLLAGEN

515 **Brecht Stechele**, Khoa Tran, Nancy Nevejan, Peter Bossier
SELECTING MICRO-ORGANISMS CAPABLE OF REMOVING THE COMMON RAS OFF-FLAVOUR, GEOSMIN

516 **Michael Beattie**, Ehab Misk, Chris Bridger
ASSESSING THE EFFECTS OF GAS INFSUION SYSTEMS TECHNOLOGY TO PRODUCE HIGH DISSOLVED OXYGEN FRESHWATER SATURATION ON ATLANTIC SALMON *Salmo salar* GROWTH AND OVERALL HEALTH WITHIN A SIMULATED COMMERCIAL HATCHERY SETTING

517 **Isidro Blanquet**, Diana Almeida, Zelia Sousa, Catarina Magalhães, Ana Paula Mucha, Eliana Silva
WATER QUALITY AND MICROBIAL COMMUNITY IN A SOLE HATCHERY RAS FOR ENVIRONMENTAL SUSTAINABILITY AND FISH WELFARE

518 **P. Yuvarajan**
BIOFLOC TECHNOLOGY – KEY TO WATER QUALITY MANAGEMENT IN FISH/ SHRIMP FARMING

519 **Frederike Schmachtl**, Gabriela Soltes Ferreira, Mirko Bögner, Felipe do Nascimento Vieira, Matthew James Slater
COMPARISON OF THE NUTRITIONAL COMPOSITION OF THREE DIFFERENT BIOFLOC SYSTEMS – CHEMOAUTOTROPH, HETEROTROPH AND MATURE BACTERIA – AND ITS EFFECT ON SHRIMP GROWTH

520 **Kabir Chowdhury**, Hervé Lucien-Brun, G.A. Bula
NEED OF FEED ENZYMES FOR EFFICIENT RECIRCULTATION AQUACULTURE (RAS) SYSTEMS: A PROTEASE PERSPECTIVE

HATCHERY TECHNOLOGIES AND PRACTICES
ePOSTERS

Board #

525 **Ahmed Md. Salem**, M. Abokadah, N. El-Bermawi, N. Abdelsalam
MARINE SYNBIOTIC DECREASED THE PHYSIOLOGICAL IMPACTS OF ESTRADIOL TREATMENT IN EARLY WEANED EUROPEAN SEABASS LARVAE

526 **Mohammed Nambyl A. Fagbemi**, Razack Oloukounle, Djiman Lederoun, Schadrac I. Baglo, Philippe A. Laleye, Carole Rougeot, Charles Melard
COMPARATIVE STUDY OF THE REPRODUCTIVE PERFORMANCES OF FIVE POPULATIONS OF *Oreochromis niloticus* (LINNAEUS, 1758) FROM THE FIRST GENERATION OF WILD BROODSTOCK COLLECTED IN THE MONO, NIGER, OUÉMÉ WATERSHED IN BENIN

527 **Alfred Jokumsen**, M. Gesto, K. Buchmann, N. Lorenzen, L.-F. Pedersen, N.H. Henriksen, J.G. Schmidt, L Madsen, P. Kania, P.B. Pedersen
SHELTERFISH: NEW TOOLS TO IMPROVE FISH HEALTH AND ENVIRONMENT IN ORGANIC AQUACULTURE

528 **Gianni Brundu**, Barbara Loi, Anuta Chindris, Philip Graham, Dimitri Bernabè, Gemma Giménez Papiol
EVALUATING THE EFFECTS OF FARMING REARING TOOLS ON THE QUALITY ASPECTS AND GROWTH OF THE PACIFIC OYSTER *Crassostrea gigas*

529 **Gianni Brundu**, Philip Graham, Anuta Chindris, Dario Vallainc, Barbara Loi, Gemma Giménez Papiol
A PILOT SCALE HATCHERY OF SHELLFISH IN SARDINIA: A REGIONAL DEVELOPMENTAL STRATEGY WITH RESEARCH AND TECHNOLOGICAL OPPORTUNITIES

530 **Dario Vallainc**, Dimitri Bernabe, Anuta Chindris, Francesca Leggeri, Stefania Piscedda, Gemma Gimenez Papiol
SUITABILITY OF MICROALGAE CULTURED IN NITROGEN-LIMITED MEDIUM FOR ROTIFER PRODUCTION

531 **Marta Castilla Gavilan**, Meshi Reznicov, Vincent Turpin, Priscilla Decottignies, Bruno Cognie
SEA URCHIN RECRUITMENT: THE EFFECT OF DIATOM BASED BIOFILMS ON *Paracentrotus lividus* COMPETENT LARVAE

532 **Jose Luis Rodriguez Villanueva**, Alexis Araujo, Noelia Fuentes, Blanca Alvarez-Blázquez, Evaristo Pérez, Antonio Vilar, Fátima Linares
EXPERIMENTS OF WRECKFISH *Polyprion americanus* LARVAL CULTURE IN GALICIA (SPAIN)

533 **Susana Prado**, Miguel Anxo Lastres, María del Carmen Andrés, Emilio Cid, Juan Luis Barja
VIBRIOS IN PHYTOPLANCTON CULTURES OF A BIVALVE HATCHERY AND PERSISTENCE IN SURFACES

Our Future - GROWING from WATER

All life on earth emerged from water and the aquaculture sector, by definition, relies upon its existence for all or part of its many and varied production cycles. The future of healthy and sustainably produced food lies in the diversity of aquaculture, from single-cell microalgae in bioreactors to fish in sea pens or freshwater ponds. This is reflected in the German aquaculture sector which is unique in its diversity, ranging from extensive cultivation systems in ponds and coastlines to intense indoor farming.

Truly unlocking this potential requires innovative ways to support the aquaculture economy, generation of new business models and support of start-ups. We need to proactively work towards the demands of existing and new markets for all our products, seeking new alliances in international trade and consumer support. Meanwhile, the challenges of climate change and scarcity of natural resources are urgent and require our full attention in respect and appreciation of the ecosystems we work with. As a result there has been huge interest in our sessions focussing on the environmental interactions with aquaculture systems as well as those for nutrient recycling and nutrient supply to aquaculture organisms.

The organisation of such a conference is a huge team effort. The Steering and Local Organising Committees, chaired by Stefan Meyer and Birgit Schmidt-Puckhaber respectively have done a great job over the last two years to structure the event and ensure that all is in place. Overall the degree of response for AE2019 in Berlin has been overwhelming. More than 900 abstracts have been submitted and as a result we have been able to offer an impressive program characterised by highly diverse sessions, thematic workshops and innovative fora. These include new inter- and transdisciplinary platforms to support exchange within the aquaculture community and between various stakeholders to generate new ideas and concepts with economic potential. Our Programme Co-chairs Carsten Schulz and Tomáš Policar have worked incredibly hard to try to accommodate this record number of abstracts. Some difficult decisions have had to be taken by session chairs and some people will of course be disappointed. But we hope that the diversity of the programme will entice you to go out of your 'normal' sessions and listen to others. I dropped in on an Aquaponics session in Las Vegas at a World Aquaculture Conference several years ago and it changed the whole direction of my research!

As you will have seen, EAS has partnered this year with NordicRAS to provide our events back to back and hence allow participants to attend both in one place. We very much hope to pursue this partnership in the years to come.

With all the new knowledge being presented at our events, there is a wealth of possibility for innovation and value creation to help develop the sector. We have therefore developed the EAS Aquaculture Europe Innovation Forum and its inaugural meeting will take place on Wednesday. The event, in partnership with Hatch Blue and the German Startups Association, will consist of plenary speakers and "dragons' den" style pitches from 12 new companies that wish to seek further investment to develop.

The trade exhibition is bigger than ever this year with over 148 booths representing 130 companies from 23 countries and we have a series of special sessions to encourage attendance from exhibitors and trade show visitors. One of these is "Women in Aquaculture," a panel discussion looking at ways to ensure greater gender diversity at all levels of the aquaculture sector. There are also meetings of European associations, the EU EATIP Day and workshops of EU projects.

A special forum has been arranged for students attending AE2019 to enable networking and exchange of ideas. The forum will have a dedicated programme and includes a special student reception. In addition, the opening plenary session will feature the inaugural Aquaculture Europe Student Spotlight Award. This is based on the prize that is presented at the EAS/WAS AQUA events and it allows three finalists the chance to give a short pitch presentation of their work at one of the keynote sessions. The winner is then selected by the audience.

The Estrell Centre is a huge complex so we suggest that you download our EAS Meetings app from the app store or google play which will keep you in touch with all the up to date information on the inevitable last-minute program changes

Finally, I would like to highlight and thank our loyal AE2019 Gold Sponsors Biomar, our session sponsor Sorgal and the Rentenbank in Germany for their support of this event. We would equally like to thank our supporting partner organisations and our media partners.

Berlin is an eccentric city with a superbly integrated transport system and a wealth of cultural and heritage sites. Make sure you take the time to explore its historic streets and buildings.

Let there be life – and a future growing from water!

Gavin Burnell, EAS President 2018-2020

AUTO- AND HETEROTROPHIC NITROGEN REMOVAL IN WOODCHIP REACTORS TREATING RECIRCULATING AQUACULTURE SYSTEM EFFLUENTS

Introduction

Woodchip denitrification reactors offer cost-efficient nitrate removal for treating nitrate-rich effluents of recirculating aquaculture systems (RAS). Currently, woodchip reactors are successfully applied in freshwater RAS (e.g. von Ahnen et al. 2018), where the nitrate removal is considered to be based on active heterotrophic microbial community growing on woodchips, that conducts denitrification i.e. reduces water nitrate into N_2 gas using carbon leaching from the woodchips as an electron donor. However, the production of marine fish species in RAS is increasing, bringing more challenges to the effluent treatment. Recently, nitrate removal was found to be significantly lower in woodchip reactors treating saline than freshwater RAS effluents (von Ahnen et al. 2019), which was suggested to be related to the dominance of autotrophic denitrification i.e. nitrate reduction using other electron donors than organic carbon (e.g. H_2S, HCO_3^-) under saline conditions. In this study, our objective was to examine if HCO_3^- addition affected the dynamics between auto- and heterotrophic denitrifiers, seen as the differences in the nitrate removal, microbial community composition and origin between woodchip reactors receiving freshwater and low salinity (7ppt) RAS effluents.

Materials and methods

The experimental set-up comprised of twelve laboratory-scale woodchip reactors, which received four different RAS effluent types: a) freshwater (F) b) freshwater with $NaHCO_3$ addition (targeted alkalinity of 1.6 g l^{-1}; FS), c) salt water (S), and d) salt water with $NaHCO_3$ addition (targeted alkalinity of 1.6 g l^{-1}; SS), n = 3 per treatment. The experiment was run for 58 days. Inorganic N concentrations were measured weekly and other water chemistry parameters three times during the experiment. For microbial community analysis, water samples from the inlet, outlet, and in the middle of the reactors,

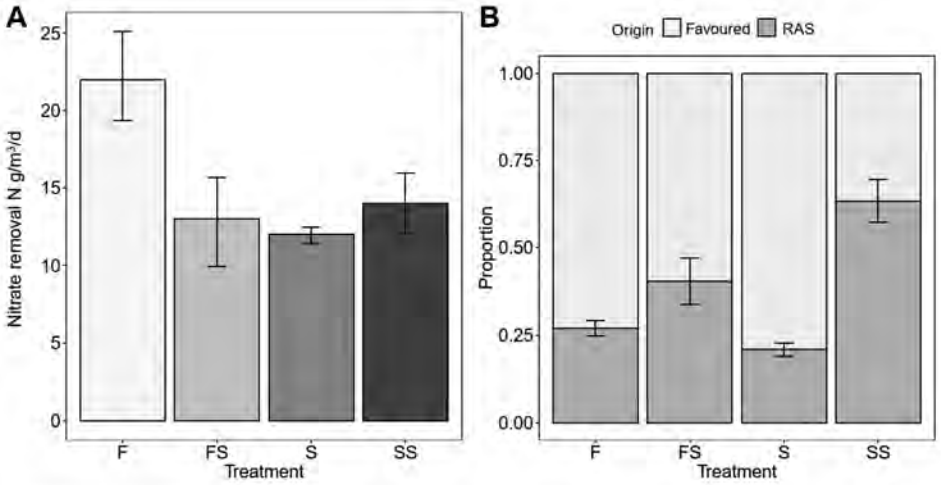

Figure 1. A) Nitrate removal rates (average ± SE), and B) the proportions (average ± SE) of microbes favoured by reactor conditions or originating from woodchip (Favoured) and microbes originating from RAS to woodchip biofilm community predicted with SourceTracker in woodchip reactors receiving four types of effluents (F = freshwater, FS = freshwater + $NaHCO_3$, S = saline water, SS = saline water + $NaHCO_3$).

(Continued on next page)

and three replicates of woodchip biofilm were collected in the end of the experiment. Microbial community composition was analysed using next generation sequencing with IonTorrent PGM targeted on 16S rRNA gene V4 region. Nitrate removal rates were calculated as in von Ahnen et al. (2019). The origin of woodchip biofilm microbes was predicted using SourceTracker method (Knights et al. 2011).

Results and discussion

Freshwater reactors (F) had the highest nitrate removal rates (Figure 1A). The addition of HCO_3^- improved slightly the nitrate removal in saltwater reactors, but suppressed the nitrate removal in freshwater reactors. Furthermore, HCO_3^- addition changed the microbial community composition in freshwater reactors, decreasing the diversity and the abundance of the key denitrifying microbial groups, whereas in two saltwater treatments, the communities were rather similar, but HCO_3^- addition increased the diversity and denitrifier abundance. Based on the SourceTracker (Figure 1B), HCO_3^- addition increased the proportion of microbes originating from RAS in woodchip biofilms in both freshwater and saltwater reactors. Altogether, these results indicate that in freshwater woodchip reactors, heterotrophic denitrification is the most beneficial process, and HCO_3^- addition promoted the abundance of non-denitrifying microbes originating from fish tanks. However, it seems that mixed autotrophic-heterotrophic denitrification system is beneficial under saline conditions, where woodchip carbon-based heterotrophic denitrification is typically suppressed. In addition, the results suggest that a substantial proportion of the autotrophic denitrifiers originates from saltwater RAS. In conclusion, efficient nitrate removal in saltwater effluents requires favourable conditions for autotrophic denitrifiers, e.g. through addition of inorganic electron donors or using H_2S produced in sulfate-rich saltwater RAS.

*Email: alrgma@yahoo.com

Introduction

A *Bacillus pumilus* is a Gram-positive, aerobic, spore-forming *bacillus* belonging to *Bacillus subtilis* group. *B. pumilus* is widely used in industrial microbiology, such as the production of many of fermented foods, based on its efficiency to degrade a lot of the pollutants, it used in the treatment of wastewater and the degradation of environmental pollutants. *B. pumilus* have the ability to produce several biological compounds such as vanillin, keratinase, xylanase, alkaline serine protease and several other bioactive substances. Numerous *B. pumilus* strains isolated from several environmental sources were applied as microbial probiotics for animals. However, numerous *B. pumilus* are harmful to human, animals, and plants. The present study was aimed to isolate a novel *B. pumilus* strain to evaluate its ability as bacterial probiotics in animals.

Materials and methods

Isolation of microorganisms: *B. pumilus* associated with the digestive tract of healthy honey bees was isolated using 100 honey bees. The digestive tracts of honey bees were extracted. a sterilization of outer surface of the extracted digestive tracts was done using ethanol solutions (70%) and sodium hypochlorite solution (7%).

Procedures and experiments: 60 adult healthy male mice *Mus musculus domesticus* were selected to obtain body weight 25±1 gm then used in the present biological experiment. All mice were grouped into three groups (20 mice for each group), the first group (control group) was dieted a standard mice diet, the second group was dieted with standard mice diet and treated with 0.20 ml of sterile normal saline solution (Orally, the solutions was given daily), the third group was treated as in the second with the replacement of the sterile normal saline solution with the bacterial suspension (The bacterial suspension was prepared from pure culture of *Bacillus pumilus* in a sterile normal saline solution (106 cell/ml)).

Statistical analysis: A completed random design (CRD) was applied in this study and statistical analyses of data were done using IBM SPSS Statistics 23.

Results and discussion

Isolation and identi ication

The aim of this study was to evaluate the biological effects of *B. pumilus* strain isolated from healthy honey bees on several biological parameters in mice. The microscopic features results showed that some the bacteria isolated from the digestive tract of healthy honey bees were rod-shaped, Gram-positive, aerobic, spore-forming bacteria. All the isolates that have previous microscopic features were selected as *B. pumilus* then the biochemical tests using HiBacillusTM Identification Kit (Himedia, india) were done to distinguish between *Bacillus* species. The data in table 1 reported that there are some bacterial isolates may be *B. pumilus* strains where each Voges Proskauer's, citrate, ONPG, catalase, sucrose, mannitol, glucose, arabinose and trehalose positive; and malonate, nitrate reduction and arginine negative bacterial isolates were considered *B. pumilus* strains.

Animal experimentation

A figure 2 shows the biological effects of the *B. pumilus* on body weight (gm) and mortality (%) of the mice. The data confirmed that *B. pumilus* has a positive impact on the body weight (gm) and mortality (%) of the mice. The *B. pumilus* led to a significant ($P<0.05$) increase in the body weight and a significant ($P<0.05$) decrease in the mortality. Differences in the mean concentration of the biological parameters were not significant in all groups. The level of the blood constituents and compounds of mice, which were investigated in this work were within normal levels comparing to the levels mentioned by Mitruka and Rawnsley (1981). The data obtained from this study reported that *B. pumilus* has no unfavorable influence on total protein, glucose, insulin, total cholesterol, WBCs, RBCs, HGB, HCT, PLT, MCV, MCH, and MCHC.

(Continued on next page)

There are several *Bacillus* species such as *B. cereus*, *B. clausii*, *B. pumilus* have been carried in numerous commercial probiotic products for aquaculture and human, and have been characterized for potential attributes including colonization, immunostimulation, and antimicrobial activity that accounted for their probiotic features.

*Email: alrgma@yahoo.com

Introduction

Different dietary patterns can have an effect on overall health since pleasure apparently acts as health promoters and worries can adversely affect health. The male population in Yemen has increased rapidly, the number of females, in relation to the total Yemenis population, grew from 51 % in 2015, (central Statistical Organization For the period 2005-2025). World average fish per capita is 20 kg while, Yemen average fish per capita is 4 kg (FAO, 2019). The analysis of dietary patterns becomes the best alternative to evaluating healthy behaviors. In this study, they decreased their weekly consumption of oily fish, sea foods, fresh fruits, cooked and the raw vegetables, pulses and olive oil while they increased their sugar, and fast food intake. The Food Frequency Questionnaire (FFQ) is commonly used to assess dietary patterns associated with clusters of frequently consumed food items.

Methodology

Sampling technique: The study included 300 male students aged 19-29 years were randomly selected three colleges (Medicine, Engendering, and Information technology) of the University of Thamar and Al saeeda.

Statistical analysis: All the data thus collected were entered into the SPSS 17 software.

For Meat/Snacks Score:

If your score is:
22-24 you are generally eating a typical American diet, which could be lower in fat.
18-21 you are making better low-fat food choices.
17 or less you are making the best low-fat food choices. Keep up the great work
If you scored 17 or less, you are doing well, this is the desirable score on this screener.

Results and discussion

Consumption frequency of different protein foods Items by male Students at Thamar and Al Saeeda University

Frequency of eating different food items for male students are mentioned below is presented in table (5). The present sample demonstrated high consumption of proteins food (eggs 72.7%%, bean71.3%, chicken 70%, meat 56.7%)**;** While were (eggs 76.7%, chicken 70.7%, bean 66.7%, meat 64%) among male Students Thamar and Al saeeda Universities respectively. While low consumption of protein food (fish 23.6%, and nuts 17.3%)**;** (fish 25.2%, and nuts 16) among male students of Thamar and Al saeeda Universities respectively. The decrease of fish consumption may be due to Length of distance from the coast, and hence the high cost of fish, as well as fish damage, due to lack of good conservation; and lack of awareness about the importance of fish consumption on overall health promotion. The negative association between nuts and consumption it might be related to the limited financial powe .

Eating habits

Meat/Snacks and fruit/vegetable/fiber intake among male Students of Thamar and Al Saeeda University

Average score for meat/snacks intake shows in fig. (1). Meat/Snacks and intake values were significantly making the best low food choices keep up the great work, where values were less than 17 (15.92) for male medical students, and high than 17, were around (21.22, and 22.52) For male students (engineering and computer faculties) of Thamar university respectively. Decreasing consumption between male medical students may be due to the lack of time among medical students that the meat and fish products need time to get them as well as to prepare them. While for male students of Al saedda university (medical, engineering and computer faculties) were (19, 20.94 and 21.32) respectively. Our results showed that moderate intake of meat/snacks pattern may be protective factors to general (BMI) and central obesity (WHR), respectively.

USE OF AN EXOGENOUS ENZYMES AND PROBIOTICS COCKTAIL TO ENHANCE THE GROWTH PERFORMANCE OF RED TILAPIA (*Oreochromis niltoticus* × *O. mossambicus*) AND ELIMINATING THE BACTERIAL COUNT IN ITS EFFLUENTS

H. M. Abdel-Ghany [1], M. El-S. Salem [1], S. Abu-Elkhair [1]

[1]National Institute of Oceanography and Fisheries (Egypt)
E-Mail: heba_elshamy85@yahoo.com

Introduction

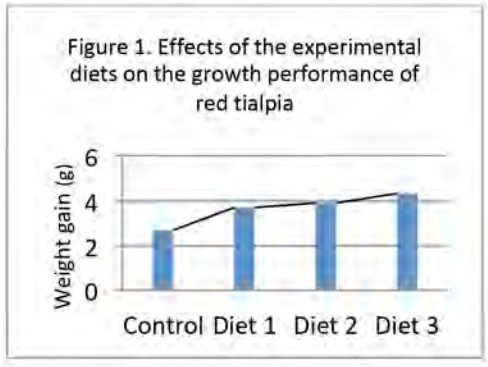
Tilapia (*Oreochromis* sp.) has become one of the most important aquaculture species globally. Artificial diets are the essential feeding source used in tilapia aquaculture. Plant-derived proteins, such as soybean meal are widely used as ingredients in tilapia diets. However, these plant-derived proteins show a low nutrient utilization of by fish which results in low growth performance as well as the pollution of the fish pond environment (Leenhouwer et al., 2007). This limitation in nutrient availability in fish diets is mostly caused by non-starch polysaccharide (NSPs) compounds and/or other anti-nutritional factors in plant-derived proteins (Sinha et al., 2011; Cheng et al., 2013). Therefore, Microbial enzymes are widely used in fish diets to minimize the negative impacts of anti-nutritional factors, thereby improving the nutritive value (Forster *et al.,* 1999), the nutrient utilization (Cheng *et al.,* 2013) and fish growth (Cheng *et al.,* 2013; Saputra *et al.,* 2016). It has been found that the probiotic and multi-enzymes inhibited the pathogenic bacteria (Jiang et al., 2015; Acosta et al., 2016). Therefore, the objective of this study was to evaluate the possible effects of supplementation of an exogenous enzymes and probiotic cocktail on growth performance, feed utilization and the intestinal microbial count of red tilapia (*Oreochromis niloticus* × *O. mossambicus*) and the bacterial count in its effluent

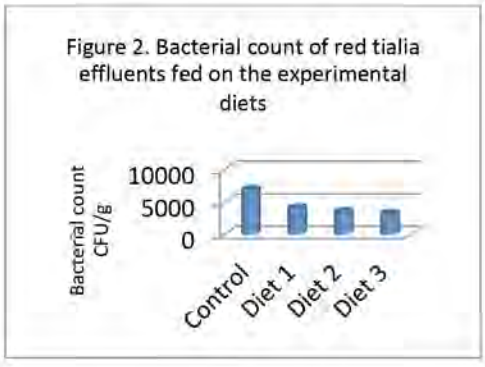
Material and methods

Red Tilapia fry (initial weight 0.35 g) were randomly assigned to four groups. The treatments were performed in triplicate. Four experimental diets were offered to the fish for 60 days. Out of the four diets, three contained the exogenous enzymes and probiotic mixture at various levels of inclusion (1.5 (Diet 2), 2 (Diet 3) or 2.5 (Diet 4) g kg^{-1} diet) and the fourth a control diet was left without any inclusion (Diet 1). The exogenous enzymes and probiotic mixture (Activity/g) is consisted of Cellulase: 1,50,000 CMCU, Arabinase: 2120 U, Beta Galactosidase: 25,000 U, Beta Mannanase: 2,00,000 U, Xylanase: 2,80,000 U, Protease: 7,00800 U, Alpha Amylase: 70,000 U, Lipase: 18,000 U, Phytase: 2500 FTU and Probiotics (CFU/g) (*Lactobacillus acidophilus* 6×109 and *Saccharomyces baulardii* 6×109).

Results

The results demonstrated that red tilapia fed on the exogenous enzymes and probiotic mixture resulted in better growth performance in terms of final body weight (FBW), weight gain (WG) and feed conversion ratio (FCR) compared to the control group ($p < 0.05$) (Figure 1). Fish fed the diets containing the exogenous enzymes and probiotic mixture showed significantly higher whole body protein and lower lipid contents ($p < 0.05$) than the control gtroup. The study demonstrates that test diets supplementation modulated the intestinal bacterial communities in intestines of red tilapia ($p < 0.05$). The inclusion of the exogenous enzymes and probiotic mixture into red tilapia diets minimized the bacterial content of fish tanks effluents $p < 0.05$) (Figure 2).





(Continued on next page)

Discussion

In the present study, the beneficial effects of multi-enzyme and the probiotic mixture on the performance of red tilapia have been indicated. This is explained by the ability of exogenous enzymes including protease, amylase, cellulose and mannase to solubilize various anti-nutrition factors and improve digestibility and growth performance (Cowieson, 2005). In support, it has been found that a multi-enzyme complex improved growth performance such as FBW, FCR and SGR of snakehead (*Channa argus*) (Dai et al., 2019). In Nile tilapia, fish fed a diet containing the xylanase-expressing probiotic, Bacillus amyloliquefaciens, had better growth performance and health status compared to fish fed a control diet (Saputra et al., 2016). The result of intestinal bacterial count showed that the probiotic and multi-enzymes improved the health by inhibiting pathogenic bacteria which is in agreement with Jiang et al. (2015) and Acosta et al. (2016). The causes for such effects may be that mixture of exogenous enzymes changed the environment of the intestine through an alteration of the pH or intestinal substrates caused by enzyme decomposition (Jiang et al., 2015).

In conclusion, inclusion of the exogenous enzymes and probiotic mixture into red tilapia diets has improved the growth performance, feed utilization, intestinal microbial communities and decreased the bacterial count of fish tanks effluents. However, future studies are needed to determine the conditions under which probiotics interact with multi-enzyme mixtures.

Carotenoid pigments cannot be synthesized by animals *de novo* and have exclusively dietary origin. Each species (or genus) adapts to the accumulation of the pigment that is more accessible. At the same time, in the fish organism there are certain biochemical mechanisms that are capable to modify carotenoids obtained from the diet into species-specific ones

Species-specific carotenoids of sturgeons are zeaxanthin, lutein and β-carotene. Under natural conditions, sturgeon fishes consume a significant amount of carotenoids contained in living food organisms. When artificially reared and in the absence of natural feed, the young fish are almost completely deprived of these pigments

Three variants of feeds were studied, in which 2.4, 4.8 and 7.2 mg of β-carotene were injected per kg of feed. As a result of cultivation, it was determined that the growth, survival rate and the level of ω3 and ω6 fatty acids and their ratio depended on the amount of β-carotene. With its greater concentration in the diet, the growth rate of the fry, in contrast to the survival and fatty acid status, increased by 20, 25 and 10% as compared with the control (Fig. 1).

Thus, at the level of β-carotene equal to 2.4 mg/kg of feed, the survival rate increased by 25%, ω3 / ω6 ratio in total lipids and phospholipids increased by 24.4 and 19.4%, respectively, mainly due to 18:3 and 22:6 fatty acids. At the level of β-carotene being 4.8 mg/kg, the differences of these parameters from the control were less significant, namely, 1.0, 1.9 and 6.7%. At the maximum level of β-carotene, the survival rate decreased by 54%, and that of ω3 / ω6 ratio in lipids by 2.8 times.

Having assessed the effect of different concentrations of β-carotene in the diet of young stellate sturgeon, we should say that 2.4 mg per 1 kg of feed is the optimal amount.

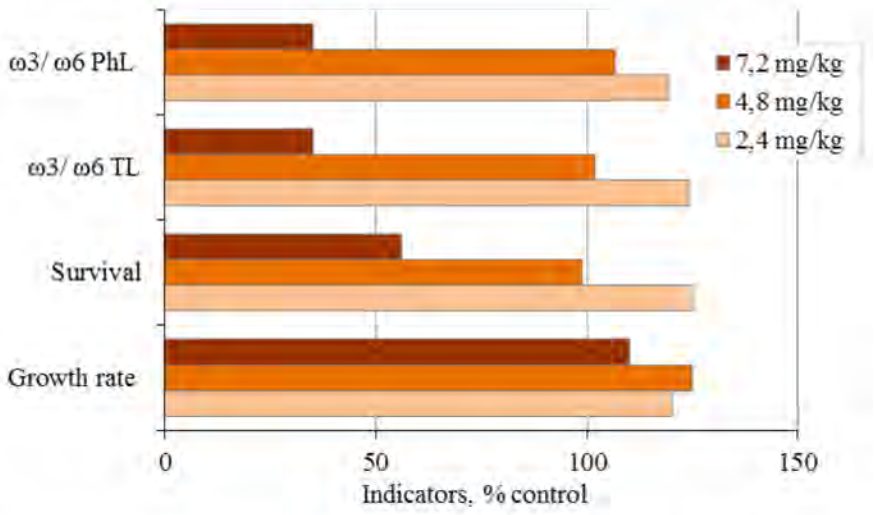

Figure 1: The results of growing young sturgeon consuming feeds with β-carotene:

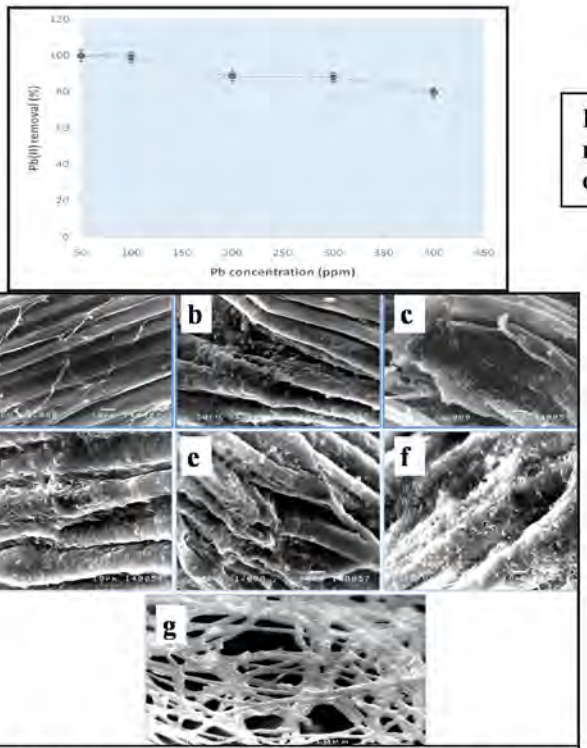
Environment pollution by heavy metals is a global disaster, lead is considered one of the persisting heavy metal pollutants throughout the world due to its continuous anthropogenic generation and non-biodegradability. Its mobilization towards aquaculture escalates its threat due to its introduction to the food chain via aquatic fish and consequently to human beings consuming fish. Removal of heavy metals by conventional methods are not economically and environmental friendly as it produce massive quantity of toxic chemical compounds. Bioremediation and biological treatments especially with filamento s fungi is an alternative methods which have gained an increasing attention for heavy metal removal and recovery due to their upright performances, low cost and huge quantities. This study is a preliminary research for a proposed bioremediation in aquaculture was carried out using 3D macroporous fungal biomat formed of *Trichoderma viride* immobilized on luffah was used for lead removal. The biomate was able to remove up to 79.44% of 400 ppm lead within 24 h and was increased to 89.05% after optimizing temperature and pH. Gamma radiation and NaOH Pre-treatment of the biomat was performed, lead removal increased to 95% within 1 hour of incubation at 30°C and pH 6. FT-IR and SEM spectroscopy indicated some changes in functionality and texture of the immobilized *T. viride* biomat. The re-use of the biomat was efficient for three consecutive cycles and was also used in fixed bed column and showed 89% removal. The biomat is very suitable for use in fixed bed reactors. and may could be used as a biofilter and contribute to water conservation.



SEM images of luffah (a), immobilized luffah biomat (b), immobilized biomat irradiated with 0.01 KGy (c), 0.1 KGy (d), 1 KGy (e), 10 KGy (f), NaOH (g). Magnifications at 1000x.

Introduction

The major carnivorous fish species farmed in Europe have traditionally been fed diets based on fish meal and fish oil (FO). Therefore, the replacement of FO with vegetable oils (VO) in aquafeeds is a viable alternative for the sustainability of the aquaculture industry. The poor ability of marine fish to convert C_{18} polyunsaturated fatty acids (PUFA) to long chain PUFA (LC-PUFA) such as 20:4n-6 (ARA), 20:5n-3 (EPA) and 22:6n-3 (DHA), together with the fatty acid profile of VOs, lead to important changes in the fatty acid composition of flesh of fish fed VOs, and therefore in its nutritional value, which include decreased n-3 LC-PUFA and increased total fat and linoleic acid (18:2n-6, LA) contents. For these reasons, replacement of dietary FO must be approached with caution. In this sense, the *Echium* genus (*Boraginaceae*) seed oils, *Echium* oil, has an interesting fatty acid profile with a good n-3/n-6 PUFA balance and a high content of unusual fatty acids, (stearidonic acid, SDA and γ-linolenic acid, GLA) that have competitive and inhibitory effects in the production of proinflammatory eicosanoids derived from ARA. Enterocytes and hepatocytes play critical roles en lipid metabolism including uptake, oxidation, conversion of fatty acids and the supply of LC-PUFA to the other tissues. Therefore, the aim of this study is to evaluate the effects of 50% substitution of dietary FO by *Echium* oil.

Materials and methods

Sea bass juveniles with an initial body weight of around 150 g were distributed into 9 tanks. Three of them were fed a commercial diet (CD), containing FO, during the whole experiment, 7 months. The other six ones were fed an experimental diet (ED) with 50% FO and 50% VO, during 4 months, that was the time in which VO composition was reflected in the muscle. Thereafter, three of these tanks continued receiving the experimental diet (7 months in total) while the other three turned back to the commercial diet (experimental-commercial diet, ECD) to the end of the experimental period. Fish were fed *ad libitum*, reared under constantly flowing seawater, and natural photoperiod at 19–19.5 °C. At the end of the experiment, the individuals were slaughtered by a sharp blow to the head, individually measured and weighed. Samples of blood, muscle and several tissues were taken for biochemical analysis. In addition, samples of intestine and liver were collected to isolate enterocytes and hepatocytes respectively. Part of both cellular suspensions were incubated with ^{14}C radiolabelled fatty acids to perform fatty acid metabolic studies, and the other were used to carry out the control lipid profile studies. The entire experiment was conducted in accordance with the Spanish law in BOtE 8th April 2013 for protection of experimental animals.

Results

The metabolic studies using radiolabelled fatty acids indicated that although desaturase delta 6 activity is present it is not directly implicated in EPA conversion to DHA, but in the conversion of 18:2n-6 to 18:3n-6 and of 18:3n-3 to 18:4n-3. Elongation activity was evident for several substrates and no delta 5 activity was detected.

After 7 months of experiment the control fatty acid profile of enterocytes and hepatocytes were analyzed and no significant differences in DHA, n-3 LC-PUFA levels and n-3/n-6 index were found between the 3 treatments. The lipid classes profile of control cells was also analized and there were not significant differences in total polar lipids, although there was an increase in triglycerides in ED fish group

Discussion and conclusions

Although the DHA level in the experimental diet was half that of the commercial diet, and there is no DHA production from EPA, it seems that the *Echium* diet has induced a selective retention of DHA. Our present results suggest that the balanced n-6/n-3 composition of *Echium* oil provides a compensatory effect on the fatty acid metabolism and tissue deposition similarly to that reported for *Sparus aurata* by our group (Díaz-López et al., 2009; 2010).

(Continued on next page)

The balanced composition of *Echium plantagineum* oil not only did not affect the DHA levels in sea bass but enhanced some parameters of interest like polar lipids and LC-PUFA after returning to the control marine based diet. *Echium* oil might be considered as a more sustainable alternative to other VO in animal diets, providing a health prometing profile for human consumption.

EPIGENETIC EFFECTS OF DIETARY MICRONUTRIENTS IN ATLANTIC SALMON (*Salmo salar*) MUSCLE

A.C. Adam*, M. Espe, T. Saito, P. Whatmore, J.M.O. Fernandes and K.H. Skjaerven

Institute of Marine Research, P. O. Box 1870 Nordnes, 5817 Bergen (Norway)
E-mail: Anne-Catrin.Adam@hi.no

Introduction

Increased dietary levels of plant proteins and oils have been shown to alter the metabolism of amino acids and micronutrients such as folate, vitamin B12 and B6, all of which are important one-carbon (1C) metabolism nutrients. Negative effects of such dietary changes were observed on growth performance and flesh quality in farmed Atlantic salmon (Morkore and Rorvik, 2001; Larsson et al., 2014; Hemre et al., 2016). This study explores how dietary micronutrients affect nutrient-responsive mechanisms in fast muscle of Atlantic salmon using a multi-omics approach. A better understanding of the underlying nutrient-responsive mechanisms, which are of molecular and epigenetic nature, can help to explain phenotypic changes to muscle. DNA methylation regulates mRNA expression, and thereby controls metabolism, which is one underlying mechanistic explanation for nutritional programming. Previous results showed that gene expression patterns and epigenetic regulation in fish are highly sensitive to nutrient levels (Skjaerven et al., 2018). Epigenetic changes in early life stages, or as early impact in pre-smolts, can program life-long consequences on physiology, robustness and growth. The results from this study will provide documentation that has potential to customize feed composition to improve healthy growth and maintain good filet quality through nutrition

Material and methods

Two experimental diets provided by Skretting ARC (Stavanger, Norway) were fed to Atlantic salmon 6 weeks prior to smoltification until 3 months after saltwater transfer in triplicate tanks. Diet A and diet B contained different levels of methionine (6.7 and 9.5 g/kg diet), folate (2.6 and 4.8 mg/kg diet), vitamin B12 (0.15 and 0.18 mg/kg diet) and vitamin B6 (6.75 and 9.31 mg/kg diet), respectively. Diet A includes 1C-nutrients at the requirement level (NRC, 2011) and diet B a surplus of 1C-nutrients to support maximal performance, as determined by others (Espe et al., 2014; Hemre et al., 2016). The main protein sources in the diets were soy protein (24%) and pea protein (15%) concentrates, and the diets included smaller amounts of fishmeal (12%) and krill meal (2%). Lipid source was a mixture of rapeseed (8.1%) and fish oil (12.6%). Muscle from pre- and post-smolts (five individuals per tank, n=3) were analyzed for free amino acids, folate, vitamin B12 and B6, and were sent to global metabolic profiling (n=3). RNA and DNA extracted from the same muscle samples (n=9) was used for RNA-sequencing (RNA-seq) and Reduced Representation Bisulfite Sequencing (RRBS) analysis, respectively.

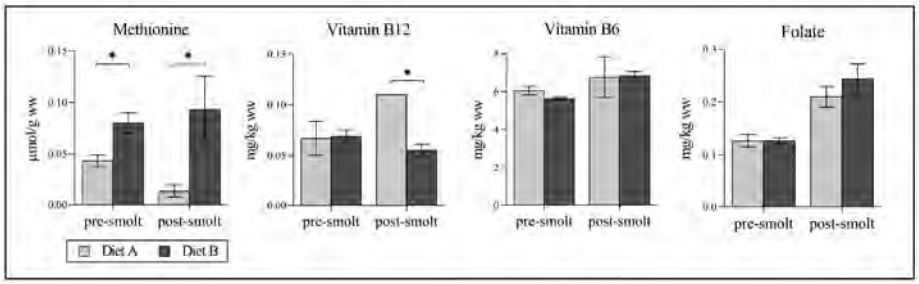

Fig. 1. Methionine, vitamin B12, vitamin B6 and folate levels (mean±SD) in fast muscle of pre- and post-smolt Atlantic salmon fed either diet A (n=3) or diet B (n=3). Asterisk indicates statistical significance using Welch's t-test for significance testing ($p<0.05$, unpublished data).

(Continued on next page)

Results

Preliminary results showed that salmon fed diet A and diet B grew from a mean body weight (±SEM) of 31.6±0.8 g and 32.2±0.5 g during the freshwater period to a final body weight of 462.5±19.2 g and 539.2±8.5 g after saltwater transfer, respectively. There were no differences in growth performance during the freshwater period, but fish fed diet B had better growth at the end of the saltwater period than fish fed diet A ($p=0.01$). Hepatosomatic index was higher in fish fed diet A (1.64±0.08) compared to fish fed diet B (1.32±0.04) during the saltwater period, but not different in the freshwater period. Feed conversion ratio and protein utilization were not different during either the freshwater or the saltwater period. Unpublished results show that higher methionine levels given with diet B increased methionine in both pre-smolt ($p=0.01$) and post-smolt muscle ($p=0.04$) when comparing with diet A (figur 1). No differences were found in folate and vitamin B6 levels in muscle during the freshwater and saltwater period. Vitamin B12 levels were the same in pre-smolt muscles, but lower in muscle of post-smolts fed diet B compared to diet A ($p=0.003$). Comparing metabolites from a global metabolic profiling of the muscle samples, most of the differences were between pre- and post-smolt than between dietary groups. Most differences between muscles from fish fed either diet A or diet B were found in the amino acid profiles. Differences between pre- and post-smolts relate to amino acids, ether lipids, unsaturated fatty acids, mono- and polyunsaturated fatty acids. Key results from metabolic, gene expression (RNA-seq, in progress) and DNA methylation profiling (RRBS, in progress) will be presented.

Discussion and conclusion

There is limited research on requirement levels for 1C-nutrients for farmed Atlantic salmon especially during periods of extensive growth and development. Diets containing 1C-nutrient levels as for diet B are recommended as they resulted in best performance during smoltification and on-growing saltwater period. Following a multi-omics approach, correlation of metabolic, gene expression and DNA methylation profiles will reveal how nutrient-responsive epigenetic mechanisms can explain how diet affects muscle growth. The knowledge obtained through this study contributes to further development of innovative methods for nutritional programming of better fish health

Introduction

Common carp aquaculture is affected by several viral disease caused by infections with cyprinid herpesvirus 3 (CyHV-3), carp edema virus (CEV) and spring viremia of carp virus (SVCV). Especially the koi herpesvirus disease (KHVD) caused by CyHV-3 and koi sleepy disease (KSD) caused by CEV can lead to extremely high losses of common carp in all age categories. However, common carp strains with a different genetic background present diverse susceptibility to some pathogens and this fact could be utilise for development strain with broad resistance to virus infections. Here we present results from first comprehensive evaluation of viral disease resistance of common carp strains and first steps for development of strains with resistance to multiple viral diseases.

Materials and Methods

Common carp strains Amur wild carp (AS), Ropsha scale carp (Rop) Prerov scale carp (PS) and koi were tested for susceptibility to CyHV-3, CEV and SVCV using bath or cohabitation infection models. Furthermore, the virus load, speed of spreading and magnitude of type I interferon responses as a first line of cellular defences against viral infection were measured in skin, gills, head and trunk kidney using RT-qPCR. New crosses were developed based on the results from infection experiments and the survival of F2 generation was measured in experimental ponds.

Results

An infection experiment confirmed significant differences in mortality and virus load during CyHV-3 infection where Rop and AS (mortality of 22% and 47%) were performing better than PS and koi (mortality of 65% and 90%). When the susceptibility to a CEV infection and the development clinical of KSD were investigated, Amur wild carp were more resistant to the infection and did not develop clinical signs for KSD while in koi mortality reached 100%. An infection with SVCV induced low (22%) mortality in PS, while Rop (with 0% mortality) was the most resistant. The evaluation of the viral loads and replication showed significant differences which correlated with mortality. The magnitude of the type I IFN response was not a good marker of resistance because it was positively correlated with virus load.

Discussion and Conclusion

Based on the results resistance results 3 crosses were developed using Rop, AS and highly productive Zator strain. The three new Rop_Z, AS_Z and Rop_AS_Z crosses should provide the resistance to CyHV-3 and SVCV, CEV and all three respectively. The crosses showed higher survival in experimental ponds in the first year of productions, showing that the challenges caused by viral diseases could be addressed by selective breeding. Further infection experiments will follow to measure the disease resistance of the novel crosses.

WIDE DISTRIBUTION OF CARP EDEMA VIRUS IN EUROPE IS CONFIRMED BY RECENT DETECTIONS IN HUNGARY, CROATIA, SERBIA AND LITHUANIA

Introduction
Koi sleepy disease (KSD) caused by carp edema virus (CEV) infection is considered an emerging disease in certain regions of the world. Especially in Europe the virus was detected only in recent years. However, after its initial detection in UK it came more into focus of diagnostic laboratories, which was followed by multiple detections. Based on this we hypothesise that both CEV and KSD have existed in the European common carp aquaculture since long time. However, due to a particular set of circumstances characteristic for CEV/KSD like: Less dramatic clinical presentation, the season of occurrence, similarity of clinical signs to koi herpesvirus disease (KHVD) or intoxication with ammonia and no ability to detect the virus by cell culturing, it was not detected.

Materials and Methods
A result which could support this hypothesis would be a wide geographical distribution of the virus in main carp producing countries and in countries with a limited carp production. Therefore, samples were collected in Hungary, Serbia, Croatia and Lithuania in 2015-2018 and screened for the presence of CEV DNA with quantitative PCR. DNA sequences of the ORF encoding for P4a core protein of the virus were used for phylogenetic analyses.

Results
Prevalence of CEV in Hungary, one of the largest European common carp producers, was the highest with 76% (13 CEV positive out of 17 locations screened). In contrast, the prevalence in countries with smaller crap production was lower: 14% prevalence was recoded in Croatia where 6 out of 44 locations were CEV positive, 30% prevalence was recorded in Lithuania (6 CEV positive locations out of 20 checked). In Serbia fish with clear signs of clinical KSD from only two farms were sampled and both locations were confirmed to be CEV positive. Phylogenetic analyses indicated the majority of the viral sequences belonged to the genogroup I which is the most common in European aquaculture; however, several Hungarian and Lithuanian sequences were clustering within genogroup IIb. Furthermore, in some cases the detected virus isolates are distributed in geographically related locations. For instance, the same virus sequence was found in neighbouring regions of Hungary and Serbia.

Discussion and Conclusion
Our findings indicate that CEV (especially from genogroup I) is widely spread in the European carp aquaculture. This could indicate that rather than being an emerging pathogen this virus was previously overlooked or misdiagnosed. Therefore, KSD should be considered in whole Europe when investigating disease outbreaks in common carp at temperatures below the optimum for KHVD.

USE OF ZEBRAFISH MODEL IN STUDIES OF VIRAL INFECTIONS AFFECTING CULTURED FISH SPECIES

Introduction
Zebrafish (*Danio rerio*) is becoming an interesting model for studying immune responses to viral pathogens thanks to significant biotechnological progress in genetics, plethora of available molecular tools, and mutants. The approach using zebrafish model could bring a significant progress in studying the diseases in farmed fish. Here *in vitro* and *in vivo* studies were performed in the search for new viral models which would help explore antiviral responses and immune functions of novel C-type lectin receptors (CTLR) in zebrafish

Materials and Methods
Initially zebrafish derived ZF4 and SJD.1 cells were tested for susceptibility to several fish pathogenic viruses including *cyprinid herpesvirus 1* and *3* (CyHV-1 and CyHV-3), carp edema virus (CEV), *chum salmon reovirus* (CSV), common carp paramyxovirus (CCPV), common carp orthomyxovirus (CCOV), and common carp birnavirus (CCBV). As positive control *spring viremia of carp virus* (SVCV) was used. Antiviral responses based on *vig-1* and *mxa* gene expression were measured by RT-qPCR. Based on the *in vitro* results, CyHV-3, CSV and SVCV were selected for testing *in vivo*. The infections were performed by intraperitoneal injection of the virus into adult zebrafish and by immersion of larvae in virus suspensions. Furthermore, several putative CTLR genes were located in the zebrafish genome, molecularly cloned and analysed for structural transmembrane classification.

Results
In vitro studies demonstrated that SVCV, CSV, CyHV-1 and CyHV-3 but not CEV, CCPV, CCOV and CCBV were able to replicate in the zebrafish cell lines ZF4 and SJD.1. *In vivo* studies showed that both CSV and CyHV-3 induce an up-regulation of *vig-1* and *mxa* expression in kidney and spleen of adult zebrafish after i.p. injection but not in larvae after infection by immersion. SVCV infection was the strongest inducer of an antiviral response. When mRNA expression of the two putative CTLR encoding genes *up463* and *up690* (likely homologues of mammalian MINCLE and SIGNR3) was measured, a strong down-regulation was noticed in adult fish under infection

Discussion and Conclusion
The presented results give a good basis for further functional studies of host pathogen interactions during devastation diseases (like koi herpesvirus disease caused by CyHV-3) affecting finfis aquaculture. Further studies on CTLR will include *in vitro* studies on the binding of bacterial and viral pathogens to recombinant proteins and further *in vivo* studies in which up463 and up690 CRISPR-Cas knockout zebrafish embryos will be infected with various viral or bacterial pathogens.

BYSTANDERS RATHER THAN KILLERS? – WHAT CAN BE LEARNED FROM THE CASES OF PRV-1 IN ATLANTIC SALMON AND PRV-3 IN RAINBOW AND BROWN TROUT IN GERMANY?

Introduction
Piscine orthoreoviruses (PRVs) are emerging viral pathogens responsible for circulatory disorders in salmonids including heart and skeletal muscle inflammation (HSMI). German aquaculture, with a substantial production of rainbow trout and conservation programs for Atlantic salmon and brown trout in several river systems, is potentially vulnerable to the impact caused by these viruses. Furthermore, German brown trout populations are declining due to the proliferative darkening syndrome (PDS), a lethal disease of unknown etiology affecting this fish in the rhithral region of alpine Bavarian limestone rivers.

Materials and Methods
Heart, kidney and spleen samples were collected from fish from two German farms breeding Atlantic salmon or rainbow trout, experiencing in 2017 some health problems leading to accumulated mortalities of 10% and 20%. Furthermore, archival samples from exposure studies performed in 2008 and 2009, in which brown trout developed PDS, were used. The samples were tested for the presence of PRV RNA with PCR based methods, PDS samples from 2009 were additionally screened in a next-generation RNA sequencing pipeline for pathogen detection.

Results
PCR examination indicated a PRV-1 infection in the Atlantic salmon and a PRV-3 infection in rainbow trout. Further analyses indicated also the presence of *Aeromonas salmonicida* in internal tissues of both species. While PRV-1 was likely the causative agent of the disease in Atlantic salmon, most of the rainbow trout suffered from a systemic infection with *A. salmonicida* and not from PRV-3. Interestingly, PRV-3 RNA was also detected in several organs of the PDS-affected brown trout in 2008 but not in 2009. However, similar virus loads were measured in control fish from 2008, which were not exposed to river water presumably holding the PDS-inducing pathogen and which did not show any signs of the disease.

Discussion and Conclusion
The results from Germany confirm a wide geographical distribution of both PRV-1 and PRV-3 in Atlantic salmon and rainbow trout also in continental Europe. However, a clear association with disease was hampered by the presence of an *A. salmonicida* co-infection. Furthermore, PRV-3 is present in German brown trout populations but is not the causative agent of PDS. Nevertheless, potential diseases induced by PRVs should be considered when investigating mortalities in salmonids.

DEVELOPMENT OF IMPROVED *IN VITRO* SYSTEM FOR TILAPIA LAKE VIRUS REPLICATION

Introduction

Infections of Nile tilapia with tilapia lake virus (TiLV) cause an emerging disease threatening the production of this fish and food security in several large developing countries. The virus is already present on three continents (Asia, African and South America), thus coordinated effort has to be taken to limit its impact and spreading. We identified several challenges in working with TiLV: 1) the lack of widely available tilapia cell lines, 2) scarcity of molecular tools for currently used E-11 cells for routine TiLV work, originating from snakehead. Therefore, in a first line of studies we explored possibilities of repurposing some cyprinid or salmonid cell lines, and the development of a tilapia based *in vitro* culture system for TiLV studies.

Materials and Methods

Precision cut slices cultures (PCSC) from tilapia brain, gills and liver were used *in vitro*. Furthermore, attempts to raise the cell line form tilapia scales or fins were made. The susceptibility of several cell lines to TiLV (Thai isolate) was measured using: RTG-2, RTgill-W1 (rainbow trout), KFC (common carp) and ZF4 (zebrafish) and compared to the E-11 reference. Susceptibility was measured by observation of CPE, estimation of viral particles produced by the cells and presence of viral RNA in the cells with $TCID_{50}$ and RT-qPCR.

Results

Over eight days culturing periods gill and brain PCSCs were replicating the virus better that liver cultures, they produced more viral particles released to the culture medium, had also higher virus RNA level in the cells. Interestingly, both rainbow trout cell lines were replicating the virus at similar levels as E-11 cells despite their cultivation at suboptimal temperature of 25°C. Also, zebrafish cells were able to replicate the virus although at much lower level, while common carp cells were nonpermissive for TiLV.

Discussion and Conclusion

The use of PCSC will allow monitoring type I IFN responses in tissues susceptible to TiLV, while the use of rainbow trout cells will allow to measure the vulnerability of the virus to type I IFN responses by using recombinant IFN and poly I:C stimulation. Furthermore, lipid raft dependence of viral entry and its blockage by 25-hydroxycholesterol will be studied.

CHOOSING THE BEST LOCATIONS FOR SALMON AQUACULTURE SITES: INSIGHTS FROM BIOPHYSICAL MODELS AND THE MOVE TO MORE EXPOSED SITES

Thomas Adams*, Dmitry Aleynik, Andrew Dale, Max Holloway, Keith Davidson

Scottish Association for Marine Science, Scottish Marine Institute, Oban, Argyll, PA37 1QA
Email: tom.adams@sams.ac.uk

Introduction

Industry targets for global aquaculture demand an increase in output over the next decade. Salmon farm operators seek to meet this need either by establishment of new sites, or by the expansion of existing sites. However, finding space for new sites can be challenging. The OFF-AQUA project (https://www.sams.ac.uk/science/projects/off-aqua/) is investigating a range of issues associated with moving salmon production sites to more exposed locations in Scottish waters, including physical, ecological, economic and fish welfare issues. A particular environmental challenge in salmon aquaculture is posed by parasitic sea lice. Enhanced availability of host fish at farms can allow lice to reach much greater numbers than they would naturally. It is hypothesised that more exposed locations will experience lower lice abundances. However, this must be weighed against increased physical exposure. We used biophysical models to make a comparison between sites covering a range of exposure levels. We show how outputs can be used by industry, regulators and other stakeholders to help to guide management of new (and indeed existing) sites.

Methods

A meteorological-hydrodynamic model covering the west coast of Scotland was developed (Aleynik et al. 2016, 2018), based on directly coupled unstructured mesh ocean (FVCOM; Chen et al. 2013) and atmospheric (WRF; Skamarock et al. 2008) models. This has been run operationally since 2013. In 2019, the domain was expanded to incorporate more exposed environments. Development also began on local fine-scale models of study sites. A biological particle tracking model (Adams et al. 2016) was used to simulate the spread of "sea lice" larvae from three focal fish farm sites, covering sheltered fjordic through to exposed open environments. Simulations covered a representative range of tide and weather conditions, which dominate local flow patterns (Edwards 2016).

Results

A range of metrics including dispersal patterns, kernels and between-site connectivity allowed characterisation of the proposed sites in the context of their surroundings (Figure 2). Sheltered sites are typically more connected to other sites and have higher "self-infection" rates. While such sites provide the most amenable conditions for operating, some more exposed sites also provided suitable conditions for farming fish

Discussion and conclusion

A range of factors must be taken into account when selecting the most sustainable approach to industry expansion, and choosing sites upon which to focus. Physical conditions at more exposed sites generally lie within the range suitable for fish, but can pose operational difficulties for site managers. More exposed sites offer an opportunity to reduce environmental impacts in terms of sea lice connectivity, with an associated reduction in outbreak frequency and risk to wild fish. They may also offer increased dispersion of excess organic material.

Introduction

Arthrospira platensis (*Spirulina sp.*) is a multicellular filamen ous planktonic cyano- bacterium with a long history of human use. Recently, it has gained a lot of attention as a nutritional supplement and food additive due to its high protein content of around 60% and several other reported health benefits (Pan-utai and Iamtham, 2019). Moreover, it can also be used as a complementary ingredient in aquaculture feeds (Usharani et al., 2012). *Spirulina* is commercially cultivated in large outdoor raceway ponds. However, the outdoor ponds are subjected to variable, daily fluctuations in water temperature and sunlight intensity, which in turn are affected by geographic location, season, and pond management strategy (Hidasi and Belay, 2018). Constant temperature, high alkaline conditions and light intensity are the main determinants of biomass production of *Spirulina* (Torzillo et al., 1991). For these reasons, a wide variety of photobioreactors (PBR) has been designed and developed (Huang et al. 2017). The main advantages of this solution instead of open ponds were a higher photosynthetic efficienc , higher concentrations and areal productivities, low contamination, the prevention of water loss caused by evaporation, and a precisely controlled environment. Although the variety of this novel solution, in the case of *Spirulina* remain the problem to maintain the strain at the optimal temperature (35°C), which represents a consistent operating cost.

We report here on the development and testing of a new photobioreactor which used geothermal water from a coal mine to heat the medium for *Arthrospira platensis*. The specific objectives were to design and build the photobioreactor, to evaluate its hydrodynamics and evaluate the growth and productivity of one strain of *Spirulina*.

Materials and methods

The photobioreactor was designed and constructed based on the shape proposed by Bahadur et al. (2013). It is composed by a tubular circuit in Boro-silicate glass. The current design (Patent n. IT 102019000001449) had a volume of 55 L. The temperature is maintained by a continuous heat exchange guaranteed through a coaxial Teflon (R) corrugated tube where geothermal waters circulate. Geothermal waters (40-42 °C) were pumped for underground safety reason, from the Seruci-Nuraxi Figus Coal Mine (Sardinia, Italy), which was recently dismissed. The circulation of the microalgae culture takes place with "air lift" technology. The system is monitored and controlled by a Programmable Logic Controller (PLC) for the temperature and pH control. The pH is regulated through CO_2 insufflation with an electronic valve controlled by the PLC. Actual gas induced liquid circulation velocity was determined using tracer analysis by inserting a colored piece of cotton fiber cloth in the photobioreactor and measuring the time needed to complete a predefined distance (Bahadur et al., 2013). *A. platensis* (M2M strain) was obtained from the National Research Council of Italy (CNR, Florence, Italy) and was grown

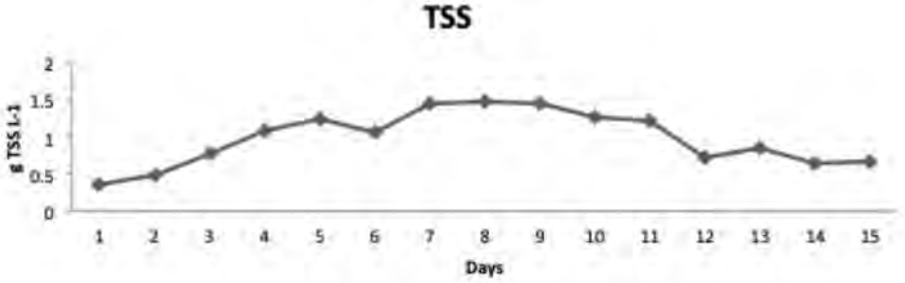

Fig. 1. Biomass algal concentration measured as g L^{-1} for *A. platensis* during 15 days of experiment.

(Continued on next page)

in Zarrouk medium. The growth was sustained in the semi-batch mode with daily monitoring of temperature, pH, spiral structure under microscope and biomass concentration. The biomass concentration was measured as dry weight biomass in terms of Total Suspended Solids (TSS) (Clasceri et al., 1999). The experiment started in March 2019 and lasted 15 days.

Results

The PBR was designed between September and November 2018 and completely built in December 2018. The liquid circulation velocity test was carried out in January 2019 resulting in a max speed of 0.5 m/s. Preliminary results of TSS showed an average value (± standard deviation) of 1.0 ± 0.3 g L^{-1} during the 15 days of experiment (figure 1). Average biomass production in the photobioreactor was 14.2 g m^{-2}/day. Changes in the spiral structure of *A. platensis* have not been observed during the experiment. The maximum temperature reached by the culture was 34 °C and the minimum was 25 °C. The average pH value (± standard deviation) was 10 ± 1.8.

Discussion and conclusion

The preliminary results obtained indicate that this photobioreactor was suitable for the cultivation of *A. platensis* maintaining good liquid velocity as well as favorable pH and a temperature higher than 25 °C. The value of biomass production was promising considering that the outdoor temperatures during the trial ranged from 5 to15 °C. Further research with different strains and modified culture medium will be conducted to assess the performance of the PBR in the di ferent seasons.

Introduction
The use of antibiotics in aquaculture is under serious scrutiny and regulation to avoid deleterious consequences of development of antibiotic-resistant pathogen and residues in fish meant for human consumption (FAO, 2011; Gent et al., 2012). Utilization of herbal products as natural alternatives to synthetic antibiotics has shown great potentials. There is paucity of information on the use of *Latuca virosa* in fish production. Therefore this study was conducted to investigate the effects *L. virosa* leaf ethanol extract on the growth performance of *Clarias gariepinus*.

Materials and methods
Fresh leaves of *Latuca virosa* were air-dried at room temperature, ground into meal and the ethanol crude extract was obtained at 1:10w/v and concentrated. Preliminary analysis on the phytochemical components of the extract was investigated qualitatively (Sofowora, 1993). Feeding trial was conducted with 300 *C. gariepinus* fingerlings in triplicates in an indoor static renewal system. The fish were fed diets fortified with 0, 2.5, 5.0, 7.5 and 10ml/kg diets at 3% body weight daily for 84 days. Mortality number and fish body weight were recorded at intervals. Weight Gain (WG), Feed Conversion Ratio (FCR) and Protein Efficiency Ratio (PER) and survival were calculated. Blood samples were obtained from the fish through the caudal vein and analyzed following standard procedures. Data were analyzed using one way analysis of variance at $P = 0.05$.

Results
The phytochemical analysis showed that *L. virosa* contained flavonoids, saponins and terpenoids. The *C. gariepinus* fed diets fortified with 2.5 - 10ml extract/kg diets had significantly higher ($P<0.05$) WG and PER than the fish fed with the control diet (Table I). Fish fed diets containing 2.5 - 10mL extract showed significantly lower FCR and survival than fish fed other diets.

The differences in the red blood cells and globulin were not significant. However, the heterophil values differed significantly ($P<0.05$) with the highest value obtained at 7.5ml/kg diet.

Discussion and conclusion
Fortification of *C. gariepinus* diets with 5 - 10ml extract of *Latuca virosa* enhanced growth performance and nutrient utilization. The improved growth performance and nutrient utilization observed in this study could be attributed to presence of phytochemical (flavonoid, saponin, terpenoids) present in the wild lettuce leaf. The phytochemicals have proven to promote secretion of digestive enzymes, feed digestibility and nutrient utilization leading to increased growth performance of fish (El-Dakar et al., 2015; Adeniyi et al., 2018) as observed in this study.

Blood parameters are significant for evaluation of physiological status of fish in response to diets or other stressor (Fagbenro et al., 2013). The insignificant differences observed on red blood cell counts in the present study is similar to Dada and Olaoye (2015) while contrary observations were reported on heterophil (Pakravan et al., 2011) and globulin (Bahrami et al., 2015) of fish fed diets fortified with herbal extracts. Utilization of *Latuca virosa* extracts at 5.0ml/kg diet is therefore recommended for production of *Clarias gariepinus*.

THE FISHES OF AKOMOJE RESERVOIR DRAINAGE BASIN IN LOWER RIVER OGUN, NIGERIA: DIVERSITY AND ABUNDANCE

F.I. Adeosun

Department of Aquaculture and Fisheries Management, Federal University of Agriculture, Abeokuta, PMB 2240, Ogun State, Nigeria
+2348038057564

Introduction

The freshwater ecosystem, though highly populated and with rich plant and animal diversity, may be the world ecosystem in greatest danger of extinction of its fish populations. Major causes of threats to global freshwater plant and animal life are overexploitation, water pollution, flow modification, destruction or degradation of habitat, and invasion by exotic species (Dudgeon *et al*., 2006).

Materials and methods

The fishes of Akomoje reservoir drainage basin in Lower River Ogun, Nigeria were studied from June to November, 2017. Fish species composition, abundance, and diversity were investigated bi-monthly. Water quality parameters were also collected and measured *in-situ* and *ex-situ* using standard methods and kit.

Table ii: Abundance and weight of fish species in Akomoje reservoir drainage system

Fish species	TOTAL		Relative Percentage (%)	
	Abundance	Wt(kg)	Abundance	Weight
Clarias gariepinus	56	14.3	5.53	21.25
Chrysichtys nigrodigitatus	610	26.5	60.28	39.38
Tilapia zilli	113	5.8	11.17	8.62
Synodontis budgetti	11	2.5	1.09	3.72
Heterotis niloticus	8	5.2	0.79	7.73
Chrysichtys auratus	51	5.4	5.04	8.02
Synodontis schall	8	0.4	0.79	0.59
Synodontis batensoda	11	0.4	1.09	0.59
Schilbe mystus	6	0.5	0.59	0.74
Oreochromis niloticus	62	2.5	6.12	3.72
Malapterurus electricus	32	0.7	3.16	1.04
Mormyrus rume	11	1.0	1.09	1.49
Parachanna obscura	15	1.2	1.48	1.78
Tilapia mariae	18	0.9	1.78	1.34
Total	**1012**	**67.3**	**100**	**100**

Table iv: Diversity indices of fish species in Akomoje Reservoir drainage system, Nigeria

Diversity index	Values
Number of species (S)	14
Total number of individual species (N)	1012
Simpson's index (D) = Σn (n-1) / N(N-1)	0.39
Simpson index of diversity (1-D)	0.61
Simpson's reciprocal index = (1/D)	2.56
Shannon Diversity index (H) = Σpi ln pi	-1.5749
Shannon's Equitability or Evenness (E_H) = H/1nS	-0.5968

(Continued on next page)

Results

1012 fish species comprising of 14 fish species from 9 families were identified. Bagrids were the most abundant fish family in the reservoir basin and *Chrysichtys nigrodigitatus* was the most dominant species contributing 60.28 % and *Schilbe mystus* was the least abundant species by number (0.59%) and weight (0.74%) (Table ii). In terms of occurrence, common species are *C. nigroditatus*, *T. zilli, O. niloticus, C. gariepinus, C. auratus* and *Malapterurus electricus* representing 91.3% while occasional and rare species represented 6.53% and 2.17% of the fish population. Diversity indices estimates were Simpson's Index (D) = 0.39, Simpson's Index of diversity (1-D) = 0.61, Simpson's Reciprocal Index (1/D) = 2.56, Shannon-Diversity Index (H) = -1.5749, Shannon's equitability (EH) or Evenness (E) of = -0.5968 (Table iv). Results of physical and chemical parameters measured were air temperature (29.23±1.27), water temperature (26.9±0.37^{0}C), dissolved oxygen (6.12±0.70mg/l), and pH (7.6±0.39). There was no significant difference ($p > 0.05$) in temperature, BOD and phosphorus all though the study period. Negative correlation was determined between water quality parameters and between water quality parameters and fish abundance.

Discussion and Conclusion

The fish families and species identified from this water body during the study revealed a decline in the fish assemblage of this water body as there was differences when compared to the findings of Adeosun *et al*. (2012) who recorded thirty-two species from thirteen families from this same water body. Negative correlation obtained between some water quality parameters indicated that increase in one parameter, will result to corresponding decrease in another. Of importance, the high negative correlation between water temperature and pH of the study area indicated that any increase in the water temperature or pH will cause a decrease in either one. The study concluded that the water quality parameters of the study location measured were still within tolerable range for fish survival, however, with the negative correlation obtained between fish abundance and water quality parameters, human activities around this river should be monitored to prevent pollution of the water body. Finally, the fish population of this river basin has been well depleted and thus more attention should be paid to the resource to prevent extinction of important fish species

Introduction

Yeast (*Saccharomyces cerevisiae*) is a unicellular organism used as bioactive and functional feed ingredient with potential to enhance growth performance, health and immunity of aquaculture species (Shurson *et al*, 2018). Dietary supplementation of yeast and yeast products (autolysed yeast inclusive) could enable aquaculture species cope with stress that accompany intensification of aquaculture operations due to suboptimal environmental conditions resulting from overcrowding and overfeeding. To this end, this study was carried out to evaluate the effect of dietary supplementation of autolysed brewer's yeast (Leiber CeFi® Pro) on African catfish *Clarias gariepinus*) growth, health and intestinal morphology.

Materials and Methods

Four iso-nitrogenous and iso-lipidic diets were formulated as Control (containing 0% Leiber CeFi® Pro), 0.3% AY (containing 0.3% Leiber CeFi® Pro), 0.6% AY (containing 0.6% Leiber CeFi® Pro) and 1% AY (containing 1% Leiber CeFi® Pro) diets. The feed ingredients were thoroughly mixed, moistened (200 mL kg^{-1}) and then cold-press extruded to produce 2mm sinking pellets. The diets were oven dried (at 60 ^{o}C) and the proximate composition analysed using AOAC protocols. Three hundred African catfish (*C. gariepinus*) of 22.5±1.15 g fis $^{-1}$ were randomly distributed (20 fish per tank, n = 3 per treatment) into a freshwater flow-through aquaculture system containing 12 tanks (of 33 L capacity each) after two weeks of acclimatization with the control diet (containing 0% Leiber CeFi® Pro). The photoperiod and water temperature (29±0.29 ^{o}C) were maintained at ambient condition and other important water quality parameters were monitored (pH, 6.85±0.34; dissolved oxygen, >5 mg L^{-1} and ammonia, 0.34±0.1 mg L^{-1}).

After seven weeks of feeding and weekly batched-weighing, the growth performance, feed efficiency and somatic indices of the African catfish (*C. gariepinus*) were determined as described by Adeoye et al. (2016)"ISSN":"00448486","abstra ct":"A study was carried out to investigate the combined effect of exogenous enzymes and probiotic supplementation on tilapia growth, intestinal morphology and microbiome composition. Tilapia (34.56±0.05g and Fawole et al. (2018). At the end of the feeding trial, blood from two fish per tank (n = 6 per treatment) was taken from the caudal arch using a 25-gauge needle and 1 mL syringe after the fish were anaesthetized with clove oil (100 mg L^{-1}). Blood samples were prepared and analysed as previously described by Adeoye et al. (2016) and Fawole et al. (2018). Two fish per tank were also sampled for histological appraisal of the mid-intestine (n = 6 per treatment) after the catfish were relived from the act with super dose of clove oil (300 mg L^{-1}). The samples were processed using standard histological procedure and the intestinal perimeter ratios (arbitrary units, AU) were assessed as described by Adeoye et al. (2016) as well as the numbers of intraepithelial leucocytes (IELs) and goblet cells in the epithelium, across a standardized distance of 100 μm.

All data are presented as mean ± standard deviation. Data were analysed using one-way analysis of variance (ANOVA). Multiple comparisons were performed using Duncan post-hoc test. Differences were considered significant at a value of $P < 0.05$. The statistical analysis was carried out using SPSS for Windows (SPSS Inc., 24.0, Chicago, IL, USA).

Results and Discussion

After seven weeks of feeding and weekly batched-weighing of the catfish, the growth indices (especially the final body weight and metabolic growth rate) of the African catfish fed diet supplemented with Leiber CeFi® Pro (at 0.3% inclusion level) performed significantly better ($P < 0.05$) than the control group fed diet containing 0% Leiber CeFi® Pro. This observation is within the optimum range of performance of African catfish of same size and age and compares favourably with the findings of Abdel-Tawwab et al. (2018) and Kemigabo et al. (2019).

(Continued on next page)

The haemato-biochemical parameters of the African catfish fed diets supplemented with Leiber CeFi® Pro showed that the fish are in good health and that Leiber CeFi® Pro had no deleterious effect on the catfish welfare. A significant change was however observed in the level of alanine transaminase (IU L^{-1}) of African catfish fed diets supplemented with Leiber CeFi® Pro; an indication that low dietary supplementation (0.3 – 0.6%) of Leiber CeFi® Pro in the diets of African catfish could help protect the membrane integrity of the liver cells.

The mid-intestine of African catfish from all treatments showed intact epithelial barriers with extensive mucosal folds extending into the lumen. Each fold consisted of simple lamina propria with abundant intraepithelial leucocytes and goblet cells. The perimeter ratio, goblet cells and intraepithelial leucocytes abundance of the African catfish fed the experimental diets are within the normal range for the catfish of same size and age under optimum condition and compares favourably with the findings of Onura et al. (2018). A significant elevation was observed in the abundance of goblet cells and intraepithelial leucocytes in the mid-intestine of the catfish fed diets supplemented with Leiber CeFi® Pro. The elevated proportion of mucus-producing goblet cells residing in the intestine of the catfish fed Leiber CeFi® Pro supplemented diets is likely to enhance the intestinal barrier function of the catfish. In similar vein, the significant increase in the abundance of intraepithelial leucocytes (component of gut associated lymphoid tissue) in the intestine of African catfish fed Leiber CeFi® Pro supplemented diets could be an indication of immune stimulation, protecting and preventing pathogenic invasion in the gut of African catfish *C. gariepinus*).

Conclusion

It could be concluded therefore that dietary supplementation (at 0.3%) of autolysed brewer's yeast is capable of improving growth performance, liver functionality and intestinal morphology in African catfish, *C. gariepinus*.

EFFECT OF TEMPERATURE AND DIFFERENT SPAWNING AGENTS ON REPRODUCTION SUCCESS OF BURBOT IN CAPTIVITY

Jurgen Adriaen[1], Joachim Claeyé[1], Thomas Abeel[1], Wouter Meeus[1], Heidi Arnouts[1]

1. Aqua-ERF, University College Odisee, Sint-Niklaas (Belgium)

E-mail: jurgen.adriaen@odisee.be

Introduction

Since a few years burbot (*Lota lota*) has been introduced as a new aquaculture species in Belgium. However there is still some concerns regarding stable fingerling production. Latter can be improved by increasing control over the reproduction. Zarski et al. (2010) suggested that temperature is the major factor during final maturation and his study showed some variations in reproduction success under different thermal conditions. In this study three different temperature profiles were tested. This set-up could then be used to specify the better thermal regime that guarantees successful reproduction under controlled conditions. Kucharczyk et al. (2018) showed that the application of salmon gonadotropin releasing hormone analogue (sGnRHa) in burbot reproduction shortened latency time, synchronized final oocyte maturation and resulted in high embryo survival. Human chorionic gonadotropin (hCG) is another spawning agent that has been used successfully in the artificial reproduction of pikeperch (*Sander lucioperca*) (Zarski et al 2015). For this the effect of these two hormones were investigated in this experiment at two different application methods (one or two injections).

Materials and methods

In 2016 burbot larvae were transported from Germany to Aqua-ERF and the largest fingerlings were reared in RAS for almost three years. Just before their third winter 126 of these burbots (61 males, ABW: 594±168.3gram; 65 females ABW: 660.7±191.9 gram) were individually tagged and distributed over nine tanks (1m²; 0.4m³) connected to their own biofilte . Total biomass per tank was 8.78±0.63 kg m^{-1}. Three cooling chambers, holding three fish tanks each, were used to assure three different temperature profiles. Temperature was lowered gently from ±±10°C till ±±5°C, then dropped fast till 1.5°C and holding this temperature for a one or two weeks before increasing it till 2°C, 3°C or 4°C, depending on the treatment. Light conditions were modulated based on natural light regime in Germany and were the same for all cooling chambers.

Part of the fish population were given 1 or 2 injection (14 days interval) with either 10 µg kg^{-1} of sGnRHa or 500 IU kg^{-1} of hCG. The spawning agents were always diluted in saline solution so that each fish received 1ml of solution per kg. All fishes that did not receive the 1st or/and 2nd injection with spawning agent received an injection with a saline solution at 1ml kg^{-1}.

Cathetering of the females was repeated every week, starting at the moment of first injection, till oocyte showed to be ready for spawning. Females were then manually stripped to obtain the eggs. Obtained eggs were weighted and a working fecundity was calculated based on following formula: (Weight of eggs/Weight of fish) x100. Males were checked every week manually if they were given sperm.

Results and Discussion

The first female started to spawn ten days after the first injection with sGnRHa, while the latest spawned on day 40. Highest frequency of spawning females occurred from day 22 till day 40. In total 46 out of 65 females have spawned (71%) during the trail and although higher spawning percentage were obtained for fish treated with sGnRHa, no significant effect was observed between the five different spawning agent treatments. This was also the case for the three different temperature regimes and the interaction between temperature and spawning agents. Temperature, spawning agents and the interaction between those two did not influence significantly the working fecundity. In the males we observed that not all males spermiated and that even the same male did not spermiated during the whole 40 days period.

This study showed that burbot reproduction in RAS with 3-year old burbot, reared from larval size in RAS, is possible. The results indicates the possibility to obtain earlier eggs from burbot females with the use of sGnRHa and even a better synchronization than with hCG. Although working fecundity was not influenced by the treatments, egg quality and further larval quality could be influenced for which further study is needed

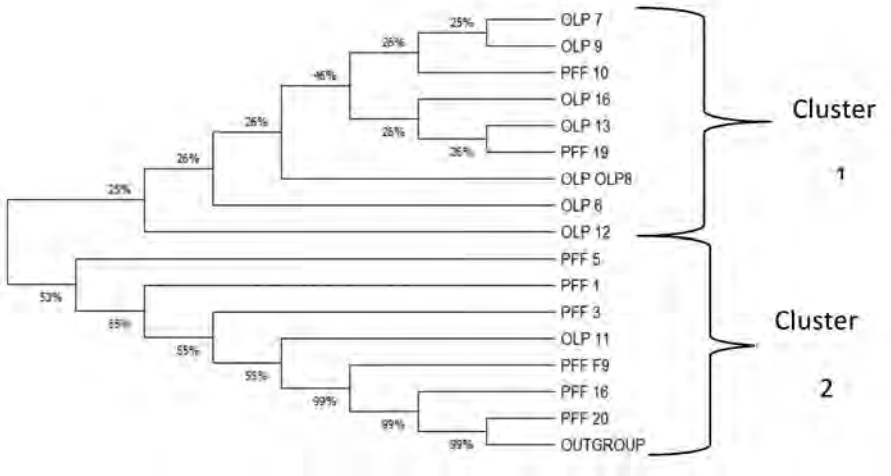
Introduction

The phenotype and gene diversity provide basic information of the species as it gives the level of diversity and population expansion within fish species. A notable genetic bottle-neck of fisheries enhancement programmes has been the discovery of genetic variation between wild and cultured stock (Islam and Alam, 2004). The Nile tilapia is a member of the cichlid family and notably one of the most important species in aquaculture worldwide (McCune, 1981). It is the most commonly farmed tilapia species in Nigeria owing to its good aquaculture qualities such as ability to withstand poor water quality and the acceptability to wide range of feed that support its cultivation. This study was designed to describe the phenotypic (morphological and meristic) characterization and genetic variations of wild and culture *Oreochromis niloticus* from different populations (Oyan dam and a private farm) in Ogun State, Nigeria.

Materials and methods

One hundred fish samples of were collected for the study comprising 50 samples each from Oyan dam being the wild population (consisting of 27 males (44.3%) and 23 females (59%)) and the private farm population situated at Ilaro, Ogun State (comprising 34 males (55.7%) and 16 females (41%)). Both populations were located within Ogun State, Nigeria. Twenty samples from each population were used for genomic studies. Morphometric and meristic variables were measured using simple standard procedures to minimize stress and precaution was taken not to compromise the fish welfare. The measured morphometric variables include: Weight, Total length, Head Length, Standard length, Preorbital length, Postorbital length, Predorsal fin length, Prepectoral fin length, Preanal fin length, Postanal fin length, Body depth, Eye diameter, Upper jaw length, Caudal peduncle depth. The meristic parameters taken were Dorsal fin spines, Anal fin ray, Number of the lateral line scales, Number of gill ray, Dorsal fin ray, Pectoral fin ray right, Pectoral fin ray, Number of ventral tail ray. The data on morphometric and meristic parameters were analyzed using descriptive statistics based on frequency and percentages. The data was also subjected to T-test and cluster analyses; significant differences were tested at $\alpha = 5\%$ using SPSS.



(Continued on next page)

Results

There were significant differences ($P < 0.05$) in the morphometric traits (except the Pre Orbital Length) and meristic parameters (except Dorsal fin spines, Pectoral fin ray right, Pectoral fin ray and Number of ventral tail ray) between the two populations. The cluster analysis based on the dendrogram of the morphological trait of *Oreochromis niloticus* from the two populations is divided into two main clusters, each with two sub-clusters. Cluster I comprised more of *Oreochromis niloticus* from culture population (Ilaro) with some from the wild (Oyan dam). Sub-cluster I.I had 31 samples from the culture with 7 samples from the wild. Sub-cluster I.II has 19 samples from the culture with 13 samples from the wild. Cluster II had all samples of Sub-cluster II.I (10 samples) and Sub-cluster II.II (20 samples) all from the wild. Both populations had high genetic variation among population and low genetic variation within species based on the distinctive classification from the cluster analysis. All sampled populations were polymorphic, but Nile tilapias from the wild were more polymorphic than the culture.

Discussion and conclusion

From the cluster analysis, higher morphometric differences were observed between the wild male and female *Oreochromis niloticus* than in the culture male and female population, though the numerical values were close. The similarity in Post Orbital Length (morphometric trait), Dorsal fin spines, Pectoral fin ray right and Number of ventral tail ray (meristic parameter) in the study species is an indication of relatedness between the two populations from different locations. The differences encountered between populations are attributable to the existence of heterogeneity between the two populations. Usually, meristic traits remain the same in the same species except otherwise conditioned by environmental pollution changing the phenotype. (Meyer, 1987; Gulliet *et al.,* 2003). *Oreochromis niloticus*, among the members of the Cichlidae family is among the fish species that is categorized in showing wide range of variations in body shapes and conformity (McCune, 1981). Although, the wild population could be a viable reservoir for high variability stock useful in fish breeding and future conservative programmes. The information obtained in this study could be useful in establishing phenotypic characterization and estimating genetic variability among other components of fish population dynamics

Introduction

Microalgae are being considered as potential novel protein ingredients for aquaculture. This is coming at a time when the supply of traditional marine feed ingredients (fishmeal and fish oil) from capture fisheries are in decline (Hardy, 2010). The use of microalgae in fish feeds, is however, constrained by their rigid outer cellulosic cell walls. The cell wall prevents enzymatic hydrolysis of intracellular nutrients embedded with the microalgae, thereby reducing their nutritional efficacy in fish (Teuling et al., 2017). The current study was undertaken to examine the correlation between *in vitro* accessibility of nutrients and *in vivo* digestibility of nutrients from *Nannochloropsis gaditana* in fish. To discern if these effects were fish dependent, comparative analyses between Nile tilapia (an herbivorous fish) (Teuling et al., 2019) and African catfish (an omnivorous fish) (Agboola et al., 2019) was conducted using data of separate experiments

Materials and Methods

Nannochloropsis gaditana biomass was subjected to physical or mechanical treatments for partial or complete disruption of its cell wall. The cell disruption treatments are untreated – no disruption treatment (UNT), pasteurization (PAS), freezing (FRO), freeze-drying (FRD), cold-pasteurization (L40) and bead milling (BEM). Nutrient accessibility from the microalgae after the cell disruption treatments was determined by *in vitro* protein hydrolysis, nitrogen leaching, ion leaching, fat extractability and buffering capacity methods. In separate experiments, juvenile Nile tilapia and African catfish were fed identical diets containing six differently treated and untreated microalgae (at 30% diet inclusion level).

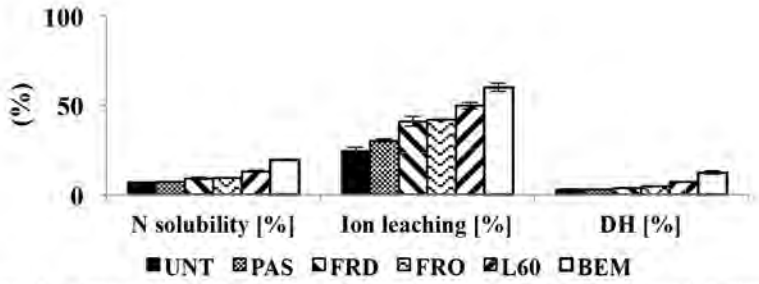

Fig. 1. Nitrogen solubility, ion leaching and protein hydrolysis of differently treated and untreated *Nannochloropsis gaditana*.

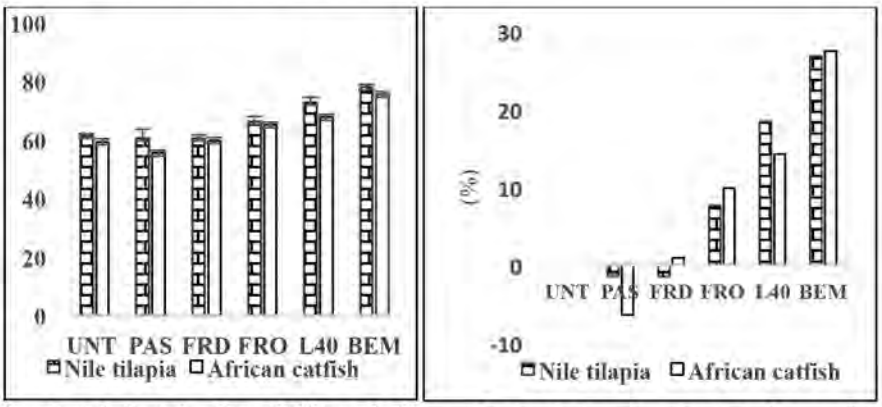

Fig. 2. (a) Protein digestibility of differently treated and untreated *Nannochloropsis gaditana* in Nile tilapia and African catfish. (b) Relative improvement in protein digestibility of differently treated *Nannochloropsis gaditana* compared to untreated. The presented values are relative to untreated microalgae (set at 0%).

(Continued on next page)

Results and discussion.

Freezing, bead-milling and cold-pasteurization cell disruption treatments resulted in an up to 4 folds increase in *in vitro* accessibility of *N. gaditana* nutrients, assessed from measurements of leaching and susceptibility to protein hydrolysis (Fig. 1). Cell disruption by FRO, L40 and BEM also improves apparent digestibility coefficient (ADCs) of nutrients from *N. gaditana* in both Nile tilapia and African catfish (Fig. 2a & 2b). In addition, there were significant interactions ($P < 0.05$) between cell disruption treatments and fish species on ADCs of crude protein and fats from *N.* gaditana, although the ADCs were higher in Nile tilapia than African catfish. This is as expected because Nile tilapia has more physiological capacity to hydrolyse plant ingredients than African catfish (Saravanan et al., 2013; Hlophe et al., 2014). In both trials, there is a strong correlation between accessibility of nutrients from the microalgae and its digestibility in fish

Conclusions

The study confirms that nutrient accessibility is a dominant limiting factor hindering nutrient digestibility of microalgae in fish. Furthermore, it was shown that freezing, cold-pasteurization and bead-milling cell disruption treatments is an effective strategy to increase nutrient accessibility and digestibility of microalgae in fish. The impact of cell wall disruption on nutrient digestibility of microalgae differs between Nile tilapia and African catfish

ACUTE TOXICITY AND BIOACCUMULATION IN EELS (*Anguilla Japonica*) BY EXPOSURE OF WATERBORNE CADMIUM

T.Y. Ahn

Gyeonggi Province Maritime & Fisheries Research Institute, Yangpyeong 12513 (South Korea)
E-mail: ahnteng@gg.go.kr

Introduction

Metals naturally exist in aquatic ecosystems, but side effects from industrialization have resulted in excessive concentrations. Cadmium is a particularly widespread and toxic example that is documented to accumulate in exposed organisms; it is used primarily in alloys, pigments, electroplating, and batteries. The purpose of this study is to investigate accumulation in muscle with determination of median lethal concentrations (LC_{50}) for Cd in adult *A. japonica*.

Materials and methods

Anguilla japonica specimens were acclimated for two weeks prior to experiments and food-deprived. An acute Cd toxicity test was conducted under laboratory conditions. Acclimated fish (n=90; average weight: 186.6±11.9g) were selected, divided into nine groups (10 per group). Water temperature was maintained with a heater at 29±1°C and the laboratory was kept in 24-h darkness to apply to environment of an eel farm. Experimental fish were exposed to waterborne $CdCl_2$ treatments of 0.25, 0.5, 1, 3, 5, 6, 7 and 9mg L^{-1} for 96h. A water-only control was also used. After a 96h Cd exposure, tissues (liver and muscle) of live fish were stored at -80°C until analysis. Tissues were analyzed using microwave with nitric acid to confirm Cd bioaccumulation

Results

LC_{50} of Cd in *A. japonica* after 24, 48, 72, and 96-h was 8.33, 6.60, 6.00 and 5.89 mg L^{-1}, respectively (Table I).

Cd exposure caused a net increase of Cd content in tested *A. japonica* tissues compared with the control (figure 1). As expected, accumulation rose with increasing exposure concentration. Significant differences were apparent at ≥ 0.25mg L^{-1} in muscle, ≥ 1mg L^{-1} in liver.

Table I. Estimated median lethal concentrations (LC_{50}) and confidence limits.

Period	Concentration ($CdCl_2$ mg L^{-1})	95% confidence limits	
		Lower	Upper
24h	8.33	7.13	11.16
48h	6.60	5.79	7.61
72h	6.00	5.31	6.69
96h	5.89	5.21	6.51

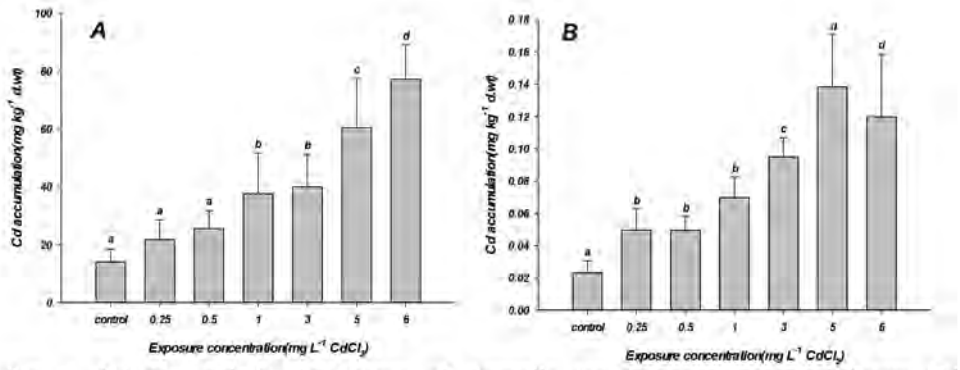

Fig. 1. Cd accumulation in tissues of *Anguilla japonica* exposed to different Cd concentrations. (A) Liver and (B) muscle. Superscript letters indicate significant differences ($P < 0.05$).

(Continued on next page)

Discussion and conclusion

This study demonstrated that *A. japonica* mortality increased with greater Cd concentration and exposure periods. Although previous research had attempted to examine acute Cd toxicity in freshwater fish, such studies were generally not sufficient for a full assessment. Nonetheless, we were able to compare our results to several reports to identify difference of Cd toxicity by experiment conditions. After 96h Cd exposure the LC_{50} in tilapia juvenile (*Oreochromis* sp.) were 0.7mg L^{-1} (Aldoghachi et al., 2016) and in adult guppies (*Poecilia reticulata*) was 30.4mg L^{-1} (Yilmaz et al., 2004). These data indicate that between-species differences in life history, genetic composition, and individual condition outweigh size and age in terms predicting fish tolerance to Cd toxicity (Rand et al., 1995)

Cd accumulation in the liver, considered the organ most sensitive to Cd toxicity, is higher than the muscle including control in results of this study. This result corroborates previous data; in *A. japonica* exposed to 50μg L^{-1} of Cd, the primary tissues that accumulated Cd were kidney and liver (Yang and Chen, 1996). Nonetheless, significant differences were indicated in the muscle at lower Cd concentration. It represent that liver is the most important organ for detoxification in acute exposure (Chowdhury et al., 2005). Despite Cd exposure at low concentration and during short period, significant increment in muscle can easily threaten to safety as food and health of consumer.

Introduction

Large trout production is increasing in France especially for fillet smoking. Besides, trout eggs production involves obtaining large post-spawning fish, but their flesh displays poor quality and as such cannot be processed before a post-spawning rearing period. The present study aims to determine whether, in rainbow trout, the rearing period following egg production leads to the restoration of technological and organoleptic properties of fillets compatible with their processing and consumption.

Materials and methods

Two-years-old diploid female rainbow trout from the same autumnal strain cohort were reared in the INRA's experimental facilities (PEIMA, Sizun, France). Following spawning, nine groups of 25 trout were placed separately into nine 2m diameter circular tanks and fed ad libitum. Fish reared in the same tank were then sequentially sampled at 0, 1, 2, 4, 8, 13, 16, 24, and 33 weeks after spawning. Immature (no egg produced) female trout from the same cohort were also sampled at the beginning (C0) and at the end (C33) of the experiment. At slaughter, the body weight and Fatmeter® value were measured, then fish were fillete , and raw fillets (skinned and trimmed) yield was calculated. After two days of vacuum-packed storage in a cold room at 4°C, fillets were traditionally dry salted (4h) and cold smoked with green beech wood (5h). Smoking yield of fillets was calculated (dividing smoked fillet weight by raw fillet weight before salting and smoking). Instrumental measures of fillet color (Minolta Chromameter CR-400 with L*, a*, b* color space) and mechanical resistance were performed on raw and smoked fillets. Mechanical resistance of the anterior part of the fillet was measured using a penetrometer (a 15 mm diameter flat-ended cylinder probe) mounted to a force gauge of 100N (Andilog®), and a Kramer shear cell mounted on a static load cell of 2kN (INSTRON®). The total work done during the measurement was calculated and divided by the sample thickness.

a.u: arbitrary units

(Continued on next page)

Results

At spawning, trout showed significantly lower body weight, Fatmeter® value and raw fillets yield than trout from C0. Furthermore, raw fillets from these trout were less colored (lower redness a*) and with higher lightness L*, and exhibited lower mechanical resistance than raw fillets from C0 trout (table I). At 13 weeks, body weight and Fatmeter® value were significantly higher than at 1, 2, 4 and 8 weeks after spawning, and continued to increase till the end of the experiment. Raw fillets yield were found to increase only after the 16th week post-spawning. Lightness of fillet steadily decreased from the 4th week to the 24th week and did not change afterwards, whereas fillet redness increased from the 8th week to the 24th week after spawning (table I). Fillet mechanical resistance increased one week after spawning, remained high until the 16th week, sharply dropped between the 16th and 24th weeks and did not change afterwards (table I). Smoking yield of fillets from post-spawned trout was significantly lower than that of trout from C0, and significantly increased only at the 24th week. Post-spawning evolution of color and mechanical resistance of smoked fillets was similar to that of raw fillets, except for the fillet lightness. At the end of the experiment, body weight and Fatmeter® value of post-spawning trout and quality parameters of their fillets were found to be globally similar to those observed in C33

Discussion and conclusion

The lower body weight and Fatmeter® value observed in post spawning trout compared to immature trout is in agreement with existing data showing that egg production induces a decrease of somatic growth and a wasting of muscle fat stores. After spawning, trout substantially increased their body weight to eventually reach that of control trout. This muscle burst of growth along with the accumulation of muscle fat likely account for the increase of the fillet yield observed after spawning. At spawning, the flesh was strongly discolored resulting from the mobilization of muscle carotenoid pigments towards ovaries. After spawning, fillets progressively recovered their color. A feature in line with previous observations reporting that pigment concentration tends to increase rapidly in the fish muscle after spawning (Choubert, 1992). The decrease in the mechanical resistance of the flesh during the period that follows spawning may be explained by the increase in muscle fat content (Lefèvre et al., 2015) and as well as muscle fibers hypertrophy, an important determinant of flesh texture (Johnston, 1999). The increase in the smoking yield can be attributed to a lower water loss associated to increase in muscle fat content in the trout fillets (Mørkøre et al., 2001).On the whole, our results indicate that technological and sensory properties of the flesh are recovered in female trout 24 weeks after spawning. Further histologic and transcriptomic analysis would allow a better understanding of the biological process involved in this quality recovery.

This study was financially supported by the European Maritime and Fisheries Fund (EMFF QUALIPOSTOV, grant n° PFEA470017FA1000012), the INRA PHASE department and the Brittany Region (France).

THE EFFECTS OF SBM AND RSM BASED DIETS ON THE GROWTH PERFORMANCES AND BODY COMPOSITION OF ZEBRAFISH (*Danio rerio*)

T.A. Aiyelari, A.S. Chaudhry

Newcastle University, Newcastle upon Tyne. NE1 7RU. UK
E-mail: antofunmi@yahoo.com

Introduction

There have been significant research efforts at improving dietary composition of feeds and maximizing fish growth for sustainable aquaculture. This is achieved by identifying sustainable source of ingredients in order to reduce dependency on highly competitive and expensive fish by-products (Hardy, 2010). Although, zebrafish (Danio rerio) have an advanced impact in laboratories research for its utility in understanding developmental biology, genetics, toxicology, and recently nutrition (Ulloa *et* al., 2014; Khan and Alhewairini, 2018), the influence of diet composition on basic growth outcomes and body composition on the fish is less well demonstrated (Smith *et al*., 2013). The aim of the present study was to compare the acceptability and effect of SBM and RSM based diets with a commercial FM based diet, on growth parameters and fish body composition through repeated but non-invasive measurements on zebrafis

Material and methods

Two iso- nitrogenous (47% crude protein) and iso-calorific (11.8 MJ DE/kg) diets were formulated and compared with a commercial diet for zebra fish. This study employed a 3 x 2 factorial arrangement involving three diets at two stocking densities. The fish were fed three times daily at 5% of their body weight, for a period of eight weeks. Morphometric measurements, water quality and feed allowances were determined on weekly basis. After the experiment, fish were euthanized with tricaine methanesulphonate MS-222 (Sigma Aldrich), frozen at -20^{o}C, and later freeze dried until processed for various chemical analysis. The length-weight relationship, condition factor and the growth parameters of the fish were determined. Samples of feeds and fish were analysed for proximate (AOAC 2005), minerals, fatty acids, and amino

(Continued on next page)

acids compositions. The minerals were analysed by using ICP-OES technology following acid digestion while the fatty acid methyl esters were analysed by GC-MS following methylation and esterification, after fat extraction (using modified method of Folch *et al*., 1957). The amino acids was analysed by using EZ-Faast amino acid derivative technique for GC-MS after acid hydrolysis. Data were analysed using T-Test, ANOVA and GLM. Tukey's post-hoc test was used to compare means to observe significance at $p < 0.05$

Results

The crude protein, nitrogen free extract and ash contents on dry matter basis were not different ($p<0.05$) for the fish fed any of the diets (Table 1). Mean live-weight gain (WG), FCR and PI were higher ($p<0.05$) in the fish fed the CFM diet than the other diets. No differences were observed SGR, FI, and PER. Palmitic (C16), oleic (C18:0), and linoleic (C18:1n9) acids were prominent in all the fish. The total saturated and omega-6 fatty acids were highest in fish fed commercial diet (34.25 ±0.75, 14.57 ± 0.13) compared to the other diets (Table 2). The Ca, K, Mg, Na and P contents were more prominent in all the fish, with Na found to be highest ($p<0.05$) in fish fed RSM diet (31.220 ± 3.63 mg/l) than those fed commercial diet (21.510 ± 2.81 mg/l) and SBM diet (22.380 ± 1.24 mg/l) respectively. There were no significant differences in the contents obtained in the amino acid composition of the fish fed the diets (Figure 1).

Discussion and Conclusion

There was no adverse effects of the SBM or RSM based diets on fish in terms of the survival rates (>95%), chemical composition and growth observed. The effect of the diet x stocking density on the growth and performance of the fish was not significant. The omega-6 and omega-3 ratio (n-6: n-3) FA of the fish are within the lower ratio of n-6: n-3 fatty acid which is desirable in the preventing chronic diseases (Russo, 2009; Bogard et al., 2015). There was no significant effect of the AAs of the diets on the fish. The study showed that both SBM and RSM diets can potentially replace FM based commercial diet for zebra fish and other finfish to reduce cost and promote sustainability of aquaculture production

ENTEROBACTER INFECTIONS OF CULTURED RAINBOW TROUT (*Oncorhynchus myk*

Tulay Akayli*, Ozgur Canak, Remziye Eda Yardimci, Cigdem Urku, Dilek Okmen

Istanbul University, Faculty of Aquatic Sciences, Department of Fish Diseases, Istanbul – Turkey
*E-mail: takayli@istanbul.edu.tr

Introduction

Rainbow trout (*Onchorhynchus mykiss*) culture was first begun in Turkey in 1970's and showed a great increase. The total production amount of Turkey has reached to 101 761 tons in 2017. Enterobacteriaceae is a large family of Gram-negative bacteria which includes the fish pathogenic genera, *Yersinia*, *Hafnia*, *Citrobacter, Klebsiella* and *Escherichia*. Upto date, various bacterial infections caused by Gram-negative pathogens were observed, but there is a limited information on the Enterobacteriaceae infections of rainbow trout except *Y. ruckeri* infections. The aim of this study is the determination Enterobacteriaceae infections of rainbow trout cultured in freshwater cage farms by using conventional bacteriologic, molecular and histopathological methods.

Materials and methods

With this aim, a cage facility located in a dam lake in our country was visited for a one-year period in April, June, July, September and December in 2017 and a total of 50 diseased rainbow trout samples were investigated. Bacteriologic inoculations from the visceral organs of moribund fish were streaked onto TSA (Tryptic Soy Agar) and bacteria were identified by conventional morphologic and phenotypic tests (Brenner and Farmer, 2009). Biochemical identification was confirmed with the PCR amplification of 16S/23S rRNA with the universal primers 27F and 907R (Lane, 1999). For histopathological examination, tissue samples were fixed in 10% formaldehyde, processed with routine methods and embedded in paraffin (Roberts, 2012). Histological sections were stained with Haemotoxylin – Eosin and analyzed under light microscope.

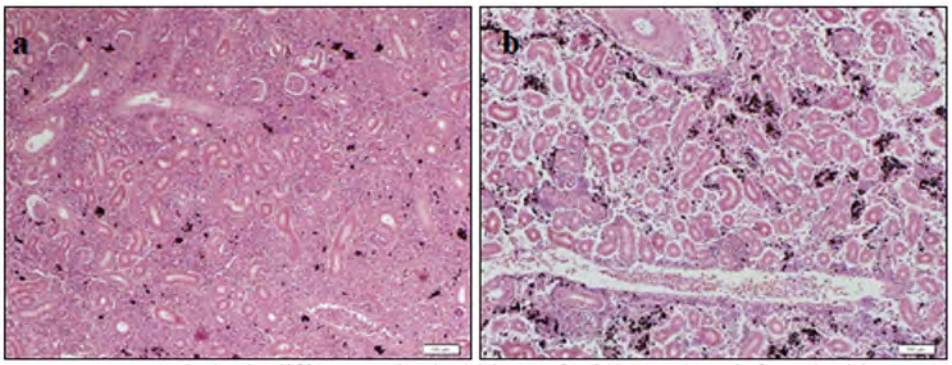

Fig 2. Pathologic differences in the kidney of rainbow trouts infected with *H. alvei* (a) and *C. freundii* (b)

(Continued on next page)

Results

In this study, of the members of Enterobacteriaceae, *Hafnia alvei* and *Citrobacter freundii* were recovered and identified from the infected fish samples. Biochemical identification was confirmed with 16S gene sequencing and blasting. Fish samples infected with *H. alvei* showed sloughing of the skin, swollen abdomen (Fig 1.a) and hyperemia in the visceral organs clinically. Histopathologically, they showed small melanomacrophage centers, hemorrhages and hyperemia in the visceral organs, and slight degenerations in the liver hepatocytes and kidney tubules (Fig 2.a). Fish samples infected with *C. freundii* showed exophthalmos, darkening of the skin, edema and accumulation of a transparent liquid in the peritoneal cavity (Fig 1.b) and splenomegaly clinically. Histopathologically, these samples showed slight necrosis in the hepatocytes but severe necrosis in the interrenal haemopoietic tissue, severe degenerations in the hepatocytes and kidney tubules and generalised melanomachrophage centers and hemosiderin accumualtions in the kidney and spleen (Fig 2.b).

Discussion and conclusion

Hafnia alvei and *C. freundii* are the members of Enterobacteriaceae, which can be mis-identified by biochemical profiling and may be confused with *Y. ruckeri*. Molecular studies and gene sequencing gives more reliable results for the identification (Austin and Austin, 2016). In this study, biochemical profiling was also misidentified our isolates but molecular studies provided the final identification of these bacteria.

The members of the Enterobacteriaceae previously caused infections in freshwater fishes after transportation, under stress or during cultivation in inappropriate conditions. Generally these bacteria cause hemmorhagic septicemia in fishes, but swollen abdomen is seen in *H. alvei* infections while *C. freundii* causes exhophthalmus and surface hemorrhages (Austin and Austin, 2016). In this study infected fish samples showed similar symptoms.

Despite these bacteria were recovered from rainbow trout previously by other researchers, there is a limited information on the histopathology of these infections. The results of our study showed that *C. freundii* infections cause more severe clinical and histopathological symptoms while *H. alvei* causes more mild pathologies in rainbow trout.

In conclusion, the results of this study revealed the need for the use of molecular methods in the identification of fish pathogenic Enterobacteriaceae species and the detailed differences of pathologies these emerging pathogens in rainbow trout were demonstrated by using histopathological methods.

BEHAVIOURAL AND MORPHOLOGICAL ASSESSMENT OF PARAQUAT TOXICITY ON JUVENILES OF NILE TILAPIA, *Oreochromis niloticus*

[1] AKINSOROTAN, A.M, [1] Jimoh J. O and [2] J.O OYEWUMI

The impact of acute exposure of *Oreochromis niloticus* juveniles to a commonly used herbicides, paraquat was evaluated through changes in their behaviour and mortality. The fishes were exposed to lethal concentration of 0.00mg/l, 3.31mg/L, 3.86mg/L ,4.4mg/L and 4.97mg/L of paraquat for 96 hours. The toxicity bioassay procedure showed that the 96 hours LC_{50} was 3.85mg/l. Restlessness, erratic swimming, loss of equilibrium, discolouration and sudden fish death were observed in the exposed fish and these varied greatly with differences in concentration of the toxicant and this shows that mortality increases with an increase in concentration. The differences observed in the mortalities of *Oreochromis niloticus* at varying concentrations were significant ($p<0.05$), an indication that mortality could be a factor of concentration and time of exposure. Observation of Opercular Ventilation Count (OVC), Tail Fin Movemant Rate (TMR) and Air Gulping Index (AGI) showed a marked difference between control and exposed fishes, indicating that the herbicides negatively impacted these parameters. These behavioural and morphological anomalies became more pronounced with increasing concentrations of the herbicides. The physico-chemical parameters of the experiment were within the tolerated limit. The result further revealed that paraquat have the ability to induce unusual behaviours in juvenile fish and can therefore serve as reliable indicators of toxicity in our environment and hence, the volume of these herbicide that get into the environment should be regulated.

ASSESSING THE MAJOR CONSTRAINTS OF INTERNATIONAL AQUACULTURE CERTIFICATION FOR EXPORT FISH FROM BANGLADESH

*M. M. Alam and M. M. Haque

Department of Aquaculture, Bangladesh Agricultural University, Mymensingh
*Email: imran01bau@yahoo.com, malam.39715@bau.edu.bd

Introduction

Aquaculture has grown rapidly in Bangladesh that contributes 56% of the total production of 4.13 million MT of fish (DoF, 2017). The sharp rise of aquaculture production started from 1990s mainly due to technological development particularly, the development of artificial seed production in hatcheries and fish feed production. Pangasius (*Pangasianodon hypophthalmus*|) and tilapia (*Oreochromis niloticus*) have become two major fast-growing aquaculture species in Bangladesh. Although, globally Bangladesh is the 5th largest aquaculture producer but the fish export trade ranked feculences (FAO, 2018). However, the demand of pangasius and tilapia has continued to increase both in domestic and international markets (Moloko et al., 2013). The international export trade of Bangladeshi pangasius and tilapia is intangible and stuck only in domestic market due to absence of implementation of standard aquaculture certification. On the other hand, the largest Asian seafood exporters such as China, Vietnam, and Indonesia established aquaculture certification meeting international third party certifier guidelines. Therefore, the introduction of aquaculture certification in Bangladesh is an urgent need and demand of the time.

Materials and methods

The study was conducted based on multiple methodological approaches including literature review, secondary data analysis, primary data collection and analysis and laboratory analysis of fish, fish feed, pond wat , and pond sludge.

Results

Bangladesh has developed some rules and guidelines to comply with the international code of conducts for export on aquaculture governance such as water use, fish feed and hatchery rules, food hygiene and sanitation, etc. In contrast, a number of guidelines of aquaculture governance such as land use and zoning plans, responsible use of drugs and chemicals rules, disease control strategy, traceability procedure, etc. yet not been established and enforced at field level properly. As a result, the framers used indiscriminate aquaculture drugs and chemicals due to lack of knowledge regarding use of chemicals, application of chemicals and antibiotics, residual effect and expiry date and diagnostic facilities for proper disease diagnosis. Similarly, the farmers used commercial medicated feed without knowing the specification such as type and percentage of drugs in feed, name of veterinarian who prescribed the drug and date of manufacture. In case of farm-made feed, the farmer mixed-up drugs and chemicals with feed without authorized instructions. Therefore, the fish flesh have been contaminated by toxic heavy metals including lead, cadmium and mercury, where lead found around 5 folds higher in both pangasius and tilapia muscle compared to the acceptable limit. Consequently, the chromium level in fish flesh was 54 times higher in pangasius and 20 times in tilapia flesh, another constraint to export aquaculture products. Although, the socio-economic characteristics of farmers in Bangladesh are mostly complementary to adopt aquaculture certification but some of them are constraints to adopt certification particularly because a large number of farms are small in size having difficulty to comply with certification code of conducts. Nevertheless, the majority of the farmers was in middle age, educated and experienced which are technically efficient to adopt aquaculture certification

Discussion and conclusion

The aquaculture certification is based on international standards and complies with relevant local, national and international laws and regulations. However, the rules and guidelines on aquaculture in Bangladesh have remained in sporadic condition. In addition, as a larger seafood producer, it is a matter of regret that the code of conducts of top international third party certifier (e.g. ASC and GlobalGAP) are not followed or very seldom emulated by pangasius and tilapia farmers in Bangladesh such as site selection and management, reproduction system at hatchery, responsible drugs and chemicals use, water usage and disposal system, animal welfare and husbandry, sampling and testing of fish, feed use and management, pest control, environmental and biodiversity management, harvesting, handling and transportation, post-harvest - operations and traceability, farm operators occupational health and safety and social and welfare criteria. Regarding food safety issues, the produced fish was found contaminated by heavy metals being originated from fish feed. Therefore, it is important to establish clear and transparent policies and procedures in aquaculture sector in Bangladesh for environmental neutrality, social acceptability and ultimately helps to improve the sustainability (FAO, 2017). Compared to the regional and international trend, it is the time to take necessary steps by the government and non-government organizations addressing the issues of exporting commercially important farmed fish from Bangladesh. Otherwise, the growing aquaculture industry in Bangladesh would not sustain only based on the domestic market-based consumption.

Introduction

Increasing fishmeal prices and the depletion of natural fish stocks drive demand for novel feed ingredients in aquaculture. Marine amphipods are a natural food source for many flatfis species and are rich in essential fatty acids hence strong candidates as fishmeal replacement in aquafeeds. Recent studies showed promising fatty acid profiles and fatty acid synthesis in marine amphipods (Alberts-Hubatsch et al. *under review*, Baeza-Rojano et al. 2014, Jiménez-Prada et al. 2018)Caprella equilibra, Caprella grandimana, Caprella penantis, Elasmopus rapax, Hyale perieri and Jassa sp. from marine water habitats and Echinogammarus sp. from freshwater habitats. Lipids, proteins, carbohydrates, ash and water contents were measured. Proteins and ash were the most abundant components in all the species, ranging between 37.9 and 44.6% and 29.3 and 39.7% dry weight, respectively. The lipid and carbohydrate contents showed lower levels (5.1-9.6% and 3.1-9.1% dry weight, respectively, which could lower the need for fish oil supplementation in finfis feeds. In this study, juvenile turbot *Psetta maxima* were fed with four different diets containing different levels of amphipod meal as fishmeal replacement: 0, 50 and 100 % of replacement and a commercial turbot feed as reference. The experimental diets were formulated to meet basic nutritional demands without added fish oil. Growth performance as well as lipid classes and fatty acid profile in muscle and liver tissue in response to di ferent feeding regimes were investigated.

Material and Methods

A 32-day feeding trial was conducted with juvenile turbot (1.43 ± 0.2 g), fed four different diets containing different levels of fish-meal replacement: (A) commercial turbot diet (BioMar Inicio) as reference diet, (B) control diet containing 100% fishmeal, (C) diet with 100% Amphipod meal, (D) diet with 50/50% Amphipod/fishmeal (Table 1). Each treatment was performed in four replicates of 20 juvenile turbot. After 14 days a subsample of five fishes per replicate was taken to show early changes in fatty acid profiles. At the end of the experiment, final growth parameters (weight, length) were recorded. Whole body as well as tissue samples of liver and muscle were taken, immediately frozen in liquid nitrogen and stored in -80°C until further analyses. Proximate analysis (crude lipids, crude protein, ash, energy) was performed using complete fishes. The lipid classes of muscle and liver were separated by thin layer chromatography and fatty acid methyl ester (FAME) of each class analyzed by gas chromatography.

Results and Discussion

Wet weight, length and SGR did not differ between replacement diets, but the commercial diet as reference exhibited higher growth rates (Table 1). However, survival rates did not differ between the treatments with 100% survival, with the exception of one fish in treatment C at day six.

Results for fatty acids and proximate analysis are still pending.

We expect differences in the fatty acids of liver and muscle, especially between diet B (100% fishmeal) and C (100% amphipod meal). We further expect differences in the lipid classes, also between the reference diet and the replacement diets. Natural feeds can exhibit more natural lipid classes that provide well-balanced lipid profiles, which often offer better palatability than processed lipid mixtures. Being part of the natural diet of flat fishes (Braber & De Groot 1973), we expect a better bioavailability of lipid classes and respective fatty acids then fishmeal diets

Generally, amphipods constitute a good source of high valued long-chain polyunsaturated fatty acids as well as other nutritional factors such as pigments. Growing interest in these species as feed ingredient in terms nutritional value and suitability as fish and crustacean feed calls for novel and sustainable culturing and processing methods for amphipods i.e. gammarids.

Introduction
Biotechnology is a multicomponent system, the functioning of which is determined by three independently existing complementary components: the cultivated organism, the habitat and external influences that affect either only the organism or the habitat, or equally on both of these components. Exhaustion of opportunities for growth of fishing with a constant increase in demand for food from hydrobionts (one of the cheapest species of animal protein) has led to the rapid development of aquaculture. In the world, artificially diluted aquaculture products occupy, according to various estimates, about 40-45% of the industry market. The developing agrobiotechnology allows to obtain high-quality environmentally friendly fish products of high qualit , as well as crustaceans and plant crops.

Materials and methods
Experimental work on agro-biotechnology of the cultivation and production of environmentally friendly products were conducted over 5 years. During this time, a large amount of research work was carried out on the selection of optimal objects of cultivation. The research was carried out in the laboratory of aquatic bioresources and aquaculture on the basis of the experimental aquarium complex "Kagalnik" (Kagalnik, Rostov region) of the southern scientific center of the Russian Academy of Sciences using a unique collection of bioresources. The object of the study was agricultural crops, hybrid form of sturgeon, Clary catfish, tilapia. When conducting research using the fish-biological methods of production of experience, applied hydro-chemical, biochemical and biotechnical methods in accordance with conventional methods and the international standard using modern laboratory equipment.

Results
The technology of growing objects integrated installation for the joint cultivation of aquatic organisms and crops. In the integrated agrobiotechnological installation cultivation of such types of fish as: hybrid forms of sturgeon, African Clary catfish, tilapia, and also crops was carried out: salad, tomato, strawberry, pepper, dill. With the joint cultivation of hydrobionts, positive results were obtained. It was found that the growth of hybrid forms of sturgeon, tilapia and Clary catfish is 12 % higher when grown in agrobiotechnological plant than in the classical RAS. Earlier studies have led to the conclusion that it is advisable to grow the method of aquaponics culture with a short growing season (45-60 days.), and for the cultivation of crops with a longer period, it was decided to use a biological product based on bacteria of microbial origin for stimulation and better development. The volume of grown products is 24% higher than in traditional cultivation in RAS. The terms of growing aquaculture products have been reduced by 8%.

Discussion and conclusion
Agrobiotechnology for obtaining environmentally friendly products of aquaculture with the use of new technical means is promising at the present stage of aquaculture development. Allows you to combine several growing processes. The most important condition necessary to withstand the ever-increasing competition in the market of fish products is the excellent quality of products, both in terms of quality of meat and in terms of consumer preferences. Therefore, the results of these studies are the basis for further development of the production of Biosafety food products.

THE USE OF MOLECULAR TOOLS TO IDENTIFY MARINE BIVALVE LARVAE IN ENVIRONMENTAL SAMPLES

J. Alexander*, S.K. Malham, L. Le Vay, J. Webb, P. Bayford, D. Fidler, & J. McDonald

School of Ocean Sciences, Bangor University, Menai Bridge, UK
E-mail:j.l.alexander@bangor.ac.uk

Introduction

Development of improved methods for identification and quantification of bivalve larvae in plankton samples can offer opportunities for improved understanding of temporal and spatial patterns of seed supply for aquaculture and also validation of hydrodynamic particle tracking models of larval dispersal and population connectivity (Robins *et al* 2013). Aquaculture production of mussels is dependent on reliable sources of wild seed, which can be a limitation to growth of the sector in some regions. However, effective monitoring of larval supply requires discrimination between planktonic larvae of many morphologically-similar bivalve species. The standard identification method is through taxonomic classification via direct microscopic observation, a particularly time consuming process which is severely hampered by a lack of experts in the field of plankton taxonomy, the accuracy of identification and human error. Polymerase chain-reaction (PCR) assays using species-specific primers present a powerful method to detect target species in environmental samples; in addition, the ability to gather quantitative real-time PCR data offers the potential for between-sample comparisons of relative larval abundance.

Methods and discussion

Species-specific assays were designed and optimised using primer pairs either gathered from published literature (Inoue, et al. 1995), generated using primer design software or manually designed using sequences aligned in MEGA7.

Blue mussel D-stage larvae were obtained from single species experimental culture and used to compare and optimise DNA extraction methods for larval samples (Figure 1).

Spawned larvae were also used to examine the quantitative potential of species-specific qPCRs, where data generated from differing concentrations of larvae were used to create
a model which predicts mussel larval numbers from real-time data.

Assays were used to analyse the bivalve content of vertical –tow plankton samples collected from multiple sites around North Wales over a two year period (Figure 2).

Main conclusions

These techniques represent a promising method for the detection and relative quantification of bivalve larvae in mixed plankton samples, which will shed new light on temporal and spatial patterns of spawning and larval transport. The methodology also has the potential to aid in aquaculture site selection and projections for optimal times when equipment deployment or installation can take place to maximise settlement potential.

Introduction

Crucian carp (*Carassius carassius* L. 1758) and tench (*Tinca tinca* L. 1758) are *cyprinid* fish species native to Central-Eastern-Europe including Hungary. They prefer to live in marshes, densely vegetated lakes and ponds, backwaters and horse-shoe lakes. Nowadays their role in aquaculture is not significant; however this may change in the future. They adapted well for higher temperatures and lower oxygen levels. The climate change may make these qualities more important and may make these species suitable for future aquaculture production. The populations of both species are on the decline in Hungary and in the neighboring countries. The main reasons of population reduction are habitat loss, human activities and in case of crucian carp the hybridization with the invasive gibel carp (*Carassius gibelio* Bloch, 1782). The conservation of the two species is on one hand important for the maintenance of biodiversity and on the other hand for the beginning of breeding work. The genetic information on natural populations in Hungary is limited so genomic and mitochondrial DNA markers are used to assess the genetic variability of the species. In case of crucian carp the extent of hybridization with gibel carp is also in the focus of our research. The future goal of this work will be the establishment and development of a live genebank and a cryobank of these species.

Materials and methods

Fin samples were collected from 310 crucian carp individuals representing 7 natural populations and 4 stocks from different fish farms in Hungary and from 160 tench individuals originating from a fish farm (Somogygeszti) in South-West-Hungary. Fin samples were stored in 70% ethanol until DNA extraction. The total DNA was extracted from the samples using the simple salting out procedure described by Miller et al. (1988). DNA qualities and quantities were measured by NanoDrop™ spectrophotometer. 5 microsatellite markers (MFW7, GF1, GF29, YJ0010 and YJ0022) were used to analyze the genetic variability of crucian carp so far. PCRs were carried out as it is described in the original papers. An automated ABI Prism 3130 Genetic Analyzer was used for the fluorescently labeled PCR products sizing. Genotyper 4.0 software package supplied by Applied Biosystems was used to estimate the length of fragments. GenAlEx6.501was used to calculate allele frequencies, observed heterozygosity (Ho), expected heterozygosity (He), number of private alleles, genetic variance (Fst), and heterozygote deficit. MICRO-CHECKER version 2.2.3 was used to detect possible genotyping errors, allele dropout and non-amplified alleles (null alleles). The genetic relationship between populations and individual assignments of fish was inferred via a Bayesian clustering analysis using the statistical program STRUCTURE version 2.3.3. The K with the greatest increase in posterior probability (ΔK) was identified as the optimum number of sub-populations using STRUCTURE HARVESTER. In case of the tench, the mitochondrial d-loop sequences were analyzed by PCR amplifi ation (primers Pro2:AACTCTCACCCCTGGCTACCAAAG and Phe2:CTAGGACTCATCTTAGCATCT TCAGTG), and BigDye Terminator sequencing (Applied Biosystems) from both ends. MEGAx and DnaSP 5.10 software were used for the analyses of sequences. A phylogenetic tree was constructed using the maximum likelihood method and Tamura-Nei model.

Results

A total number of 48 microsatellite alleles were described throughout the eleven populations and stocks of crucian carp. The lowest number of alleles was found on locus GF1 (3) while the highest number of alleles (26) was detected on GF29. The number of alleles ranged from 10 to 27 in the different populations. Altogether 10 private alleles were found with the frequency ranging from 0.017 to 0.093. The private alleles were found mostly in the wild populations. The average expected (H_e) and observed heterozygosity (H_o) for all populations and loci was 0.427 and 0.389 respectively. In case of most of the natural populations the H_e and H_o values were relatively close to each other while in case of two farmed stocks the Chi-square tests for Hardy-Weinberg equilibrium presented significant heterozygote deficit in four of the five loci. The AMOVA analysis showed that 34% of the whole molecular variance is among populations, while 12% is among

(Continued on next page)

individuals and 54% is within individuals. Genetic differentiation (pairwise Fst) between population pairs ranged from low to high values (0.022 and 0.592) supporting the existence of population substructure. The structure analysis supports the existence of at least two subpopulations in Hungary. The tench mitochondrial d-loop sequences contained 34 polymorphic sites among the 793 nucleotides and 14 haplotypes were identified in the population. Forty-four percent of the individuals carried the most frequent haplotype (Hap_8), while 5 moderately common (23-5.6%) and 8 rare haplotypes were also present. The phylogenetic tree shows two distinct groups of the haplotypes.

Discussion and Conclusions

Based on the so far limited microsatellite results one can say that the natural crucian carp populations in Hungary are genetically diverse and generally the natural populations have higher variability. There were only two exceptions found. These are small and totally isolated pond populations with small number of individuals. Some of the farm stocks have a very limited number of alleles and the proportion of heterozygotes is low. This phenomenon can be explained with a probable founder effect. The farm stocks were probably established with the use of limited number of broodfish. In the future process of the establishment of genebanks of the species, we have to practice extreme caution to avoid this mistake and collect the individuals with proper genetic background, representing the variability of the Hungarian populations. With the future mtDNA investigations and the analysis of diagnostic microsatellite markers, the potential crucian carp-gibel carp hybrids must be excluded from the genebank. The preliminary analyses of the Somogygeszti tench population shows high haplotype diversity, however the analyses of the nuclear genome is also necessary for conclusions. To build a tench gene bank, further wild and farmed populations should be analyzed and used to preserve proper genetic variability.

This research is supported by the GÉN-NET 21 VEKOP-2.3.2-16-2016-00012 project.

β-GLUCANS, SODIUM ALGINATE AND THYROXINE HELP IN ENHANCED SURVIVAL RATE, STRESS TOLERANCE AND IMMUNITY IN BLUEFIN BREAM (*Sparidentax hasta*) LARVAE

H. Al-Gharabally*, A. Saheb and S. El-Dakour

Kuwait Institute for Scientific Research, .O. Box 24885 SAFAT 13109, Kuwait
*Email: hgharabally@gmail.com

Introduction

Bluefin bream is one of the important commercial species in Kuwait and the Arabian Gulf. Reducing the mortality rates, in the larval rearing stage between day 7 and 35, caused by several types of pathogenic bacteria, is the aim of this study. One alternative method-gaining acceptance within the aquaculture industry is the use of immunostimulants. Because of the previous project FM074K results (Al-Gharabally H. et al., 2013) which showed that β-Glucans enhanced survival rate and disease resistance of sobaity larvae, ß-Glucans was chosen again along with Thyroxin (T4) and Sodium Alginate (SA) because both gave impressive results in enhancing immunity in general (Yamano 2005; Klaren et al., 2008; Schnitzler et al., 2011; Cheng et al., 2013; Liu et al., 2006). This study is aimed at evaluating the effects of the thyroxine (T4) and sodium alginate (SA), in comparison with β-glucans (BG), on the survival rate, stress tolerance, and immunity of Bluefin bream (*Sparidentax Hasta*) larvae.

Materials and methods

Dose optimization experiments must be carried out to identify the optimized doses of T4 and SA which will be applied with the already determined optimized dose of ß-Glucans in a dietary experiment which will continue for 35 days focusing on ages from 7th day post hatch (dph) till day 35 dph for improving the non-specific immune responses. Immune parameters will judged by haemagglutinin, bacterial agglutinin, lysozyme and phagocytic assays. Larval quality is evaluated by carrying out the following stress tests based on importance and frequently used methods in aquaculture: salinity, handling and formalin. For evaluating disease resistance, a sample from the immunostimulated and control larvae are challenged with pathogenic bacteria *Proteus vulgaris* spp at 10^7 colony-forming unit (CFU)/ml suspensions for 30 min, after which the challenged larvae will be transferred into fresh seawater aquariums of 30 l capacity to observe survival and mortality.

Results

The optimized doses for T4 and SA were best at 0.01 ppm and 3 g/l, respectively, in enhancing the overall survival for the first 7 d post hatching (dph). The evaluation of optimized doses of T4 (0.01 ppm), SA (3 g/l) and BG (45 mg/l) revealed that the best enhancement in growth and survival of larvae until 14 dph was with T4 treatment. However, BG was better than T4 at 21 dph. The stress test conducted at 35 dph showed that the immunostimulated larvae, irrespective of the stimulant used, were significant y better in their survival response after salinity and formalin stress. Immune parameters suggest a superior performance of the immunostimulated larvae in their phagocyte response, lysozyme activity, hemagglutinin, and bacterial agglutinin levels. The best survival in a challenge test of stimulated larvae against live *Proteus vulgaris* showed a higher survival response with SA and T4 (92 and 88% respectively) followed by BG (75%) and lastly 58% for the control group.

Discussion and conclusion

Immunostimulation of the larval stages of fish is an important step in the fish health management strategy as the fish at this stage of their life cycle are either immature histologically to handle antigens or immunologically to mount considerable defense to overcome the pathogens. Immunostimulation with T4, SA and BG was effective when applied to larvae from 14, 21 dph in case of enhancing larval growth. Immune response of immunostimulated larvae was also superior in the immunostimulated fish. Stimulation with T4 followed by BG can be helpful in enhancing survival and immunity.

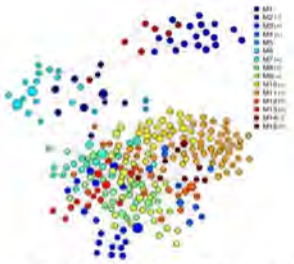

Figure 1. Bacterial co-occurrence network generated by SPIEC-EASI. Network modules detected by Louvain clustering are shown in different colours. Node size corresponds to the average sequence proportion operational taxonomic units in intestinal and faecal samples. No symbol indicates common modules, while bacterial clusters/sub-communities in healthy and diseased shrimps are indicated by (-) and (+), respectively.

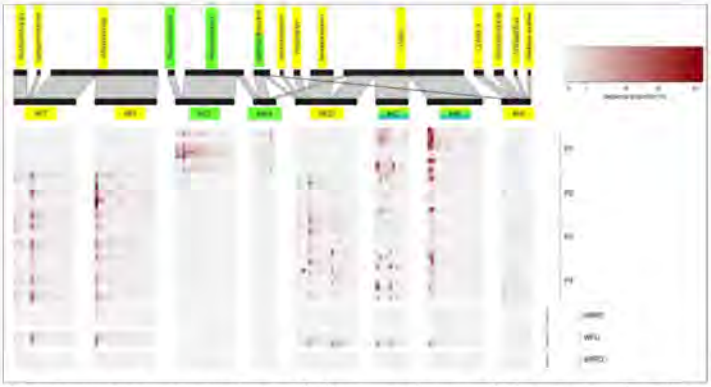

Figure 2. The sequence proportion of the members of the most dominant and most distinguishing network modules between healthy shrimps (P1 and green) and diseased shrimps (P2, P3, P4, and yellow) as well as their contribution to the particle-associated fraction from the respective ponds and sampling points. Their taxonomic affiliation is provided on genus level. Water samples were not used for the network construction.

Email: rosa.allshire@stir.ac.uk

Introduction: Salmon gill poxvirus is an emerging viral disease in the Scottish salmon farming industry and has been associated with high mortalities throughout the production cycle. Although severe gill pathology is generally associated with disease outbreak, little else is known about the pathogenesis of the disease. In order to better understand the transmission routes and potential outbreak triggers, two comparable cohorts of farmed salmon were studied over a 6 month period and through an SGPVD outbreak.

Methodology: Two cohorts of Atlantic salmon fry in a hatchery were studied concurrently in separate recirculation systems with varying histories of SGPV. Both systems share similar husbandry techniques, water source and fry intake, but only one has had SGPV recently. During the study period, one cohort became infected with the virus while the other remained naïve. The progression and effects of the disease were studied in order to better understand the prevalence of the virus and it's correlation to disease outbreak.

Blood, serum, histology and gill samples were taken from 14 randomly sampled fish from each cohort, at two week intervals, over a six month period. Once SGPV was detected, sampling was increased to twice weekly for two weeks in order to document the disease outbreak. As a result, the virus prevalence, spread and effects in various organs were documented throughout the outbreak.

Gill tissue was tested for viral load using qPCR, histopathology samples were screened for any pathology caused by the disease, blood samples were tested for red blood cell count, total and differential white blood cell counts and packed cell volume and serum was taken for serology and potential biomarker identification

Results: Results of the comparative study of naïve and infected cohorts will be presents in the final poster as analysis is ongoing.

CHARACTERISTICS AND QUALITY OF PRODUCTION DATA IN AN ATLANTIC SALMON (*Salmo salar* L.) PRODUCER'S LEGACY DATABASE

R. Alvestad[1*], K. H. Liland[2], I. Måge[1], C. Noble[1], and B. -S. Sæther[3]

Intensive, commercial aquaculture production operations such as Atlantic salmon farming have more and more come to rely on a data driven and information intensive form of production management, facilitated by the acquisition of data from a multitude of sources such as electronic sensor devices and manually recorded observations (Aunsmo et al., 2008; Lee, 2000; Menzies et al., 1996). This data acquisition provides for the producers accumulating increasingly large and heterogeneous datasets, comprising numerous variables pertinent to production and stock management, including water quality measurements and indicators of the biological performance of the cultivated animal (Aunsmo et al., 2008; Lee, 2000). While typically being used to inform day-to-day management and for benchmarking purposes (Soares et al., 2011; Aunsmo et al., 2008; Lee, 2000), these datasets, given the appropriate analysis, may also carry the potential for discovery of new knowledge that can aid in better understanding and improving the production process.

To achieve a proper use and analysis of data, in which meaningful and interpretable results are to be obtained, an assessment of data quality with subsequent cleansing and pre-processing steps is necessary (Bocca and Rodrigues, 2016; Maletic and Marcus, 2009; Fayyad et al., 1996). Particularly, complex data sets require an assessment of which variables are available, their completeness, dependencies, geographic or temporal resolution, and what constitutes typical and atypical variation (Bocca and Rodrigues, 2016; Karr et al., 2006; Lacroix et al., 1997). Atlantic salmon producers' records are examples of such complex data sets given their size and heterogeneity, and with variables often being subject to temporal and spatial dependencies.

The objective of this study was to assess what characterises a typical production data set from Atlantic salmon farming, to establish which variables are available and to which extent they fulfil certain quality aspects, and to identify constraints to proper use and analysis and how data treatment can mitigate these. To achieve this, we obtained access to the legacy database of a large, vertically integrated, commercial Atlantic salmon production company, comprising production records from all the company's seawater cage sites in Norway. Data from full production cycles completed during the last 9 years were acquiesced from the database and subjected to an exploratory analysis and quality assessment, with a selection of variables chosen for further treatment.

This presentation will summarise the main findings of the exploratory analysis, demonstrating the database's adherence to relevant data quality principles, and review the procedures followed in data cleansing and pre-processing. Key challenges, particular to the analysis of aquacultural production data, will be highlighted.

NILE TILAPIA GROWTH PERFORMANCE USING XYLANASE AND BETA GLUCANASE

Alexandra K. Amorocho*, Elkin R. Montecino, Diego Remolina and D. Allen Davis

School of Fisheries, Aquaculture and Aquatic Sciences
Auburn University Auburn, AL 36849
akamorocho@solla.com

The purpose of this study was to evaluate the production performance of Nile tilapia *Oreochromis niloticus* when supplemented with a commercial beta xylanase and beta glucanase enzymes. Two practical basal tilapia diets were formulated to contain 32% protein and 6% lipids. One basal diet formulated to contain a low level of fiber (LF) based on soybean meal, was modified by top coating liquid enzyme to produce five levels of enzyme inclusion (0.00, 0.015, 0.030, 0.045, and 0.060 g/100g). A second basal diet was formulated to contain a high level of fiber (HF). To increase the fiber content, 30% distillers dried grains with solubles were used as a replacement for soybean meal. This basal diet was modified by top coating liquid enzyme to produce five levels of enzyme inclusion (0.00, 0.015, 0.030,0.045, and 0.060 g/100g). The test diets were offered to sex reversed juvenile tilapia (mean initial weight 10.31 ± 0.31 g) over a 70 - day growth trial. Four replicate groups of 20 fish per aquaria were offered the test diets at near satiation levels. At the conclusion of the growth trial, survival was near 100% and weight gain was around 600%. The inclusion of beta xylanase and beta glucanase resulted in significan differences in final mean weight ($P = 0.0029$), percent weight gain ($P = 0.0128$), thermal unit growth coefficients ($P = 0.0046$) with no change ($P > 0.05$) in feed conversion ratio ($P= 0.2153$), apparent net protein retention, apparent net energy retention, hepatosomatic index and intraperitoneal fat index. In general, fish maintained on the high fiber diet performed better to the addition of the enzyme. The use of beta xylanase and beta glucanase showed clear advantages, improving growth performance of Nile tilapia.

FISH ENERGY BUDGET OF THE ZEBRA SEABREAM (*Diplodus cervinus*) UNDER OCEAN WARMING AND ACIDIFICATION

Introduction

Climate change is one of the greatest environmental challenges that cause profound impacts on marine organisms and ecosystems (IPCC, 2014). According to the latest report of the Intergovernmental Panel on Climate Change (IPCC, 2014), it is predicted seawater pH decrease (0.2-0.6 units) and seawater surface temperature increase (0.3–4.8°C) in estuarine and coastal areas by the end of the 21st century with strong local variations. Indeed, ocean warming and acidification represent the major threats to many marine organisms, particularly fish, deeply affecting their physiological responses in ways that often compromise their energy budget, i.e. the energy intake and expenditure within the whole organism (Jobling, 1994; Yurista, 1999). The impacts of these environmental stressors on fish bioenergetics remain unclear and still require further understanding. In this context, the main goal of this work was to study, for the first time, the effects of ocean warming (+4°C, i.e. 23°C) and acidificat on (ΔpH=−0.4 units equivalent to ΔpCO_2~1000 µatm) on the energy budget (i.e. growth, excretion, metabolism and food consumption) of juvenile zebra seabream (*Diplodus cervinus*).

Materials and methods

Juvenile zebra seabream (*Diplodus cervinus*) specimens (4.8±0.9 g total weight) were exposed to four scenarios during 61 days to understand the potential consequences to organisms under current and future expected conditions (i.e. seawater warming, Δ=4°C and ΔpCO_2~1000 µatm equivalente to ΔpH=−0.4 units according to IPCC projection scenario RCP8.5; IPCC, 2014): i) Scenario 1 – Control, i.e. seawater temperature set at 19°C and pH at 8.0 (pCO_2~405 µatm; current conditions used in juvenile zebra seabream rearing in Iberian Peninsula); ii) Scenario 2 – Warming – seawater temperature set at 23°C and pH at 8.0 (pCO_2~405 µatm); iii) Scenario 3 – Acidification – seawater temperature set at 19°C and pH set at 7.7 (pCO_2~1000 µatm) and; and iv) Scenario 4 – Warming + Acidification – seawater temperature set at 23°C and pH set at 7.7 (pCO_2~1000 µatm). During the experimental period, specimens were fed with 3% of the average body weight (divided in two meals per day). Four specimens per replicate/tank (n=12 per treatment) were randomly weighted and sampled at the end of the experiment, freeze-dried (whole fish) and kept at -80°C until further analyses. Biochemical analyses (dry matter, ash, total lipids, crude protein and gross energy) were determined in the diet and fish body according to the Association of Official Analytical Chemists methods (AOAC, 2005). For calculation of energy budget equation (C=G+F+U+R), growth (G), excretion (faecal, F and nitrogenous losses, U), routine metabolism (R) and food consumption (C) were determined. For growth, fish were weighted every week and energy content in fish and faeces was measured by combustion in an adiabatic calorimeter pump. To calculate energy loss through excretion, faeces were collected daily, oven-dried at 65ºC to constant weight and stored at -20°C for analysis of energy. Nitrogenous compounds (ammonia-N) were determined at the end of the experiment using 12 individually fish enclosed in 500 mL glass bottles during 1h for each treatment. Regarding respiration, routine metabolic rates (RMRs) were determined at the end of the experiment according to previously established methods (Anacleto et al., 2018) with some modifications.

(Continued on next page)

Results and discussion

Energy proportion spent for growth dominated the mode of the energy allocation of juvenile zebra seabream under the combined effect of ocean warming and acidification. Acidificati n alone strongly decreased the ammonium excretion rate (AER), but increased fat and protein contents, as well as the viscerosomatic index, VSI. On the other hand, under warming conditions, an increase in metabolic rates (RMRs) was registered, likely since temperature directly affects the rate of all biological processes. Nevertheless, the combined effects of both stressors promoted an increase of fish growth, but a decrease of the hepatosomatic index (HSI).

Conclusions

Overall, such extreme conditions of ocean warming and acidification, is expected to greatly affect the energy budget of marine fish, leading to impacts on fish communities and ecosystems. Such studies are extremely relevant to unravel the partitioning of energy in the different physiological processes of fish species. Further research combining other stressors (e.g. hypoxia or presence of contaminants) are needed to better understand and forecast fish ecological effects, in order to develop potencial mitigation measures.

Introduction

Madeira is a small Portuguese Island in which the aquaculture industry started developing fish farms in 1996. Currently the island has three *Sparus aurata* offshore fish farms, all located in the south coast. The most recent one, MARISMAR, located in Calheta, is where this study took place.

Plastic debris imposes a real threat to the marine ecosystem, approximately 60 to 80% of the marine debris in the world is plastic (Derraik, 2002) and almost 10% of the annual production ends in the ocean where degradation can take several hundred years (Avio et al., 2017). The threats to marine life are primarily mechanical due to ingestion of plastic debris and entanglement (Laist, 1987, 1997; Quayle, 1992).

A previous preliminary study of this thematic was done last year in the same fish farm and showed that further work was needed.

The aim of this study is to monitor macroplastics in the fish farm cages and its impact on the livestock

Material & Methods

In order to avoid the need and costs of diving to identify and quantify plastics in the exterior side of the cage's nets, a camera attached to an extensible tube was used to film the cage's perimeter on the surface, and in depth in 4 areas (north, east, south and west).

S. aurata stock analysis was made by examining the gut content of dead individuals in the cages. This methodology allowed to quantify the mortality due to plastic ingestion and the types of plastics that were most often ingested. It was also possible to analyze the gut content of individuals in good health that were sampled once a month by the company.

In addition, weather conditions and ocean currents were also monitored in order to determine its influence on the presence of plastics and beach surveys were made to compare the plastics that were present on the coast with the ones that were found at the cages.

Results

Preliminary results showed that out of a total of 62 video samplings that were analyzed, we were able to identify in 12 videos, plastic fragments. Most of the plastics were plastic bags, but also ropes and fragments of the cage's structure. The weather conditions, particularly, the rain seems to affect the presence of plastics on the cages, as well as on the beaches surveyed.

Regarding the stock analysis, we analyzed gut content of 157 fish, of a sample of 289 dead fishes (some were unfit for gut analysis). Regardless, all fish had their morphological data taken (weight and standard, fork and total length). From the 157 fish suitable for gut analysis, 9 had plastics (4 in the intestine and 5 in the stomach), all the same type- seem to be fragments of plastic bags. The analysis of the monthly sampled fishes in good health (total of 166) did not show any plastics so fa .

(Continued on next page)

Discussion & Conclusion

The study is still ongoing so further analysis regarding the influence of weather and ocean currents is still needed. Most of the plastics found in the sea cages seem to be from domestic disposal (shopping/garbage bags), agriculture activities (plastic bags used in banana plantations) and the aquaculture itself (ropes and pieces of the cages). According to Li et al. (2016), plastic debris originates from two major sources, land-based and ocean-based, with domestic, industrial and fishing activities being the most important contributors.

The stock analysis showing the same type of plastic being ingested could mean the individuals are ingesting plastic selectively because more than one type of plastic was observed in the video samplings. Although, this seemingly selectiveness could be due to the thin nature of plastic bags, making it easier to enter the cages. Carpenter et al (1972) examined several species of fish with plastic debris in their gut and observed that only white plastic fragments where ingested, indicating that the individuals were feeding selectively. So far most of the plastics found in fish have been white, however we also found a blue one and two black ones.

Plastic pollution in the marine environment is now recognized as a real threat with a global-scale distribution and adverse effects. Due to the long-life of plastics on marine ecosystems, harm to marine life would continue for many decades even if the production and disposal of plastics suddenly stopped (Avio et al., 2017).

Introduction

Aquaculture has grown at a very fast rate during the last years and this growth has been supported by a significant research effort directed to increase the industry´s sustainability. During the last two decades, intense research efforts have focused on the potential of plant-derived ingredients as an alternative to substitute fishmeal and fish oil in aquafeeds formulation. However, dietary replacement of fishmeal by plant sources may result in an unbalanced supply of selected nutrients, among which taurine has been identified. Taurine is known to be involved in many important physiological processes (such as bile salt synthesis, control of plasma cholesterol levels, cellular osmoregulation, control of endocrine tissues physiology, among others), and it is considered an essential nutrient for marine fish. But taurine is virtually absent in terrestrial plant ingredients, while it is particularly abundant along the marine food chain. Thus, when feeding marine fish with terrestrial plant protein-based diets taurine requirements may not be fulfilled

This presentation will review the work developed during the last years to understand the importance of taurine for a marine fish species important for Southern European aquaculture – the Senegalese sole (*Solea senegalensis*). Senegalese sole is a high value flatfis species, which requires the incorporation of particularly high levels of proteins in the feed (60% DM crude protein) to reach maximum protein accretion during their juvenile stage. The main objectives of these studies were: to evaluate the effects of dietary fishmeal replacement by plant protein-sources on growth and metabolism of juvenile Senegalese sole; and to understand if dietary taurine supplementation had beneficial effects on fish physiology and performance.

Materials and Methods

The different experiments performed used two basal diets: a fishmeal-rich diet (FM), with a formulation similar to a commercial diet for Senegalese sole, and a plant protein-based diet (PP), in which plant protein sources replaced 85% of proteins from marine origin. Taurine content in PP and FM diets were 0.09% and 0.5% (dry matter basis), respectively. Based on PP and FM formulations, experimental diets diets were further supplemented with different taurine levels. All diets were isonitrogenous and isoenergetic.

Senegalese sole (*Solea senegalensis*) juveniles were used as model species for all experiments (13-150g, depending on the experiment).

Due to the passive feeding behaviour of Senegalese sole juveniles, the first experiments were developed to guarantee a reduced leaching of dietary taurine and other amino acids to the environment and to ensure an efficient and reliable delivery at fish tissues. Therefore, taurine encapsulation was tested and dietary taurine leaching in water was analysed and post-prandial taurine kinetics in fish plasma was monitored.

Growth trials using the two basal diets and diets supplemented with taurine were performed, and the impact on Senegalese sole growth performance, feed consumption and utilisation, and several physiological indicators were analysed. Furthermore, short-term experiments using radiolabelled nutrients were performed in order to analyse the effect of dietary taurine levels on nutrient (such as protein and lipids) absorption and metabolism.

(Continued on next page)

Results and Discussion

Strategies to microencapsulate taurine proven to be successful. Growth was impaired in Senegalese sole juveniles fed diets with high levels of fishmeal replacement by plant protein-sources and detailed analysis revealed negative repercussions at physiological and metabolic level. Negative effects were detected, for instance, on intestinal epithelia, on ion transport at intestinal level, on bile salt synthesis and transport, on lipid digestion and absorption, and on protein metabolism. Al least part of these negative effects could be reversed by an appropriate level of dietary taurine supplementation to plant-based diets. The results obtained in the several studies indicate that taurine should be included in high plant-based diets has a strategy to mitigate the negative effects of these diets on Senegalese sole performance and metabolism.

Introduction

In the Basque Country (SE Bay of Biscay) the interest for offshore aquaculture has increased considerably during recent years. In 2012 AZTI set up an experimental facility at 2km off the coast of Mendexa (Biscay), to test the feasibility of culturing shellfish in open waters. This facility is installed at a deep of 45-50m and consists of longlines; the organisms cultured are mainly mussels (*Mytilus galloprovincialis*). However, the supply of mussel seed is critical for the development of industrial mussel production. Small mussel populations can be found along the Basque coast (Azpeitia et al., 2017); yet, the spatial and temporal dynamics of mussel spat arriving to this coast are highly variable and poorly understood. Therefore, the aims of the present study are i) to evaluate the settlement and recruitment seasonal patterns of mussel seed from natural resources using five different collector types and ii) to assess the effect of collector type, to make recommendations on the most efficient collectors to producers.

Material and methods

In March 2018 five different spat collectors were deployed in the experimental longline in Mendexa. The collector ropes were 10m long and were suspended at a water depth of 1m within 1m of distance between each other. The collectors, provided by a local supplier, were namely: P ("peluda"), R ("rizada"), G ("grope"), L ("loch") and B ("brae") (Figure 1). The different collector designs offer different textural properties and structural complexity which may enhance the strength of seed attachment.

With a sampling frequency between 45 to 60 days, spat attachment was assessed in May, July, August and October 2018 and January 2019. In each sampling, 3 replicates of 10 cm of each collector type were retrieved. Additionally, in order to characterize the experimental zone, environmental parameters were analyzed monthly. For the determination of settlement and recruitment patterns, the abundance of individuals per rope meter and the length of mussel seed were estimated. The procedure to evaluate larval settlement and recruitment was adapted from the methodology described elsewhere (Filgueira et al., 2007; Fuentes-Santos and Labarta, 2015).

Results

Results showed that the highest seed settlement (*i.e.*, mussels passing through a 5 mm sieve) occurred in July 2018 in all collector types. However, the most filamentous ropes (namely Loch and Brae) were the ones that presented the highest abundance, showing values up to 25,000 ind/m of rope (Figure 2). In August, as mussels continued growing, the abundance of settlers decreased while the first recruits (*i.e.*, mussels retained on a 5 mm sieve) appeared in the collectors, especially in G and B ropes. The highest recruitment was detected in October 2018 in G, L and B ropes. However, in January 2019, the recruitment decreased but the collectors with the highest abundance were L and B ropes.

Discussion and conclusion

The highest seed settlement that occurred in July 2018 corresponded with the spawning season of natural mussel populations which takes place mainly in spring in the Basque coast. In turn, this temporal settlement variation could be partially explained by seasonal fluctuatio s in environmental factors, such as temperature and some nutrients In both, settlement and recruitment phases, G, B and L rope types presented the highest mussel seed density followed by R rope type and to a less extent by P. Other authors have obtained similar results in Galicia (NW Spain) indicating that filamentous ropes possess a higher surface area for seed attachment than non-filamentous ropes (Filgueira et al., 2007).

In conclusion, results showed that collector type had an effect on the seed abundance, either at settlement or recruitment phase. Filamentous collectors (G, B and L ropes) were the ones in which a higher quantity of seed was settled and in which higher recruitment abundance was recorded in January. Thus, filamentous ropes are the one recommended for natural seed collection to producers.

Introduction

The sea urchin *Paracetrotus lividus* is a valuable fishing resource due to its gonads ("roe"), greatly appreciated in Europe as a seafood delicacy, where local populations have been heavily exploited. The interest on echinoid aquaculture has been increasing in the last two decades. The production of echinoderms constitutes a challenge mainly due to the existence of different states over its lifecycle and the complex biotic relationships that occur during phase transitions larval and post-larvae. The quality of the microalgae provided is a primordial factor having a direct (nutritional properties) and indirect (water quality) impact on growth, competence (capacity for settlement) and survival. In the last years several microalgae species have been tested in order to optimize the larvae culture. *Skeletonema costatum* is a diatom commonly used in the bivalve larval cultivation. Nutritionally it is characterized by a relatively high levels of EPA and DHA in its lipid profile. It is also notorious for the high antioxidant and antiflammatory activity (Franca, 2019). However, the use of this diatom in *P. lividus* larval cultivations is poorly known. The main aim of this works was to test the use of *Skeletonema costatum* on *P. lividus* larvae and post-larvae cultivation.

Materials and Methods

Three diets were tested: *Rhodomonas* spp. (D1), *Skeletonema costatum*, (D2) and a mix (50/50) of *Rhodomonas* and *S. costatum* (D3). Four 6L glass balloons were used for each treatment. 15,000 larvae with 2 days after hatching (DAH) were introduced in each ballon. Daily microalgae were provided in order to obtain a concentration of 3.000 cell mL^{-1}, 10,000 cell mL^{-1}, 15,000 cell mL^{-1} and 20,000, depending on the development phase. Survival and biometric sampling were performed at 2, 4, 8, 12 and 15 DAH. Settlement trial was performed on 20 L fibe glass tanks (2 replicates each diet) with an initial n=15,000 larvae each. At 50 DAH biometric sampling and survival rate was assessed. Microbiological quality of the water was analyzed using TSA (non-selective medium) and TCBS (*Vibrio* selective medium).The inoculated media were incubated at 25 oc for 48 – 96hrs, then isolated bacteria were subjected to taxonomical analysis according to Bergey's manual of Determinative Bacteriology (1994) and isolated bacteria were identified by using API20 E system.

Results and Discussion

During the larval cultivation assay it was verified that the larvae fed with the D2 diet (55.8%) and D3 (39.9%) had a survival at 15 DAH substantially higher than D1 (5.5%). When compared with similar studies, the survival obtained with diets D2 and D3 were similar or even higher in some cases (Ahmed et al., 2016; Carboni et al., 2012; Castilla-Gavilán et al., 2018). The low survival in D1 was possibly due to the higher microbiological load (*Vibrio alginolyticus* and *Vibrio pectenicide*) that apparently develops more easily in a *Rhodomonas* spp culture environment. It was observed, however, that larvae fed only with *S. costatum* (D2) showed a relatively lower development than D1 and D3 diets (table 1). It was also found that the competency index used (rudiment length/body length) was significantly lower for larvae fed with the D2 diet ($P < 0.001$). In general, these results are in accordance with other similar studies, showing that the microalge diversified diets contribute to a better development of *P. lividus* larvae. During the settlement and post- settlement phase there was also a lower growth of the sea urchins fed with the D2 diet ($P < 0.001$) and a relatively higher survival for the ones fed the D3 diet (42.5%).

Conclusions

Through this study it was found that the diatomaceous *S. costatum* is an adequate food for the larval cultivation of sea urchins *P. lividus*, providing a high survival of larvae and post-larvae. Associated with other microalgae, as in this study, the development, settlement and post-larva development may be further potentiated.

Introduction

Different physiological strategies leading to differential growth encompass endogenous (i.e. inter-individual and inter-familiar) variability in energy demands (Bayne, 2004). Dietary composition, in addition to gross energy income are determining of growth trajectories (Kreeger et al, 1996). Therefore, in this work we analyzed the effect of N content of diets on elemental (C, H, N) composition of seed tissues of *Ruditapes philippinarum* as well as the differential effects resulting from inter- and intra-familiar differences.

Materials and methods

Fast (F) and slow (S) growing seeds of the Manila clam *Ruditapes philippinarum* were selected from each two families (1 and 8) created in hatchery. Two aliquot subgroups from each of the four groups (F1, F8, S1 and S8) were conditioned to either a N-rich (N+) or N-poor (N-) diet for 30 days. These diets consisted of the microalga *Rhodomonas lens* at either exponential (N+) or stationary (N-) growth phase of culture, the latter presenting a C:N ratio that was 2.5 times the C:N ratio of the former. After determining elemental balances under both diets (following Tamayo et al., 2014), tissues were dissected separately and elemental composition of each tissue was analyzed by means of an Euro EA Elemental Analyzer (CHN) from EuroVector, using acetanilide as standard. Finally, dry and organic tissue weight was recorded for biometrical analyses.

Results

%N content of tissues was significantly higher when conditioned to N+ diet, which promoted significant reductions of %C and C:N ratios (Table I). No significant differences were found for growth category (F vs S) in any of the parameters while differences between families were only significant for %C. ANOVA interaction terms among factors only showed significant differences when tissue was involved, reflecting the high impact of tissue composition above the rest of factors.

C:N ratio of the digestive gland was, among the different tissues, the most affected by diet and seed condition, and reflected the net balances of C:N (see figure 1 left and center)

On the other hand, C:N ratios of the whole tissues exhibited a different behavior according to growth category (Figure 1, right): While F seeds maintained a rather constant ratio, C:N of S seeds tended to decline with N+ (but only in Family 8) and to increase with N-.

Finally, growth of clams (in terms of live weight, see Table I) was affected by diet, and especially by growth category. Furthermore, condition indices only showed differences between families, where family 8 reached values > 30% than family 1, in which shell weight was the responsible of these differences.

Discussion and conclusion

Diet composition was able to promote changes in soft tissues of clams after a month of exposure, although effects differed among selection groups: While whole body composition of slow growing seeds fluctuated according to diet composition, F seeds were able to maintain C/N homeostasis; this differential behavior did not occur in the digestive gland. On the other hand, S seeds behavior differed among families, with Family 1 showing a high degree of homeostatic regulation of C/N composition.

Additionally, N+ diet enhanced growth rates, which suggests that nutritional limitations would come from N content rather than energy content of the food (Kreeger et al, 1996). Finally, differences in condition index between families could be indicative of different allocation profiles: The rate of energy assignment to soft tissues growth would be higher in Family 8 while Family 1 would invest comparatively more energy into shell thickening.

The sea louse *Caligus rogercresseyi* is an insidious ectoparasite that affects farmed salmonids in Chile. Effective control of the sea lice requires the use of antiparasitic drugs, which are administered to fish as immersion treatments. These are complex procedures in which a drug solution is poured into the fish cage. Salmon companies have developed their own strategies to perform immersion treatments. These practices have not been fully described nor evaluated in terms of treatment success. The objective of this study was to identify and quantify the effect of different practices on treatment success, through an expert elicitation process. This process consisted in the design of a questionnaire, its application to experts through personal interviews and a group discussion. We organized the relevant factors using a causal diagram (Fig. 1) and the expressed associations as likelihood ratios (LRs). Experts indicated that the most important factors impacting treatment success were: 1) treatment duration, 2) drug concertation in water, 3) preparation of the drug solution, and 4) distribution of the drug solution. This study constitutes the first effort made in Chile to identify the best practices for performing immersion treatments across the salmon industry.

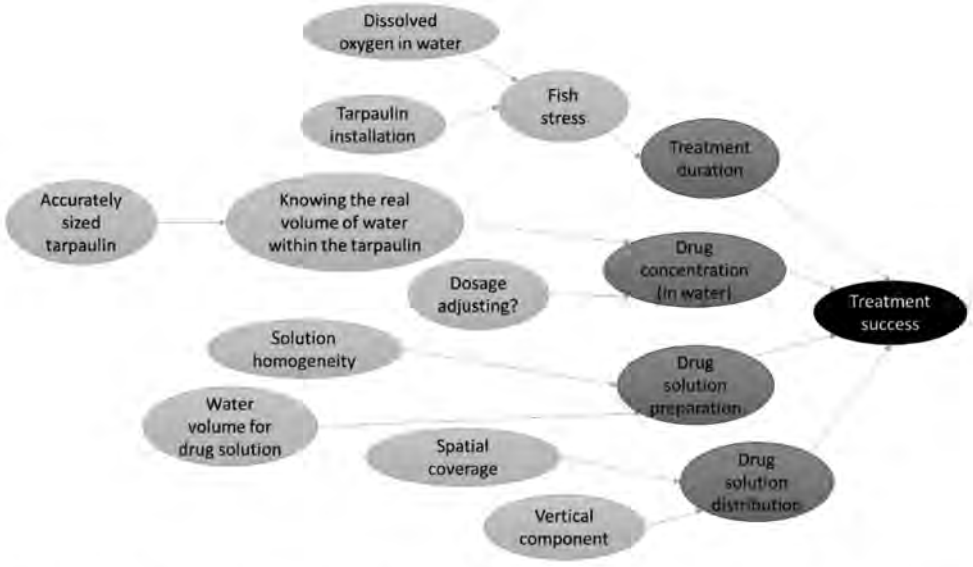

Figure 1. Final causal diagram of antiparasitic treatment success, based on expert opinions. Direct factors are presented in dark gray, while indirect factors in light gray.

THE ROLE OF EPIDEMIOLOGY IN THE SURVEILLANCE AND CONTROL OF PREVALENT FISH DISEASES – THE CASE OF SEA LICE IN FARMED SALMONIDS IN CHILE

Gabriel Arriagada*

Instituto de Ciencias Agronómicas y Veterinarias, Universidad de O'Higgins, San Fernando, Chile
E-mail: gabriel.arriagada@uoh.cl

Chile is the second larger producer of farmed salmon in the world. The sea lice *Caligus rogercresseyi* is one of the most challenging fish health problems for this industry because of its complex control (as the sea lice quickly develop tolerance to chemotherapeutants), and due to the fact that it is ubiquitous in sea water. In Chile, sea lice is under an official surveillance and control program administered by the health authority SERNAPESCA.

The aim of this abstract was to highlight the role of epidemiology in surveillance and control of prevalent aquatic disease, such as the case of sea lice.

Surveillance of sea lice in Chile involves weekly reports of sea lice levels for every single farm rearing Atlantic salmon or rainbow trout. The amount of surveillance data makes it difficult to appreciate spatial and temporal distribution patterns of sea lice. Using quantitative epidemiological approaches such as linear mixed effects models it was possible to observe that sea lice: 1) has a clear east-west spatial pattern (Fig. 1); 2) increases over the salmon production cycle (Fig. 2A); and 3) has decreased over the last 6 years (Fig. 2B). Epidemiological methods have been also used to investigate the recent expansion of sea lice to regions where it was thought that environmental conditions were not optimal for their development.

In terms of control, epidemiological quantitative methods have been successfully used to: 1) evaluate the field efficacy of antiparasitic drugs on different sea lice developmental stages (i.e. juvenile, adult males, gravid females); 2) to provide the first evidence of the sensitivity loss of sea lice to the organophosphate azamethiphos; and 3) to demonstrate the beneficial effect of the synchronization of antiparasitic treatments among farms within an area.

E-mail: gabriel.arriagada@uoh.cl

Infectious diseases are major challenges for the sustainability of the farmed salmon industry worldwide. Particularly in Chile, Caligidosis and Piscirickettsiosis are the diseases with the greatest biologic and economic impacts. Caligidosis is caused by the ectoparasite *Caligus rogercresseyi*, commonly called sea lice, provoking extensive skin damage, chronic stress and worsen feed conversion efficienc . Piscirickettsiosis is caused by *Piscirickettsia salmonis*, an intracellular facultative Gram-negative bacterium and is recognized as the most important bacterial disease for the salmon industry in Chile, generating high mortality rates. The relationship between *C. rogercresseyi* and *P. salmomis* is unknown, but it may help explain the high prevalence of this two pathogens in Chile. The objective of this study was to determine if *C. rogercresseyi* infection is associated to Piscirickettsiosis mortality early in the production cycle of Atlantic salmon and rainbow trout in Chile.

Data on Caligidosis and Piscirickettsiosis was obtained from the respective Official Programs for Surveillance and Control (OPSC), administered by the Chilean Fisheries and Aquaculture Service (SERNAPESCA). Caligidosis data consisted in weekly *C. rogercresseyi* mean abundances, classified by juvenile (chalimii stages), mobile adult (male adults plus non-gravid females) and gravid female stages, recorded at the farm level. Data on Piscirickettsiosis corresponded to weekly specific mortality due to *P. salmonis*, recorded at the farm level as well. Mortality was attributed to Piscirickettsiosis if fish presented clinical and/or pathological signs, and the presence of *P. salmonis* was confirmed by IFAT or RT-PCR. Our study was restricted to data collected from 2014 to 2016. We modeled Piscirickettsiosis mortality as a function of mobile *C. rogercresseyi* abundance, using a linear regression model. Other predictors included in the modeling process were the salmonid species (i.e. Atlantic salmon or rainbow trout) and the administrative region where fish farms were located (i.e. Los Lagos or Aysén).

The final model showed a positive and significant association between the log mobile *C. rogercresseyi* mean abundance and the log Piscirickettsiosis cumulative mortality early in the production cycles of both Atlantic salmon and rainbow trout (Table I).

Our study provides evidence, for the first time, that the first Piscirickettsiosis outbreak in the production cycle of Atlantic salmon and rainbow trout in Chile could be caused to some extent by *C. rogercresseyi*.

Table I. Final model showing the effect of mobile *C. rogercresseyi* infestation on Piscirickettsiosis mortality early in production cycles of Atlantic salmon and rainbow trout in Chile.

Introduction

Lumpfish, *Cyclopterus lumpus* is a high value aquaculture species which is widely distributed in the North Atlantic Ocean. Juveniles of lumpfish are mainly produced and used as a biological (green) control against sea lice (*Lepeophtheirus salmonis*) in Norwegian Atlantic salmon production. Sea lice infestation is a major problem for the aquaculture industry in Norway, causing production and economic losses estimated at 5 billion NOK in 2015 [1]. As a result of the large economic losses, the use of lumpfish as a cleaner fish has increased dramatically in aquaculture with nearly 24 - 25 million juveniles produced and sold as cleaner fish in Norway in 2016 [2]. Lumpfish is also appreciated for meat, caviar and roe production, and is considered highly nutritious. The emerging importance of lumpfish demands development of economical genetic resources along with the exploration of potential for selection methods (classical vs. advanced) for effective breeding programs to efficiently improve traits of economic importance

Material and Methods

A lumpfish population of ca. 60 full-sib families with an average of 25 full-sibs per family (ca. 1500 offspring in total) derived from the lumpfish breeding program established by Nofima AS was used for this study. Individuals of this population with an average weight of 54.75 g (10-154 g) were cohabitated with an Atlantic salmon population at the rate of 1 lumpfish per 4 salmon individuals. Cohabitation was kept for a total of 21 days, and the lice eating ability of each lumpfish was recorded at day 21 by the use of gastric lavage. The fish for which lice was present in the stomach were considered to be lice eaters (trait recorded = 1) and those without lice in the stomach were considered non-eaters (trait recorded = 0).

Tissue samples were collected from all PIT-tagged individuals for DNA extraction, library preparation using ddRAD and genotyping by sequencing. Libraries were sequenced using Illumina Hiseq 4000 platform (100bp paired-end sequencing), and the sequence data were used to generate genome-wide SNP genotypes for all the samples. The individual specific quality reads were aligned to the reference sequence which was developed using genomic TruSeq libraries sequenced at ~100X depth. The mpileup function of SAMtools version 1.2 was used to call variants and the call option of bcftools [3] was used to call the genotype at each variant site for each animal.

Genotypic data and the pedigree information were further used to estimate genetic variation for the trait, develop a linkage map, perform genome wide association analysis (GWAS) and for the estimation of breeding values. The heritability estimates for the binary trait were obtained using ASReml 4.0 with a pedigree (A) or genomic (G) relationship matrix. Linkage map construction was conducted using Lep-Map v2 [4] and GWAS was performed using the GCTA program with "–mlma-loco" function to detect marker ~ trait associations. Pedigree vs. genomic breeding values for lice eating ability were estimated to compare selection accuracy. The predictions were performed using PBLUP, GBLUP, BayesB, BayesC, and Bayesian Lasso models using the R/BGLR [5] program. The following linear mixed model was used for the estimation of heritability and predictions, where is a vector of phenotypic records on lice eating ability on each individual, is an overall mean, is a vector of additive genetic effects distributed as , or , where and are genomic and pedigree relationship matrices, respectively; is the corresponding incidence matrix for additive effects, and is the vector of random residual

Table1: Heritability estimates for lice eating ability using genomic vs. pedigree information.

Model	Liability Scale	Observed Scale
PBLUP	0.16 (0.07)	0.07 (0.03)
GBLUP	0.16 (0.08)	0.06 (0.03)

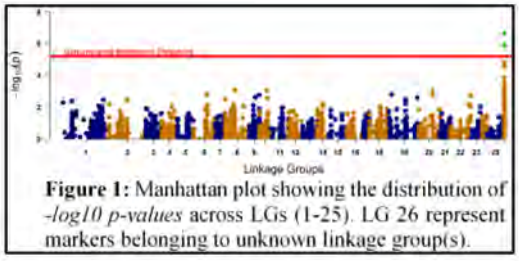

Figure 1: Manhattan plot showing the distribution of *-log10 p-values* across LGs (1-25). LG 26 represent markers belonging to unknown linkage group(s).

(Continued on next page)

effects with . GWAS was performed by applying the same above model with a parameter included to obtain SNP effects. Accuracy of prediction was computed using validation scheme by random masking the phenotypes of ~ 20% of the offspring. The accuracy was computed as the correlation of the estimated breeding value (pedigree/genomic, PEBV/GEBV) with the phenotype which was scaled by the square root of heritability.

Results and Discussion

The genotyping process using ddRAD sequencing resulted in a dataset containing 7,729 quality SNPs. Linkage mapping resulted in 3,474 markers grouped into 25 linkage groups (LG) which are consistent with the karyotype of this species. Heritability estimates for lice eating ability computed on observed and liability scale using pedigree vs. genomic information are detailed in **Table 1**. These estimates show that the lice eating ability has significant genetic variation. GWAS analysis revealed two low frequency SNPs presenting significant association (**Figure 1**) to the trait with *p-value* significantly lower than the genome-wide Bonferroni corrected threshold (*p-value* = 6.47×10^{-6}). Average accuracies of prediction by applying prediction models with pedigree vs. genomic information were 0.395 ± 0.199 and 0.420 ± 0.227 respectively.

In conclusion, results revealed the existence of low but significant genetic variation for lice eating ability and estimated breeding values using genomic (GBLUP) vs. pedigree (PBLUP) information presented 6.3% higher accuracy, which should ultimately be reflected in overall genetic gain

Introduction

In ecological studies, stable isotope analyses is a reliable tools for elucidating the trophic niche and inferring pathways of energy flow in food webs (Cifuentes et al., 1988). This method involves the comparison of stable isotope ratios between consumers and food supplies (Deegan and Garritt,1997). While $\delta^{13}C$ allows the carbon source to be differentiated, $\delta^{15}N$ permits the relative trophic position of an organism to be assessed. Hence, by using carbon isotopes, it is now possible to infer the relative importance of each carbon source to organisms in food webs (DeNiro and Epstein, 1981), since carbon isotope ratios remain relatively unaffected by trophic transfer. By using nitrogen isotopes, on the other hand, it is possible to accurately determine the trophic levels occupied by organisms (DeNiro and Epstein, 1981). The consistency of nitrogen enrichment at each trophic transfer provides a convenient quantitative measure of relative trophic position within a food web, and may be correlated with contaminant concentrations to estimate metal concentrations and biomagnification rates (Hoekstra et al., 2002).

Like sediments, organisms may show concentrations of metallic elements up to several thousand times those found in the water column, with the advantage that these levels reflect the availability over time of these metals to the biota (Wilson and Elkaïm, 1992). Therefore, the metal content in the biota may be analyzed to establish spatial and temporal variations in the bioavailability of heavy metals in the marine and estuarine environment, offering time-integrated measures of ecological relevance (Rainbow, 1995).

This study aims to assess the potential impacts of trace elements on marine benthic environments and to assess accumulation in biofilm. For this, a monitoring study was performed and a two models used to predict trace elements emissions (MAMPEC) and wastage marine dispersal (MERAMOD) were parameterized and evaluated with the comparative study of isotopic niche and trace elements composition of biofilm.

Materials and methods

The Western Mediterranean coast is currently one of the most aquaculture intensive areas in Spain, focused on the production of gilthead sea bream and sea bass, with an average production of around 11.000 metric tons per year. The farming is exclusively carried out in open marine water cages with an average depth of 37 meters. Samplings were carried out during the end of summer of 2018 at 2 fish farms. The farming is carried out in open marine water cages 6 km from the coast. The field assays were performed using glass slides as the artificial substrate for the biofilm community to attached to them. Glass slides were supported by slide holders. The slide holders, in turn, were maintained 3 m below the water surface by an anchoring system and a buoy. Slides were deployed from a fish cage located at the edge of the fish farm facility along a horizontal transect at 0, 25, 75, 175 and 650 m from the cages.

The model used in the present study was MAMPEC (Marine Antifoulant Model to Predict Environmental Concentrations). It is a steady-state 2D integrated hydrodynamic and chemical fate model with a user friendly interface. MAMPEC is based on the Delf3D-WAQ and Silthar model.

The released trace elements from the marine fish farm wastes was estimated with MERAMOD model, a particle tracking model containing grid generation (bathymetry, cage layouts), particle tracking, resuspension and benthic impact response modules. This model estimates the flux or total deposition of waste material (faeces and feed) at the sea bed discharged from mariculture operations.

(Continued on next page)

Results

The isotopic signatures clearly differentiated the biofilm community along the environmental gradients. The $\delta^{13}C$ content was significantl lower at 0 than at 650 m from the fish farm. The $\delta^{15}N$ content was significantly lower at 0 than at 650 m from the fish farm. Isotopic niche of biofilm showed higher similarity to fish feed $\delta^{13}C$ and $\delta^{15}N$ composition at the sampling stations located near of cages. The PCA analysis indicated a higher metal bioaccumulation in the sampling stations with an isotopic niche influence by fish farm waste

The results of this work indicated that biofilm was a useful and effective bioindicator in terms of both community composition and metal bioaccumulation. It present discernible differences for the majority of measured parameters on spatial scales and hold a key position within the food-web. The isotopic niches and metal bioaccumulation were correlated with the results of the two models used to predict trace elements emissions (MAMPEC) and wastage marine dispersal (MERAMOD).

Discussion and conclusions

The field results confirm that there are clear accumulation of metals and other trace elements in biofilm along environmental gradients, which suggest that waste dispersion influence on biofilm accumulation. However, the field study indicated a higher metal accumulation in biofilm close to the fish cages as it was predicted by the MERAMOD mode

The results from the present study showed that metal concentrations varied between both fish farms studied in function of fish farmed annual production. In the fish farm 1, with high annual production, metal concentrations were significantly higher at 0, 25, 75, m for biofilm samples. However, there were only significant differences in fish farm 2 (lower annual production) at 0 and 25 m. MAMPEC model indicated that the metal contamination due to antifouling paints could be negligible due to the low concentrations. The results from MERAMOD model indicated that fish food could be the main source of metals in biofilm

ECOINTENSIFICATION OF AQUACULTURE: INNOVATIVE MORTALITY DISPOSAL IN A CIRCULAR ECONOMY PERSPECTIVE

Hallstein Baarset* and Johan Johansen

Waister, Åslyveien 15, NO-3170 SEM, Norway
E-mail: hallstein.baarset@waister.eu

Among the main side streams from intensified aquaculture are mortalities and discarded fish. Statistics shows a typical loss of 15-20 % of the fish from sea cages, which equals 6-9 % of the biomass. This represents an annual cost of more than €100 million for the Norwegian aquaculture industry.

GAIN (Green Aquaculture Intensification in Europe), a recently awarded Horizon 2020 project, aspire to deliver services and technologies to market within the project period to contribute to the ecointensification of European aquaculture production. Resource efficienc , reduced environmental impact, increased precision and valorisation throughout the production chain are all key elements in the approach to improve seafood self-proficiency and regional stabilit .

Current method for mortality disposal in Norwegian aquaculture is facing challenges for health, safety and environment, as well as representing a costly handling. Waister has investigated an innovative method of mortalities disposal based on drying at site and transport of the dried and sanitized product.

In accordance with facilitation of a circular economy, Waister will make necessary valorisation of the dried product for use in in compliance with government regulations in EU and Norway. By proving safe application of the dried and sanitized product, further applications may emerge, requiring adaptations or amendments to current government regulations.

A GAIN demonstration facility has been established at a Norwegian Atlantic salmon smolt producer, for evaluation, documentation and professional training on relevant substrate in industrial scale. A dryer system for mortalities will be demonstrated at this site with processing of the amount received from the smolt production.

We will present a comparison of the current method and the innovative method and point out potential increase of value of the dried product in compliance with government regulations.

ZEBRAFISH EMBRYOTOXICITY OF OLIVE OIL MILL WASTEWATER AND CONSIDERATION OF IT'S RENEWABLE POTENTIAL

Introduction

Olive mill wastewater (OMW) is a by-product from the olive oil production. In a short period of time, an amount of 6 x 10^6 of OMW is annually produced mainly in the Mediterranean basin. Its pollution load is mainly related to OMW's high biological and chemical oxygen demand, but also with a high content of phenolic compounds, organic and solid matter, metals, mineral substances, and acidic character (Pardo et al., 2017; Caporaso et al., 2018). Since no dedicated EU legislation exists on OMW management, the OMWs are usually directly spread into sewer systems, lakes, sea, etc. thus posing threat to the aquatic ecosystem. The present study was undertaken to evaluate the environmental impact of OMW to living organisms, to identify the OMW components among phenolic group which are directly correlated with OMW's toxicity and to complete this research with pointing out a huge potential of their use as a renewable resource.

Materials and methods

Fresh OMW was obtained from olive oil production plant located in Slovenian Istria, which uses a traditional discontinuous press for the extraction of olive oil. Prior to the extraction, an initial chemical and physical determination of OMW main constituents was performed. Polar fraction was obtained by solid-phase extraction (SPE) of raw OMW sample (De la Torre-Carbot et al., 2005). Analysis of phenolic compounds in polar fraction was carried out using gas chromatography-mass spectrometry (GC-MS).

Zebrafish embryotoxicity test (ZET) was performed on raw OMW and its polar fraction using zebrafish *Danio rerio* embryos, in accordance with OECD 236 Guidlines (2013). Lethal and sub-lethal effects were estimated up to 96 h of exposure.

Results

The Folin-Ciocalteu procedure (Vitali Čepo et al., 2017) revealed tested OMW sample as highly enriched in phenolic compounds (9.22 ± 0.17g GAEa L^{-1}). The identification of individual phenolic compounds by GC-MS pointed out tyrosol and catechol as the most abundant polyphenolic compounds.

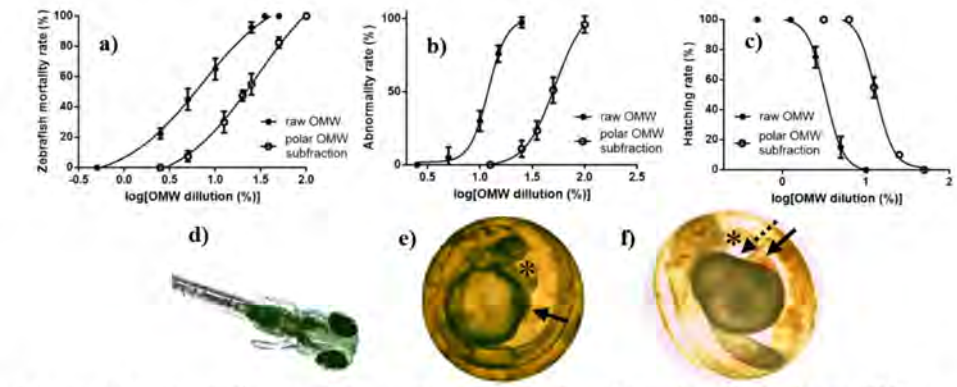

Figure 1. Concentration-response curves representing the toxic effect of raw OMW and polar fraction on 96-h old *D. rerio* a) survival, b) developmental abnormality, c) hatching. Raw OMW (e) and polar fraction (f) caused pericardial edema (asterisk), blood accumulation at the yolk sac (arrow), yolk sac edema (dashed arrow), lack in pigmentation formation. Picture d) represents control larvae on artificial water.

(Continued on next page)

Both, raw OMW and polar fraction induced negative impact on zebrafish ontogenesis, which manifested through high acute toxicity (Fig. 1; a) with LC_{50} values of 7.05 and 28.96%, respectively. Interestingly, almost the same abnormalities (pericardial edema, blood accumulation) were observed on both tested samples (Fig 1; e, f). Among observed endpoints, hatching appeared as the most sensitive (LC_{50}= 3.28% of the raw OMW).

Discussion

Although the chemical characterization of OMW gave us an insight into the chemical composition of this complex matrix, accurate assessment of OMW toxicity was obtained by determining its impact on zebrafish embryos. Similar toxicity trend was observed during exposure to raw OMW and polar fraction, which emphasizes an important role of polyphenols in OMW overall toxicity. According to the Urban Water Directive (Directive 1991), OMW tested within this study should not be released directly into the sewer systems or water bodies because the amount of phenols in wastewater exceeds the value of 1 mg/L. At the same time, it should be pointed out that the most abundant polyphenols in tested OMW were tyrosol and catechol, which are beside their toxic potential, well known for their antioxidant, anti-allergic, anti-inflammator , anticancer and antihypertensive activities (Caporaso et al., 2018). For that reason, an approach for using OMWs as a renewable resource is of global interest. Polyphenols from olive oil mill wastewaters can be converted into a valuable source of antioxidant compounds, that can be added to food in order to improve the nutritional properties and preserve their quality. Such exploitation of waste resources will not only prevent environmental pollution but also provide an economic opportunity and enable sustainable environmental management.

1,25-DIHYDROXYCHOLECALCIFEROL-GLYCOSIDES OF NATURAL ORIGIN IN AQUACULTURE

H. Bachmann and K. Buehler

Herbonis Animal Health GmbH, Rheinstrasse 30, CH-4302 Augst, Switzerland
E-Mail: h.bachmann@herbonis.com

Introduction

Land animals can produce vitamin D3 (VD3) in skin under the influence of UV light. However, under intensive agricultural conditions endogenous VD3 production is not sufficient and additional VD3 has to be supplemented with the diet. Even though some fish can also produce VD3, most VD3 is ingested through the nutrition. Most of the aquatic VD3 is produced by plankton near the surface. Nevertheless, similar to farmed land animals, fish and shrimp in aquaculture also needs VD3 supplementation.

Whereas the physiological role of VD3 in birds and mammals is quite clear, there are still many open questions when it comes to fish. In terrestrial animals VD3 is converted in the liver to 25-hydroxyvitamin D3 (25D) which acts as storage form. In a next step, the metabolic active form 1,25-dihydroxycholecalciferol (1,25D) is produced in the kidney. This metabolite binds in the target tissue to a VD receptor (VDR) and the formed complex in turn binds to the responsive gene and triggers the biological action. Primary function is regulating calcium and phosphor uptake and bone mineralization. 1,25D has also beneficial e fects in muscle and immune functions as well as in cell differentiation and proliferation.

In fish the same VD metabolites as in terrestrial animals are formed and VDR is also present in many tissues, however, there are quantitative differences whose underlying reason are not yet clear. In terrestrial animals 25D acts as storage form and are present in the blood in a 1000-time higher concentration than 1,25D. This is mainly because of a tight regulation in formation and a fast elimination via 1,24,25D. Different to mammals and birds, 1,25D seems to be the predominant metabolite in fish

Early experiments in VD-depleted aquatic animals demonstrated the essentiality of VD3 in fish by finding reduced growth parameters in low VD3 diets.

(Continued on next page)

As mentioned above, farmed fish and shrimp rely on dietary VD3 supplementation, which is 1500 to 3500 IU/kg feed for fish (DSM Vitamin Supplementation Guidelines 2016). Given the dominant content of 1,25D in fish, it is possible that supplementation of this specific metabolite has positive effects. Here, we describe first experiments in farmed fish with a standardized product of the plant *Solanum glaucophyllum* which naturally contains 1,25D in a glycosidic form.

Material and Methods

Test article is a product, based on *Solanum glaucophyllum* and standardized to an analytical content of 10 µg/g dry mass of analytical determined 1,25D. In both experiments described in detail below, the test product was given on top of the commercial supplementation of VD3 (2500 IU/kg).

In both trials rainbow trouts (*Oncorhynchus mykiss*) of mixed sex were used. The fish were kept in tanks at 14°C with twice daily feeding to apparent satiation.

Experiment 1 (dose finding): 35 animals per tank in 6 replications for 32 days. Diet in %: **Fish meal 25**; Wheat flour 17; Vegetable protein 44; Vitamin premix 0.72; Mineral premix 1.2; Others 4.94; Defatted rice bran 1; Fish oil 6.5; ad 100%.

Treatments: G1: control; G2: 1 µg 1,25D3/kg feed; G3: 2 µg 1,25D3/kg; G4: 10 µg 1,25D3/kg; G5: 50 µg 1,25D3/kg; G6 100 µg 1,25D3/kg.

Experiment 2 (fish meal replacement): 40 animals per tank in 6 replications for 62 days. Control diet (T1) in %: **Fish meal 40**; Wheat flour 19; Vegetable protein 35; Vitamin premix 0.35; Mineral premix 0.8; Fish oil 6.5; Others 0.36; Defatted rice bran 0. Diet low fish meal (T2): **Fish meal 25**; Wheat flour 14.6; Vegetable protein 44; Vitamin premix 0.72; Mineral premix 1.2; Fish oil 8.5; Others 4.8; Defatted rice bran 1.14. And Treatment T3: low fish meal with 10 ug 1,25D3/kg diet

Results and Discussion

The result of experiment 1 is shown below. The product was well tolerated, and survival rate was 100% in all treatments. Best performance and optimal Ca and P retention were achieved with 10 µg 1,25D3/kg feed.

The aim of experiment 2 was to see whether the addition of 1,25D from plant would compensate for reduced fish meal content in the diet. It was shown, that average body weight under 1,25D supplementation was numerically over-compensating the reduction in fish meal from 40 to 25%. Statisticall , it was equal to the control diet T1.

Conclusion

Application of a standardized herbal product containing 1,25-dihydroxycholecalciferol-glycosides to young trout on top of the usual vitamin D supplementation is able to improve Ca and P utilization. This may allow a P reduction in feed without reducing growth performance. It could also been shown that 1,25D can compensate for a reduced fish meal content. Further trials are planned to expand the application to other fish species and other stages of development

COMMERCIAL AQUAPONICS: TWO ECONOMIC SCENARIOS FOR A DOUBLE CIRCUIT SYSTEM

Gösta Baganz*, Daniela Baganz, Georg Staaks, Hendrik Monsees, and Werner Kloas

Forschungsverbund Berlin e.V. –
Leibniz Institute of Freshwater Ecology and Inland Fisheries (IGB)
E-mail: g.baganz@igb-berlin.de

Introduction

Coupling the production of aquatic animals (e.g. fish) and plants (e.g. vegetables) in greenhouses forms the basis for aquaponic systems. Despite the fact aquaponics as a nearly zero-waste food production method has an important potential in terms of sustainable development in the food sector it is still a niche market. An aquaponic research facility in Waren, Germany operating with a controlled-environment agriculture (CEA) approach served as basis for the economic evaluation. Its recirculating aquaculture system (RAS) and its hydroponic system (HS) are unidirectional coupled on demand but maintain separate water cycles in both production units. A one year full operation period delivered the initial situation dataset.

The present study had three goals: First, to provide a short report about the aquaponic facility within its distinct boundary conditions. Economic calculations were done as an Ex post analysis based on the data recorded over the course of twelve months. Second, to present a scenario using the assumption of an explicitly improved productivity of the facility. Third, to develop a scenario as a generalisable example that emphasises the core idea of aquaponics and maximises the transfer of the RAS waste water to the HS. To examine the profitability of the facility an Ex ante cost benefit analysis (CBA) was performed on both scenarios.

Material and Methods

At the initial situation (InitS) the RAS unit for rearing African catfish (*Clarias gariepinus*) consists of 12 fish tanks with a productive water volume of 26.4m³. The HS in Waren uses 320m² net-acreage of the 352m² greenhouse area. No artificial light was employed for plant cultivation; therefore a production break of two months (winter break) took place which was used for disinfection and maintenance work. Energy was provided by a heating demand controlled combined heat and power unit (CHP) which was supported by photovoltaic power.

The factors describing the changed boundary conditions of the cases are given in Tab. I.

Tab. I Overview on the boundary conditions factors concerning the three cases

		InitS	ScenA	ScenB
RAS	Volume	1	1	1
	Yield	1	**1.64**	1.64
	Investment	1	1	1
HS	Area	1	1	**3.44**
	Yield	1	**2.46**	**8.46**
	Investment	1	1	**2.66**
SUM	Investment RAS/HS	1	1	**1.38**

Tab. II Profits and losses per functional unit

		InitS	ScenA	ScenB
Product		per kg	per kg	per kg
	Fish	-0.28 €	0.31 €	0.31 €
	Tomatoes	-2.74 €	-0.21 €	1.29 €
Functional unit (FU)		per FU	per FU	per FU
	Tomatoes per kg fish	0.4 kg	0.61 kg	2.09 kg
	FU incl. Energy sales	**-0.45 €**	**0.76 €**	**3.59 €**

Concerning the cost structure, fish feed had the main cost share in all cases in RAS whereas labour had the main cost share in HS. For the InitS 35% of the RAS were attributed to fish feed and 61% of the HS costs to labour. In ScenB these shares increase to 42% (fish feed) of the RAS and respectively 66% (labour) of the HS costs.

(Continued on next page)

Based on the existing aquaponic configuration of the InitS, a scenario A (ScenA) was conducted assuming to reach the full productivity potential of the RAS as well as of the greenhouse. This scenario is based on the existing aquaponic configuration and serves as a direct comparison to the initial situation. A second scenario B (ScenB) seeks to maximise the utilisation of the fish waste water for plant irrigation and to minimize the environmental impact of the aquaponic facility waste water by a greenhouse extension.

Results

The factors describing the changed boundary conditions of the cases are given in Tab. I.

The economic results of InitS showed that the initial operation of the facility caused overall net debts. The profits and losses per functional unit for the three cases are given in Tab. II. The first scenario (ScenA) covered the operation costs of the facility and made a bargain with the sold electricity, generated by the CHP, but failed to return the investment within a reasonable time span. The second scenario (ScenB) extended ScenA by featuring a more than threefold enlarged HS unit. For this aquaponic configuration it could be shown that it was possible to reach a level of economic viabilit .

Concerning the cost structure, fish feed had the main cost share in all cases in RAS whereas labour had the main cost share in HS. For the InitS 35% of the RAS were attributed to fish feed and 61% of the HS costs to labour. In ScenB these shares increase to 42% (fish feed) of the RAS and respectively 66% (labour) of the HS costs

Discussion and Conclusion

InitS does not achieve profitability even if due to a stable, regional market a high tomato price could be achieved. The main reasons were (1) the low productivity concerning both fish and plants, (2) the inexperienced staff, and (3) the ongoing research which consumed additional efforts.

According to the scenario calculations ScenB is economical feasible even with a winter-break production schedule. Main credits based on local funding opportunities have a period of 15 years, the assumed operation life of the facility. The operation balance of 78k€ surpasses the annual annuity payment of 61k€ and thus ScenB achieves a positive outcome of 17k€ per year. The Waren aquaponic facility was built within a research project and therefore with a limited financial budget. ScenB was invented to mitigate the weaknesses of the InitS, but even being feasible, it has still optimizing potential.

Despite the extension of the greenhouse within ScenB, the facility is only mid-size in the rural context where rather larger facilities make sense. In contrast in urban application cases also smaller facilities may be of importance due to the competitive pressure concerning space and locations. Thus it is encouraging to learn that even mid-size aquaponics may be economical and thus can be implemented into the urban fabric.

Introduction

The treatment of nitrogen compounds in recirculating aquaculture systems (RAS) is a rigorous task to ensure optimal water quality and fish production. In nature, the concentration of different species of nitrogen is controlled by photosynthetic organisms and by different microbial metabolisms, including nitrifying bacteria. The traditional treatment of RAS water is to separate the solid matter and the metabolic waste to avoid the decomposition of this material which increases the concentrations of total ammonia nitrogen (TAN). Even at low doses, these nitrogen species are toxic to fish. Despite this first treatment, a non-negligible fraction of TAN is found in water and requires a second treatment by nitrification. Ammonium will be oxidized to nitrite and nitrate. Nitrite is also toxic to fish and nitrate, although more stable, does not enter the fish diet but may cause growth inhibition beyond a certain concentration (vanRijn et al., 2006, Davidson et al. 2014). As a result, nitrate-rich waters are regularly renewed and are released into the environment, polluting lake and river ecosystems through eutrophication.

Nitrification is a widespread method for eliminating TAN because, thanks to the acidifying power on the medium, this process allows a good control by preventing the new formation of ammonia nitrogen and in particular volatile ammonia. However, the acidification due to the increase of CO_2 dissolved in the environment is very problematic because it affects the quality of water for fish. This CO_2 must be removed before recirculation in the fish pond by a fairly energy-consuming system requiring an oxygen supply. A TAN treatment system based on microalgae would be very advantageous because it directly assimilates ammonia nitrogen and CO_2 to transform it into biomass while producing oxygen. This biotechnology offers the possibility of directly exploiting the algal biomass produced, for example, by processing into a food packaging medium or as a feed for fish farming

Methods

The research project starts with the assembly, the setting of parameters and finally the operation of the photosynthetic biofilm reactor to allow biofilm development. Then, it is intended to operate two tests: one for the treatment of the final effluent leaving the RAS and the other, for the treatment of the RAS water simulating as much as possible the volume of water retained and the daily treatment of a biological filte .

Fig. 1. System for water treatment from RAS by a photosynthetic biofilm culture reactor and generation of bioproducts based on algal biomass.

(Continued on next page)

Preliminary results

A previous project called AlgOnfilm allowed to validate under industrial conditions (Wastewater Treatment Plant of Yverdon-les-Bains) and for 6 months, the pilot biofilm photobioreactor system. The main goal was to treat the daily water volume attributable to 1 EH (equivalent-inhabitant) on a ground surface of 1 m^2. The most important results were a total N reduction around 60% while for P it was 100%. For ammonium the reduction was 100%. The concentration of heavy metals in water was also reduced on average (on all metals) by 20%. Another meaningful result was the production of a fairly homogeneous bioplastic resin by mixing 30% lyophilized algae and 70% biodegradable polyester.

Scenario analysis of nutrient removal from an industrial RAS facility:

The water analysis allows establishing the stoichiometric reaction of biomass production in relation to the reduction of nitrates and the production of oxygen. With a N: P ratio of 36:1 and considering that all the inorganic nitrogen is in the form of nitrate, it is predicted that photosynthetic activity assimilates N and P in this way:

$$CO_2 + 0.72\ H_2O + 0.36\ NO_3^- + 0.01\ H_2PO_4^- \rightarrow CH_{1.78}O_{0.36}N_{0.36}P_{0.01} + 1.56\ O_2 + 0.37OH^-$$

Oxygen production based on the ground surface will be the result of the quantum yield (moles of O_2 released per mole of absorbed photons) multiplied by irradiance (which is the surface density of flux of light energy). The quantum yield is a hypothetical value based on a theoretical maximum efficiency of 0.1 and which takes into account several losses (reflection, respiration, photo-saturation or -inhibition), while the irradiance can be estimated for any location and for any period of the year. Oxygen production based on the ground surface for an installation in the Jura-Nord Vaudois District between the months of April and October = 2.08 moles $m^{-2}\ d^{-1}$ (with a quantum yield of 0.06 and an average irradiance of 34.66). This O_2 production will therefore be accompanied by a production of 1.33 moles $m^{-2}\ d^{-1}$ of algal biomass, which from the elementary recipe of algal biomass, means an estimated production of 33 $g^{-2}\ m^{-2}\ d^{-1}$.

According to this production, the NO_3^- consumption of the system can also be deduced. Following the elemental molar composition of the algal biomass (defined from these culture conditions), the fraction of nitrogen corresponds to 20% of the total biomass. Thus, the rate of nitrogen consumption will be 6.6 g $m^{-2}\ d^{-1}$.

Expected impact

The project idea is to generate a synergistic approach for the integration of microalgae production in the aquaculture context in order to develop an economic model taking into account its transformation to a bioproduct. For modern aquaculture systems in particular, the technology offers the advantage of reducing the budget for water consumption (water renewal today is 33% while it could be 5%) as well as the power consumption costs when compared to filters based on nitrification which require constant aeration. Additional revenues can be expected from the recovery of algal biomass as a feed for fish farming or as a raw material for the production of bioplastic materials.

Cyanobacterial blooms, especially of *Microcystis spp* have become a widespread phenomenon in aquatic systems, where they profoundly affect many properties of ecosystems causing decrease in dissolved oxygen and pH increase (rev. Havens, 2008; Huisman et al, 2018), which in turn may have significant impact to other aquatic organisms. More detailed studies of algal populations in cyanobacterial blooms dynamics are needed. To address this question, we developed FlowCam-based imaging flow cytometry approach to differentiate *Microcystis spp*. morphoforms (Malashenkov et al., 2019; Zhantuyakova et al., 2019) and used it to carry out mesocosm experiments in May-October 2018.

Shortly, mesocosm samples were collected from longest-running lake mesocosm experiment in the world (Lake Mesocosm Warming Experiment (LMWE), Lemming, Denmark; established in 2003 (Liboriussen et al, 2005), and water parameters, turbidity, pH, nutrient composition (TN, TP), oxygen, conductivity, and chlorophyll-a were recorded. We selected three replicates of the enriched nutrient treatments differed in their temperature scenarios. Groups 1 represents the tanks with enriched nutrients (N:P) and unheated ambient temperature, whereas group 2 and group 3 represents an IPCC climate scenarios X2 and X2 + 50% (Intergovernmental Panel on Climate Change). Samples were fixed with glutaraldehyde 1% and acquired using FlowCam VS-4 imaging flow cytometer instrument (10x objective). Obtained data were further classified and quantitatively analyzed using VisualSpreadSheet software (Fluid Technologies Inc. USA) and statistical software. Analysis by FlowCam instrument allowed to differentiate and quantitate various phytoplankton groups, such as colonial cyanobacteria (*M. wesenbergii, M. novacekii, M. smithii, M. aeruginosa, M. ichthyoblabe),* green algae, dinoflagellates, different groups ofdiatoms, cryptomonads etc. The spatiotemporal distribution of major phytoplankton taxa and different *Microcystis* morphophorms were quantified to estimate the relative contribution of di ferent groups and bloom dynamics.

Colonial cyanobacteria (*Microcystis spp*.) were prevalent during summer months and made a large contribution to phytoplankton biomass in tanks with enriched nutrients. Increase in the temperature (tanks groups X2) led to early cyanobacterial bloom formation and colonies size growth. Cryptomonads blooms were observed later in the season in tanks with unheated ambient temperature and in X2-tanks. However, further increase in temperature (tanks X2+50%) led to suppression of colonial cyanobacteria and cryptomonad dominance which was not associated with a particular season. During peak and blooms dying-off *M. wesenbergii* samples include a “half-empty” phenotype colonies; i.e. sheets filled with occasional empty spaces (Fig. 1) or even without any cell inside (“empty” sheets). There is an increase of “empty sheets” as well as “half-empty” colonies of *M. wesenbergii* among group X2 tanks (higher temperature) in August when the abundance of *M. wesenbergii* is decreasing significantly (dying-off blooms). The potential scenario is that during cyanobacteria bloom development, *M. wesenbergii* colonies are growing in size, and some of them losing cells and sharply changing density that leads to increase in buoyancy. We hypothesize that it may contribute to *Microcystis* colonies re-distribution in water column and facilitation of wind-forced migration of colonies in surface layer of water even against flow stream (rivers).

EFFECT OF MANGROVE DEFORESTATION AND ITS CONSERVATION

R. Balaji[1*], P. Yuvarajan[1], R. Velmurugan[1] and B. Ramji[1]

Introduction

Mangrove is a small tree that grows in coastal saline or brackish water, which serves as natural barrier against ocean dynamics along the shoreline. Mangrove refers to a tidally influenced wetland ecosystem within the intertidal zone of tropical and subtropical latitudes. Healthy mangrove forests are key to a healthy marine ecology which serve as nursery ground for many of fishes and habitat for birds and other reptiles. The mangroves make an enormous contribution to the food chain that supports the coastal fisheries and also involving in treating the polluted ecosystems. However, more than 35% of the world's mangroves are already gone. The figure is as high as 50% in countries such as India, Philippines, and Vietnam, while in the Americas they are being cleared at a rate faster than tropical rainforests. This article reviewed the importance, impacts and conservation of mangroves.

Mangrove deforestation

Reduction/destruction of mangrove forest is called mangrove deforestation. According to United Nations Environmental Program (UNEP) about half of the world's mangrove areas have been destroyed. The reason is over exploitation for firewood, poles, and charcoal production; conversion to agriculture, salt plane development, and coastal aquaculture & urbanization. As per the Network of Aquaculture Centre for Asia Pacific (NACA) report about 20–50% of all current mangrove deforestation is due to shrimp farming or coastal aquaculture practices.

Mangroves are naturally destroyed by flood, hurricane, cyclone, insect pests such as woodborers, caterpillars, drying of mangrove trees and fire accidents. Mangroves are naturally destroyed by anthropogenic threats such as tree felling for fuel wood and wood products, reclamation for agriculture and aquaculture, urbanization, industrialization and pollution.

Conservation of the Mangrove ecosystem:

- Afforestation
- Strict implementation of legislation (including laws and policies)
- Monitoring and Surveys (MCS) - land and aerial, etc.
- Protection (including conservation, parks and reserves development, etc.)
- Creating awareness among the stakeholders

Mangrove ecosystem can be utilized for culture (Agriculture, Aquaculture -capture fisheries, culture fisheries), natural products useful for medicinal purposes, drugs, etc.), other products (timber, salt production, honey, etc.), socio-economic aspects, tourism and traditional medicines.

If deforestation of mangroves will continue, it could lead to severe losses of biodiversity and livelihoods, in addition to salt intrusion in coastal zones and the siltation of coral reefs, ports and shipping lanes, with consequent losses of income from tourism and the loss of knowledge of mangroves. To overcome the problems, government and stake holders should take necessary actions like proper monitoring, planning and policy making to protect the mangrove ecosystem for upcoming generations.

IN VITRO OVULATION METHOD CAN BE USED TO MONITOR THE PRE-SPAWNING STATE IN STURGEON FEMALES

D. A. Balashov, K. V. Kovalev and A. V. Recoubratsky

Filial of Freshwater Fisheries of Russian Federal Research Institute of Fisheries and Oceanography (Russia)
balashofff@gmail.com

Introduction

It is often not known in which physiological condition surgeon females are during the hibernation and pre-spawning period status changes. The present study shows that the injection of an emulsion of fatty acids improved reproductive properties of Siberian sturgeon females and that this improvement was accompanied with an increase of the part of oocytes ovulated *in vitro*. Thus, in vitro ovulation method can be used to monitor the pre-spawning state of females and to accurately predict their reproductive qualities.

Material and methods

The work was carried out in 2019 during winter and spring. Twenty females of Siberian sturgeon from the stock of Konakovo Sturgeon Breeding Farm (Tver Oblast)were used. All females were kept at a temperature of 2-8°C, i.e. they were at a pre-spawning hibernation state.

All females in the wintering period were subjected to two biopsies for isolating ovarian follicles which then were incubated *in vitro*. The 1st biopsy was performed on February, 5, a second on March, 5. After the 1st biopsy, a half females received an intraperitoneal injection of an experimental drug. The drug contained high purified fish oil -5 g; wheat germ oil – 5 g; soybean lecithin – 2 g and up to 100 ml purified distilled wate . The dose injection was of 1ml per kg of body weight.

After biopsy follicles were placed into 55 mm Petri dishes, 33±2 follicles per dish. 5 replicates per females. Each Petri dish contained 10 ml RMS with adding 0,75 g/l of sodium bicarbonate and antibiotics (Goncharov, 1978; 2009). After placed of follicles was added progesterone to concentration 333 ng/ml. Follicles were incubated at 16°C.

To obtain eggs, females received the pituitary injection in the period 12-26 April. The quality of the eggs was an assessment by fertilization and hatching rates (%).

Results

In females whose oocyte responded to progesterone stimulation after the first biopsy, the percentage of ovulation *in vitro* increased considerably after the second biopsy (fig.1a). In treated females, these differences were significantly higher than in intact females (fig.1 b)

The difference between treated and intact females *in vivo* fertilization rate was not found. However, an effect fatty acids drug manifested in increase hatching rate. It was significantly higher in treated females (fig. 2)

The results obtained during the experiment were used for correlation analysis at the different pair variable (table 1). The table shows that the *in vitro* ovulation rate after 2nd biopsy has a significant positive relation with *in vivo* fertilization and hatching rates.

Discussion and conclusions

In the present study was shown that a single injection of the drug consisted of fatty acids can increase the *in vitro* ovulation rate in treated females. It shall be noted that the increasing percentage of ovulation oocytes *in vitro* under the influence of the drug affected on the prognostic potential in relationship to reproducing characteristics of females in vivo. Thus, we have demonstrated the ability to monitor the physiological state of females during the pre-spawning period using the method of incubating ovarian follicle in vitro.

[2] Research National Centre for Biodiversity and Gene Conservation, Gödöllő, Hungary, Isaszegi St. 200, 2100

Introduction

Common carp (*Cyprinus carpio*) is a widespread freshwater species in Eurasia with high importance in aquaculture and fisheries. However, the native wild populations of common carp are considered vulnerable to extinction by the International Union for Conservation of Nature (IUCN). In Hungary common carp is produced in the highest amount in aquaculture and different genotypes ("landraces") were developed during the last centuries. Microsatellite markers are particularly suitable for numerous applications including population genetics, parentage analysis or marker assisted selection, nevertheless, no proper, cost-efficient, and rapidly applicable multiplex microsatellite set is available at the moment for common carp. During this study a novel multiplex microsatellite set was developed and tested on three different common carp strains.

Materials and methods

The available common carp genome was investigated with *in silico* analysis by the GMATA (Genome-wide Microsatellite Analyzing Tool Package) software (Wang and Wang, 2016) in order to obtain tetranucleotide microsatellite markers genome-wide. Primers were designed for the flanking region of the detected 64000 microsatellites. The number of potential markers was restricted to 36 by the annealing temperature, specificit , primer-dimer formation and genomic location of the primers. The amplification reactions (PCR) for the selected markers were optimized individually and their polymorphism was checked by capillary electrophoresis on 3100 Geneteic Analyzer (Applied Biosystems) using Gene Scan LIZ 500 size standard (Applied Biosystems). Alleles were identified by GeneMapper 4.0 software. Four different pentaplex sets were assembled from the most congruous markers designed with tailed forward primers and tail specific fluorescent primers (PET, VIC, NED, FAM) suitable for simultaneous fragment analysis. The utilisation of this newly designed microsatellite multiplex set was tested on 75 individuals from three Hungarian common carp populations: 1. the broodstock of Velencei landrace from Kajászó, 2. a population of Balatoni Sudár landrace from Irmapuszta, 3. a natural population of lake Hévíz (which is a thermal lake). The first two landraces belongs to the *Cyprinus carpio morpha accuminatus* form, while the third belongs to the *Cyprinus carpio morpha Hungaricus* form of the wild carps. Data analysis was carried out by Genealex ver. 6.5, Microsatellite Toolkit ver. 3.1.1 and RStudio ver: 1.0.143 software.

Results

Half of the detected 64000 tetranucleotide markers located on chromosomes, the others on genomic scaffolds with unknown locations. For further analysis 32000 microsatellites were used which located on chromosomes and 36 ideal markers were selected thus every one of them located on different chromosomes. Monomorph markers and microsatellites that amplify alleles from more homologue locus (more than two alleles – consequence of ancient carp genome duplication) were excluded from further investigation. Four different pentaplex sets were developed according to the annealing temperature and primer-dimer formation and tested with 75 individuals with the following results: the average number of alleles (Na) per locus was 5.75±3.77 with a range from 2 till 16. The mean Simpson diversity index (1-D) for the alleles of these marker sets was 0.414, showing relatively high number of alleles with even distribution (evenness= 0.629). We calculated the PIC (polymorph information content) numbers for these markers and 6 of them were highly polymorphic (PIC>0.5). For population genetic analysis, we calculated the observed (average Ho= 0.188±0.01) and the expected heterozygosity (He= 0.42±0.06), which indicated heterozygote deficiency in all three populations. Deviations from Hardy-Weinberg Equilibrium were tested by Chi^2 test and it was significant ($p<0.05$) with 14, 3, and 1 markers in the Kajászó, Hévíz, and Balaton populations, respectively. The AMOVA (Analysis of Molecular Variance) analysis revealed that the overall genetic variance is explained in 42 % by the genetic variance among populations, which was confirmed by discriminant analysis of principal components as well.

(Continued on next page)

Discussion and conclusion

We conclude that this novel multiplex microsatellite set is a powerful tool for fast and cost effective analysis of both natural stocks and farmed populations of common carp. The markers were appropriately polymorph and informative to perform genetic evaluation within and between populations. Our study proves that the investigated populations differ from each other significantl , implying no panmixis among the populations. Deviations from Hardy-Weinberg Equilibrium suggest inbreeding, especially in the farmed population from Kajászó.

FATTY ACID PROFILES OF GREEN, BROWN, AND RED SEAWEEDS AS A CHEMOTAXONOMIC TOOL

N.M. Bandarra*, R. Gomes, C. Cardoso, and C. Afonso

Division of Aquaculture and Upgrading (DivAV), Portuguese Institute for the Sea and Atmosphere (IPMA, IP), Lisbon, Portugal
E-mail: carlos.cardoso@ipma.pt

Introduction

Seaweeds are still a not very well-known marine resource. Namely, there is a deficit of studies on their lipid fraction, which may be partly due to the very low fat level. However, this fat may be rich in bioactive fatty acids (FA), such as the n-3 polyunsaturated FAs (n-3 PUFA), which are known to play an important role in the prevention of cardiovascular and some autoimmune diseases, possessing anti-tumoural and anti-inflammatory properties. Furthermore, the study of its FA profile may convey meaningful insights. A possible application is the utilization of the knowledge regarding the seaweed FA profiles as a chemotaxonomic tool. In particular, though seaweed FA profiles are usually rich in polyunsaturated FAs (PUFA), there is a very significant variability in the quality and quantity of these FAs. For most species, n-3 PUFA are predominantly composed of shorter chain FAs, such as C16 n-3 and C18 n-3. However, there are also some species with significant amounts (on a dry matter basis) of eicosapentaenoic acid (20:5 n-3, EPA). This study was based on a hierarchical cluster analysis (HCA) of the FA profiles of many different European green, red, and brown seaweed species determined by IPMA team.

Materials and Methods

The following European green, red, and brown seaweed species were studied: *Alaria esculenta*, *Chaetomorpha linum*, *Gelidium sesquipedale*, *Halopteris scoparia*, *Osmundea pinnatifida*, *Petalonia binghamiae*, *Pterocladiella capillacea*, *Rhizoclonium riparium*, *Ulva* spp. The fatty acid profile was determined by Gas Chromatography- Flame Ionization Detector as described by Bandarra et al. (1997). An internal standard was used in order to attain the absolute content of each fatty acid.

Results and Discussion

It was observed that red seaweed (e.g. *Osmundea pinnatifida*, *Pterocladiella capillacea*) could reach very high EPA contents (> 12 % of total FA), rare in green and brown seaweeds. However, there were red seaweed species poor in EPA, for instance, *Gelidium sesquipedale*, whose n-3/n-6 ratio was only 0.61 ± 0.02. This ratio also varied widely among brown and green seaweeds, reaching a value near 2 in *Alaria esculenta* (brown) and near 4 in *Chaetomorpha linum* (green). While these high ratios in green seaweeds were mainly supported by C16 n-3 and 18:3 n-3, in brown seaweeds this role was taken by 18:4 n-3 and EPA. In addition, the dichotomy between genetic influence and the action of environmental factors was shown to be relevant. Though HCA did not substantiate a phylogenetic relationship for the orders of seaweeds investigated, differences at the specific level seem to exist and be consistent. Indeed, the case of these seaweeds raises questions on the relative importance of the phylogenetic proximity *vs* environmental and other factors in determining a specific FA profile. On the one hand, FA signatures are claimed to differentiate among marine seaweeds, at least among ordinal and family ranks, on the basis of a thorough multivariate statistics analysis (Galloway et al., 2012). On the other hand, it is known that the FA profile and total A amounts of seaweed vary significantly throughout the year (Manivannan et al., 2008)

On the whole, taking into account the various seaweed taxonomic groups, a balanced assessment must highlight the complexity of interacting seasonal, spatial and species-specific drivers a fecting the FA composition of seaweeds.

Introduction

Sea urchins are a marine resource whose demand has been growing worldwide. In particular, sea urchin gonads, the edible part, are considered a *delicatessen*, whose size, texture, and taste are valorized. In Europe, *Paracentrotus lividus* is the most relevant. Over the last two decades, interest in echinoid aquaculture has been increasing. Used diets are critical. Though macroalgae may be better for the development and growth of sea urchins, they entail logistical and economic difficulties, namely, the availability and stocking of good quality macroalgae. Hence, combining with ingredients from terrestrial plants, such as maize, is important. The objective of this work was to feed captivity born juveniles during 4 months with macroalgae and maize, thereby evaluating growth, survival, and fatty acid (FA) profile of *P. lividus*.

Materials and Methods

Accordingly, each of two alternative diets was fed to sea urchins in four replicate tanks: diet U - *Ulva* sp. and diet M+U - 40 % of maize grains + 60 % of *Ulva* sp., w/w. The fatty acid profile was determined by Gas Chromatography- Flame Ionization Detector as described by Bandarra et al. (1997). An internal standard was used in order to attain the absolute content of each fatty acid.

Results and Discussion

Concerning the results, survival during the trial period was 100 %. At the end of the trial, sea urchin fed diet U showed better somatic growth than M+U animals. The substitution of maize in the diet formulation altered its FA profile. The most impressive change was the reduction of n-3 PUFA level and increase of n-6 PUFA level with the replacement of macroalgae by maize, thus leading to a decrease of the n-3/n-6 ratio from 13.2 ± 0.4 to 1.1 ± 0.2 (Table 1).

The observed FA profiles of the U and M+U diets largely reflect the usual composition of *Ulva* sp. and maize. With respect to the FA profiles of the gonads of farmed urchins fed the two alternative diets, they were similar to the FA profiles of the diets in the proportion of the saturated, monounsaturated, and polyunsaturated FAs, as well as in the relative importance of almost all main FAs. However, there were departures from the diet's FA profile. The eicosapentaenoic acid (20:5 n-3) and arachidonic acid (20:4 n-6) were remarkably higher in the urchin gonads than in the U and M+U diets, respectively. These comparisons strongly suggest that *P. lividus* is able to self-synthesize long chain PUFA (with 20 carbons) by incorporation of precursors (C16 and C18) of these FAs directly from their diet, as previously observed in another study with *P. lividus* (Prato et al., 2018) and for other sea urchin species (Chen et al., 2013).

Introduction

The Pacific white leg shrimp, *Litopenaeus vannamei*, is one of the widely cultured shrimp species in the world with an annual production exceeding 3 million tonnes (FAO, 2017). The shrimp farming sector is often affected by disease outbreaks. White spot syndrome virus (WSSV) is still among the most dangerous pathogens affecting shrimp worldwide (Escobedo-Bonilla et al., 2008; Sánchez-Paz, 2010). Selective breeding for WSSV resistance is a sustainable way of supplying robust seed to the shrimp sector (Gjedrem and Rye, 2018; Nguyen, 2016). The heritability of WSSV resistance in *L. vannamei* has been estimated to be low (Gitterle et al., 2006, 2005) to moderate (Trang et al., 2019), and the trait shows an unfavourable genetic correlation with growth (Gitterle et al., 2005; Trang et al., 2019). Genomic selection is expected to increase the selection accuracy for resistance traits (Vela-Avitúa et al., 2015), and hence to be the optimal selection method for WSSV resistance.

The *L.vannamei* Cartagena (C) family based breeding program operated by Benchmark's Genetica Spring at the Atlantic coast in Colombia is currently at 17th generation, applying selection for growth, high pond survival, robustness and resistance to acute hepatopancreatic necrosis disease (AHPND) and Taura Syndrome (TSV) under strict biosecurity protocols. In parallel, Genetics Spring runs an additional breeding program for *L. vannamei* in Tumaco (T) at Colombia's Pacific coast, mass selected for 10 generations for increased resistance to WSSV. The aim of this study was to improve WSSV resistance in C (nucleus) and commercial multiplier lines through genome enabled selection. Here, we test the accuracy of genomic selection and present results from our genome-wide association study (GWAS) looking for loci associated with WSSV resistance.

Material and methods

Forty GWAS families were created for GWAS study by crossing 10 pure sires each from C and T with 20 pure dams each from C and T where 1 sire was mated with 2 dams, resulting in; 10 pure C (CC), 10 pure T (TT) and 20 crossbred (CT) families. A separate experimental training population, consisting of 58 families with pure T (TT) and crossbred (CT), was created for genomic selection to improve WSSV resistance as described by Lillehammer et.al. (2019). Challenge tests were conducted separately on shrimp from the GWAS families (n=200 pure TT, 200 pure CC and 400 crossbred CT) and training data families (n= 751 pure TT and 696 crossbred CT) in four-ton tanks, using artificial seawater at 30ppt salinity and 26^{o}C temperature. In brief, juvenile shrimp of average weight 3g were infected with WSSV using minced infected tissue fed at a rate of at 3% biomass. Mortalities were recorded each hour for the duration of the test. WSSV infection was confirmed by PCR and histopathology. Selective genotyping (by choosing early and late dying animals within the families) was performed on the GWAS family animals (CC=144, CT=190 and TT=147) to increase the power of detecting rare alleles

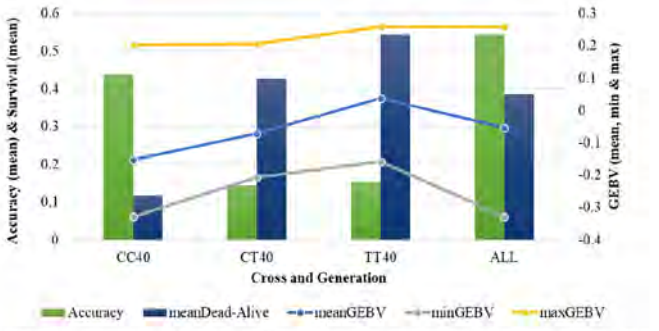

Figure 1. Accuracy of GEBV prediction (mean), phenotype dead/alive (mean) and GEBV prediction (mean, min and max) for the GWAS families for the trait dead or alive using linear model

(Continued on next page)

of large effect (Xing and Xing, 2009), whereas, all animals from the training families were genotyped using an Illumina ~19K SNP chip. GWAS was performed for two traits; binary survival ("dead or alive") at end-of-test, and "hours survived". A genomic relationship matrix was used for estimation of variance components and to predict genomic breeding values (GEBVs) using genomic BLUP (GBLUP) methodology. The accuracy of the genomic prediction (correlation between estimated genomic breeding values and phenotype, divided by the square root of the heritability) was evaluated using genomic data from the training family as training data and the GWAS family as validation data.

Results and Discussion

Accumulated mortality for the duration of the challenge test for GWAS and training families was 64% and 61%, respectively. Among the GWAS families, the pure C (CC) had highest mortality (89%) followed by crossbred (CT; 58%) and pure T (TT; 46%). Among the training families the highest mortality was found in crossbred (CT; 76%) compared to the pure T (TT; 46%). The heritability estimates for the binary dead or alive trait was moderate irrespective of whether a linear model (0.26 ± 0.04) or threshold model was used (0.27 ± 0.04). The estimated heritability for hours survived was 0.38 ± 0.04. These heritability estimates are higher than reported for a previous study on the Cartagena population (Gitterle et al., 2005), as well as for an un-related population (Trang et al., 2019), most likely due to the high level of resistance present in the combined C and T stocks studied here. In the previous study by Gitterle et.al. (2006), only the pure C (CC) population was used, and average mortality rates were much higher than seen for the TT and CT families in the present study.

The GWAS for WSSV resistance for both traits in GWAS families showed polygenic inheritance with large number of SNP markers explaining genetic variance (Figure not shown). This suggests that a genomic selection approach, exploiting both within-and between-family genetic variation, will be more suitable than conventional family-based selection. The accuracy of genomic prediction for the binary trait ranged from 0.14 (pure TT) to 0.43 (pure CC) with an overall accuracy of 0.54 (ALL) (Figure 1). In contrast, Lillehammer et al. (2019) reported relatively high cross validation accuracy (0.64 to 0.69) using the training population alone. Slightly lower overall accuracy found in this study for GWAS families is most likely due to the relationship between training and validation data; the validation data did not consist of direct full-sib relatives of the training population. In addition, lower accuracy observed among CC, CT and TT GWAS families was most likely because of the limited data available due to selective genotyping followed within these groups. High Pearson correlation (~0.98) was observed between mean GEBV prediction and mean observed survival (dead-alive) in GWAS family groups (Figure 1) possibly indicating accurate GEBV predictions in the absence of relevant phenotypic information: a scenario for the breeding candidates not exposed to WSSV. Though the observed mean survival and mean GBEV prediction for example for pure C (CC) was low, it was still possible to identify animals with high GEBVs for WSSV resistance (max GEBV, Figure 1), like what we can find in highly resistant pure T (TT).

Introduction

An increasing number of new food products (including new aquaculture products) fail in the marketplace (Fuller, 2016). Even though, it is already established in the literature that having an value-added, superior product in the eyes of the consumers makes a significant advantage on the marketplace, still new product developments are often company and not consumer-driven (Banovic et al., 2016). Strong market and consumer knowledge, as well as labelling schemes are key success factors to obtain the product-market fit and assure acceptance of new aquaculture products (Banovic et al., 2019). The present study uses a cross-cultural context to investigate European consumers' acceptance of new aquaculture products and define the relative perceived value consumers place on different labelling schemes, such as nutrition and health claims, country of origin (COO) label and ASC eco-label, thus separating winners from losers. Besides investigating new aquaculture product acceptance, the current study further uncovers consumer segments which would be more willing to accept new aquaculture products.

Materials and methods

The consumer acceptance of new aquaculture products (i.e., fresh/chilled, smoked, and canned) was modelled by using conditional logit and latent class analysis to investigate aquaculture products' choice and consumer segments in the five European countries (France, Germany, Italy, Spain and the UK). The selection of attributes and their levels has been based on previous studies (Banovic et al., 2016; Reinders et al., 2016) and secondary data on recently launched fish products, used labelling schemes (e.g., health and nutrition claims), and prices for the countries under the study. Based on the above, consumer perceived value of health and nutrition claims, COO and ASC eco-label, as well as consumers' willingness to pay was investigated in the context of new, aquaculture products (for more information see Banovic et al., 2019). Data collection has been undertaken through on-line choice experiments (30 minutes per study) in each of the five study countries and for

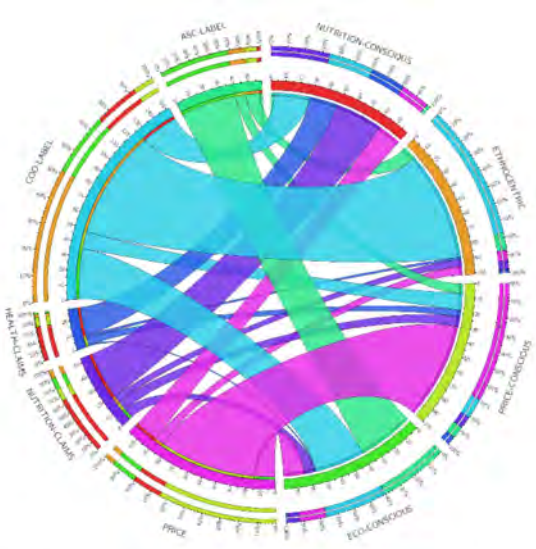

Figure 1. Importance of health and nutrition claims, country-of-origin (COO) and eco (ASC) label per consumer segment: "nutrition conscious", "ethnocentric", "price conscious" and "eco-conscious"; graphical abstract from Banovic et al. (2019).

(Continued on next page)

each of the three selected products (i.e. fresh/chilled, canned, and smoked). In total, one thousand five hundred and ninety eight participants participated in the study with approximately 500 participants per selected product. Quotas on age, gender, and income have been applied across countries and products to avoid sampling bias (for three selected products: mean age = 40.8 years, 50% male, ~ 65% of participants had average income).

Results

What separate "winners" from "losers", on the general level, in the eyes of these consumers when choosing aquaculture products, is COO label, i.e., aquaculture products produced or sourced from the own country in combination with ASC eco-label (see Banovic et al., 2019). However, consumers from different segments are willing to accept new aquaculture products depending on their own personal interests and relative importance of the different attributes, see Figure 1. Thus, the results further show presence of similar consumer segments across all five investigated European countries, named "nutrition conscious", "ethnocentric", "price conscious", and "eco-conscious" consumers and their criteria for acceptance of new aquaculture products.

Conclusions

What makes the aquaculture product a success is providing added-value (in terms of communicated attributes) that deliver unique benefits to the "right" consumer. A segmented view of the European consumer in this study gives guidelines that could facilitate development of new aquaculture products for improved targeting to further marketing effort and to generate better competitive advantage. This is particularly appropriate now in light of the upsurge of the new aquaculture products on the market.

Introduction

To protect wild seaweed species and populations that are often overexploited due to their known value, humankind has cultivated seaweed as an alternative source. Seaweed culture optimization is thus essential to achieve profitable growth and production rates, with at least the same, if not better, biochemical value as their wild counterparts. Hence nutrient composition of any given formula is one of the many elements that may be manipulated within a seaweed culture system, playing a key role in seaweed functional composition.

One of the most well-known medium in seaweed culture is the Von Stosch Enriched (VSE) formula; its modified version is highly beneficial to the growth of the agarophyte *Gracilaria gracilis*, with reckonable success due to its high content in ammonia (NH_4^+) and phosphate (PO_4^{3-}), among other essential nutritive elements. However, VSE formulation is both laborious and costly and thus, the present work aims to seek out a cheaper, easier-to-make alternative, among other culture media and commercial fertilizers. Our goal is to increase the overall profit by decreasing both cost and labour in choosing and formulate this substitute, while avoiding to compromise *G. gracilis* growth rates and biochemical value, which are partially shaped by its nutrient source.

Materials & Methods

Specimens of *G. gracilis* were selected and harvested during low tide in Lagoa de Óbidos (39°24'01''N, 9°13'10''W), Portugal, and transported to the lab inside dark cooler boxes. All specimens were individual and thoroughly washed, and all necrotic parts removed. The cleaned seaweeds were then placed under acclimatization for one week in 60 l plastic open dark containers provided with clean seawater (20ºC, 30-35psu, 16:08 Light:Dark). Afterwards, carefully selected *G. gracilis* tips, were cut, cleaned, and distributed across 250 ml flat-bottom flasks with constant aeration, under a grolux plus daylight combo (1500lux), in a climatic room at 20ºC. All individuals were provided with sterilised seawater at 35psu, supplemented on a fortnight basis with a nutrient source. Culture media and fertilizers tested were f/2, FloraNova Bloom (FNB), FloraNova Grow, and Nutribloom, while Von Stosch Enriched (VSE) medium modified for red seaweeds (Redmond et al., 2014) was kept as control. Both FloraNova and Nutribloom formulas were used both unchanged and boosted with a NH_4^+ source. All assays were performed in triplicate and individuals were weighted prior to culture media renewal. Daily growth rates were measured after 28 days, according to Hayashi et al. (2011).

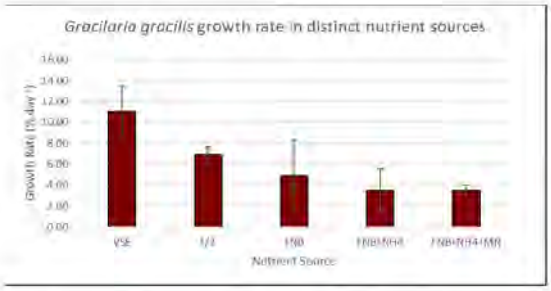

Fig. 1. *Gracilaria gracilis* growth rate under controlled conditions, and supplied with distinct nutrient sources. VSE: Von Stosch Enriched nutrient medium; f/2: f/2 medium, FNB: FloraNova Bloom; FNB+NH4: FloraNova Bloom supplied with ammonia; FNB+NH4+MN: FloraNova Bloom supplied with ammonia and manganese.

(Continued on next page)

Results

Results show that the best overall growth was observed for *G. gracilis* tips supplied with VSE medium (11.3%.day^{-1}), followed by those grown with f/2 medium (6.96%.day^{-1}) (Fig. 1). The commercial fertilizer and both its modified formulations show lower growth rates than the above mentioned (ranging from 3.51 to 4.89%.day^{-1}, the latter from the standard FNB formula with no modifications). Work is still in progress regarding the remaining mentioned fertilizers, to determine whether it is relevant to supply the standard nutrient media formulas with extra elements relevant to *Gracilaria*, while also taking into consideration the nutrient composition and concentration already present in each formula.

Discussion

According to Fig. 1, VSE still stands as the best overall nutrient source. However, the standard FNB formula may also be considered a viable alternative in the long term, provided its lower cost and still noticeable effectiveness in growing *G. gracilis*. Curiously, adding extra nutrients to this fertilizer showed no improvement to *G. gracilis* growth, when comparing these results to those from the standard formula. The f/2 medium is a commonly used nutrient source for algae, having however NO_3 as the main source of ammonia, instead of NH_4^+; although results show a positive effect in *G. gracilis* growth, this nutrient source also shares the same drawbacks as VSE's in terms of costs and easiness to prepare, and would thus be an alternative worth exploring only if it had presented growth rates even greater than those obtained with VSE.

In all assays, *G. gracilis* showed no visible signs of stress, keeping its natural dark red colour throughout the 28 days, which stands as an evident sign of healthy individuals. Most thalli also presented active growing along the tip, as well as a number of ramifications developing and expanding across the thallus length

Conclusion

Similarly to other seaweeds, *G. gracilis* requires several key macro and micronutrients to grow and thrive, such as ammonia, phosphates, iron, manganese, as well as the vitamins biotin, thiamine, and vitamin B12. These elements are also required by several land plant species and are thus present in commercial fertilizers tailored for them, which are also a cheaper alternative to culture media designed and formulated from scratch. However, not all fertilizers have the ideal nutrient set for seaweed growth; thus it is necessary to assess whether it is sensible and cost-effective to further enrich and tailor the nutrient source with additional nutrients to respond to any given species needs, and thus promote growth rates and quality of the end product.

Introduction

Aquaculture production systems present a set of limitations and constraints, which hinder the health and welfare of fish and shellfish. High density populations, regular handling, poor water quality, improper feed quality and the presence of pathogens, can trigger stressors that favour the emergence of pathogenic outbreaks. The presence of pathogens causes low food conversion rates, reduced growth and ultimately low survival rates, leading to significant economic losses. One of the ways of preventing the occurrence of disease, particularly of bacterial origin, can be the supplementation of the fish feed with bioactive compounds with antimicrobial activity. The use of seaweeds in the fish feed, either directly or in the form of extracts, can be an asset, providing not only compounds of nutritional value, but also several bioactive compounds, with known benefits. In general, seaweeds present antimicrobial and immunostimulant effect, but also anti-viral, prebiotic and antioxidant activities, among others. Recently there has been a growing interest regarding the potential of seaweeds as a source of nutritional and health related compounds, and the genus *Gracilaria*, a renowned agarophyte extensively cultivated worldwide, is no exception. The objective of the study was to evaluate the *in vitro* antimicrobial activity of crude extracts of *Gracilaria gracilis* against XX pathogens of bacterial origin, common in aquatic environment, seeking to assess the value of these extracts as additives in fish feed.

Materials & Methods

Gracilaria gracilis (Stackhouse) Steentoft, Irvine & Farnham, was collected from Lagoa de Óbidos (39º24'01''N 9º13'10''W), Caldas da Rainha, Portugal. The ethanolic or aqueous extracts were prepared using a 1:10 ratio of biomass: solvent (w/v), with agitation at room temperature, and different extraction times were tested (Vlachos et al. 1996, Chan et al. 2015). Extracts were filtered, centrifuged and concentrated in a rotary evaporator (ethanolic extracts) or freeze-dried (aqueous extracts). All extracts were tested against several bacterial fish pathogens: *Vibrio anguillarum*, *Vibrio alginolyticus*, *Photobacterium damselae* subsp. *piscicida*, *Photobacterium damselae* subsp. *damselae*, *Aeromonas hydrophila* subsp. *hydrophila*, *Aeromonas salmonicida* subsp. *Salmonicida* and *Edwardsiella piscicida*. For the evaluation of the antibacterial activity, the Agar Disk Diffusion Method (Bauer and Kirby, 1966), was used, according to the National Committee for Clinical Laboratory Standards. Briefl , target strains were prepared to obtain a working culture containing approximately $1x10^8$ cells ml^{-1}. Aliquots of each bacterial suspension, were inoculated using the spread plate method on Muller-Hinton agar plates with 1.5% NaCl (Thanigaivel et al. 2015). To perform the assays, the crude extracts (20µl) were dissolved in 1ml of the respective solvent, and used to soak sterile disks (6mm in diameter, Oxoid), that were applied to the inoculated plates. Disks containing 30µg of chloramphenicol were used as a positive control, disks soaked with 20µl of the respective solvent were used as a negative control. Plates were incubated 24h-48h at ideal temperature of each strain and the inhibition zone was measured (mm). All tests were performed in triplicate.

Results

In general, ethanolic extracts present a superior antimicrobial activity to aqueous extracts, thus revealing ethanol as the most suitable solvent for extraction. The results also indicate that extraction times of 30 minutes and 1 hour show the best results. Inhibition halos were recorded against *Vibrio anguillarum* (8mm), *Aeromonas hydrophila* subsp. *hydrophila* (9mm), *Aeromonas salmonicida* subsp. *salmonicida* (8mm), *Photobacterium damselae* subsp. *damselae* (9mm) and *Photobacterium damselae* subsp. *piscicida* (10mm).

Discussion and conclusion

Gracilaria gracilis is a natural source of antimicrobial compounds with potential value to human or animal health and can be used in food or feed to increase resistance to several pathogenic bacterial strains, as shown by the results. The effects observed under *in vitro* conditions are quite interesting in view of the devastating effects some of these pathogens may have on several aquaculture fish species. The effects of dietary seaweed biomass supplementation with *Gracilaria* sp. were previously assessed in meagre (*Argyrosomus regius*) subjected to infection with *Photobacterium damselae* subsp. *piscicida* (Peixoto et al. 2017), indicating that the inclusion of seaweeds may confer advantages in coping with biotic stressors, as oxidation damages were reduced. Based on the current research, seaweed extracts show promising properties as antimicrobial agents and health promoting agents, but further research is needed. The use of *G. gracilis* extracts, and their effects on mortality, as well as in the immune response parameters, is currently being tested in order to understand the *in vivo* effects of this seaweed extracts.

Introduction

Aquaculture plays an important role in food production worldwide. However, the presence of pathogens is currently a major constraint for its development, leading to disease outbreaks and therefore causing severe economic losses (Romalde, 2002; Essam *et al*., 2016). *Photobacterium damselae* subsp. *piscicida* (*Phdp*) is the causative agent of photobacteriosis, formerly known as fish pasteurellosis, a bacterial septicaemia. *Phdp* is able to infect a wide variety of marine fish with economic relevance, including the yellowtail (*Seriola quinqueradiata*) in Japan and gilthead seabream (*Sparus aurata*), European seabass (*Dicentrarchus labrax*), sole (*Solea senegalensis* and *Solea solea*) and meagre (*Argyrosomus regius*) in Europe (Romalde, 2002; Essam *et al*., 2016; Costa *et al*., 2017).

The aim of this work was to compare cellular and humoral immune responses of gilthead seabream and meagre against *Phdp*.

Materials and methods

A time-course study was performed at CETEMARES (Instituto Politécnico de Leiria) facilities, with gilthead seabream (mean wet weight 40 ± 7.3 g) and meagre (mean wet weight 65 ± 11.9 g) juveniles obtained from the Aquaculture Research Station-EPPO (IPMA, Olhão, Portugal). Among each population, 12 fish were randomly selected and sampled before infection (time 0 h). Thereafter, the remaining animals were randomly selected and intraperitoneally injected (IP) with 100 µl of 1 10^5 CFU ml^{-1} of *Phdp*, while control fish were sham-injected with 100 µl a phosphate buffered saline solution. Afterwards, fish were randomly distributed as a completely randomized design into 12 tanks of 60 l closed recirculation systems (i.e. triplicates per experimental condition, for each studied species). Two animals per tank (n=6) were randomly selected and sampled at 3, 6, 9, 24 and 48h after IP injection. At each sampling point, fish were anaesthetized with 2-phenoxyethanol and blood samples were collected for haematological procedures such as total, differential counting of peripheral leukocytes and total circulating erythrocytes. The remaining blood was centrifuged and plasma was collected for the assessment of innate humoral immune parameters. Every recirculation system was kept at 25°C for 21 days and pathological signs and mortality were observed and recorded.

Results

Infected meagre mortality started at 24 h and exhibited a mortality rate of 100% at 48 h post infection. The individuals showed reduced appetite, lethargy and abnormal swimming behaviour, whereas no mortality was observed in infected seabream. Regarding white blood cells both species presented a similar response, since total cell counts increased in infected groups across time. However, peripheral lymphocytes showed a differential response depending on the host, since those numbers increased over time in infected seabream, whereas meagre dropped lymphocyte counts for both infected and sham injected treatments. In contrast, neutrophil counts decreased in infected meagre, while gilthead seabream did not show any changes in this phagocyte population. In both seabream and meagre juveniles, circulating thrombocytes increased over time in infected individuals compared to sham injected controls. Plasma peroxidase activity increased in infected meagre and seabream but seemed to be particularly high in infected seabream. Plasma bactericidal activity increased in infected meagre with no changes in seabream.

Discussion and conclusion

In the case of the infected seabream individuals it was observed a migration of lymphocytes to the bloodstream in response to this pathogen, while in meagre the lymphocytes decreased. These distinctive immune responses may indicate immunogenic stimulation or immunosuppressive conditions, resulting in lymphocytosis or lymphocytopenia for the same

(Continued on next page)

pathogen (Clauss *et al*., 2008). These results can be directly related with the specific response of each specie. For the white blood cells, the levels increased as early as 3 h post-infection for both species, revealing a mobilization of these cells to the infected tissues (Chaves-Pozo *et al*., 2005). The fish innate immune response is considered to be an important component to rapidly avoid the proliferation of a pathogen (Whyte, 2007). In this study, the innate immune response to *Phdp* infection lead to an increased bactericidal activity levels in infected meagre. Neutrophils are regarded as part of the innate immune response; however, they can interact using cytokines and chemokines with some cell-mediated responses, making them a bridge between defence systems (Rosales *et al*., 2017). It is already established that some pathogens, overcome the neutrophils defence, by means of blockage of chemotaxis and phagocytosis (Rosales *et al*., 2017), being *Phdp* capable of extensive apoptosis of macrophages and neutrophils that results in lysis of these phagocytes by post-apoptotic secondary necrosis (do Vale *et al*., 2005). This effect was especially relevant in meagre, occurring a neutrophil decrease in the infected treatment relatively to the control, reaching almost zero 24h post-infection. Although the infected seabream did not perish, the studied immune parameters did not show the reason behind the seabream ability to survive to this pathogen. Therefore, different parameters should be analysed to reach a conclusion regarding these results. A deeper study about the reaction of the immune parameters to the same pathogen in different fish species may provide valuable biomarkers to identify and avoid the proliferation of bacterial pathologies.

EUGENOL INDUCES A SEAZURE-LIKE STATE DURING SHORT-TERM EXPOSURE IN FISH

L. A. L. Barbas[1*], M. J. M. Feitosa[1], M. F. Torres[1], B. M. P. A. Costa and M. Hamoy[2]

Introduction

Eugenol is one of the most commonly used and commercially available plant extractives for anaesthesia/immobilisation of fish. However, stress, ventilatory failure and medullary collapse have been reported in fish exposed to this compound (Sladky et al., 2001; Davidson et al., 2000; Readman et al., 2013). Many of the current drugs or alternative products recently put forward as novel anaesthetics are regarded as general anaesthetics based on the premise that loss of reaction to visual or mechanical stimuli after exposure to the drug is accompanied by unconsciousness (Ross and Ross 2008). Yet, the use of behavioural markers alone, such as the observation of latency to reaching a stage of general immobilisation, does not prove general anaesthesia with unconsciousness or analgesia. Animals may reach a stage of sedation and be completely immobilised but not unconscious or pain free. The aim of this study was to evaluate through electroencephalographic (EEG) recordings the extent to which eugenol promotes depression of the central nervous system (CNS), acting as a general anaesthetic for fish.

Materials and methods

Tambaqui, *Colossoma macropomum* were acclimated for 15 days in semi-static systems prior to the beginning of the experiment. Eugenol (Quimidrol™, Joinville SC – Brazil) was purchased from a commercial establishment. A stock solution of eugenol was prepared by diluting it in commercial alcohol (96%) at a ratio of 1:9, and stored in an amber glass bottle at 4°C until use. Eugenol baths at 65 µL L^{-1} sufficed to promote a fast induction (< 3 min) to "anaesthesia", *ie*., absence of or minimum opercular beating with loss of reaction to tail pinch stimulus as reported by Roubach et al. (2005) for this species. For the design of appropriate equipment and recording of electrophysiological data, the methodology of Pineda et al. (2011) was used. Fish [3.4 g ± 0.58 (SD); 5.5 cm ± 0.8 (SD), total length] were assayed in three groups as follows: a) sham control; b) fish exposed to eugenol and c) fish in recovery. Nine fish per group (n = 9) were used; each individual was considered a replicate, and used only once. For the recording of EEG, fish were individually netted from the maintenance tanks and equipped with the electrode set, after which fish were placed into the experimental chamber, inside a 1–L fish tank, previously filled with the same aerated water (0.5 L) from the maintenance tank and added by eugenol at 65 µL L^{-1}, or anaesthetic-free water, accordingly. During induction, recordings of the field potential in brain, including baseline profile in sham control were performed in the course of 5 min. EEG during recovery was also registered in anaesthetic-free water immediately after the anaesthetic exposure (10 min recordings).

Results and Discussion

EEG in sham control showed low amplitude of tracings (Fig. 1A, left) and the spectrogram indicated that energy intensity was concentrated in frequencies below 10 Hz (Fig. 1A, right). Mean basal amplitude recorded in the mesencephalon of tambaqui was 0.0220 ± 0.0007 mV^2 / Hz x 10^{-3} (Fig. 2) whereas the induction process was characterized by intense brain activity with excitability, which evolved to a seizure-like state showing amplitude recordings of 0.0824 ± 0.0078 mV^2 / Hz x 10^{-3} (Fig. 2). During induction, elevations in frequencies were observed as shown in Fig. 1B (left). A 10s magnification of the tracings within the first third of the EEG recordings showed the occurrence of action potential bursts (Fig. 1B, centre), being the spectrogram of frequency in line with the tracing pattern attained, showing high intensity of energy throughout the record (Fig. 1B, right). During recovery, fish resumed normal brain activity and excitability gradually decreased (Fig. 1 C, left), with mean amplitude of 0.0181 ± 0.0030 mV^2 / Hz x 10^{-3} (Fig. 1C, left). The fragment amplification of the EEG during recovery revealed a similar pattern of tracings compared to that of sham control (Fig. 1A and C, centre). At the beginning of the record, the spectrogram showed that energy consumption was higher, indicating an extra effort for recovery. However, the intensity of the signal decreased over time, and fish were fully recovered at the end of the EEG recording (Fig. 1C, right, and 2).

(Continued on next page)

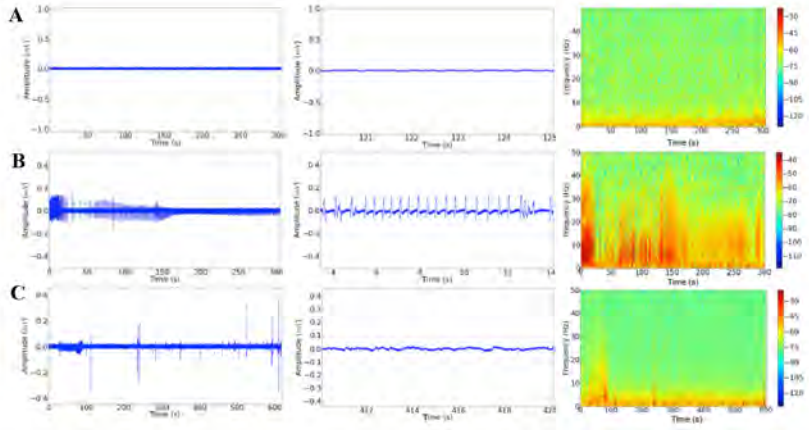

Fig. 1. Electroencephalogram (EEG) recordings of the mesencephalon region in juvenile tambaqui, *Colossoma macropomum*. A – Recordings in sham control in 300s (left), fragment amplification of EEG (10s) (centre) and spectrogram of frequency (right). B – EEG in fish exposed to eugenol at 65 µL L^{-1} for 300s, fragment amplification of EEG (10s) (centre) and spectrogram of frequency (right); C – EEG recordings during recovery in eugenol-free water 600s (left); fragment amplification of EEG (10s) (centre) and spectrogram of frequency (right).

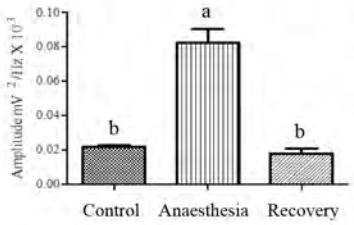

Fig. 2. Mean amplitude (± SE) recordings from the mesencephalon region of juvenile tambaqui, *Colossoma macropomum* in frequencies of up to 50 Hz. Electroencephalogram (EEG) recorded in sham fish (Control) (300s), during exposure to eugenol at 65 µL L^{-1} (Anaesthesia) (300s) and after eugenol exposure (Recovery) (600 s). Distinct letters above columns denote significant differences after ANOVA and Tukey's test, $p < 0.05$, $n = 9$.

During exposure to eugenol, although complete body immobilisation was attained, fish presented an intense neuronal excitability, which was consistent with a seizure-like event. Recovery was gradual albeit it required twice the time used for induction. Our results showed that eugenol did not adequately anaesthetize fish during short-term exposure, for it failed to promote depression of the CNS and therefore was not effective as a general anaesthetic and not compatible with a deep anaesthesia state in tambaqui, *C. macropomum*.

OCEAN ACIDIFICATION AND MULTIPLE STRESSORS AFFECT LARVAL BUT NOT JUVENILE STAGES OF THE EASTERN OYSTER (*Crassostrea virginica*)

Michelle Barbosa*, Caroline Schwaner, Emmanuelle Pales Espinosa, Bassem Allam

School of Marine and Atmospheric Sciences, Stony Brook University, Stony Brook, New York 11794 (United States of America)
E-mail: Michelle.Barbosa@stonybrook.edu

Introduction

Ocean acidification (OA) is considered to be a major threat to the future of our oceans. The altered seawater chemistry associated with OA is predicted to be particularly threatening for calcifiers such as sensitive bivalve species, particularly during early life stages. This study was designed to assess and compare the effects of OA on larval and juvenile eastern oyster (*Crassostrea virginica*) viability, growth, and immunity, and evaluate the impact of food availability on resilience to OA.

Materials and Methods

For larval studies, adult oysters were spawned and larvae were cultured under ambient (400ppm) or elevated (1000ppm) pCO_2 conditions. Viability and growth were assessed after two weeks. Larval susceptibility to bacterial pathogens (cocktail of *Vibrio coralliilyticus*, *V. alginolyticus*, and *Listonella anguillarum*) was evaluated on 7-day-old oysters. The effect of trophic resources on viability was assessed following a diet of high (100% recommended agal quantity) or low (10% recommended) food for a period of 24h.

For juvenile studies, oysters (shell length 5mm ± 1.5mm, n=1,600) were procured from hatchery stocks and transferred to ambient or elevated pCO_2 conditions. Following an acclimation period, oysters were exposed to fed or completely starved conditions for 10d, then exposed to *Roseovarius crassostreae* (etiological agent of Juvenile Oyster Disease) for 4 weeks.

Results

Overall larval mortality was highest under OA after a two-week exposure. Larval growth was lowest under OA. Under combined OA and food limitation mortality was higher than all other conditions (Fig. 1). Under OA, larval oysters are significantly more susceptible to bacterial pathogens (Fig. 2)

Juvenile mortality was highest under ambient pCO_2 and starvation conditions (Fig. 3). OA or OA and starvation did not significantly affect the survival of juvenile oysters. Starvation significantly reduced the length of oysters within their relative pH treatment, and overall length was smallest in juveniles under OA and starvation. Starvation of juvenile oysters increased susceptibility to ROD, however, susceptibility was highest in oysters under ambient pCO_2 conditions.

Discussion

Results suggest that larvae are more susceptible to the effects of OA with regard to viability, susceptibility to infection, and viability under food limitation as compared to juvenile oysters. However, both larvae and juveniles face reduced growth under OA conditions suggesting shell building and maintenance are particularly challenging for oysters under acidified conditions.

Ongoing work seeks to further determine the molecular basis for resiliency to OA and identify specific molecular features associated with survival. These findings provide greater insight into the specific effects of OA on *Crassostrea virginica* physiology and how multiple stressors may work synergistically to affect the resiliency of oysters to environmental stress.

Introduction

Tambaqui (*Colossoma macropomum*) is a native fish species of the Amazon basin, being one of the main species in Brazilian aquaculture. LC-PUFA can be obtained through the diet or endogenously produced (biosynthesis) through the combined action of two enzymes, namely fatty acyl elongases (Elovl) and desaturases (Fads). Studies have established that tambaqui is an herbivorous fish that can fulfil its essential FA requirements with dietary provision C18 PUFA LA and ALA. The functional and molecular characterization of Fads2, elovl5 and elovl2 established that they can operate towards a variety of PUFA substrates with chain lengths ranging from 18 to 22 carbons (Ferraz et al. 2018). These enzymes have been extensively studied in several aquaculture species in an effort to understand the ability of fish species to utilize dietary vegetable oils (VO) replacing fish oils (FO) in current aquafeed formulations indeed. To elucidate these questions in tambaqui, we combined different sources of oil and levels to investigate lipid metabolic pathways. The present study aimed at understanding the ability of tambaqui to satisfy its LC-PUFA requirements when fed on VO-rich diets commonly; gene expression of key enzymes involved in LC-PUFA metabolism (FADS2, ELOVL5 and ELOVL2) in the liver and the brain were evaluated.

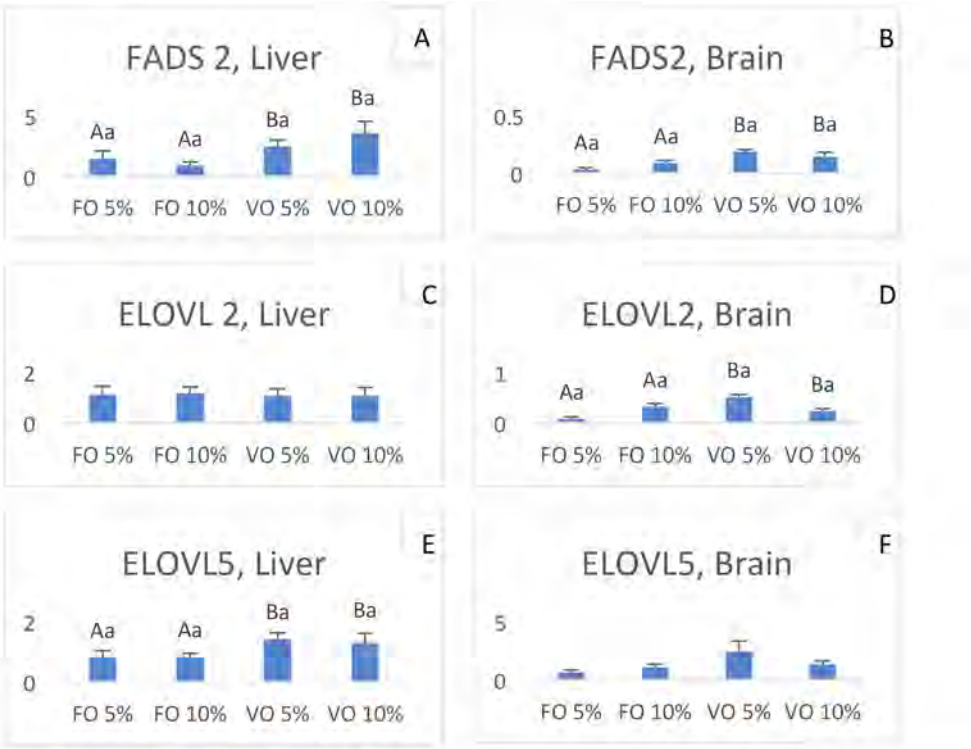

Fig. 1. Expression of genes involved in long-chain polyunsaturated fatty acid (LC-PUFA) biosynthesis. Expression of Fads2 in liver (A) and brain (B), Elovl 2 in liver (C) and brain (D), Elovl 5 in liver (E) and brain (F) determined by real-time quantitative PCR. Different letters represent significant different between diets (ANOVA, $P<0.05$) where the fast letter is the effect of font od oil and second is about percentage of oil.

(Continued on next page)

Materials and methods

The present study was conducted to evaluate the influences of different dietary fatty acid profiles on the biosynthesis of LC-PUFA in juvenile tambaqui. Four diets were prepared (FO5%, FO10%, VO5% and VO10%). A 9-week feeding trial was conducted using juvenile fish (8.61 ± 1.38g). Fish were dissected and samples of liver and brain were preserved in an RNA stabilization buffer. Total RNA was extracted using the "illustra RNAspin Mini Kit" (GE Healthcare). cDNA was synthesized from 1000 and 500 ng total RNA, respectively from the liver and brain, using the "NZY Fist-Strand Cdna Synthesis Kit" (NzyTech) following the protocol. Fluorescence-base quantitative PCR was performed with the NZYSpeedy qPCR Green Master Mix (2x) (nzytech gene and enzymes). Relative gene expression was calculated with the ΔΔCt method including the PCR efficiencie of the target and reference gene. Target gene expression was normalized utilizing the geNorm software, using a multiple reference gene approach (normalization with β-actin, tubulin and microgobulin).

Results

The present study demonstrated that, in the period of 9 weeks, no difference in body weight gain (BWG), feed conversion ratio (FCR) and survival were observed between treatments with dietary vegetable oil (5 and 10 %) and dietary fish oil (5 and 10 %). Expression of LC-PUFA biosynthetic pathway genes (Fads2, Elovl5 and Elovl2) was determined in tambaqui liver and brain using qPCR (Fig. 1). The expression of Fads2 and elovl5 in the liver increased in fish fed the VO source (VO5%, VO10%) (Fig. 1, A and E). Effects of VO on the expression of Elovl2 in liver was not detected (Fig. 1, C). Similarly, the brain presented high expression of Fads2 and Elovl5 in VO (Fig. 1, B and D), and no difference in the elvol5 (Fig. 1, F).

Discussion and conclusion

In this study, the expression of fads2 and elovl5 in the liver was up-regulated when the fish were fed by the VO dietary source. A similar profile was observed in the brain. These results suggest that fish fed high dietary VO have more available C18 substrates such as LA (18:2n–6) and LNA (18:3n–3) for elongation and desaturation. Additionally, in the brain the higher expression levels of elovl2 suggests that a greater contribution of this metabolic step to the production of docosahexaenoic acid (DHA). In conclusion, these results suggested that fish oil can be replaced by vegetable oil for tambaqui and that the percentage of 10% is not high to the point of disrupting the animal's metabolism.

EXPLORING MACHINE LEARNING METHODS FOR GENOMIC PREDICTION OF DISEASE RESISTANCE AND BODY LENGTH IN THE GILTHEAD SEA BREAM

O. Tassiello, L. Montanucci, M. Babbucci, S. Ferraresso, P. Carnier, L. Bargelloni*

Department of Comparative Biomedicine and Food Science, University of Padova, viale dell'Università 16, 35020 Legnaro (Italy)
E-mail: luca.bargelloni@unipd.it

Introduction
The use of machine learning (ML) methods is rapidly increasing in genomic science (Schrider and Kern 2018, Ho et al. 2019, Telenti et al. 2019). ML methods have also been proposed as alternatives to statistical methods for predicting breeding values in the context of genomic selection. Although in particular scenarios ML approaches are reported to outperform parametric methods for genomic prediction (Howard et al. 2014), increasing evidence suggests that relative performance largely depends on the analysed data sets (*e.g.* González-Camacho et al. 2018, Montesinos-Lopez et al. 2019). Here we evaluate ML methods applied to predicting phenotypes for two traits, body length and resistance to fish photobacteriosis in the gilthead seabream, one of the most important species for European aquaculture.

Methods
Two published data sets (Palaiokostas et al. 2016, PAL2016; Aslam et al. 2018, ASL2018) were re-analysed starting from pre-processed sequence data to obtain a common SNP data set for nearly 2,000 individuals. After quality filtering, raw sequence reads were mapped against the draft sea bream genome (Pauletto et al. 2018) using BWA. SNP variants were called using SAMTOOLS. Loci showing high missing data rates (>30%) and minor allele frequency lower than 0.05 were filtered out. Genotype imputation was carried out using BEAGLE yielding over 80,000 SNPs were obtained. Two traits were recorded in the original experiments: survival time after infection with *Photobacterium damselae piscicida* and total body length. Individual survival data were transformed into binary data (dead or alive at day 10 after challenge) or continuous data (age-normalized length). Parentage relationships were reconstructed using CERVUS on five random subsets of 1000 SNPs. For ML, support vector machine (SVM) and linear bagging (LB) were implemented either as classification or regression algorithms. For parametric methods, Bayes B, Bayes C,Bayes Lasso, Bayes Ridge Regression, which was shown to be equivalent to GBLUP, were used. The ASL2018 experimental population was used for training and cross-validation, while PAL2016 was used as an independent test set. Accuracy and Matthews correlation coefficient (MCC) were calculated and compared across methods.

Results
Higher accuracy was observed when predicting survival than body size. Cross-validation showed higher performance for ML methods, particularly for LB (MCC=0.48) than Bayesian regression methods, which had comparable performance (MCC=0.38-039). Accuracy for body size prediction was lower for all methods (Pearson correlation<0.25). Using trained algorithms on ASL2018 to predict the independent data set (PAL2016) show consistently poor performance.

Discussion and conclusions
Revisiting two existing data sets allowed us to demonstrate genotype data imputation using genomic information increased the number of genotyped loci. These expanded data sets were then used to compare parametric and ML methods in their ability to correctly predict two traits: survival after experimental challenge with *P. damselae piscicida* and age-corrected body length. Accuracy estimated through cross-validation was extremely high especially for disease resistance using ML methods. However, the ability to predict either phenotype on independent samples was much less promising. Several factors might have led to reduced predictive power in the present case such as different age of animals and different protocols for experimental infection. It is possible, however, that estimating accuracy using a single population might fail to consider that in other genetic backgrounds the genomic basis for the same trait is different.

MUSCLE TRANSCRIPTOME RESPONSE TO FASTING-REFEDING IN FAST-GROWING COMPARED TO AGE- OR SIZE-MATCHED SLOW GROWING INDIVIDUALS IN THE GILDHEAD SEA BREAM

M. Pauletto, S. Ferraresso, M. Babbucci, G. Radaelli, L. Maccatrozzo, D. Bertotto, L. Bargelloni*

E-mail: luca.bargelloni@unipd.it

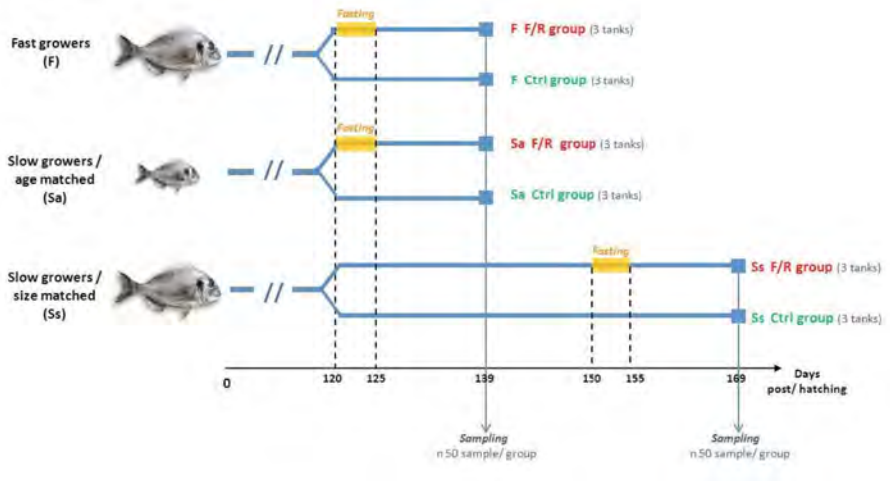
Introduction

Compensatory growth is a phase of rapid growth, which can triggered by refeeding animals after a period of prolonged fasting. period. In fish, compensatory growth has been related to increased feed intake and possibly in feed conversion efficiency (Ali et al. 2003). As skeletal muscle accounts for over 60% of total body mass in fish, understanding how muscle gene expression profile changes during compensatory growth is quite interesting especially in farmed species, where body and fillet size represents a key trait. Fish also show large within-species genetic variation in growth rates, particularly in unselected populations. Contrasting the transcriptomic basis of compensatory growth in fast- and slow-growing animals might then reveal the genomic basis of differences in muscle physiology between individuals with divergent growth performance.

Methods

Juvenile sea breams all originating from a single spawning event across unselected parents were raised in a single tank until they reached 120 days of age. Fish were then selected by size (weight and length). The upper 10% of the population was considered as "fast grower" (F), while the lower 10% as "slow grower". The latter was subsequently divided into two sub-groups (Sa and Ss). Groups F and Sa were subjected to six days of fasting and then fed ad libitum for 14 days until sampling. Group Ss was farmed under identical conditions until the average size reached that of group F at the start of the fasting experiment (Figure 1). Group Ss was then subjected to the same fasting-refeeding protocol described above. For each group, control-fed fish were kept under identical conditions except for the fasting part. White muscle tissue samples were collected as shown in Figure 1.

RNA was extracted from individual samples for each condition (F-F/R, F-ctrl, Sa -F/R, Sa-ctrl, Ss-F/R, Ss-ctrl). Four biological replicates per condition (each made of a pool of three individuals) were used to construct indexed cDNA libraries. All libraries were sequenced on a Illumina Hi-Seq 2500 (SE). Quality-filtered reads were mapped against the sea bream assembled genome (Pauletto et al. 2018) by means of STAR aligner following the two-pass mapping mode. Read counts for each sample, at the gene level, were extracted by GeneCounts quantification while running STAR. Analysis of differential gene expression was conducted in EdgeR. For each sample, the sum of raw cpm (count per million) of all genes was calculated by means of aggregate function on R. Genes showing a cpm value lower than 1 in more than half of the samples for each species were filtered out. Remaining genes were normalized with the Trimmed Mean of M-values (TMM) method and, after estimating common and tagwise dispersions, Likelihood Ratio Test (lrt) as provided in EdgeR was employed to assess differentially expressed genes (DEGs) between conditions.



(Continued on next page)

Results

A large number of genes were found to be differentially expressed when using a threshold of logFC>1 or FC<1 and FDR<0.05 between F and S control groups. Groups F and Sa (age-matched slow growers) showed much greater similarity in muscle transcriptome profile than size-matched slow growing animals. However, when the transcriptomic basis of compensatory growth was compared across groups, the list of differentially expressed genes between groups was very short. A single gene (pyruvate dehydrogenase kinase 2, PDK2) stands out showing a much greater down-regulation (logFC=-2.7) in fast growing animals during compensatory growth.

Discussion and conclusions

Muscle transcriptome in age-matched slow growing animals appears to be closer to fast growers in size-matched animals suggesting an ontogenetic shift in expression profiles. The high similarity in transcriptome profiles of compensatory growth, on the other hand, seems to indicate that the potential for muscle growth is quite similar for either fast- and slow-growing fish. However, a key gene in the regulation of mitochondrial metabolism (PDK2) showed a consistently divergent pattern between fast- and slow-growing animals during compensatory growth. Fasting induces the repression of pyruvate dehydrogenase (PDH), which mediates the switch between carbohydrates and lipid oxidation in the mitochondria, favoring the consumption of lipids during starvation (Gudiksen and Pilegaard 2017). Significant down-regulation of PDK2, which inhibits PDH, during compensatory growth compared to control-fed animals suggests that in fast-growing fish mitochondrial metabolism shows a marked preference toward carbohydrate oxidation.

Introduction

On the French Atlantic coast, the possibility of expanding shellfish aquaculture, which traditionally takes places in intertidal areas, to offshore locations is considered to be a real possibility to overcome problems of carrying capacity, water quality and ecological impacts issues. Finding new sites into which to expand oyster aquaculture offshore relies on the co-occurrence of a combination of different requirements, but a basic prerequisite is to be able to obtain significant growth, survival, and quality of the product. This work is based in Bourgneuf Bay, south of the Loire estuary (France), where offshore experiments have been carried out since 2008 by a regional organization that supports innovation in the shellfish industry (Syndicat Mixte pour le Développement de l'Aquaculture et de la Pêche en Pays de la Loire (SMIDAP)). The main objective of this study was to highlight the potential for offshore Pacific oyster (*Crassostrea gigas* (Thunberg)) cultivation, and to investigate spatial patterns therein using satellite image time series data.

Materials and methods

Bourgneuf Bay is highly turbid, with annual mean Suspended Particulated Matter (SPM) concentration ranging from 27 to 129 mg L^{-1} from south to north, and maximum values exceeding 1000 g L^{-1} during spring tides (Gernez et al., 2017). This high turbidity has a negative impact on oyster growth and, which in turn contributes to the relatively slow growth of oysters in the bay (Gernez et al. 2014). A simple technique using bottom-cages was tested to collect off-shore growth data. These were used to calibrate a Dynamic Energy Budget (DEB) model of Pacific oyster growth, which incorporates SPM as a forcing variable in order to take the influence of high SPM concentrations on the bivalve ingestion (Thomas et al. 2016). The model was run with satellite-retrieved chlorophyll-a (Chl-a) as a proxy for food availability (mostly phytoplankton), SPM, and sea surface temperature (SST) as the driving variables. SST data were obtained from the Advanced Very High Resolution Radiometer (AVHRR) operated by the US National Oceanic and Atmospheric Administration (NOAA). SPM and Chl-a concentrations were obtained from the European Space Agency's Medium Resolution Imaging Spectrometer (MERIS) in full spatial resolution (300 m), with existing algorithms to obtain SPM and Chl-a concentrations locally-tuned for Bourgneuf Bay specifically (i.e., calibrated and validated using separate matchups between in situ and satellite datasets for the bay). All SST, SPM, and Chl-a products were aggregated to ten-day averages from 2003-2011 to create the regular time series data needed to run the model, given irregular overpass frequency (2-3 days) and gaps due to cloudiness of the original data. Oyster growth indicators were then mapped and compared at existing intertidal and hypothetical offshore farm sites within Bourgneuf Bay.

Results

The model output comprises oyster growth (shell length, transformed allometrically to total weight as described above, and dry flesh mass) maps at the same timestep as the input data (i.e., every ten days). Growth of total weight over time was then further transformed into several industry-meaningful growth performance indicators, using key market timings and market weight thresholds identified through consultation of producers and professionals from Bourgneuf and the neighbouring Marennes-Oléron Bay (Fig. 1).The results confirmed that offshore sites have better potential for oyster growth than the traditionally oyster-farmed intertidal sites overall, but that this is highly spatially variable. The current work uses higher spatial resolution input data than has previously been used, allowing corresponding higher spatial resolution model outputs, coherent with the farm-scale and therefore more applicable and relevant to the end-users considered. The output maps of growth over time can be used in Spatial Multi-Criteria Evaluation together with layers of other spatialized data that may influence whether production may be possible (e.g., bathymetry and distance from harbours, which determine feasibility) or how favourable it may be at a given site (e.g., presence of conflicting uses, such as fishing or tourism

Introduction

The term failed fish (or runt) syndrome is a synonym for a fish with impaired growth or substantially slower growth rate after sea-transfer (Skjelstad and Gu, 2016). Although observed throughout salmonid aquaculture, (typically ~10%) it is greatly increased for rainbow trout (*Oncorhynchus mykiss*) reared in full salinity where failure levels of >30% are often encountered. Rapid acclimation to increasing salinity through physiological modifications is crucial in euryhaline teleost (Guner et al., 2006). Thus, this study objective was to compare the clinical chemistry and tissue structure differences in rainbow trout pre and post seawater transfer to investigate the impacts and potential causes of this syndrome.

Materials and methods

The study took place in a fish farm, under aquaculture conditions. Blood samples were initially taken from random pit-tagged fish 4 weeks before seawater transfer. Second blood samples were taken 8 weeks post seawater transfer. Fish condition was measured and tissue samples were taken for supportive histopathological analysis in both time points. All serum samples were analysed within 3 months of freezing on the clinical chemistry analyser Daytona RX (Randox Laboratories Ltd., Crumlin, UK) using commercial kits. Routine histology was used to produce tissue sections for histological inpection of trout tissues. Statistical analysis was performed using the General Linear Model (GLM) and Linear Discriminant Analysis (LDA) to classify the two groups according to their biochemical profiles

Results

Fish serum biochemical analysis showed significant increase activity ($p<0.05$) of ALP (alkaline phosphatase) and concentration of ammonia, recorded in the fish with good condition after the transfer to seawater. In comparison, fish with retarded growth had significantly higher activity of LDH (lactate dehydrogenase), together with decreased activity of amylase and concentrations of potassium, while concentration of chloride was higher after the transfer to seawater. Interestingly, despite no statistical differences could be found for the majority of measured endpoints in freshwater environment, it is noteworthy that the parameters with potential effect on osmoregulatory balance and nutritional deficit, chloride, sodium and zinc concentrations, respectively, were identified as the variables that distinguish best these two groups at initial stage of growth. Moreover, no significant differences in fish condition were observed. Histopathological evaluation of stunted fish liver showed hepatocyte shrinkage along with marked glycogen reduction. Furthermore, tissue damage to the eye chamber was evident in form of exfoliation of cornea.

Discussion and conclusion

Results of the present study indicate that initial fish size does not have any particular role in predisposition to runt syndrome. Runt fish showed signs of poor nutritional status that was observed through serum metabolic endpoints, but also some evidence of osmoregulatory dysfunction. Moreover, there was a proof that fish from the freshwater, that later became failed in seawater, had disturbed osmoregulatory function and zinc deficienc . Cataracts induced by zinc deficiencies have been described wild and farmed salmon (Bjerkås et al., 2004). A study by Bjerkås and Sveier (2014) demonstrated that fluctuation in water salinity caused higher intraocular pressure. This could be due either to increased influx through the damaged cornea, or as increased water uptake in the whole body due to poor fluid regulation through periods of osmotic stress. In addition, another possible cause for this syndrome in trout could be reduced vision due to cataracts that prevents normal feeding and eventually led to trout emaciation and mortalities. Blood biochemistry shows excellent potential to investigate fish health status and was associated with organ/tissue damage. Further research to evaluate the genetic aspect of this syndrome and better bloodstock selection could add to improvements in sea trout aquaculture.

Introduction

Outbreaks of disease caused by some *Vibrio* species represent one of the main production bottleneck in shellfish hatcheries (Prado, 2006). Monitoring the routes of entry of bacteria should be the first step to prevent proliferation of these opportunistic pathogens in the bivalve cultures and the subsequent detrimental effects.

Phytoplancton, used as food and produced by mass culture, is one the main sources of bacteria. Previous studies have demonstrated that the marine heterotrophic bacteria were at level $\approx 10^6$ cfu/ml in the mixture of microalgal species utilized in the hatchery (Dubert et al., 2015). Vibrios were present, but not the main component of the population of culturable bacteria. In this work, we studied specifically the interactions between vibrios and active microalgal cultures of *Chaetoceros* spp., to deepen in the knowledge of the dynamic of the pathogens in the hatchery.

Materials and methods

The larval pathogens assayed were (P1) *Vibrio neptunius* PP-145.98, (P2) *V. ostreicida* P-203, (P3) *V. europaeus* PP-638 and (P4) *V. bivalvicida* PP2-605.

Two different species of *Chaetoceros*, *C. calcitrans* and *C. muelleri*, were cultured. In each experiment, one stock of microalgae in exponential stage and vibrio-free was distributed in sterile glass carboys with 2 l. of phytoplancton. The pathogens (suspensions in sterile seawater) were inoculated to reach final concentrations of 10^3-10^4 cfu/ml. Cultures without bacterial addition were maintained as control.

Cultures were performed following the routine in the hatchery of the Centro de Cultivos Mariños. They were kept for 7 days in the isothermal chamber, at 19±1ºC and under constant illumination. Each *Chaetoceros* species were assayed in two experiments, with two replicates.

Samples were collected in sterile containers and immediately processed *in situ*, following Prado et al. (2005) for enumeration of vibrios in Thiosulphate-Citrate-Bile-Sucrose (TCBS) plates. Results were expressed as cfu/ml. Microalgal cells were counted in cell chamber, with a light microscopy, expressing the results as cel/µl.

Results

Chaetoceros calcitrans

The growth of the microalga *C. calcitrans* was similar, independently of the presence of pathogens in the culture. Regarding to the pathogens, all of them decreased until low levels or even no detection at the end of the experiments.

Chaetoceros muelleri

The two stocks of *C. muelleri* showed different initial density, higher in the second experiment. Independently of this fact, the pattern of growth of the microalga was not completely similar between control and some inoculated cultures. In particular, P3 and P4 reached higher densities than control at the end of both experiments.

The results of the pathogens differed between experiments. In the first one, all the strains decreased since the initial samples, being below the detection threshold at the end. In the second one, P1 and P2 showed a similar pattern to the first challenge, while P3 and P4 increased their levels in the first 24 h, and decreased later but still found at the end

Discussion and conclusion

The experiments were performed under "real" conditions, with the aim of study the behaviour of the pathogens in the hatchery, specifically their ability to survive in phytoplancton cultures, as well as their possible pathogenicity for microalgae.

(Continued on next page)

As a first conclusion, this pathogenicity was discarded in all the cases. Regarding to the survival of the pathogens in *Chaetoceros* active cultures, at the end of the experiments all of them were at very low levels or even under the detection threshold, meaning an important decrease in relation to the initial concentrations. In contrast with these results, in laboratory assays the algal cells and the supernatant of *Chaetoceros* cultures did not display inhibition against any of the pathogens, suggesting that the active culture is an essential condition in the interaction.

These results could explain the low frequency of detection of vibrios in phytoplancton cultures. However, the survival of some larval pathogens together with the lack of pathogenicity for microalgae, also imply that the phytoplancton may be an "asymptomatic carrier" of vibrios.

Therefore, routine microbiological controls should be established in the hatcheries to prevent the possible transmission of vibrios from food to the larval cultures.

Introduction

Bivalve hatcheries are currently the only viable solution to fulfil the spat demand for shellfish aquaculture. This fact is particularly relevant in species like the flat oyster, *Ostrea edulis*. The decline of natural beds and natural recruitment has led to the need of hatchery production of seed not only to sustain the aquaculture, but also, and not less important, to restore the original populations. Unfortunately, episodes of larval and post-larval mortalities compromise this production worldwide, being the aetiological agents of these episodes mainly bacteria belonging to some species of the genus *Vibrio*. A wide knowledge about the pathogens which affect the production of flat oyster hatcheries is the first step to develop innovative procedures to solve the problem.

In this work, we report a heavy outbreak of disease which affected the flat oyster cultures in a Galician hatcher .

Materials and methods

A'Ostreira is the only hatchery in Galicia, and one of the few in the world, that produces flat oyster spat. Recently, heavy mortalities were recorded simultaneously in the larval cultures, once they reached 180µm. The batches were spawns from different broodstocks, obtained from natural beds (wild oysters) and from rafts ('batea'), respectively. Given the gravity of the situation, microbiological analyses were performed to elucidate the origin of the problem. Samples of larvae, seawater of culture tanks, and phytoplancton used as food were processed and spread on Thiosulphate-Citrate-Bile-Sucrose (TCBS) plates. Bacterial isolation, preservation and identification of isolates followed the methodologies described in Prado et al. (2014). In addition, virological analyses were performed to detect the possible presence of ostreid herpesvirus OsHv-1 or OsHv-1 µVar by Realtime-PCR using the specific primers OsHV1BF/B4 and B probe (Martinot et al. 2010; OIE, 2018)

Results and discussion

The pathogen *Vibrio bivalvicida* was isolated from diseased larvae, regardless the broodstock, as well as from the seawater of culture tanks. The microbiological sampling of phytoplancton cultures used as food (*Tisochrysis*, *Isochrysis*, *Diacronema*, *Chaetoceros* and *Tetraselmis*) allowed to rule out the microalgae as the source of the problem. Similarly, the seawater used to fill the tanks was also discarded

All the samples analysed were negative for the detection of OsHV-1 or OsHV-1 µVar.
This is the first report of the pathogen *V. bivalvicida* in an episode of mortality of *O. edulis* in hatchery. All the oyster cultures were affected, with acute signs when they reached 180µm, which indicates that this pathogen is a real threat.

Regarding the origin of the pathogen, in this case, phytoplancton and seawater was discarded, while the broodstocks seemed highly unlikely as the source, considering the simultaneous mortalities in all the larval batches. Considering the previous detection of this pathogen in the hatchery, the risk of its persistence associated to the surfaces should be considered. The biofilm formation may confer important ecological advantages (resistance to antibiotics, bleach or desiccation, acquisition of genetic traits...) to the pathogen and imply the risk of re-emergence. Therefore, this approach should be introduced in the hatchery studies and management.

NOVEL LARVAL REARING TANK DESIGN: CAN A NEW APPROACH TO HYDRODYNAMICS CHANGE THE WAY WE PRODUCE MARINE FISH LARVAE?

A. Barreto*[1], R. Serradeiro[1], J. Oca[2]

Introduction

For a successful expansion of the Aquaculture industry, the production of robust, high quality juveniles with high growth potential needs to be enhanced, so the numbers of fish that eventually reach the market can suppress the consumer needs. However, fish larviculture is often considered a bottleneck in fish farming due to the variable quality of juveniles produced, with direct impact on survival and growth performance results during ongrowing. The mass mortality of larvae is one of the most significant problems that occur in the initial stages of production and can be due to small flow modifications in the larval rearing tanks caused, for example, by inadequate handling of the aerators or the inlet flow rates. Frequently, the management of the water flows in the larval tanks is based on the empirical knowledge of the growers (Sumida et al., 2013). Excessive flow can hinder larval feeding and force them to spend too much energy to maintain its position (Tucker, 1988), which can lead to mass mortality. On the other hand, if the flow is too weak, it usually induces the formation of "dead zones", with inadequate water quality for the larvae (Shiotani et al., 2003). However, not many studies have analyzed the influence of the flow pattern in aquaculture tanks, and those that focus on tanks for larval culture are even more scarce (Sakakura et al., 2007 and 2018, Blanco et al., 2014, Moorhead 2015).

In larval culture systems, tank geometry, water inlet and outlet devices, as well as aeration systems when they exist, play a key role in the distribution of the water velocities generated (flow pattern) and condition: 1) larval swimming activity, 2) buoyancy or sedimentation of food and microalgae, and 3) cleaning of solid waste generated (feces and food not ingested). In the last decade, significant research efforts have been made in the development of inert microdiets that can replace live feeds in larviculture, as early as the onset of the larvae exogenous feeding. However, the introduction of inert microdiets at first feeding can strongly deteriorate water quality in rearing tanks since the larvae have poor locomotory capabilities and feed needs to be given in excess so it is constantly available and within reach. As the tanks currently used are designed for live feeding, this excess accumulates at the bottom of the tanks and its removal is a difficult and a time-consuming task

Therefore, the objective of this study is to design a larval culture tank, which allows the generation of an effective water flow pattern, adjustable according to the size of the larvae. The maintenance of a uniform flow will be prioritized, favoring the homogeneous distribution of the larvae in the volume of the tank, avoiding relevant velocity gradients, which cause the larvae to collide with the walls of the tank and with the devices installed inside. Additionally, tank design will consider cleaning efficienc , aiming at ensuring excellent water quality and reducing labor associated with tank cleaning.

Methods

After analyzing the advantages and disadvantages of different tank geometries a first prototype of semicircular vertical section and rectangular horizontal section was selected. A second tank prototype was also constructed with circular horizontal section and rounded vertical section at its bottom. The capacity of each of the prototypes is about 90 liters and have air-lift systems that control the flow velocity. In addition to the hydrodynamic conditions, the specific design of each of them considered the ease of cleaning, the oxygen supply and the ability to control the water velocity. Moreover, both tanks have transparent sections that allow the characterization of the water flow using tracer particles that, properly illuminated, allow to register their trajectories and the distribution of speeds in their interior.

After tank hydrodynamics characterization, larval rearing success will also be assessed.

In the end of the study, one of the prototypes will be selected and real scale models will be produced and tested.

(Continued on next page)

Results

At the moment of this submission, the characterization of the relationship between the water flow induced by the air lift system and the angular velocity of the water in the first tank prototype has been accomplished. The water flow pattern obtained was, as intended, capable of homogenously distributing the particles in the water column. The efficiency of the cleaning system designed has also been demonstrated.

At poster submission deadline, it is expected to have further results on the hydrodynamic characterization of the second prototype, as well as, data that prove the adequacy of both prototypes for larval rearing.

MICRODIETS SUPPLEMENTED WITH NUTRITIONAL ADDITIVES AS A TOOL TO IMPROVE IMMUNE CONDITION AND ENHANCE GROWTH PERFORMANCES OF WHITE-LEG SHRIMP (*Penaeus vannamei*) POST LARVAE

A. Barreto*[1], B. Costas[2], L. Conceição[3], W. Pinto[3], R. Serradeiro[1], A. Laranjeira[1]

Introduction

The white-leg shrimp (*Litopenaeus vannamei*) produced in aquaculture is a highly valued commercial product whose demand has substantially increased in recent years. To meet the market demands, larvae and post-larvae yields in hatcheries increased intensively, globally originating around 4.2 million tonnes of adult shrimp per year (FAO, 2018).

Nevertheless, initial developmental stages are critical and frequently associated with sub-optimal growth and low survivals due to opportunistic pathogens, often originating poor quality post-larvae with high disease susceptibility. Therefore, there is room for the creation of innovative microdiet solutions that can enhance development during the initial stages and consequently improve the shrimp quality in the posterior phases, increasing their resistance to stress and pathogenic factors.

In fact, industrial shrimp farming is extremely susceptible to pathogenic episodes resulting in disastrous consequences to production (Flegel, 2012). The use of antibiotics in the aquaculture industry is limited due to inherent environmental issues and the increased resistance between pathogens. Furthermore, shrimp depend uniquely on their innate immune system and cannot be vaccinated, which makes immune stimulation an extremely important strategy, with some authors already verifying an increase in survival of immune stimulated shrimp (Smith et al., 2003; Yogeeswaran et al., 2012). Since the modulation of the immune system through nutrition is currently possible the potential of innovative nutritional solutions that improve the immune condition of shrimp is foreseen as tremendous.

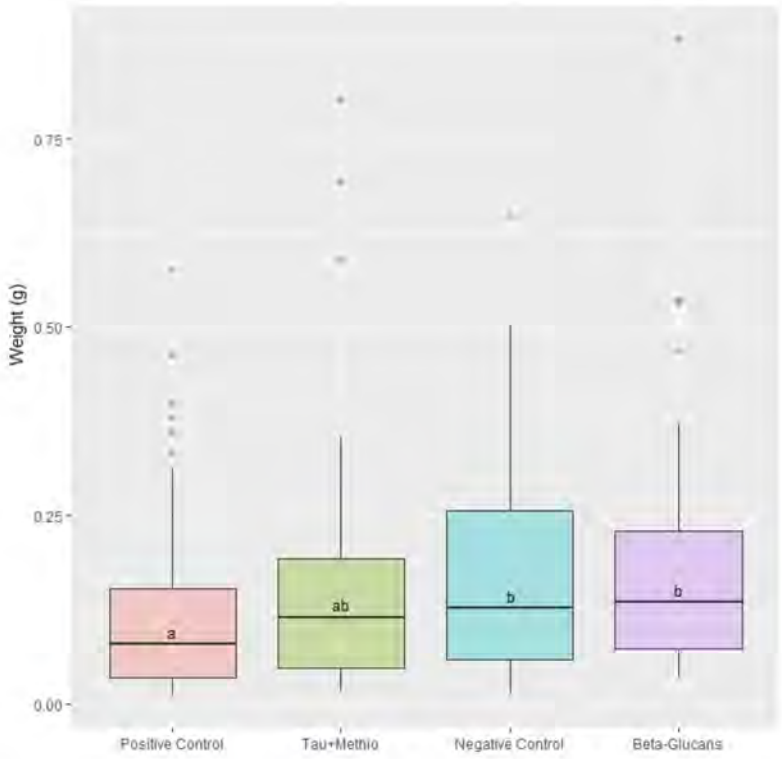

Figure 1 - Final body weight of white-leg shrimp post-larvae at the end of the trial (n=3 experimental units). Different subscript letters indicate statistical differences ($p<0.05$) between treatments.

(Continued on next page)

This study aimed to evaluate the effects of several health promoting nutrients/additives (i.e. vitamins C and E, beta-glucans, taurine and methionine) supplemented in microdiets on the growth performance, oxidative status and immune condition of white-leg shrimp post-larvae.

Methods

White-leg shrimp post-larvae (mean wet weight 5 mg) were fed isonitrogenous and isocaloric diets supplemented with different feed nutrients/additives. A commercial diet was used as Positive control whereas a Negative control diet was considered with vitamin C and E supplementation levels below than those used in the commercial diet. The two remaining diets consisted on the commercial diet supplemented with beta-glucans or taurine plus methionine. Each diet was tested in triplicate tanks. Shrimp were kept at around 28 ºC and fed *ad libitum* for 23 days. At the end of the trial, shrimp were individually weighted for growth performance determination and samples were collected for oxidative stress parameters and immune status assessment.

Results and discussion

Significant differences in growth performances between treatments were observed. Shrimp from the Negative control and Beta-Glucans dietary treatments achieved a higher final body weight than those from the Positive control at the end of the trial (Figure 1). However, no significant differences between treatments were observed in feed conversion ratio, relative growth rate and survival. These results will be further discussed in light of the oxidative stress and immune status assessment.

Introduction

The use of nucleotides in fish nutrition has several benefits including, increased food intake, rapid intestinal repair, improved mucosal gut flora and mucosal surfaces (Li and Gatlin III, 2006). Nucleotides supplementation in salmonids diet increased resistance to infections caused by bacteria and viruses, and increased the efficacy of vaccination and osmoregulatory capacity (Burrells, *et al*., 2001a; 2001b). Literature approved the growth promoting effect of MOS and Immune-stimulatory power of β-glucan (Gu *et al*., 2011; Murthy *et al*., 2009).

The objective of this study was to evaluate the effect of yeast as nucleotide source on growth performance, oxidative stress, immune response, expression of some immune related genes and mortality of Tilapia (*Oreochromis niloticus*) challenged with *Aeromonas hydrophila* and *Lacococcus gravaeie*.

Material and Methods

A total of 270 *O. niloticus* (50.7 ± 0.8g of body weight) were distributed in a completely randomized design, with 3 treatments: 1- Control; 2- 0.2% of *Saccharomyces cerevisiae* as a source of nucleotides (YNU - Hilyses®, ICC Brazil Company); 3 – 0.2% of YNU, with 3 replicates each (glass aquaria of 40x30x100cm with 20 fishes each). The fishes were fed with 3% of its total biomass during 3 months and, the acclimation period was 2 weeks. The growth parameters measured were body weight (BW, g/ind.), body weight gain (BWG, g/ind.) and feed conversion ratio (FCR) at 1 and 2 months. Also the clinicophatological, oxidant parameters, relative quantitative PCR of immune gene expression, phagocytic activity (%) and index, lysozyme activity (µg/mL) were evaluated at 2 months, as weel the histological examination of liver, spleen, kidney and intestine. After 2 months (after the end of feeding trial), a challenge test was carried out with 10 fishes/group replicate inoculated intra-peritoneal with Gram positive bacteria *Lacococcus gravaeie* (0.2mL containing $3x10^8$CFU/mL) and Gram negative *Aeromonas hydrophila* (0.2mL containing $1.5x10^8$CFU/mL). Also, 10 fishes per each microbieal chellenge were injected with saline solution (Negative Control). The mortality rates were observed during 1 week. The challenge tests were executed two times. Un-paired one-way ANOVA test was used to test significance between groups at $p \leq 0.05$ after that post hoc test (Tukey) was used for pairwise comparison

Table I. Growth performance, oxidative stress, expression of immune related genes, innate immunological and mortality parameters, after challenges 1 and 2 with *L. gravaeie* and *A. hydrophila*, of Nile tilapia

Parameters	Control	0.2% YNU	0.4% YNU
BW (g) 2 months	97.86^{a}±1.18	123.6^{b}±2.54	130.5^{b}±4.08
BWG (g)	48.1^{a} ±1.96	71.3^{b} ±2.14	80.5^{b} ±2.04
FCR	2.1^{a}±0.26	1.65^{b}±0.11	1.5^{b} ±0.07
Catalase	268.73^{a}±43.8	354.87^{b}±39.6	402.27^{c}±25.4
G-redutase	142.7^{a}±3.5	160.76^{a}±2.34	269.93^{b}±20.6

Mortality (%) *A. hydrophila*[2]	97^{b}	53^{a}	43^{a}

*Different letters in the same line indicate differences by Tukey test ($P<0.05$).

(Continued on next page)

Results

YNU supplementation improved the growth performance in relation the control group ($P<0.05$). Similary, YNU in both levels increased catalase and G-redutase activities, and expression of immune related genes parameters ($P<0.05$). Also, the phagocytic and lysozyme activity were increased ($P<0.05$). After the challenge with the both bacteria's, mortality decreased ($P<0.05$) in both groups with YNU (Table I).

There was no significant difference in clinicopathological parameters between 0.2% and 0.4% of YNU supplemented groups versus control group ($P<0.05$).

The spleen of YNU supplemented Nile tilapia showed focal wide area of melano macrophage aggregation in the white pulps. The YNU groups showed the intestine with mild hypertrophy in the lining mucosal epithelium with wide area for the crypts. Also, focal lymphoid cells proliferation was detected in the mucosa and submucosa. There was no histopathological alteration in the liver, the greater vaculation of the hepatocytes indicated well nourished fish. The kidney showed mild vacuolization in the tubular lining epithelium, focal lymphoid cell aggregation was detected between tubules in the fished of the group supplemented with 0.4% of YNU.

Conclusion

In general, the inclusions of 0.2 and 0.4% of YNU has proven to improve the growth performance of Nile tilapia, boost the immune response and increase the resistance against diseases.

Introduction

Antimicrobial peptides (AMPs) are one of the host's first line of defenses against a wide range of infectious agents. Apart from the antimicrobial activity, AMPs are known to influence other biological processes, such as immunomodulation and iron metabolism (Chaturvedi et al, 2018; Neves et al, 2015). Fish present a specific group of AMPs, the piscidins. These peptides have been characterized in several fish species, being altered when fish are subjected to an infection, and showing antimicrobial activity against multiple pathogens. Furthermore, several studies have shown the potential of using synthetic peptides to promote fish survival upon infection (Katzenback, 2015). However, in the European sea bass (*Dicentrarchus labrax*), a commercially important fish produced in aquaculture, the identification of the several piscidin types and their biological roles remains poorly explored. Here, we characterize the piscidin family in sea bass. The expression of piscidin genes is evaluated under different stimuli, as well as the antimicrobial activity of piscidin peptides against several fish pathogens.

Material and Methods

European sea bass *(D. labrax*), with an average weight of 50 g, were subjected to different experimental conditions and piscidin expression was evaluated. Infection: different groups were i.p. infected with 1.0×10^5 CFU of *Photobacterium damselae* spp. *piscicida (Phdp)* or *Vibrio anguillarum* and samples collected at 24, 48, 72 and 96 hours post infection. Iron overload: sea bass were i.p. injected with 2 or 5 mg of iron dextran and samples collected at 1, 4, 7, 10 and 14 days post iron administration. To determine the antimicrobial activities of piscidins, 1.0×10^6 CFU of different bacterial strains were incubated for 24 hours with serial dilutions of the synthetic peptides. The following bacteria were used: *P. damselae* spp. *piscicida*, *P. damselae* spp. *damselae*, *V. anguillarum*, *V. alginolyticus*, *Aeromonas salmonicida*, *A. hydrophila*, *Edwardsiella tarda* and *Yersinia ruckeri*. Healthy sea bass were used for piscidin characterization at genomic and protein levels and basal expression.

Results

We identified seven different piscidins in sea bass, with different amino acid sequences and antimicrobial activities, depending on the pathogen and piscidin peptide. Most of piscidin genes present the highest basal expression in the intestine, except for piscidin 2, that is highly expressed in the gills. Our data show an up-regulation of piscidin genes after infection with *Phdp;* however, after infection with *V. anguillarum*, the expression of piscidins is, in general, down-regulated. Furthermore, preliminary results show that piscidin gene expression increases in fish that received a high dose of iron dextran, in a dose-dependent manner.

Discussion and conclusions

Our findings indicate that, *in vitro*, piscidin peptides have a direct effect against pathogens. However, different outcomes are observed for the piscidin genes during experimental infections. While infection with *Phdp* promoted an increased regulation of these genes, *V. anguillarum* seems to suppress the expression of piscidins. Furthermore, modulation of piscidin expression in our experimental models of iron overload shows that piscidins also respond to iron modulation, indicating that these AMPs may have other yet undisclosed functions asides antimicrobial activity. It is known that iron is also essential for bacterial progression during infection. Thus, iron is in a continuous regulation to be available for body processes, being also modulated to ensure that is inaccessible to pathogenic microorganisms. Further studies will focus on the administration of peptides in fish, to understand the role and mechanisms of action of piscidins under the context of immune response and iron metabolism regulation, and to possibly uncover a novel function for these particular peptides in fish

Introduction

Short Tandem Repeats (STRs) or microsatellites are molecular markers harbouring tandemly repeated oligonucleotide sequences (one to six nucleotides) that are ubiquitously distributed in eukaryotic genomes (Vieira et al. 2016). Based on their location in the genome, STRs are classified as Type I or Type II, where the former is located within functional genes and the latter within non-coding intergenic regions (Selkoe and Toonen 2006). Type I (transcriptome-derived, EST-STRs) and Type II (genome-derived, g-STRs) STRs are widely used in molecular ecology studies, conservation initiatives and marker-assisted breeding programs of numerous plant and animal species (Selkoe and Toonen 2006; Vieira et al. 2016). Maduna et al. (in revision) used an *in-silico* approach to develop a total of some 232,000 genome-wide STR from genome and transcriptome sequence data for the commercially important lumpfis *Cyclopterus lumpus* (L. 1758). Out of these genome-wide STR, multiple primer pairs per locus were successfully designed for 6926 STRs. The main objective of this study was (i) to construct and catalogue an online database of microsatellites and primers called *Cyclopterus*-STR for the commercially important lumpfis *Cyclopterus lumpus* (L. 1758), and (ii) assess the amplification efficienc , allele size, and level of polymorphism (i.e., number of alleles) of a small subset of primers reported by Maduna et al. (in revision).

Material and methods

The user-friendly interface for the *Cyclopterus*-STR database was developed using HTML, PHP language, JAVA scripts and MySQL database. The database has six tabs (Home, Tutorial, STRs, About, Contact and Related) and provides different search criteria for EST-STRs and g-STRs, primers, amplification efficienc , flanking sequences and physical map information (Fig. 1B). A total of 80 STRs (33 g-STRs and 47 EST-STRs) were selected for small-scale validation in a panel of 36 lumpfish individuals collected along the Norwegian coastline. Total genomic DNA was extracted from finclips using the *DNeasy*® Tissue Kit following the manufacturer's instructions (Qiagen). We amplified loci following the standard amplification reaction and cycling conditions outlined in Skirnisdottir *et al*. (2013) with modifications inherent to the present study, which involved optimizing the annealing temperature for each locus. Genetic diversity descriptors per locus, which include the number of alleles per locus (A_N), observed heterozygosity (H_O), and unbiased expected heterozygosity (H_E) were calculated in GENALEX v.6.503 (Peakall and Smouse 2006).

Results

Cyclopterus-STR web application provides the first repository of genome-wide STR markers for *C. lumpus*, which allows users to search for their desired marker properties such as type of repeat motif, repeat number, amplification success and level of polymorphism (if *in vitro* validated). Moreover, the user is presented with several primer sets per locus for *in vitro* testing. Fig. 1 shows a preview of the *Cyclopterus*-STR database, as well as different search options for STRs. Out of 33 g-STRs, 22 (67%) loci successfully amplified, of which, 17 were found to be polymorphic with A_N, H_O and H_E, ranging from 2–10, 0.012–0.821 and 0.012–0.829, respectively. While 37 out of 47 (79%) EST-STRs successfully amplified with 18 loci found to be polymorphic with A_N, H_O and H_E, ranging from 2–15, 0.040–0.923 and 0.040–0.918, respectively.

Fig. 1. Schematic representation of screenshots of the *Cyclopterus*-STR database. (a) Search for EST-STRs (applicable to g-STRs too) by repeat motif length and frequency or repeat sequence, and by linkage group (if available). (b) Search results along with primer information.

(Continued on next page)

Discussion and conclusion

The present study presents the first user-friendly web based molecular marker repository for *C. lumpus*. The molecular resource reported in *Cyclopterus*-STR are freely available to the scientific community to aid in constructing linkage maps and mapping loci involved in quantitative trait loci (QTL) for foraging-related traits in *C. lumpus*. Moreover, the genome-wide panel of STR will enable the use of marker assisted selection of desired traits in breeding programs of *C. lumpus*.

The overall amplification success rate was 73.75% from the 80 primer sets selected for in vitro validation, with the EST-STRs having a slightly higher success rate. The level of polymorphism per locus were higher for EST-STRs, indicative of substantial genetic variation in functional gene regions in the wild. Therefore, the reported EST-STRs will indeed aid in assessing adaptive genetic diversity which will provide valuable insight into the impact of escapees from aquaculture farms on the genetic patterns of functional variation in wild population (*sensu* Jónsdóttir et al. 2018).

EFFECT OF PLANT DENSITY IN COUPLED AQUAPONIC SYSTEMS ON THE WELFARE STATUS OF AFRICAN CATFISH (*Clarias gariepinus*)

Björn Baßmann*, Harvey Harbach, Stephan Weißbach, and Harry W. Palm

Department of Aquaculture and Sea-Ranching, University of Rostock (Germany)
Email: bjoern.bassmann@uni-rostock.de

Introduction

Very little is currently known about the effects of aquaponic systems onto fish welfare (Yildiz et al., 2017). However, Baßmann et al. (2017) described that African catfish (*Clarias gariepinus*) reared in a coupled aquaponic system had significantly fewer external injuries of skin, fins and barbels than fish reared in a control RAS without plant cultivation. Wounds i.a. facilitate pathogenic entry into the fish body, thereby impairing fish welfare (Huntingford et al., 2006). So, there is evidence that aquaponics not only supports sustainability and is resource-conserving technology, but also has advantages for fish welfare. Fish react to environmental influences through various physiological and behavioural adaptations (Barton, 2002) that allow conclusions to be drawn about their well-being. In this study, different welfare indicators were used to assess the welfare status of African catfish reared in coupled aquaponic systems with different numbers of basil plants (*Ocimum basilicum*) to determine the effects of the plant density.

Material & Methods

Three small-scale RAS were compared over 85d, each including fish tanks and hydroponic units in triplicates with a varying number of basil plants (control: n=0; moderate plant density, mpd: n=48; high plant density, hpd: n=144). African catfish were reared in an extensive stocking density (11.0 – 21.7 kg/m^3). Water changes and additional plant fertilisation were not conducted. Water quality and plant growth was documented; fish welfare indicators such as growth performance, mortality, plasma cortisol, glucose, lactate, biting wounds, and different behavioural patterns (agonistic behaviour*, air breathing*, curiosity, escape attempts*, stereotypy*, and swimming activity*) were analysed by visual and video observations (*ethology after van de Nieuwegiessen et al., 2008; 2009) in regular intervals. Prior to blood sampling, stress was induced by 10min air exposure and subsequently 1h confinement (after van de Nieuwegiessen et al., 2009) to observe potential alterations of the endocrine stress response. The data were statistically verified (p at 0.05). The results of different fish welfare indicators were evaluated using a newly developed ranking system, where the actual values were replaced based on their magnitude by numbers of 1-9. The higher the total sum of a treatment group, the lower the fish welfare was considered relative to the other groups.

Results

Most water parameters did not differ significantly between the groups; merely oxygen showed significant differences, with the highest mean concentration in the control (8.4 mg/L) and the lowest in the hpd (8.2 mg/L). pH slowly decreased from approx. 7.5 at the beginning to 5.3-6.1 ($p > 0.05$); on day 38 this was adjusted by application of an alkaline buffer, which raised the pH up to 8.3-8.4. This acted as an additional stressor and led to temporal alteration in the cortisol responses of the control and mpd group. Both showed elevations, whereas the hpd group showed an elevation priorly and lagged this acute response. Due to this progression cortisol showed significant differences (control: 18.8 ng/mL, mpd: 19.9 ng/mL, hpd: 25.8 ng/mL). Glucose and lactate levels did not differ significantly (control: 5.5, 2.6 mmol/L; mpd: 5.6, 2.7 mmol/L; hpd: 5.3, 2.6 mmol/L). The hpd fish showed the least activity (control: visual 77.8% / video 81.6%; mpd: 74.6% / 82.6%; hpd: 63.2% ($p < 0.05$) / 78.8%). High agonistic behaviour (control: 5 / 131; mpd: 4 / 57; hpd: 1 / 45) and the highest number of skin lesions (control: 3.9; mpd: 2.9; hpd: 3.4) were observed in the control. Growth performance and mortality of the fish did not differ significantl .

Discussion

Compared to literature data, water quality results were adequate for African catfish in each system; also growth and survival rate were regular. Some differences in welfare indicators between the groups were detected. For instance, in the hpd group an acute cortisol response reaction to the pH adjustment was suppressed. Based on the multivariate evaluation method, and considering the behavioural patterns, wounds and physiological indicators, the fish welfare inside coupled aquaponic systems was nevertheless assessed as high compared with the control. The presence of the plants as well as the increasing plant density proofed a positive effect on the fish. A possible explanation could be an allelopathic influence of either the plants or the associated microorganisms, in particular from the rhizosphere (Yildiz et al., 2017).

(Continued on next page)

Conclusions

Although welfare indicators do not always present a uniform picture and inter-individual differences may occur, the results demonstrate a visible effect of the aquaponic cultivation on fish welfare. According to the newly developed evaluation method (Baßmann et al., 2018), the fish associated with a high number of plants inside the same system showed the comparatively highest level of well-being.

EFFECTS OF MONO AND MIXED BLOOMS OF COSMOPOLITAN HARMFUL ALGAE *Alexandrium, Karenia,* and *Chattonella* ON THE REPRODUCTION OF JAPANESE PEARL OYSTER *Pinctada fucata martensii*

Leila Basti*, Jyoji Go, Kyohito Nagai

Several species of harmful algal blooms (HAB) cause mass mortalities of fish in aquaculture farms, including the cosmopolitan PSP- and non PSP-producing *Alexandrium catenella* and *A. affine*, ichthyotoxic dinoflagellate, *Karenia mikimotoi*, and the raphidophyte, *Chattonella marina*. Several aspects of the toxinology of these harmful algae remain intractable due to the complexity of the toxicity mechanism underlying the fish- and shellfish-kills. In addition, several harmful algal species have been recently shown to affect the reproduction of shellfish at very low cell densities. The effects of mixed blooms of harmful algae on aquatic organisms, however, have not been explored.

The Japanese pearl oyster was used as a model bivalve. Under laboratory conditions, the gonads of adult pearl oyster, *Pinctada fucata martensii*, were stripped of spermatozoa and oocytes, and artificial fertilization was carried out. Early developmental stages and larvae were used for experimental exposure to *K. mikimotoi*, *A. catenella*, *A. affine*, and *C. marina* in mono-specifi and mixed bloom experimental frames. The quality of gametes, fertilization success, embryogenesis as well as larval survivorship, activity and anti-oxidant enzymes were assessed during the exposures.

Differential negative effects on gametes, fertilization, embryogenesis, as well as larvae were found. Several interactions in mixed blooms of the harmful algae were found. The results of the current study, along with our recent findings, stress the effects of harmful algal species on the reproduction of bivalve molluscs and the importance of monitoring mixed harmful algal blooms in coastal areas and shellfish aquaculture farms

THE IMPACT OF GENOMIC SELECTION IN COMMERCIAL BREEDING PROGRAMMES FOR FOUR IMPORTANT SPECIES IN EUROPEAN AQUACULTURE

John W.M. Bastiaansen*, AquaIMPACT Consortium

Wageningen University & Research Animal Breeding and Genomics, PO Box 338, 6700 AH Wageningen (the Netherlands)
E-mail: john.bastiaansen@wur.nl

Background
Genomic Selection has transformed animal breeding over the last two decades, especially for the major agriculturally important species. In aquaculture the implementation of genomic innovations in breeding are mixed. Genomic tools, such as SNP genotyping arrays, have been available for Atlantic Salmon and rainbow trout, and genomic selection is widely applied in these species. For European seabass and gilthead seabream the genomic tools are coming commercially available currently. Optimization of family structures to maximize benefits from genomic selection has been described (Nielsen et al. 2009; Sonesson & Ødegard 2016). The impact of genomic selection in practical breeding programmes needs to be demonstrated to support further implementation by the breeding industry. The application of genomic selection for quality and disease traits and also the use of partial datasets needs practical methods to be developed. For some species the design of genomic selection programmes with group matings needs to be investigated.

Materials and methods
Parameters from the designs of current commercial breeding programmes are obtained. These parameters include the number of parents and selection candidates, mating designs, as well as types of traits to be measured and their genetic parameters. The value of adding genomic data is assessed using deterministic predictions (Dekkers 2007; Rutten et al. 2002) when the designs allow for this, such as programmes where family designs are implemented. For other designs, such as group mating designs, the use of stochastic simulation is implemented in R software (R). In addition to phenotypes measured on selection candidates, including traits in the breeding programme that can only be measured in the commercial environment will be specifically ta geted.

Results
The impact of using genomic information within the current designs of commercial breeding programmes will be presented. The important measures of comparison are genetic progress over time and the rate of inbreeding under the alternative selection scenarios, with and without the use of genomic information. An assessment of implementation cost is made in terms of the number of genotypes required. Causes for differences between the impact of genomic information between the targeted species will be discussed.

Future work
Genomic selection is implemented in practical breeding programmes of four species that are important to European aquaculture as part of the European research project AquaIMPACT. In this project the application of genomic selection is focused on traits that need to be recorded in commercial conditions.

Introduction

Defatted yellow mealworm (*Tenebrio molitor*, TM) larvae meal is already industrially produced at a large scale. TM is a rich source of protein (up to 70%) with a well-balanced amino acid and fatty acid profile. This study evaluated the feasibility of replacing fishmeal (FM) by this sustainable ingredient in European seabass (*Dicentrarchus labrax*) juveniles. The growth performance, nutrient utilization, intestinal morphology, tissue composition, humoral innate immunity and flesh quality was evaluated in fish fed th TM as a partial and total substitute of FM.

Materials and methods

Four extruded isonitrogenous diets (48% crude protein on a dry matter basis) were formulated to replace increasing levels of FM by TM meal: 0 (CTRL), 40 (TM40), 80 (TM80) and 100% (TM100) replacement. Each diet was assigned to triplicate homogeneous groups of 25 fish (initial average body weight 55 ± 5 g) fed until apparent satiation for 10 weeks. Fish were subjected to a 12-hour light/12-hour dark photoperiod regime and kept in a recirculating saltwater system (35‰, 22±1°C). At the end of the growth trial, fish were individually weighed and measured. Five fish from each tank were sampled for whole body composition. Muscle was collected for total lipid content a fatty acid (FA) profile analysis and colour and texture measurements. A portion of intestine was sampled, fixed and processed for histological analysis. Plasma was collected to analyse alternative complement pathway (ACH50), lysozyme and peroxidase activity. The apparent digestibility coefficients of the experimental diets were also determined, according to Cho & Slinger (1979), after including 1% Cr_2O_3, as inert marker, in the experimental diets.

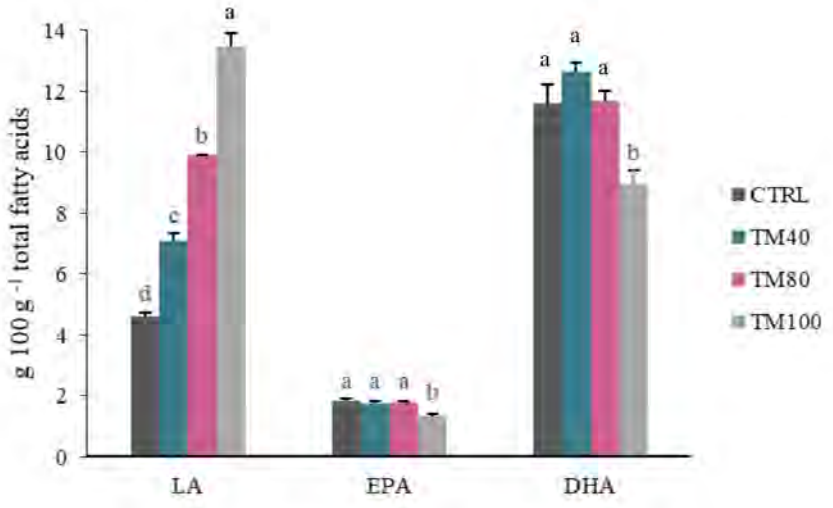

Fig. 1. Muscle level (g 100 g $^{-1}$ total fatty acids) of linoleic (LA), eicosapentaenoic (EPA) and docosahexaenoic (DHA) acids of fish fed experimental diets. Values are presented as mean ± standard deviation. Different superscript letters differ significantly ($p < 0.05$).

(Continued on next page)

Results

Total replacement of FM by TM meal significantly reduced the protein digestibility of European seabass juveniles compared to the CTRL diet. The voluntary feed intake also decreased in fish fed TM100. But these fish had the best feed conversion ratio resulting in similar final body weight among treatments. Despite the significantly decrease of protein digestibility in fish fed TM100, the morphologic integrity of the intestine was maintained. Although whole body lipid content and the hepatosomatic index increased in fish fed TM100, flesh total lipid content, colour and texture remained similar among dietary treatments. The inclusion of TM meal resulted in a concomitant increase in the muscle level of linoleic acid (LA, 18:2n-6), whilst the eicosapentaenoic (EPA, 20:5n-3) and docosahexaenoic (DHA, 22:6n-3) acids remained unaffected in fish fed diets up to 80% replacement level (Fig.1). The inclusion of TM meal did not alter the ACH50 and lysozyme activity but increased plasma peroxidase activity.

Discussion and conclusion

The present study shows that it is possible to replace up to 80% FM by TM meal without impairing European seabass juveniles' growth performance, nutrient utilization, flesh quality, intestinal morphology and humoral innate immunity. In fact, up to 80% of replacement of FM by TM meal fish resulted in fair levels of EPA and DHA in muscle (0.46 g 100 g $^{-1}$), which was above the recommended level for human consumption to decrease the risk of cardiovascular diseases (0.25 g 100 g $^{-1}$ portion of fish; EFSA, 2010). Altogether, these results evidence a great potential of TM to replace FM in diets for European sea bass juveniles.

Introduction
Defatted yellow mealworm (*Tenebrio molitor*, TMd) larvae meal can be an interesting alternative to fishmeal (FM), due to its high content in protein (up to 70%), well-balanced amino acid profile and eco-friendly features. Besides, its industrial production is already well established. This study assessed the feasibility of replacing FM by this sustainable ingredient in European seabass (*Dicentrarchus labrax*) from juveniles to market size. The growth performance and nutrient utilization of fish fed TMd as a partial and total substitute of FM was compared to that of fish fed a control diet

Materials and methods
Three extruded isonitrogenous and isolipidic diets (47% crude protein and 20% crude fat on a dry matter basis) were formulated to substitute 50% (TM50) and 100% (TM100) of fishmeal by TMd. Each diet was assigned to quadruplicate homogeneous groups of 15 fish (initial average body weight 68.6 ± 5 g) fed until apparent satiation for 16 weeks. Fish were subjected to a 12-hour light/12-hour dark photoperiod regime and kept in a recirculating saltwater system (35‰, 22 ± 1 °C). At the end of the growth trial, all fish were individually weighed and measured and four fish from each tank were collected for whole body composition analysis and nutrients balances calculations. Additionally, 30 fish per treatment were taken after a 48-h fasting period for the evaluation of fish slices by a sensory panel

Results
The experimental diets were well accepted by fish and no mortality occurred during the experiment. Fish fed TM50 had the lowest voluntary feed intake but attained similar final body weight, resulting in the best feed conversion ratio (FCR) and highest protein efficiency ratio (PER) among treatments. Fish fed TM100 had higher whole body fat content than fish fed CTRL, but the hepatosomatic and viscerosomatic index (HSI and VSI, respectively) remained unaffected by TMd inclusion.

The inclusion of TMd to replace FM resulted in a significant increase in fat and phosphorus retention, without affecting nutrients' gain. The sensory panel could not perceive any significant differences in the slices global acceptance from fish fed the different experimental diets; all the samples were positively characterized by their good aspect, odour, texture and flavou . Textural properties were also similar among fish, but fish fed with TMd showed a higher flesh juiciness than those fed the CTRL diet.

Discussion and conclusion
The present study shows that the substitution of 50% FM by TMd significantly improves FCR and PER, without affecting fish growth. Likewise, total replacement of FM by TMd didn't impair European seabass growth performance, HSI and VSI, but increased the whole body fat content, suggesting a strong impact on lipid metabolism. On the other hand, the increased fat retention in fish fed diets with TMd may explain the higher juiciness of its flesh.

These results evidence the great potential of TMd to replace FM in diets for European seabass, but the total substitution of FM has to be addressed with caution in a long term trial.

Salmon louse (*Lepeophtheirus salmonis*) infection is still a large problem for salmon aquaculture in Norway as well as in other salmon-producing countries, although knowledge about this species is increasing. To be able to find solutions to this problem, more knowledge is needed on the basic biology and behaviour of the species. Investigating the light response behaviour of the salmon louse infectious stage, the copepodite, is important regarding responses to both natural and artificial light in the ocean, as well as in exploring the potential of using light as remedy to decrease infection rates.

Light responses of copepodites were investigated using a laboratory experimental setup modified after Miljeteig et al. (2014). The light sources used were the wavebands white, blue, and green, and each of these were tested at different irradiance levels and pulsation settings. The first set of experiments (E1) was performed in a 40x12cm aquarium with 150-200 copepodites per trial, to investigate the movement of the copepodite group relative to the light stimulus. The second set of experiments (E2) was performed in a 20x12cm aquarium with 12 copepodites per trial, to track individual copepodites and investigate parameters like swimming speed and directionality, using the same light stimuli as in E1.

The movement of the copepodites were registered using an infrared-sensitive camera with adjustable frame rate, and data was extracted from the videos using image processing. For E1, positions of the copepodites, and thus distance from the light stimulus, were detected throughout the experiments. For E2, an additional tracking algorithm was developed and applied.

Results will be presented at the conference.

The experimental setup and the data processing methods developed in this study can be adjusted to application on many different planktonic species and with other types of stimuli, and has thus the potential to be used for a wide range of studies.

Introduction

Genetic Adaptions to new environmental conditions are crucial in the evolution of fish populations. Especially in aquaculture facilities, sudden changes in nutrition can occur, due to changes in the composition of the feed. The use of fishmeal is being controversially discussed due to overfishing of the oceans. Therefore, the replacement of fishmeal with alternative protein sources is a main and timely scientific focus. Supplementations might lead to slower growth or affect fish health or animal welfare.

"Sustainable Trout Aquaculture Intensification - SusTAIn" is a cooperative project that explores the genetic variability of trout to adapt to novel resources in order to use these for a sustainable aquaculture. The impact of feeding substitute protein sources on the health of fish is a main focus of the project. This aspect is examined by evaluating chronic stress and analysing gene expressions in order to assess immunological responses and the susceptibility to trout specific pathogens.

Materials and methods

Eight local strains of rainbow trout and a commercially available strain were fed with differently supplemented feeds (control feed, feed supplemented with *Hermetia illucens* or *Arthrospira platensis*) and compared in growth performance and susceptibility to trout-specific pathogens. The susceptibility of trout to the viral haemorrhagic septicaemia virus (VHSV) was evaluated by *in vitro* and *in vivo* studies for the best and worst performing strains. For the *in vitro* evaluations, fin tissue and primary cell cultures from scales from the different trout strains, which were fed with the differently supplemented feeds were infected with VHSV. The grade of replication of VHSV in the *in vitro* infections was evaluated using titration on RTG-2 cell cultures with determination of the 50 % tissue culture infective dose ($TCID_{50}$). For the *in vivo* studies, fish from each feeding group and strain were infected with VHSV. Mortality was evaluated on day 29 post infection.

Results

The analysis of *in vitro* infection of fin tissue of parents of eight trout strains under control feed did not show any significant differences in virus replication.

The analysis of *in vitro* infection of fin tissue of the three feeding groups of best and worst performing strains did not show any significant di ferences in virus replication.

Results of *in vivo* experiments indicated that the some trout strains showed significant differences in mortality rates with over 75 percent difference between most susceptible and resistant strain. The mortality was independent from growth performance of given strains of fish, also feed supplements had no impact on mortality under VHSV-infection.

Conclusion

The preliminary results indicate, that the survival of rainbow trout from VHSV-related disease under severe disease pressure, is predominantly influenced by the genetic background. These results proved to be independent from feeding of fishmeal substituted feed and growth performance. Summarising: Fish meal protein replacement with *Hermetia illucens* or *Arthrospira platensis* should not influence the susceptibility of the rainbow trout to VHSV.

IDENTIFICATION AND PATHOGENICITY OF *Vibrio* spp. ISOLATED FROM RECIRCULATING AQUACULTURE SYSTEMS (RAS) STOCKED WITH PACIFIC WHITE SHRIMP (*Litopenaeus vannamei*)

J. Bauer[1], F. Teitge[1], L. Neffe[1], M. Adamek[1], A. Jung[2], C. Peppler[3], D. Steinhagen[1], V. Jung-Schroers[1]

[1] Fish Disease Research Unit, University of Veterinary Medicine Hannover, Bünteweg 17, 30559 Hannover (Germany)
[2] Clinic for Poultry, University of Veterinary Medicine Hannover, Bünteweg 17, 30559 Hannover (Germany)
[3] Polyplan GmbH, Überseetor 14, 28217 Bremen (Germany)
E-Mail: julia.bauer@tiho-hannover.de

Introduction

Some *Vibrio* sp. play an important role as pathogens in aquaculture of shrimps (e.g. *V. parahaemolyticus*, *V. harveyi)*, others can be the cause of wound or diarrhoeal infections in humans (e.g. *V. parahaemolyticus*, *V. vulnificus*). Still, these bacteria are ubiquitous in marine and brackish aquatic environments and a part of the normal flora of shrimps´ digestive tract and skin. For the detection of *Vibrio* spp. a reliable method of identification is necessary and for evaluation of the potential risk that derives from these isolates the analysis of different pathogenicity factors is possible.

Materials and methods

Different methods of identification, which are suitable for standard diagnostics in laboratories, were compared. Biochemical identification and identification using mass spectrometry (MALDI-TOF) were conducted. Furthermore, parts of the *16S* rRNA gene with two different sequence lengths (V1-V5, V1-V8) and parts of the housekeeping gene *pyrH* were sequenced.

Known pathogenicity factors were analysed that induce an elevated pathogenicity in certain *Vibrio* spp.. These include factors that elevate the pathogenicity of *V. cholerae* (VPI, ToxR, ToxS), as well as different haemolysins (*vhh*, *vfh, tdh, trh*). The motility of the isolates was analysed and the presence of different flagelline gene loci was investigated, as these contribute to motility in bacteria and can promote the adhesion on mucous membranes.

Results

The identification of *Vibrio*- isolates from RAS and type strains using different methods of identification proved to be highly divergent. Sequencing of the variable regions V1-V8 of the *16S* rRNA gene and MALDI-TOF mass spectrometry proved to be the most reliable methods. Identification using MALDI- OF was especially efficient for pathogenic species.

Analysing pathogenicity factors showed that RAS are a habitat for potentially pathogenic *Vibrio* spp.. Even in RAS with healthy shrimp potentially pathogenic *Vibrio* spp. could be found. Therefore, the analysis of pathogenicity factors can only give hints toward a risk of infection.

Conclusion

The identificati n of *Vibrio* spp. using standard diagnostic methods was difficult and for many isolates, the identification results were divergent. The investigations on isolates from different systems showed that potentially pathogenic *Vibrio* spp. can be found in RAS. Missing entries of sequences in the databases, low numbers of comparable isolates and high interspecific similarities of biochemical characteristics or nucleotide sequences are the main reasons for the difficulties in reliably identifying some *Vibrio* sp.

DEVELOPMENT OF OFFSHORE BIVALVE SHELLFISH PRODUCTION IN THE EASTERN IRISH SEA

P. Bayford*, J. Webb, J. Alexander, S. Ward, L. LeVay, S. Malham

Centre for Applied Marine Sciences, School of Ocean Sciences, Bangor University, Menai Bridge UK
E-mail: p.bayford@bangor.ac.uk

Blue mussel (*Mytilus edulis*) is an important aquaculture species in the UK and particularly Wales (Ellis et al, 2015). The traditional method currently utilised in the Menai Strait involves collecting and placing wild seed mussel on the sea bed, followed by management to market size. The Menai Strait production area supports harvests of 7-10,000 tonnes of mussels per annum, accounting for 30-50% of all UK mussel production (Blue New Deal, 2018).

Reliance on wild mussel seed is a limiting factor to industry expansion (Çelik et al, 2016). In Wales recent observations have suggested that mussel seed beds have been in decline with inconsistent seed availability potentially affecting volume and profitability of current mussel production. The use of longlines and raft systems for seed collection as well as mussel grow-out are commonplace globally (Kammermans and Capelle, 2018) and represent a potential alternative for sourcing mussel seed.

The Menai Offshore Subsurface Shellfish Systems (MOSSS) project is a collaboration between Bangor University and the Menai Strait mussel industry. The aim is to develop innovative offshore rope systems to ensure a reliable supply of good quality mussel seed. Research is focussed on assessment of the site as a suitable area for the production of mussels and assessment of the collection seed on artificial substrates. Despite the failure of intertidal and benthic seed settlement plankton surveys indicate that bivalve larvae remain highly abundant in coastal and offshore areas in the eastern Irish Sea.

Within MOSSS mussel seed collection is being developed using a longline system at a pilot commercial-scale offshore site in north Wales. The site was selected based on key physical and biological parameters. For example, we used results from biophysical modelling of mussel larval dispersal from known adult populations, observations and simulations of waves, tides and winds, seabed survey data and analysis of vessel traffic in the area. Furthermore, we conducted planktonic monitoring including; genetic analysis to accurately quantify bivalve larvae at species level and initial technical trials have tested different collection materials and practical operation of mussel seed lines in an area with a large tidal range.

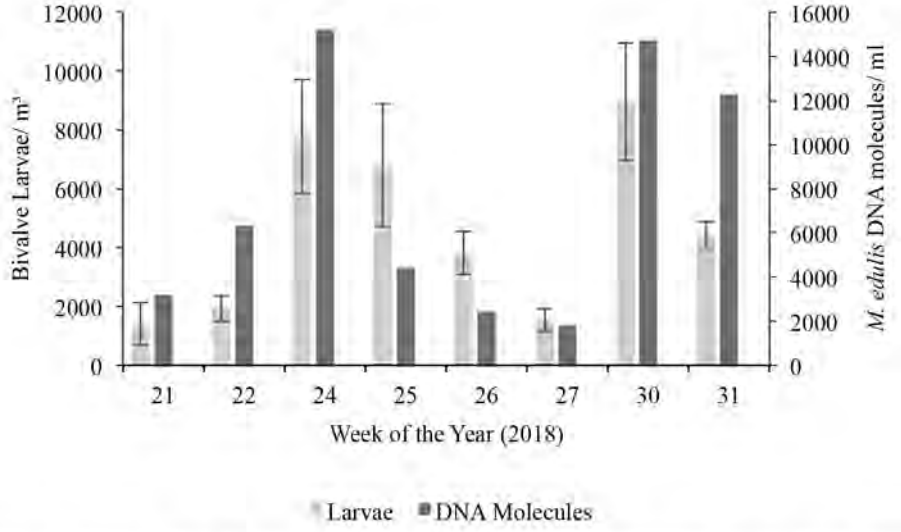

Figure 1. Mean bivalve larval abundance (light grey) and concentration of *M. edulis* DNA molecules (dark grey) in plankton samples collected from the experimental longline site between week 21 and 31, 2018.

(Continued on next page)

Regular monitoring of the plankton during the summer of 2018 demonstrated high quantities of bivalve larvae, with peaks in bivalve larval abundance coinciding with peaks in *M. edulis* DNA, indicating a high supply of mussel larvae at the experimental site (Figure 1). Settlement of spat during the summer of 2018 was successful, and after a three-month growing period, five header lines, each holding 1500 m of rope yielded 30 tonnes of seed, with the most successful lines carrying a maximum of 3.6kg m^{-1}.

This initial investigation into the potential for suspended mussel seed collection has been a success, though consistency of seed supply and settlement still needs to be evaluated. The integrity of the rope system over the following extreme winter of 2018/2019 also demonstrated the possibility for offshore grow-out cultivation even in such a high energy location with extreme wind and wave events and a tidal range of >7m.

In the summer of 2019, the MOSSS project will trial methods for assessing the potential for grow-out of mussels at the experimental site. The aim is to extend the existing site by considering operational experience gained thus far along with hydrodynamic (wave and tide) modelling. The project will outline the development of a multi-criteria assessment of potential areas for offshore mussel production in the Eastern Irish Sea for use by stakeholders to identify expansion of the aquaculture industry in this region.

ASSESSING THE EFFECTS OF GAS INFUSION SYSTEMS TECHNOLOGY TO PRODUCE HIGH DISSOLVED OXYGEN FRESHWATER SATURATION ON ATLANTIC SALMON (*Salmo salar*) GROWTH AND OVERALL HEALTH WITHIN A SIMULATED COMMERCIAL HATCHERY SETTING

Ehab Misk[1], Chris Bridger[2], Michael Beattie[3*]

[*]mike@gasinfusionsystems.com

Technological advances that promote optimal growing conditions for enhanced fish performance and fish health are necessary to ensure RAS systems are operated in a cost-effective manner. Dissolved oxygen is an essential and costly component for RAS but having the ability to supersaturate water with elevated infused dissolved oxygen concentration while not increasing total gas pressure presents interesting possibilities to explore optimal aeration for RAS performance.

GIS Gas Infusion Systems Inc., has developed a unique oxygen infusion system based on the principal of “mass gas transfer”. This involves a one to one molecular exchange in water between nitrogen (removed) and oxygen (infused) resulting in no increase to total gas pressure.

The current study objective was to assess the effect of the GIS technology on performance, growth, survival and overall fish health over a period of 264 days. A total of 13,500 Atlantic salmon first feeding fry were equally distributed into nine study tanks. The experimental setup involved 3 tanks for each treatment: DO ambient (90-100%), DO medium (140-160%) and DO high (190-210%). A density reduction plan was designed to simulate commercial stocking densities and all fish were fed to satiation. Bulk weights for each tank occurred monthly, in addition to individual fish weights and body condition scores at cutbacks. Dead fish were removed daily, recorded and necropsied. Serum samples were collected pre and post smolt to assess Hct levels. At 520-degree days post vaccination, further serum samples were collected and analyzed for IgM titer levels using ELISA.

Major study outcomes include the following: 1) both high and medium DO groups demonstrated a 168% increase in weight over ambient, 2) high and medium DO groups had a minimum 50% increase in survivability over ambient, 3) there was no statistical difference in precocious male percent for all treatment groups, 4) no acute or near-term mortalities (60 days post smolt) were associated with smoltification from high/medium DO freshwater directly into ambient saltwater, 5) median IgM optical density increased by 0.06 (doubled) for high/medium DO groups compared to ambient.

The study results give a clear indication that the GIS infused dissolved oxygen levels at 150% provided enhanced fish performance levels, improved fish health for an optimal economic return. RAS operators now have the technology to achieve “faster growth – better health” with a unique, scalable oxygen infusion system.

SENSITIVITY OF NORTHERN SHRIMP *Pandalus borealis* TO COMMERCIAL FORMULATIONS USED AS ANTI-PARASITIC DRUGS

Introduction

The ecto-parasitic salmon louse (*Lepeophtheirus salmonis*) is one of the main challenges in marine aquaculture. Chemical delousing is used in addition to alternative methods like cleaner fish and mechanical removal of the crustacean parasite. The use of chemicals as medicine has raised concerns over the impact on non-target crustaceans like Northern shrimp *(Pandalus borealis),* a keystone species in the marine ecosystem.

Materials and methods

A series of laboratory experiments has been performed, exposing shrimp to environmentally realistic exposure concentrations of four commercial formulations used as anti-parasitic drugs; 1) the in-feed drug Releeze, containing the chitin synthesis inhibitor diflubenzuron (DIF); the bath treatments Alpha Max (2) and Salmosan (3) with the neurotoxic compounds deltamethrin (DEL) and azamethiphos (AZA), respectively, as the active ingredients; and the bath treatment Paramove (4) containing hydrogen peroxide (H_2O_2). Shrimp were exposed to DIF medicated feed under current (C: 7.0 °C, pH 8.0) and future global change conditions (Ocean Acidificatio and Warming; OAW: 9.5 °C and pH 7.6) in flow-through exposure systems. DEL, AZA and H_2O_2 were only tested at current conditions. To document potential delayed effects, a recovery period in clean water was included in all experiments.

Results and discussion

Effects of DIF on shrimp larvae. Two weeks exposure to DIF medicated feed caused significantly increased mortality. The effect of OAW and DIF on mortality of shrimp larvae was additive; 10 % mortality in C, 35 % in OAW, 66 % in DIF and 92 % in OAW+DIF. In OAW+DIF feeding and swimming activity was reduced for stage II larvae and none of the surviving larvae developed to stage IV. Due to shorter intermoult period at elevated temperature, the OAW+DIF larvae were exposed throughout two instead of one critical pre-moult period. This can explain the more serious sub-lethal effects for OAW+DIF than DIF larvae. A single day exposure at 4 days after hatching did not affect DIF larvae, but high mortality was observed for OAW+DIF larvae, possibly because they were exposed closer to moulting when crustaceans are more sensitive to chitin synthesis inhibitors. The additive effect of DIF (local driver) and OAW (global drivers) on survival of shrimp larvae emphasize the importance of managing the local drivers (reducing pollution) to slow down the detrimental impact of future global environmental changes

Effects of DIF on adult shrimp. Ovigerous shrimp were exposed to DIF medicated salmon feed for two weeks before their post-hatch moult. The shrimp were exposed to DIF under the same current and future environmental conditions as the shrimp larvae. The mortality of DIF exposed shrimp was approximately 60 % higher than mortality of control shrimp, and while more than 60 % of the control shrimp moulted successfully, only 2 - 7 % of DIF exposed shrimp survived moulting. Most of the mortality occurred during moulting in the depuration period, and even after four weeks of depuration, when the mean tissue concentration was still 33 ng g^{-1} w/w, mortality was higher for DIF exposed shrimp. High mortality was observed for adult shrimp after consumption of approximately 0.1 g of DIF medicated feed. Mortality was also higher in OAW than in C, but the combined effect of DIF and OAW was less than additive. In an additional experiment, where adult shrimp without eggs were exposed to DIF medicated feed, high moult-related mortality was observed already after four days exposure. Some exposed shrimp did, however, moult successfully after two-three weeks of depuration.

Effects of H_2O_2. The Paramove treatment solution for salmon contains 1500 mg/L H_2O_2. Increased mortality and reduced feeding rate were observed after exposure to three 2-hour pulses of 1.5 mg/L. Increased mortality was also observed after one 2-hour pulse of 15 mg/L. Mortality occurred around three days after the first pulse (delayed effect). Gill damage and evidence of lipid peroxidation in the hepatopancreas was documented after one hour exposure to 1.5 mg/L and 15 mg/L H_2O_2, and the effects were more evident at the highest concentration.

(Continued on next page)

Effects of DEL. The Alpha Max treatment solution for salmon contains 2 µg/L DEL. When adult shrimp were exposed to seven 2-hour pulses of 2 ng/L DEL they survived, but the feeding rate was significantly reduced during and after the exposure. Tissue damage in the hepatopancreas was also observed. Continuous exposure to 2 ng/L DEL for up to 24 hours was lethal to adult shrimp. Shrimp larvae were even more sensitive to DEL than the adult shrimp. High mortality of larvae was observed after one 2-hour pulse of 2 ng/L DEL, and few of the survivors were able to swim.

Effects of AZA.The Salmosan treatment solution for salmon contains 100 µg/L AZA. When adult shrimp were exposed to seven 2-hour pulses of 100 ng/L AZA there was no effect on survival, swimming activity or feeding rate, but indication of tissue damage was observed in the hepatopancreas. One 2-hour pulse of 100 ng/L AZA did not affect survival of shrimp larvae.

Conclusions

High mortality of shrimp was observed after exposure to Releeze medicated feed (DIF) and after a few hours of exposure to Alpha Max (2 ng/L DEL) or Paramove (1.5 mg/L H_2O_2). This means that the shrimp were affected at 1000 times diluted salmon treatment solution for these bath chemicals. Similar dilutions of Salmosan (AZA) had much less effect on the shrimp. The results from these experiments combined with results from dispersion modelling (e.g. Refseth et al. 2016) indicate that the use of chemicals against salmon lice is a risk to shrimp stocks living in areas with frequent use of chemical delousing.

Acknowledgements. This research was supported by the Research Council of Norway (Project number 267746/E40 and 234407/E40), EU (ECOAST) and Solvay. The results from the experiments with DIF are published in Bechmann et al. (2017, 2018). In addition, we are working with revisions of a MS about effects of H_2O_2 submitted to Ecotoxicology and Environmental Safety, and with papers about the results from experiments with DEL and AZA.

FACTORS DETERMINING THE CONDITIONS OF THE MARINE AQUACULTURE (CAGE CULTURE) DEVELOPMENT IN THE SOUTHERN CASPIAN SEA

M. Behgozin[1*], A. Roohi[2]

[1]Islamic Azad University, Lahijan Branch, Young Researchers Club, Lahijan, Iran
[2]Caspian Sea Ecology Research Center, Iranian Fisheries Science Research Institute, Agricultural Research, Education and Extension Organization, Sari, Iran
Corresponding: Mb.behgozin@gmail.com

Introduction

The Caspian Sea is currently the largest internally drained lake in the world, with a total area of 375.000 km2, and is located in south-central Eurasia, between Iran, Azerbaijan, Russia, Kazakhstan and Turkmenistan. It is situated at 28 meters below from world ocean level. Classified as a deep inland sea for its size, depth, chemical properties, and peculiarities of thermohaline structure, water circulation the Caspian Sea conditionally divided into three parts: South Caspian, Middle Caspian and North Caspian (Aladdin and Plotnikov, 2004). Due to its closed ecosystem, the Caspian Sea has a high potential and high risk in non-native aquatic species introduction. The Caspian Sea, as one of the most important water resources in Iran, has good weather and maritime aquaculture abilities. Many breeding species have the ability to breed in this region for half a season or all-round, with the depths of the Caspian Sea in the southern region and a wide range of temperature variations throughout the year (6 to 32 ° C) and average salinity of 12.5 ppt.

More than 62 countries are currently active in cage aquaculture. Total crop production in cages in 2005 was about 3.4 million tons and the total aquaculture production in the world in 2006 (with aquatic plants) was about 66.7 million tons worth 85.9 billion dollars and the share of aquaculture was cultivated 19.3 million tons and marine fish were 2.2 million tons. By 2025, the forecast of marine fish production will be about 10 million tons, and Malaysia, Thailand, Vietnam, China, Norway and Iceland are the leading countries for fish farming in this way (Halwart et al., 2007)

Cultivation of fish in Iran with rainbow trout has been started in recent years with floating cages at depths of 30-50 m in the southern Caspian Sea.

Materials and methods

Physico-chemical parameters data were collected via water bottle sampler along regions which the fish cage culture site located in Nowshar off the Iranian coast of the southern Caspian Sea in the bottom depths of 30 m in years of 2013-18. Economic and Social data were also collected through library archives via relevant experts in the department of aquaculture of the Iranian Fisheries Organization as well as Rainbow trout fish cage culture site in Mazandaran province, Iran. In this study, the growth of salmon fish was evaluated based on the production input of each floating cage with a diameter of 20 meters and a height of 8 meters in the southern part of the Caspian Sea during autumn and winter and based on the initial inputs (fish and food costs). Also, the study of efficiency (production to cost), net worth value (NPV), internal rate of return or guaranteed rate of return (IRR), investment evaluation through descriptive statistics was analyzed.

This study, based on the assumptions about the production of 25-20 tons per cage and the experiences of fish breeding in cages in 2013 (autumn and winter) based on the amount of final produce and food consumed and the purchase of fry fish between the two initial storage weights of 150 and 250 g has come to fruition.

In this study, fish prices and food prices in 2014 were used. Therefore, the price of pre-paid fish for each kilogram of 5 USD and the price of food per kilo of 1 USD and the forecast of the price of fish in the harvest of 4 USD were used

Table 1: Statistical data of the average profit from fish farming in marine cages

Profit (%)	Sale (USD)	Food cost (USD)	Fry fish cost (USD)	Initial weight (g)	Fish Cage#
15.1	117	54	21	500	5 site

(Continued on next page)

Results

The purpose of this study was to evaluate the physico-chemical parameters effective on water quality as well as the economical and social feasibility of cage fish farming in the southern Caspian Sea.

Results showed that the amounts of water temperature, transparency, pH, dissolved oxygen, BOD5, total alkalinity and TSS ranged from 9.00 to 29.00˚C, 0.50 to 12.00 m, 8.05 to 8.74, 5.76 to 12.85, 21 to 195 and 0.00 to 0.12 mg/l, respectively which could be favorable for fish rearing in the sea. The proper temperatures for cultivation of salmonids species in this area were begun in October and ended in March. In the current study, results of pH and dissolved oxygen were consistent with the standard range of pH (7.80-8.50) and dissolved oxygen (>5 mg/l) for cage fish farming.

The results of rainbow trout breeding in cage culture in the Caspian Sea in 2013 showed the range of the number of fry stocks were 8500 to 58500 individuals with an average weight of 35 to 250 g, that the average profit during the 4 months was 7.3% (Table 1).

Discussion and conclusion

One of the most important factors in fish breeding in cages is the use of appropriate species in terms of adaptation to the biological conditions of the region and its economic significanc . In the current situation, rainbow trout can be one of the options, given the outstanding features of aquaculture and adaptation to the environmental conditions of the South Sea region. Therefore, in this study rainbow trout as an appropriate breeding species in the southern part of the Caspian Sea was used in this assessment. This region with a coastline of 250 km from a depth of 20 to 100 m and 2027 km^2 has the cage aquaculture capacity. Mazandaran with a population of more than 3 million and about 4.9 percent of the population has an area of 1.46 percent of Iran (23,842 km^2). Considering the potential of the aforementioned region in the coastal strip of the southern Caspian coastline, at least 200 cage-producing sites could be expected with 40 cages per site and produce 160,000 tons, and generate employment of 1,000 directly and 2000 indirectly with 2000 Billions income per year and average net profit of 40% can be expected to be 800 billion, which producing part of the country's protein requirement, will create jobs, prosperity, prosperity and prosperity of the region's economy.

Introduction

Nowadays increasing the consumption of fish production and aquatic organisms pushes aquaculture to produce fish more intensively. The trend of increasing aquaculture production leads to automation of processes for increasing the profits and facilitate the cultivation process. Automation of fish cultivation process helps to control general issues of aquaculture. The idea of automatization of fish production is the general aim of precision fish farming concept where control – engineering principles are applied to fish production process, increase the possibilities of fish farmers to monitor, control and document all biological processes of fish cultivation process (Fore et al., 2017). One of the main parts of automation of the process of fish cultivation are fish identification and tracking the fish trajectory in tank. Individual identification of fish is mostly based on fish marking and tagging (Pine et al., 2003). These methods are invasive and negatively effect on a fish, increase the mortality risks, injuring and highly stressful for the fish (Ombredane et al., 1998). Despite, today studies about non–invasive identification of individuals in fish groups are not described and fully studied. There are just few papers dealing with identificati n of individual fish with limited the number of individuals (Hirsch et.al., 2015; Al – Jubouri et al., 2018). Non-invasive method of fish identification such as image-based identification is significantly important because it can reduce the different negative effects on a fish welfare. The aim of this paper is proving the concept of non-invasive image-based fish identification of individuals using the visible patterns on a fish body and stability of these patterns during cultivation period. For identific tion of individuals we were used visible features on a Sumatra barb *Puntigrus Tetrazona* body represented by black stripes along the body.

Material and methods

Sumatra barb (25 fish individuals) small ornamental fish was used in this study. The fish was chosen for the study because of unique black vertical stripes on their body. These patterns can be used as visible features for individual identification of commercially important fish of this kind of patterns, for example pike-perch *Sander lucioperca* and European perch *Perca fluviatilis*.

The digital camera (Nikon D90), with controlled lighting, the background and the fish position, was used for data collection. Data were collected under different angle and position, images were taken from one side view of all fish. Data were collected two times during two weeks for fish inside the aquarium. Tree images of each individual were taken in every data collection. Fish detection procedure consists of standard image segmentation based on the color subtraction, object detection, filtration and parametrization. Different texture descriptors were tested for image parametrization. The best result was achieved using histogram of oriented gradients (HOG) (Dalal et.al., 2005) descriptor. First the specific subpart of the fish body was localized based on the fish length and height. The selected region (central part of the body) was parametrized and as used as feature vector.

Each fish was represented by three images for one data collection. The identification was then tested on two datasets. The classification was based on the simple nearest neighbor classifier where the measure of the similarity was based on HOG descriptor.

Results

The first step of the identificatio was the image processing. The use of standardized background and illumination enables to easily detect the fish in the image and do the parametrization. Fish object localization worked for all images without any significant problem (fish body was localized correctly). The identification of 25 individuals was tested as the classification within one data collection and between two data collections (test of pattern stability). The overall accuracy of classification based on the selected part of fish body was 100% for data collection in one day and 88% in between two data collection.

(Continued on next page)

Discussion and conclusion

This study successfully shows that fish individuals of the same species can be automatically identified based on the visible pattern on the body using computer vision during the time of the fish cultivation. We proved that the selected pattern can be used for individual identification because the classification accuracy within the same day data collection was 100%. The test of the pattern stability for long term identification was represented by the identification between two data collections with the accuracy 88% (3 fish were identified incorrectly). The lower classification accuracy is caused by the not optimal quality of the collected images. The classification accuracy clearly show that the fish pattern is unique to distinguish between 25 individuals of the same species. The small-scale research studies usually use comparable number of the fish; therefore, the method is promising to substitute conventional procedure of fish identification (e.g. tagging or marking). The restriction in the data collection (illumination, background) does not allow to generalize the results to the real conditions. To fully automatize the identification based on the visible pattern, more fish should be involved in the study and the data should be collected under the real conditions of the experimental studies or fish cultivation. Data collection is very important part of the experiment, better data collection will enable better results. The visible patterns, in our case it is vertical stripes, can be used for identification of Sumatra Barb (*Puntigrus tetrazona*) and these patterns are stable during the growing of the fish. However, this is not just limited to Sumatra Barb, the approach can be applied to any fish species with visible pattern on the body (stripes or dots). The approach could be beneficial for commercial fish species and even for pike-perch and European perch.

USE OF THE PROBIOTIC, PREBIOTIC AND SYMBIOTIC AS GUT PRIMERS IN EUROPEAN EEL LARVAL CULTURE

E. Benini[1], S. Politis[1], S.R. Sørensen[1], S. Engrola[2], J. Tomkiewicz[1]

[1]Technical University of Denmark, National Institute for Aquatic Resources, Lyngby, Denmark
[2]Centro de Ciencias do Mar, Universidade do Algarve, Faro, Portugal

Introduction

European eel is a targeted, high-value species for aquaculture, which utilizes resource-efficient recirculating aquaculture systems (RAS). Recently, efforts to establish a closed cycle production have been intensified. Thus, European eel research via assisted reproduction has recently succeeded in producing viable larvae and currently focuses on establishing first feeding larval culture and development of methods facilitating metamorphosis into leptocephali (Butts et al., 2016, Politis et al., 2018). The necessity to fill gaps in knowledge relating to nutritional requirements and digestive capacity of European eel larvae drives the focus on molecular and physiological mechanisms regulating feeding, digestion, and growth. Numerous studies have shown that administration of probiotics (live microbial feed supplements that modulate gastro-intestinal microbial communities) and prebiotics (non-digestible feed additives, which stimulate the abundance or activity of beneficial gastro-intestinal microbes) can help shaping the gut microbial community in fis larvae (Egerton et al., 2018). These "biotics" beneficially affect host welfare and survival by driving and improving colonization of the gut microbiome (Daniels et al., 2010). Thus, the aim of this study was to test gut-priming probiotics (*Pediococcus acidilactici*), prebiotics (mannan-oligosaccharides) and synbiotics during development of European eel yolk-sac larvae to evaluate potential improvement of ingestion and digestion capacity at first-feeding

Material and methods

All fish were handled in accordance with the European Union regulations concerning the protection of experimental animals (EU Dir 2016/63). The experiment was conducted at the EEL-HATCH facility in Hirtshals (Denmark) where broodstock maturation, gamete production and embryonic rearing were performed according with the procedures described in Politis et al. (2018). Two days post hatching, ~400 larvae were gently transferred into 24 acrylic 2L jars (drz400sm hank, JugDesk Type, Taipei, Taiwan), divided in four groups and connected to four RAS units, representing the 4 treatments (control, pro-, pre- and syn-biotics).

Each RAS unit consisted of a 50 L capacity wet biofilter filled with RK bio-element, a protein skimmer (Wavereef, China), a 100 L reservoir hosting the main pump and a 180 L header tank. Six jars were connected to each system and water flow was set to ~0.2 L/min. Within the jar, an upwelling flow created enough turbulence to keep the larvae in suspension and maintaining optimal oxygen levels for the larval rearing. The outlet was placed on the top part of the jar, where a 250µm filter enabled a good water exchange. In order to keep the bacteria level under control, each system was connected to a UV filter (active from 9 pm to 9 am). Water temperature was kept at 19 ± 1 °C and salinity was progressively reduced from 36 to 18 psu over a period of 4 days according to Politis et al. (2018) in order to improve larval survival. Probiotics (Bactocell, Lallemand SAS, France), prebiotics (AgriMOS, Lallemand SAS, France) and synbiotics (Bactocell + AgriMOS) were added to the corresponding RAS according to the company's recommendations (Table 1). One RAS received no additives (control). When larvae reached 9 dph, 0.3 ml of food was added to each jar five times a day (at 9,11,13,15 and 17) with the water flow on in order to get the larvae used to the feed and the feeding regime. After first-feeding (13 dph), 0.5ml of food was provided at the bottom of the jara and the larvae allowed to feed for 30 minutes, with no water flow present, 5 times a day. At the end of each feeding session, the flow was turned on in order to flash out excess food. Temperature, salinity and larval mortality were recorded daily. To evaluate bacterial density water samples were taken at 2, 4, 8 13 and 18 dph using the Bactiquant method (Mycometer A/S, Denmark). At the beginning of each trial, ~15 larvae per batch (3×) were randomly sampled and photographed. Additionally, on 4, 8, 13, and 18 dph, from each batch (3×), treatment (4x) and replicate (3x), randomly selected i) ~15 larvae were sampled and photographed using a zoom stereomicroscope for assessment of larval morphometrics, ii) ~30 larvae stored in RNAlater for molecular analysis, iii) ~10 larvae, washed with osmosis water and stored in -20 °C freezer to assess the enzymatic activity and iv) ~10 more larvae stored in neutral 10% formalin buffer (Hounisen, Denmark) for histological analyses.

(Continued on next page)

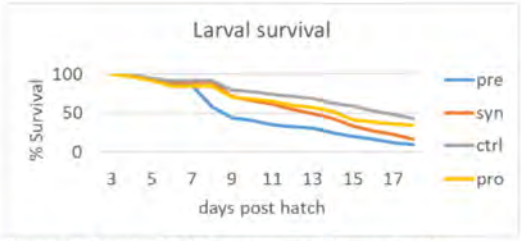

Figure 1 Survival of European eel larvae under different gut-priming treatments until 18 days post hatch

Results and Discussion

We hypothesized that administration of probiotics, prebiotics or the combination of the two (synbiotics) to eel larvae during early ontogeny, would cause an earlier activity of digestive enzymes (and related gene expression) towards better ingestion and digestion capacity, survival and growth. Preliminary results showed that prebiotics and synbiotics did not promote survival of European eel during early life history compared to the control, while survival was slightly higher when probiotic supplements were provided, similar to, larvae reared with no additives in the water. Regarding ingestion rate, we could not observe any effects of the use of pro-, pre- or synbiotic during the feeding period. Further analyses will investigate the influence of these gut-priming supplements at a molecular level combined with the detection of main digestive enzymatic activity (amylase, protease, lipase, phosphatase, trypsin) during the experimental period.

Introduction

Farming of salmonids has grown rapidly in Norway since its onset around 1970, and in 2017, the total production of salmonids was 1 303 352 tonnes, of which about 95% was Atlantic salmon, *Salmo salar*, and 5% rainbow trout, *Onchorhyncus mykiss* (Directorate of Fisheries, Bergen Norway). Today, fish farming is the major part of the Norwegian fisheries and aquaculture sector, which together constitutes the second largest industry of Norway, as measured in terms of export value. This growth has not come without conflicts with other users of the coastal zone, in particular with wild salmonids and salmonid fisheries due to proliferation of sea lice and genetic influence of escapees (Taranger et al. 2015), but also with other wild fish and invertebrates.

In particular saithe, *Pallachius virens* has been demonstrated to aggregate in close vicinity of salmonid cages (Bagdonas et al. 2012, Dempster et al. 2010). Farms are also interconnected due to migration by wild fish moving among farms. Excess fish pellets have been shown to a fect the fatty acid composition and taste of wild saithe (Skog et al. 2003).

The impact of delousing agents to wild crustaceans has caused great concern. Flubenzurons are orally administered agents that act by interfering with the synthesis of chitin in the salmon lice. They are effective against all crustaceans that undergo moulting, including the larval and pre-adult stages. Since the bioavailability of tefluorobenzuron in Atlantic salmon is low (approximately 10%) and the metabolism is minimal, most of the drug will be released from the fish as parent compound via faeces. Solubility of diflubenzuron and teflubenzuron in water has been demonstrated to be low, the substances associate readily with particles rich in organic content, and degradation time is slow (Samuelsen 2016). This has caused concerns on effects of in particular crustacean benthic biota, but the compounds are toxic to any species that undergo moulting in their life cycle including lobsters, crabs and shrimps.

Recently, the effects of another delousing agent, hydrogen peroxide, H2O2 has come into attention (Fang et al. 2018). It has long been viewed environmentally friendly, because it is degraded to water and oxygen. The acute effects of high concentrations of H2O2 are largely unknown, however, major differences in sensitivity between species are seen (Fang et al. 2018 and references therein).

Materials and methods

Systematic stakeholder interviews with saithe and shrimp fishermen, representatives from the aquaculture industry and managers in the public sectors were carried out. A GIS based conflict analysis (GRID, GeoReference Interactions Database, developed within COEXIST (www.coexistproject.eu) - an EU funded project) was carried out. The case study area is identical to Production Area 3 of the Norwegian coast, mainly constituted by the Hardanger Fjord and areas in its vicinity. There is a large salmon farming industry in the area, presently with 169 sites. Furthermore, the hydrography is significantly influenced by hydroelectric power plants surrounding the fjords. Three Marine Protected Areas are present.

Results and discussion

The purpose of this study was to assess the impact of fisheries and aquaculture on coastal ecosystems, as well as synergies and conflicts between these and other human activities in a Western Norwegian area with high concentration of industrialized aquaculture.

(Continued on next page)

The GIS based GRID system could be used to score conflicts and synergies among fisheries, aquaculture and environmental protection associated with geographical location. It aims to analyze and locate conflicts as well as synergies between several coastal activities. GRID calculates conflict scores and provides interaction matrices and maps, in a static vie .

The stakeholder survey demonstrated that in particular shrimp fishermen were affected by environmental changes believed to be associated with fish farming. Shrmp fishing grounds inshore were little used. The saithe fishermen gave more diverse responses. In general they reported reduced quality, in particular when large numbers of farmed salmon were present in the vicinity. Others also reported that the catches were generally high, probably due to increased biomass.

The aquaculture industry stakeholders all acknowledged that environmental constraints hampered growth, and they emphasized the need for technological development. In general farmers operating inshore considered that closed systems were the best solution, whereas some farmers believed more in offshore systems. Most companies were involved in tecnological development projects.

CORDINET AND COPERNICUS MARINE – ON THE USE OF EARTH OBSERVATION DATA FOR MARINE ENVIRONMENTAL MONITORING

Ø. Bergh, H. Wehde, V.S. Lien

Institute of Marine Research, PO Box 1870 Nordnes, NO-5817 Bergen, Norway

Introduction

Copernicus is the European Earth Observation infrastructure. As partners in the Cordinet project (Horizon 2020) we at IMR focus on: promoting and facilitating Copernicus Marine observations, particularly in the High North, and along the Norwegian coast. Aquaculture, fisheries and other marine activities are examples of users

Copernicus Marine

is a "one-stop-shop" providing freely available operational data on the state of the marine environment for use by marine managers, advisors, and scientists, as well as intermediate and end users in marine businesses and operations. The Copernicus Marine offers operationally updated and state-of-the-art products that are well documented and transparent. The European Commission's long-term commitment to the Copernicus program offers long-term visibility and stability of the Copernicus Marine products. Furthermore, Copernicus Marine offers a dedicated service desk, in addition to training sessions and workshops.

The service addresses four segments:

- Coastal and marine environment
- Marine resources
- Marine safety
- Weather, climate, and seasonal forecasting

Some examples of users:

- Ship-routing in ice-covered areas
- Support to seismic ship operations
- Ice information service
- Monitoring potential oil spills
- Predicting man-overboard drift trajectories

Parameters of particular relevance to aquaculture:

- Algal blooms, including harmful algal blooms
- Surface temperature
- Surface currents
- Seawater pH.

The CoRdiNet project is:

- An open network with five Copernicus Relays with a coordinating function on local, regional, cluster and national levels

- Supporting, promoting and stimulating digitalization and new business solutions based on earth observation data from the Coperniocus project.

- Bundling the local expertise in the Civil use of Earth observation close to the needs and offers of citizens, administration and businesses, and will share them with other Copernicus Relays, Academies and new Earth observation players.

(Continued on next page)

Three of the Copernicus Relays have a regional focus (Basilicata, University of East Midlands, Bavairia, one has a national focus (IMR) and the fifth contributres the expertise of a space application company (GMV

NEREUS the network of European Regions using Space Technologies comprises 26 regions. NEREUS is active in exploiting the benefits of space technologies while supporting European regional space policies

CoRdiNet organizes joint outreach and dissemination activities, bilateral events, and aims to link users and suppliers of services that use Earth observation data. Join CoRdiNet as an associated partner and learn from five experienced Copernicus Relays how to:

- Better understand the Earth observation related strengths and needs of your region and activity.
- Create better regional strategies and policies related to Copernicus data.
- Inform and train your public administrations and get them engaged in using Copernicus data

Watch out for the open calls for Expression of Interest on theCoRdiNet´s website www.cordinet.net

The CoRdiNet project is financed by the European Commission under the Horizon 2020 program, grant no. 8219 1.

CONSTRAINTS AGAINST GLOBAL DEVELOPMENT OF AQUACULTURE: COMPETITION FOR SPACE, RESOURCES AND SOCIETAL COMMITMENT

Ø. Bergh

Institute of Marine Research, PO Box 1870 Nordnes, NO-5817 Bergen, Norway

Introduction

Aquaculture is essential to contribute to unravelling and solving the climate-food-ocean challenges and to unlock the economic and Food and Nutrition Security (FNS) potential of the oceans. In this context, developing aquaculture is as a means to build resilience for food security, and thus, even peace. (Buck and Langdon 2017, SAPEA 2017).

The oceans cover around 70% of total Earth surface This invaluable source of area can contribute much more to both the blue economy and FNS in a changing world[15]. Aquaculture is specified as a core sector in EU's Blue Growth strategy (European Commission 2012, 2014, European Union 2014). Realizing this potential requires higher levels of economic productivity through diversific tion, technological upgrading and innovation, while simultaneously promoting societal equality and sustainable management of land, soil, inland and marine waters and engaging all food system actors. This requires the systematic utilization of knowledge, technologies and innovation throughout the aquaculture value chains. Not the least challenge is to allocate space for aquaculture activities, which was the core problem studied by the EU project Aquaspace.

Methods

Based on 17 Case studies in Europe, Asia, Australia, New Zealand, China, Canada and the USA, we studied the constraints as well as the drivers of the development of aquaculture activities. The case studies were highly different in terms of size, species and development. Some were highly industrialized and significant contributors to food security as well as local and national economy, whereas others were of smaller, and essentially local scale (Strand and Bergh 2017). Stakeholder workshops and investigations were arranged in all case studies,

Results and discussion

Today, more than 95% of the global food production comes from agriculture. Available arable land is limited, and future needs will put a strong pressure on the world´s remaining rain forests and other natural environments. The sea supports at least 50% of primary bio production, and we cannot afford to leave its resources underutilized. This situation demands increased understanding and improved management of marine ecosystems and increased efforts on sustainable aquaculture (SAPEA 2017).

Marine Spatial Planning was a key issue overarching all cases. Conflicts with other users of the coastal zone is limiting aquaculture development. The other users include (amongst others) tourism, nature protection, fisheries, energy production, and transport. The importance of different competing users is highly variable among the case studies. A general observation is that development of aquaculture is dependent on a willingness to allocate area at the expense of other users, that has to be politically and societally accepted (Galparsoro et al. 2019).

Furthermore a general observation was that co-use for different purposes, notably energy, but also tourism and marine protection areas, could reduce the level of conflict, thereby allocating more space for aquaculture, as was also discussed by the previous COEXIST project Stelzenmüller et al. 2013).

Introduction

Global warming will gradually increase the temperature of Norwegian and North European coastal waters and have significant effects on the aquaculture industry. Unlike wild fish stocks, farmed organisms are quite literally locked into specific localities, and conditions may be less suitable for the species´ physiological demands. Thus, optimal farming conditions for the species common in European and Norwegian aquaculture today are expected to gradually move northwards in a parallel shift.

In many places, fish farms will have to be relocated and/or farming technology modified in order to reduce the undesirable effects of higher temperatures. Current sites could in turn be suitable for other species than those farmed today, and cultured species that are presently farmed in Southern Europe could gradually enjoy better conditions in Norway than further south. Examples of species that may be more important in aquaculture along the North Atlantic shores are turbot, sea bass, sea bream, oysters and scallops.

Aquaculture is a relatively new industry in Norway and Northern Europe, and in contrast to the fisheries, it lacks the historical reference to, and experience with, natural changes in climatic conditions. The fisheries have adapted to natural climate cycles for centuries. (Stenevik and Sundby 2007) In contrast, the cold winters along the Norwegian coast during the early part of the 20th century would have caused severe problems for the salmon farming technology of today, if it had been present.

Furthermore, despite the dramatic global context, most models of global warming point out that the expected changes will be relatively slow in the context of industrial life-cycles. Although there is every reason to expect, and plan for, a gradual movement of the aquaculture industry northwards, there is no reason to quit salmon farming in Southern Norway tomorrow.

What can be expected?

Present-state studies of the future climate show that air temperatures will rise by 2-4°C during the 21st century. In the seas off the coast of Norway, the temperature will raise by 1.5-2.0°C (Stenevik and Sundby 2007). This implies that the temperatures presently found in Southern Norwegian coastal waters will be common along the coast of Northern Norway in a 50-100y perspective. The change in the mean temperature is however not a major obstacle for farming of the presently most important species in Southern Norway, Atlantic salmon, rainbow trout and Atlantic cod. On the contrary, culture of cold-blooded animals would in principle benefit from higher temperatures up to the point where they exceed or compromise the biological limits of the organisms.

In a biological context, the extreme temperatures may be more important than just the average temperatures, especially considering the impact of high temperatures on the immune system and the proliferation of pathogenic agents. Periods with high temperatures suboptimal to the fish will be longer, and events with temperatures higher than the biologically safe limits of the farmed species will be more common. It can be assumed that this will alter parasite-host-dynamics in a negative way for aquaculture.

(Continued on next page)

Other major effects of the expected climatic changes along the Norwegian and North European coast the next century will be increased intensity and frequency of storms and increased rain, plus a moderate increase of high tidal level. Such effects will cause a need for improved technological solutions, and significant investments may be needed. However, they do not constitute “impossible” biological or technological problems. Intense storms may, however cause damages to fish farms, and increase the with high numbers of escaped fish. However, as escapees are considered a major environmental problem, improved technological solutions must be developed and implemented, as they presently are.

Diseases

Many (but not all) diseases may occur more frequently in warmer weather, particularly bacterial infections with bacteria or parasites adapted to relatively high temperatures (Johansen et al. 2011) . Just as important as the temperature range of bacteria and parasites, is the temperature range of the cultured fish. Rearing a species at too high or low temperatures inevitably may compromise the immune system, leading to increased disease problems. For instance, important diseases such as francisellosis, vibriosis, furunculosis, as well as several viral diseases and parasites are typically associated with high water temperatures.

On the other hand, winter ulcers and cold water vibriosis are typical examples of diseases occurring in cold waters. In this context, the extreme temperatures are much more important than the middle temperatures.

Reproduction of parasites like salmon lice is temperature dependent, thus shorter generation times, and thereby increased infestation rates may be expected with higher average temperatures. Spreading of salmon lice may also be altered by increased freshwater along the coast, particularly in the fjords. Improved modelling of water movements in fjords and coastal environment in various climatic scenarios may be a useful tool for predicting changes, as is the case for predicting salmon lice migration today Asplin et al. 2014, Johnsen et al. 2016). It should be noted however, that hydroelectric power plants may have a greater impact on hydrography than the anticipated climatic changes in this century.

SALMON CAGES SUPPLIED FRESHWATER FOR CONTROL OF SEA LICE

A. Bergheim*, M. Gausen, N. Hovden, H. Grundvig and C. Barth

Oxyvision AS, Trelastveien. 8, 6652 Surnadal (Norway)
E-mail: asbjorn@oxyvision.com

Introduction

Reduced salinity has demonstrated significant effect to control infestation of two major parasites in seawater salmon cages, sea lice and the amoeba causing amoebic gill disease (AGD). Efficient treatment of AGD is achieved in low-saline water of less than 3ppt, while survival and infectivity of mobile sea lice decrease stages at < 27ppt (Powell & Clarke, 2002; Bricknell et al., 2006). The chalimus and adult lice stages are relatively resistant to low-saline water; however, freshwater treatment in well-boats for 3-8 hrs has turned out to efficient y remove lice (e.g. Haarsaker, 2013). The present study describes introduction of enclosures in salmon cages supplied freshwater as an protective attempt to control sea lice.

Materials and methods

Circular enclosures with circumference of 50m were put in large commercial net cages. Tarpaulin-covered sides from surface to 7m depth excluded horizontal mixing of water between enclosure and cage. Thus, only vertical intrusion of seawater through the open bottom area impacted the salinity of the enclosure's water column added desalinated water at the surface. The adjacent desalination unit (reverse osmosis), kept on a platform raft, produced 30 – 50 m^3 water/h and supplied two enclosures, i.e. each enclosure received 15 – 25 m^3/h. Salinity, temperature and dissolved oxygen were frequently monitored at different depths. Fish abundance measurements were performed within and outside the enclosures for 3 weeks with an echosounder system (type: CageEye).

Results and comments

The salinity was strongly fluctuating within the enclosures due to vertical flow motion and unstable production of desalinated water (Table 1). Several technical attempts, such as optimization of tarpaulin design, buoyancy capacity, oxygen injection and better power supply of the desalination process should be tested to improve the stability of the brackish water layer.

During the 3 week study period, the fish density was consistently lower inside the enclosures compared to outside. On average, the fish abundance was reduced to 31±4% in the enclosures and the fish stock also seemed to avoid the layers beneath the enclosures (14 – 18m depth). However, a notably increased abundance throughout the study may indicate that the fish gradually get used to such installations in the cage

FARMING WARMWATER FISH ON LAND IN A COLD COUNTRY – A CRAZY IDEA OR A NEW SUSTAINABLE SEAFOOD SUPPLY CHAIN?

Kristina Bergman*, Patrik Henriksson, Sara Hornborg, Max Troell, Malin Jonell, Friederike Ziegler

RISE Agrifood and Bioscience, PO Box 5401, 402 29 Gothenburg, Sweden
kristina.bergman@ri.se

Introduction
Landbased aquaculture of warm water species such as tilapia *Oreochromis niloticus*, clarias *Clarias gariepinus* and shrimp *P. vannamei* constitute an emerging food sector in Sweden. The heated sustainability debate related to both wild-caught and conventionally farmed seafood, in particular shrimp, has likely been a major driver. Several small, but fast-growing companies who profile themselves as more sustainable than conventional aquaculture have started producing seafood in recirculating aquaculture systems (RAS). Their products are marketed to environmentally conscious Swedish consumers as alternatives to salmon (tilapia), tuna (fresh clarias), eel (smoked clarias) and also to imported shrimps (*P. vannamei*)

Methods
In this study, we used Life Cycle Assessment (LCA) methodology to analyze environmental pressures of the seafood products from one of these companies. LCA is widely used to characterize the environmental impacts of product supply chains and identify improvement options and been used to evaluate numerous aquaculture production systems.

Results
We present results on environmental pressures (e.g. greenhouse gas emissions and eutrophication) for the product supply chain of tilapia and clarias farmed in Sweden and identify environmental hotspots and improvement options. We found that the feed is of paramount importance, also for this type of infrastructure- and maintenance-intensive aquaculture system. Inclusion of resource-intensive feed ingredients such as animal by-products increase the environmental footprint considerably. We also illustrate how the source of electricity for water heating and recirculation affects results. The importance of the contribution from the farming system in relation to feed production is presented. Our results identify which aspects are most important to consider in the future development. Finally, comparisons with previous LCA results for the farmed fish these products are intended to replace are presented

Introduction

Volga pikeperch is an economically important gamefish and has a great industrial potential in Central and Eastern Europe. According to former studies the meat quality is similar to the pikeperch (*Sander lucioperca*). However Volga pikeperch is less sensitive for stress and tolerate more the reduced oxygen level as well than the mentioned relative species. Its propagation has been already published (Bokor et al. 2007). However the efficiency of commercial production is needed to be improved. Cryopreservation allows the simplification of the broodstock management and can reduce the costs of the propagation and rearing process (Bokor et al. 2019, Cabrita et al. 2010). The technique also allows to help the reintroduction of natural populations of the species and to satisfy the increasing angling demand. Limited information is available regarding to sperm cryopreservation in Volga pikeperch (Bokor et al. 2007).

Materials and methods

In our study, 3 different experiments were carried out to improve the sampling process and sperm cryopreservation methods in Volga pikeperch males (*N*=39). The spermiation was hormonally induced using 3 mg bodyweight kg^{-1} of carp pituitary 24 hours prior to sampling. Sperm was collected 4 different methods according to the experimental design. The progressive motility (pMOT) in both fresh and cryopreserved samples was recorded with a CASA system (Computer-assisted Sperm Analysis, Sperm VisionTM v. 3.7.4., Minitube of America, Venture Court Verona, USA) using 50mM NaCl solution (buffered with 30mM Tris, pH: 8, Lahnsteiner et al. 2011). In our study, 3 different extenders was compared (modified Tanaka extender: 137 mM NaCl, 76.2 mM $NaHCO_3$, Bernáth et al. 2015; Pike extender: 150 mM glucose, 75 mM NaCl, 30 mM KCl, 1 mM $Na_2HPO_4 \times 12H_2O$, 1 mM $MgCl_2 \times 6H_2O$, 1 mM $CaCl_2 \times 2H_2O$, 20 mM Tris, and 0.5% BSA, pH: 8.0 ± 0.2, Várkonyi et al. 2018; Glucose extender: 350 mM glucose, 30 mM Tris, pH: 8.0 ± 0.2, Bokor et al. 2007). Diluted sperm (1:9) was loaded into 0.5 or 5mL straws. In all experiments, cryopreservation was carried out in a Polystyrene box at 3 cm above the surface of liquid nitrogen for 3 or 7 minutes according to the size of the straw (Bokor et al. 2019, Horváth et al. 2003). As cryoprotectant, 10% of methanol was used. The 0.5 mL (13 s) and 5mL (35 s) straws were thawed at 40 °C using a waterbath (Bokor et al. 2007 and 2019).

Experiment 1. The comparison of 4 different sampling methods
Sperm from 5-5 males was collected using regular stripping methods, catheter, stripping into Pike extender and squeezing of testis. Motility was compared in all groups.

Experiment 2. The comparison of 3 different extenders
The testis of 7 males was squeezed and the sperm was diluted in modified Tanaka, Pike and Glucose extenders. Samples were cryopreserved using 0.5 ml straws.

Experiment 3. The comparison of 0.5 and 5 mL straws and 2 different sampling methods at hatchery conditions
Samples were collected using squeezing and regular stripping (6-6 males). Motility was compared in both groups. Item, squeezed sperm from 5 males was loaded into 0.5 and 5 mL straws and cryopreserved in P. box.

(Continued on next page)

Results

In *Experiment 1.* the highest motility was measured in the case of the catheter (92±5%). A significantly lower movement was measured using the regular stripping method (5±7%) and using the Pike extender (8±11%) in comparison with the catheter and the squeezed testis (63±12%). In *Experiment 2.*, a significantly higher pMOT was measured in the case of modified Tanaka (40±15%) and Pike extender (25±16%) compare to the Glucose extender (2±1%). A similar movement was recorded in the control group (49±9%) and modified Tanaka extender. In *Experiment 3.* a similar pMOT was recorded with squeezed testis (68±21%) and the regular stripping method (65±35%). No significant difference was observed between the 0.5 (42±8%) and 5 (28±12%) mL straws. A significant reduction in pMOT was measured in both cryopreserved groups following thawing in comparison with the control (73±19%).

Discussion and conclusion

According to our results both the regular and catheter stripping of sperm, as well as squeezing of testis can be applicable during the propagation process. However the volume of sperm can be obtained is the highest by the squeezing method. Modified Tanaka extender and the two sizes (0.5 and 5 mL) of straws is applicable for Volga pikeperch sperm cryopreservation at hatchery condition.

UNRAVELLING CHANGES DURING INDUCED SEXUAL MATURATION OF FEMALE EUROPEAN EEL (*Anguilla anguilla*) THROUGH RNA-SEQ: WHAT HAPPENS TO THE LIVER?

Introduction

For the aquaculture industry, closing the life cycle of European eel in captivity is of interest, given the critical status of the stock. In captivity, sexual maturation can be successfully induced by hormonal treatments (Pedersen, 2003). At a biological level, sexual maturation involves the hypothalamus-pituitary-gonadal-liver axis, which generate massive changes of the physiology of the animals, also considering that the females do not eat during the maturation process. The development of high-throughput sequencing technologies can provide useful tools to investigate those changes at a whole and deep scale allowing an increasing understanding of the major biological and molecular pathways that are altered during induced vitellogenesis by determining how the expression of thousands of genes changes from immature stage to pre-spawning stage. In this work, we will focus our attention on one of the main organs involved in the maturation process, the liver.

Material and methods

The study included a total of 16 female farmed eels: 8 immature eels and 8 receiving a constant weekly dose of CPE (Carp Pituitary Extract; 20mg/body weight) to induce hepatic vitellogenesis and follicular development. Immature eels were sampled before maturation at week 0 (average weight ±standard deviation: 862 ±107.41g) and at week 9 of maturation (average weight: 901.25±50.94g). Liver and ovaries were sampled. Gonadosomatic index (GSI) and liver index (LI) were calculated and maturational state was confirmed by histological analyses.

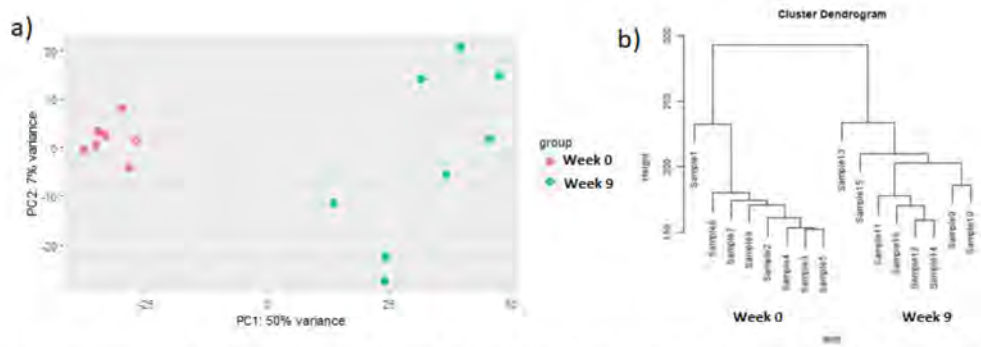

Fig 1 Principal component analysis (PCA) plot and cluster analysis of all RNA-seq samples. (a) PCA plot of all RNA-seq samples. (b) Cluster dendrogram of all RNA-seq samples. The log2-nomalized values of all the genes were used for PCA and cluster analyses.

Fig 2. Gene enrichment results of the lipid related GO terms. Green boxes represent the involvement of that gene in the function. All genes related to the GO terms were upregulated.

(Continued on next page)

RNA was extracted from liver samples, RIN (RNA integrity number) was calculated to check the integrity and the samples were sequenced with the Illumina HiSeq 2000 platform. Trimmed reads were aligned to the European eel reference genome (Henkel et al 2012) with Hisat2 (Kim et al. 2015), retaining only uniquely mapped reads. The software StringTie (Pertea et al. 2015) was used to predict transcripts, using the *in silico* genomic annotation file to increase the accuracy of the transcript prediction. Then, only transcripts with an overlapping >70% with the in-silico gene annotation were used for reading count and differential expression. Read count was performed with HTSeq (Anders et al. 2015) with intersection-strict as intersection option, after sorting the reads by name as recommended in the manual. Differential expression analysis was performed with Deseq2 R package (Love et al. 2014). Transcripts were considered differentially expressed with a Padj<0.01 and a log2fold ratio >|1.5|. Enrichment was performed with the differentially expressed genes with the tool Gorilla (http://cbl-gorilla.cs.technion.ac.il/), retaining GO (Gene Ontology) terms with $P<10^{-3}$.

Results and discussion

As an effect of hormonal treatment, average GSI increased from 1.46±0.27 in immature females to 16.75±7.04 in mature females, concurrently the LI increased from 0.78±0.11 to 1.25±0.27, showing high correlation (0.90). *RNA-seq* on liver generated approximately 20 million of paired-end reads each sample For each sample, app. 65% (±2.49 standard deviation) of the reads generated from the Illumina sequencing uniquely mapped the reference genome. The StringTie analysis identified 71,756 different transcripts and 53,319 predicted genes. Here, only the transcripts that overlap with those previously detected in silico where considered, retaining 31,632 genes. This is done because the current annotated version of the Eel genome is composed by more than the 75% of the scaffold below 1Kb, and therefore may overestimate the number of genes. With the expression level (normalized read count) of the retained genes it is possible to clearly clusterize the two groups (pre-maturation and close to spawning), as shown by both the PCA (Fig1a) and the dendrogram (Fig 1b). For the PCA analyses, the variance on the PC2 is higher across the week 9. This may indicate that, despite the same treatment and conditions at week 9, there is a higher individual variability in terms of overall gene expression.

The differential expression analyses revealed 916 differentially expressed genes (595 upregulated and 321 downregulated). Among the upregulated genes, the highest score was detected (8.09 log2fold ratio) for the vitellogenin gene (VTG1). While the expression level of this gene was anticipated to increase in the liver during eel ovarian development (Parmeggiani et al., 2015), it is interesting to notice that this gene had the highest upregulation score among the 595 upregulated genes. Furthermore, the enrichment analysis showed upregulated genes involved in lipidic metabolism, as shown in Fig 2. Other enriched pathways were mainly allocated in GO terms related with the transport of molecular components, biogenesis and multicellular organism development that includes the progression from immature stage to mature stage, where mostly of the genes detected were downregulated.

Conclusions

These results provide new insight of the molecular changes and genes/biological pathways involved at the molecular level in the liver, which help to understand the massive phenotypical changes that occur during induced maturation, where European eel do not eat but reallocate several metabolic resources.

MONITORING SHORT-TERM MICROBIOLOGICAL DYNAMICS WITH FULLY AUTOMATED ONLINE FLOW CYTOMETRY IN REALTIME

Michael D. Besmer[1]* Frederik Hammes[2] and Konstanze Schiessl

[1]onCyt Microbiology AG, Hauriweg 9, 8038 Zürich, Switzerland
michael.besmer@oncyt.com

Introduction

Microorganisms are omnipresent and crucial players in all aquatic systems and hence also in aquaculture. Mostly, they are harmless but occasionally they can have negative effects on water quality or the infrastructure itself. However, bacteria and algae are also actively used in production processes as well as water treatment. In all cases it is crucial to closely monitor these organisms and to make informed choices about whether they need to be managed and what the best options would be for that. One critical aspect in this is the tracking of microbial dynamics at short timescales (seconds to days) given that those systems are usually highly variable rather than stable over time.

Tracking of these dynamics requires sampling and analysis at very short intervals and ideally in real-time allowing for immediate interpretation/reaction. For decades this was impossible with conventional cultivation-based methods but also with advanced molecular methods, which are still too labour-intensive, time-consuming, and costly for such applications. One promising approach is the use of flow cytometry. This detection method has been adapted from medicine and has specific advantages including: rapidness, sensitivity, reproducibility, accuracy in quantification, and differentiation of total and intact cells.

Material and methods

We have developed a fully automated online flow cytometry system that overcomes the tedious and restricting practice of grab-sampling and subsequent cultivation on agar plates Besmer et al. (2014). In short, water samples were drawn directly from the water resource of interest every 15 min, mixed with a fluorescent stain, incubated, and then measured with the flow cytometer. Rinsing and extended cleaning were performed regularly and periodically respectively. The resulting large sets of flow cytometry data were batch processed with custom software.

Results

Over the last years we discovered a myriad of short-term microbial dynamics in engineered and environmental aquatic ecosystems. The high frequency, in situ measurements allowed for the detection of subtle changes in cell concentrations during measurement periods ranging from weeks to months. We detected interesting and often unexpected microbial dynamics in every investigated system at time scales from hours to weeks and bacterial concentrations levels between 10^4 and 10^7 cells ml^{-1} (Figure 1). For example, clear diurnal fluctuat ons in bacterial concentrations were linked to photosynthesis in rivers (Figure 1A), to intermittent water extraction in groundwater (Figure 1C), to varying water production rates in a drinking water treatment plant (Figure 1D), and to daily water usage in a building (Figure 1E). In addition, the influence of precipitation events and increased discharge on bacterial concentrations over time was accurately quantified in rivers (Figure 1A), springs (Figure 1B), and groundwater (Figure 1C).

Discussion and conclusion

These results boost the idea of advanced monitoring of microbial dynamics, which is critical for a better understanding of underlying causes of fluctuatio s as well as the ecological and operational consequences thereof. While originally applied for bacteria in drinking water, applications of both fresh- and saltwater are in progress looking at bacterial and algae concentrations and viability in parallel.

We expect that these findings will massively stimulate improvement of process monitoring, water treatment design and improvement (e.g., disinfection in RAS/CSS, ponds), optimisation of feed and other production processes, and conceptual approaches to smarter sampling schemes, but also open up new applied and fundamental research directions.

Introduction
The development of formulated diets and feeds is essential to increase production of farmed tuna species. Although there is limited knowledge in this area for Pacific Bluefin tuna (*Thunnus orientalis*) in Japan, no major attempts have been made with Atlantic Bluefin tuna (*Thunnus thynnus*; ABT). In the present study, two trials were performed using inert formulated diets as juvenile feeds for weaned ABT in order to establish adequate dietary levels of both lipid and omega-3 long-chain polyunsaturated fatty acids (LC-PUFA).

Materials and methods
The nutritional trials consisted of two consecutive 10-day feeding trials (A and B) with weaned 41 dah ABT juveniles, from two different batches of spawned ABT eggs. Each trial investigated two experimental extruded feeds in comparison to the commercial reference feed (MGK) to bench-mark the growth performance of the experimental feeds. In the first trial, ABT (initial weight = 2.9±0.9g) were fed for 10 days with either MGK or two experimental feeds, differing in dietary lipid levels (15 or 20%), using krill oil (KO) as the sole lipid source in order to estimate the optimal lipid content. In the second trial, fish (initial weight = 3.3 ± 0.6g) were fed either MGK, 15KO or a feed containing 15% lipid with a combination (1:1, v/v) KO and rapeseed oil (RO) (15KORO). At the end of each experimental trial samples of liver were collected for lipid and molecular analysis.

Results
In Trial A, fish fed MGK displayed the highest growth, followed by 15KO, with 20KO displaying the lowest growth although no differences were found in terms of fish survival. Thus, a lipid content of 15% was considered better than 20% for ABT juveniles. In Trial B, fish fed 15KO and 15KORO showed the highest growth in terms of weight and fork length (including weight gain and SGR). Increasing dietary lipid level or adding RO to the feeds did not increase liver lipid content as compared to 15KO. The liver fatty acid profile largely reflected dietary intake confirming very limited LC-PUFA biosynthetic activity for this teleost species. Consequently, the liver of fish fed 15KO and 20KO displayed the highest contents of docosahexaenoic acid (DHA). The hepatic expression of genes for lipid and fatty acid metabolism, transcription factors, and antioxidant enzymes was investigated with many of the genes showing regulation by both dietary lipid and LC-PUFA contents.

Discussion and conclusion
The present study showed promising results that suggest ABT juveniles can be grown on inert dry feeds that support good fish growth and the accumulation of the health-promoting fatty acid DHA. Results from the trials indicate that diets with relatively high protein to lipid ratios of between 3 and 4 could support good growth of juvenile ABT. Diet had no significant impact on survival, partly due to high variability among treatments. In the present study, liver fatty acid profiles generally reflected those of diets, as shown previously in other fish studies (Betancor et al. 2014; Araújo et al. 2017). This clearly indicates that, despite being relatively short, the feeding trials were sufficiently long in these very fast growing animals to result in changes to the biochemical composition that would be expected in fish doubling their weight

(Continued on next page)

In conclusion, the present study suggests that ABT juveniles can be grown on inert extruded dry feeds that result in good fish growth and accumulation of the health-promoting fatty acid DHA. Furthermore, a blend of VO and KO could be used as the dietary lipid source up to a dietary lipid level of 15 % without affecting fish performance. The expression of lipid metabolism genes in ABT liver showed a different response to dietary lipid level/fatty acid profile, consistent with previous data indicating limited n-3 LC-PUFA biosynthetic capability in ABT. However, gene expression showed some differences between the two trials, which highlight how the genetic background of different batches of ABT juveniles could affect the regulation of metabolic gene expression and thus be a factor in weaning success. The expression of antioxidant enzymes was also altered by diet, related to dietary contents of antioxidant nutrients. Thus, further studies are required in order to fully elucidate the lipid and fatty acid requirements of this iconic species in relation to dietary sources and production costs.

Introduction

There is a growing gap between the supply and demand of omega-3 (n-3) long chain polyunsaturated fatty acid (LC-PUFA)-rich fish oils (FO) for use in aquaculture, and so sustainable alternative supplies of these health-promoting fatty acids are required. Although vegetable oils (VO) have been used, they are characteristically rich in C_{18} PUFA but lack the n-3 LC-PUFA, eicosapentaenoic and docosahexaenoic acids (EPA and DHA, respectively), which compromises the nutritional quality of the farmed product. One viable alternative is to use oilseed crops that have been metabolically engineered with the capacity to synthesize EPA and DHA. One such crop, *Camelina sativa*, has been genetically modified using algal genes in order to produce seed oils containing EPA+DHA. The aim of the present was to evaluate the new GM Camelina-derived oil as substitute for FO in feeds for sea bass (*Dicentrarchus labrax*), known to have a very limited capacity to biosynthesize LC-PUFA.

Materials and methods

The EPA+DHA Camelina oil was evaluated in sea bass (16.7 ± 0.09 g, initial weight) in a 16-week feeding trial in triplicate tanks (3 treatments x 3 tanks = 9 tanks, each with 50 fish). The transgenic Camelina oil was compared with a commercial control and a diet containing levels of EPA+DHA similar to those found in the GM-Camelina derived oil diet (3 treatments). Diets were isolipidic and isoproteic using non-defatted fishmeal and plant meals as the protein source which fulfilled fish nutritional requirements. Fish were acclimated to the experimental tanks for two weeks and fed a commercial feed prior to the onset of the experimental feeding period. Fish were kept at a light cycle of 12 h light and 12 h dark and hand-fed to satiety. At the end of the dietary trial, a total of 8 fish per tank (n = 24 fish per treatment) were sacrificed. Two fish were sampled from each experimental tank (2 fish x 3 tanks = 6 fish per treatment) for whole proximate analysis. Muscle, intestine, brain and liver were removed from another six fish per dietary treatment (two per tank; n = 6 fish per treatment) and frozen for fatty acid analysis.

Results

All the experimental feeds were accepted by the fish, more than doubling their weight at the end of the experimental trial. No differences were observed in fish total or fork length ($p = 0.088$ and 0.117, respectively), weight ($p = 0.179$) or specific growth rate ($p = 0.204$). Similarly, no differences in survival were observed ($p=0.867$) at the end of the experimental trial, being over 95%. Tissues generally reflected the fatty acid composition of the diets, with liver showing certain biosynthetic capacity that was also reflected in the gene expression analysis

Discussion and conclusion

Previous trials in marine fish that completely replaced FO with VO in feeds resulted in reduced growth that was probably related to a reduced intake of essential LC-PUFA, which are not found in VO (Fountoulaki et al., 2009). In the present study we evaluated the complete substitution of FO by an oil obtained from a GM-oilseed crop in sea bass feeds. The GM-derived oil proved to be an effective substitute for FO, displaying growth rates that were similar to those achieved by control fish fed different diets containing blends of FO and VO. Similarly, recent studies employing GM-derived oil as substitutes for FO in both Atlantic salmon (*Salmo salar*) (Betancor et al., 2015; 2016a; 2017; 2018) and gilthead sea bream (*Sparus aurata*) (Betancor et al., 2016b) feeds showed that fish fed these oils were as successful as those fed FO. In summary, the genetically engineered Camelina oil was shown to be a viable source of n-3 LC-PUFA and a potential candidate to replace FO in feeds for sea bass.

Introduction
In order to optimize Atlantic bluefin tuna (*Thunnus thynnus*, L.; ABT) production, further knowledge of the nutritional requirements of the species is pivotal, and understanding biological mechanisms of nutrient assimilation in larvae is a key area. Taurine appears to be a crucial nutrient for teleosts, especially top predator species such as ABT. While dietary taurine supplementation has been highly recommended, studies on taurine assimilation and biosynthesis are lacking for this iconic species. The present study aims to provide insight into the molecular mechanisms involved in taurine biosynthesis and transport in ABT by determining tissue distribution and ontogenetic development of expression of enzymes involved in taurine synthesis and metabolism: cysteine dioxygenase (*cdo*), cysteine sulfinic acid decarboxylase (*csad*), 2-aminoethanethiol dioxygenase (*ado*) and taurine transporter (*tauT*). Additionally, the expression levels of these genes in response to graded levels of dietary taurine supplementation was also studied.

Materials and methods
Samples of ABT tissues including brain, gills, heart, kidney, spleen, liver, intestine, white muscle, red muscle, adipose tissue, ovary and testis were obtained from broodstock tuna for tissue distribution of taurine metabolism genes. ABT larvae in the standard production protocol were sampled at 1, 13, 15, 18, and 25 days after hatch (dah) to determine the expression of taurine metabolism genes during early ontogenesis. Tissue and larvae samples were collected and processed in RNALater®. For the taurine nutritional trial, ABT larvae were fed from 2 to 14 dah with rotifers enriched with either 0.0 g (tau0), 0.5 g (tau05), 1.0 g (tau1) or 2.0 g (tau2) taurine per 10^6 rotifers. Samples of ABT larvae and tissues (n=6, 50 ABT larvae per replicate) were used for molecular analysis. Sequences of genes encoding for taurine metabolism (*tauT*, *cdo*, *ado* and *csad*) were obtained by identifying their sequences on SRA and primers designed for quantitative analysis (qPCR) plus antioxidant enzymes, digestive enzymes and housekeeping genes. Taurine and amino acids were determined in rotifers and ABT larvae by the Waters UPLC® AccQ-Tag Ultra Method®.

Results
Rotifers effectively accumulated taurine with ABT larvae fed treatment tau2 attaining the highest concentration of taurine. However, ABT larvae fed tau1 (3.7 mg taurine g^{-1} rotifer) displayed higher growth, survival and flexion index at 14 dah, than larvae fed the other taurine levels. The full open reading frame (ORF) for *cdo* and partial sequences for *csad*, *ado* and *tauT* were obtained, with the translated polypeptides being 202, 176, 166 and 324 amino acids, respectively. All three showed characteristics such as cupin motifs in Cdo and predicted N-glycosylation sites in Taut that are common to these genes in other species. Phylogenetic analysis showed that the ABT sequences clustered with sequences of other teleosts, and separately from mammals and molluscs. Tissue distribution varied, with adipose tissue, kidney, white muscle and testis/brain showing highest expression of *cdo*, *csad*, *ado* and *tauT*, respectively. Whole larvae expression of *csad* peaked at 15 dah, whereas the other genes generally increased throughout development to show highest expression at 25 dah. Larvae fed tau1 also showed generally higher expression of *tauT* and *cdo* and digestive and antioxidant enzyme genes.

Discussion and conclusion
In summary, the present study indicated that ABT larvae possess enzymes necessary for the biosynthesis of taurine through the two main pathways. The three enzymes and the taurine transporter showed differential tissue expression and could be detected before the onset of external feeding. Expression of the biosynthesis enzymes was not obviously regulated by dietary taurine level, possibly indicating a nutritional requirement for this nutrient. In contrast, *tauT* expression was upregulated when dietary levels of taurine were low, indicating a role for this gene in maintaining taurine levels in muscle and taurine homeostasis in ABT. Rotifers supplemented with taurine at 1 g per 10^6 rotifers improved the growth of ABT larvae, without affecting final survival. In conclusion, despite the presence of taurine biosynthesis genes, ABT larvae required a supply of dietary taurine at around 3.7 mg g^{-1} feed (rotifer; tau1) in order to ensure adequate growth and development.

Although fish meal (FM) has been considered the most preferred protein source in aquafeeds because of its high degree of utility by fishes, intense focus has been given on the reduction and/or elimination of FM protein over the past several decades due to its high price and insufficient supply. FeedKind (FK, Calysta, Inc., CA, USA), which is primarily comprised of the methanotroph, *Methylococcus capsulatus,* is considered as a promising alternative due to its high protein content (~70%). Its utility was determined in yellowtail, *Seriola quinqueradiata*, which is one of the most important marine species in Japan.

Two trials were carried out in this study to find out optimal replacement level of FM by FK. In Trial 1, six iso-energetic diets were prepared as follows: control diet (C) with FM as protein source, and FM of diet C was replaced at 25, 50, 75 and 100% by FK and subsequently referred to as FK25, FK50, FK75 and FK100, respectively. In another diet, 3% of FK in diet FK100 was replaced by enzyme-treated FM (EFK). Fifteen fish of mean weight ca. 126g were randomly distributed into each of eighteen 500 L circular tank and set in triplicate for each treatment. Fish were fed to apparent satiation with the experimental diets twice per day at 09:00 and 15:00, 6 days per week, for 8 weeks. In Trial 2, seven iso-energetic diets were prepared as follows to further confirm the optimal replacement level: diet C similar to Trial 1, and FM of diet C was replaced at 20, 25 and 30% by FK and referred to as FK20, FK25 and FK30, respectively. FK from diet FK25 was replaced either by further grinding FK (FK25J) or slightly lower digestible FK (FK25L). Furthermore, 3% of FK in diet FK25 was replaced by enzyme-treated FM and referred to as EFK. Ten fish of mean weight ca. 80 g were randomly distributed into each 500 L circular tank in triplicate for each treatment and fed to apparent satiation with the experimental diets twice per day at 09:00 and 15:00, 6 days per week, for 8 weeks.

In Trial 1, all growth parameters and nutrients retention efficie cy showed similar pattern and no significant differences were observed between fish fed with diets C and FK25 ($P>0.05$). However, other experimental diets showed significantly lower growth performance compared to diet C, and enzyme-treated FM could not stimulate the performance ($P<0.05$). When differently processed FK was used and feed formula was slightly adjusted in Trial 2, even diet FK30 (30% of FM by FK) together with all other experimental diets produced similar results compared to the control group and there were no significant differences in the growth performance, nutrients digestibility and retention efficienc , except for lipid retention. Again, enzyme-treated FM could not significantly improve the growth performance ($P>0.05$). Overall, the results suggest that 30% of FM can be replaced by FK used in this study without compromising the growth performance of yellowtail.

LARGE-SCALE CULTIVATION OF SEAWEED IN WEST CORK: AN IRISH SUCCESS STORY

Silvia Blanco González*, Fiona Wanjiku Moejes and Julie Maguire

Bantry Marine Research Station Ltd., Gearhies, Bantry, Co. Cork, Ireland, P75 AX07
E:mail: sblanco@bmrs.ie

Background
Rich in bioactive compounds including antioxidants, soluble dietary fibers, proteins, minerals, vitamins, phytochemicals, and polyunsaturated fatty acids, the potential of seaweed as food stretches beyond its use in Japanese cuisine. Seaweed has played a role in Irish cuisine for centuries; ranging from the use of carrageen (*Chondrus crispus*) in jelly-like puddings, to the use of dulse (*Palmaria palmata*) in baking (Indergaard and Minsaas, 1991). In the past, the seaweed biomass was primarily sourced from beach-cast seaweed, an unreliable method for any large-scale production of seaweed-based foods .

Globally, over 95% of all harvested seaweed is sourced from seaweed farms, with China producing approximately 47% of all seaweed biomass (FAO, 2018). However, the seaweed farming industry in Europe is still in its infancy, with less than 3% of the seaweed biomass produced in Europe coming from cultivation activities (Skjermo *et al.*, 2014). Although small in comparison to the global market, Europe has a unique set of assets envied by market leaders such as China, including an Atlantic coastline that harbours more than 3 000 seaweed species in nutrient-rich and clean waters, providing a stockpile of high diversity and high quality biomass.

Seaweeds can be produced in mono-culture or integrated aquaculture systems, on-land (using tanks or raceways) and at-sea (using long-line structures) (Pereira and Yarish, 2008). In Europe, the production of kelp (brown seaweeds e.g. *Alaria*, *Saccharina*, *Laminaria*, etc.) follows the same techniques used in Asia. Basically a) collection of fertile sporophytes; b) production of microscopic gametophytes in land facilities and seeding of lines/ropes with fertilized zygotes; c) germination of the plants until a certain size and transfer of these substrates with young blades to open-water sites; d) grow out phase at-sea in long-lines until harvest.

Globally, the seaweed bioeconomy is expected to rapidly increase to an estimated US$17.6 billion by 2021. In Ireland, the Sea Change Strategy stated that they aimed for the seaweed sector to reach a market size of €30 million by 2020 (Heffernan, 2006). However, wild seaweed stocks simply will not be able to fulfil the demand. Therefore, we must turn to cultivated or "farmed" seaweed.

Bantry Marine Research Station Ltd (BMRS), based in the south-west of Ireland, is one of the only institutions with a large-scale at-sea seaweed farm in Europe. Based on a 6-hectare site, BMRS currently cultivates over 10 tonnes (wet weight) of *Alaria esculenta* on long-lines in Bantry Bay annually. *A. esculenta* contains various high-value compounds, including fucoxanthin and phlorotannins, with the potential to enhance both human and animal nutrition and general well-being. However, optimal deployment and harvesting dates of the long-lines must be identified in order to optimise the cultivation of *A. esculenta* for these high-value bioactives.

Methods
Long-lines were deployed in a staggered manner in the autumn/winter of 2017 (year 1) and 2018 (year 2), and sampled at intervals during the spring of 2018 and 2019. Morphological and biomass data was collected for each sample point. Fucoxanthin was extracted and characterised using UHPLC methods (completed for year 1 only). Antioxidant activities of both compounds were also determined (completed for year 1 only).

A method for analysing phlorotannins (membrane-bounds and cytoplasmic) is being developed.

Results
Highest biomass was found in the ropes deployed last (09/12/2017; year 1) and harvested on 28/05/2018. The average weight was 12kgs per 1m of line (wet weight) when harvested. A general observation was that the weight increased over time, but the length of the blades reached their maximum at the beginning of May (2.25m), after which they became broader rather than longer.

(Continued on next page)

Initial analysis of the biomass in year 2 indicates a higher yield overall, with the highest biomass found in the ropes deployed last (11/12/2018). In general, the *A. esculenta* showed a faster growth rate in year 2 with longer blades on average than those in year 1.

For year 1, fucoxanthin levels were highest in the rope deployed last (09/12/2017) and harvested on 05/05/2018, three weeks before final harvest.

The results also indicated that freeze-dried samples had a more consistent moisture content and had a higher fucoxanthin content when compared to oven-dried samples.

Conclusions

Based on the results of year 1, delayed deployment of the long-lines provided better overall yields. Furthermore, the fucoxanthin levels observed were comparably higher than those reported.

The project is in its second year, and analysis on the biomass from the year 2 sampling timepoints are due to be completed in July/August of 2019.

Introduction

Recirculating aquaculture systems (RAS) are a promising technology of fish production to reduce aquaculture environmental impact by reducing water usage, optimizing waste management and nutrient recycling (Martins et al., 2010). Water recirculation relies on the stability of physical, chemical and biological processes to improve biosecurity. Disruptions can cause fish disease outbreaks by opportunistic pathogenic bacteria. The beneficial bacterial community used to treat fish metabolic waste that is released into the water is still a challenging area to monitor. Next Generation Sequencing (NGS) technologies have permitted a deeper understanding of its diversity and abundance (Martínez-Porchas & Vargas-Albores, 2017). The aim of this study was to characterize the water microbiota across the different sectors of a sole (*Solea senegalensis*) RAS unit, and understand its relation with the water quality parameters.

Materials & Methods

Samples were collected from an established aquaculture production unit with four main systems: Open System inlet (OS), Breeding Stock (BS), Weaning (W2) and Pre-Ongrowing (PO). The later three are independent systems; BS and W2 are kept at salinity 35 while PO is kept at salinity 15. Water was filtered into Sterivex™ Filter Units with a 0.22µm Millipore Express (PES) membrane for DNA extraction. DNA extraction was performed with PowerWater Sterivex™ DNA Isolation Kit, extracted DNA was quantified by Qubit™ 4 fluorometer with a required concentration higher than 5ng/µL. Samples were prepared for Illumina Sequencing and sequence data was processed at Genoinseq (Cantanhede, Portugal). Sequences were then processed by the NGS analysis pipeline SILVA rRNA gene database project (SILVAngs 1.3) (Quast et al., 2013). In addition, water was characterized in terms of temperature, salinity and pH provided by the production daily monitoring.

Results & Discussion

In the sole hatchery in study, *Proteobacteria* and *Bacteroidetes* were the most abundant phyla in the diverse water compartments examined, with reported abundancies between 34-87% and 7-55%. They are followed by *Chloroflexi* (0.1-21%), *Patescibacteria* (0.1-15%) and *Planctomycetes* (1-5%). The bacterial community structure appears stable in the different sampling points belonging to the matching RAS system (Figure 1). A different observation was found when linking the three independent systems analysed, with PO being led by the genera *Leucothrix* and *Pseudoalteromonas*; the BS by *Polaribacter* and an uncultured *Cryomorphaceae*; and W2 by *Tenacibaculum* and an uncultured *Ardenticatenaceae*. The dominating genera in the OS were *Novosphingobium* and *Pseudoalteromonas*. Changes in microbiota composition appear to be connected with shifts in salinity, besides with other water quality parameters. Current work is focused on the description of the relations between the microbiota community and the environmental parameters, as well as on the relation between different microbiota groups with significance for water quality and fish welfare. We aim to add relevant data for the definition of the core microbiome diversity and structure of a healthy and beneficial community in this particular aquaculture unit, so we can determine ideal conditions for fish welfare and environmental sustainability of the production.

A PRACTICAL SWIMMING ACTIVITY FOR THE EUROPEAN SEA BASS CULTURE (*Dicentrarchus labrax*): EFFECT ON GROWTH AND METABOLISM

Fernández-Borràs J, Perelló M, Yu S, Sánchez-Moya, A, Gutiérrez J and Blasco J*

Department of Cell Biology, Physiology, and Immunology, Faculty of Biology, University of Barcelona. Av. Diagonal 643, 08028 (Barcelona, Spain)
Email: jblasco@ub.edu

Introduction

Sustained but moderate swimming enhances growth in diverse fish species, even in early phases of culture, as we have observed in gilthead sea bream (Blasco et al., 2015). The swimming speed for optimal grow may be near optimal swimming speeds, according to Palstra and Planas (2011), where the cost of transport is lowest and the energetic efficiency highest. In sea bass yearlings, the improvement of growth through swimming activity has not yet been established. The main objective of this work focused on (1) the energy cost of sustained swimming, (2) the effect on growth and (3) on the metabolism of sea bass yearlings.

Materials and methods

Determination of a practical swimming speed for sea bass culture

Swim tests were conducted in a swim tunnel with an intermittently closed respirometer (Loligo system). Seven groups of five fish (5g mean body weight, 6 cm total length) were allowed to habituate for more than 30 minutes at a swimming speed around 0.25 BL·s^{-1} until oxygen consumption (MO_2) stabilized. Measures were taken at 0.5, 1, 1.5, 2, 3, 4, 5, … BL·s^{-1} for 15 minutes at each step, until one of the fish could no longer swim against the flo . Maximum O_2 consumption (MO_2max) was determined; the routine metabolic rate (MO_2r) was calculated from the exponential curve at zero speed, and aerobic metabolic scope (AMS) calculated as the difference.

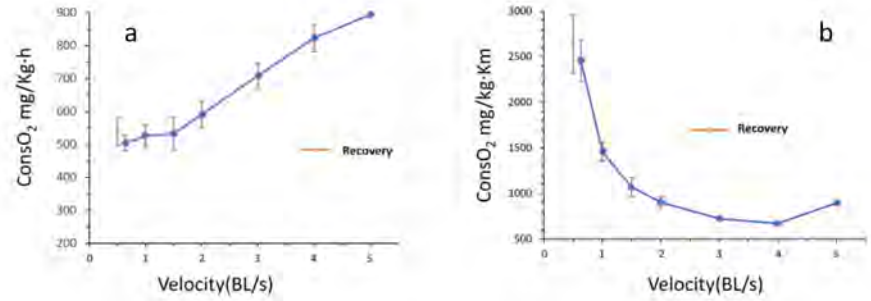

Figure 1. a) O_2 consumption rate (MO_2) and b) Cost of transport at different swimming speeds. Values are mean ± s.e.m. N=7 groups of five fingerlings.

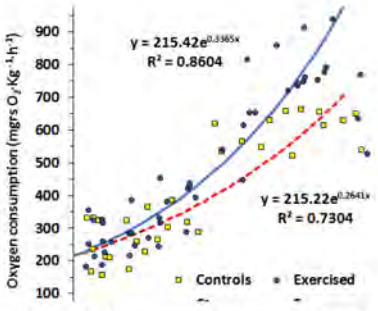

Figure 2. O_2 consumption rate (MO_2) of individual sea bass after 42 days of sustained swimming (EX) or voluntary activity (CT).

Table I. Effect of 6 weeks of sustained swimming on aerobic capacities of sea bass.

	CT (control)	EX (exercise)
MO_2 routine	215.4	215.2
MO_2 max	648.3	820.4
Aerobic scope*	432.9	605.2

aerobic capacities (Figure 2, Table I).

* MO_2 max - MO_2 routine (in mgrs O_2·Kg $^{-1}$·h^{-1}). N=6

(Continued on next page)

Swimming effects on the growth performance

Six-hundred sea bass fingerlings (3-4 g body weight) were randomly distributed into eight 200L, 60 cms diameter circular tanks (1.5 $kg \cdot m^{-3}$) and maintained during 6 weeks into a semi-closed recirculation system (22°C, 12L:12 D photoperiod). Four tanks (control group, CT) were kept on a water vertical flux, where fish movement was voluntary. Other four tanks were on a circular flux equivalent to 1.5 $BL \cdot s^{-1}$ of the initial total length (exercise group, EX). Fish were fed a commercial diet three times a day to apparent visual satiety. Feed intake and growth were recorded daily, and growth fortnightly. After 42 days, 12 fish per group were anesthetized, euthanized, and samples of white muscle were frozen in liquid N_2 and stored at -80ºC. White muscle main components (protein, lipid and glycogen) and their recycling by increasing $\delta^{13}C$ and $\delta^{15}N$ isotopic composition were analyzed, together with the genes expression and the enzyme activities of citrate synthase and cytochrome c oxidase.

Swim test response of untrained and trained fis

Six untrained and 6 trained fish were assayed as described before, and swimming performances and oxygen consumptions were compared.

Results and Discussion

Oxygen consumption increased slowly until 1.5 $BL \cdot s^{-1}$ and linearly until 4 $BL \cdot s^{-1}$. The slope change at 5 $BL \cdot s^{-1}$ shows that part of energy was supplied by anaerobic metabolism (Figure 1a). The cost of transport also changed its slope around 1.5 $BL \cdot s^{-1}$

(Figure 1b).

At the end of the experimental growth period (6 weeks), no significant differences were observed in final body weight, condition factor and growth indexes between control and swimming groups (CT, EX). Higher white muscle RNA/DNA ratio (+ 40%) and COX/CS ratio (+30%) suggested improvements of the protein synthetic capacity and of the functional mitochondria adaptation, respectively. ^{15}N-white muscle isotopic fractionation ($\Delta^{15}N = \delta^{15}N$ muscle - $\delta^{15}N$ diet) significantly decreased in swimming fish (CT: 2.0±0.04; EX: 1.7±0.06*** in ‰) suggesting protein sparing effect, as it was seen in swimming gilthead sea bream (Blasco et al., 2015). Moreover, fish swimming at 1.5 BL/s for 6 weeks significantly increased their aerobic capacities (Figure 2, Table I).

Conclusions

Sea bass fingerlings maintained at a practical swimming speed of 1.5 $BL \cdot s^{-1}$ expanded their aerobic capacity and showed white muscle metabolic changes related to potential improvements in the use of nutrients.

THE IMPACTS OF BIOFOULING CONTROL MEASURES ON FISH HEALTH AND INFRASTRUCTURE, AND HOW TO MITIGATE THEM

Nina Bloecher*, Kevin Frank, Lionel Eisenhauer, Morten Bondø, Oliver Floerl

SINTEF Ocean, P.O.Box 4762 Sluppen, 7465 Trondheim, Norway
E-mail: Nina.Bloecher@SINTEF.no

Biofouling, the unwanted growth of organisms on cage nets and other farm infrastructure, is a major challenge in aquaculture. If left untreated, it can impact fish health and welfare and affect farm integrity. To control the growth of algae, hydroids, and similar fouling organisms, nets are often coated with antifouling paint and cleaned regularly using high-pressure washers. This strategy is not only labour intense, costly, and environmentally problematic, but especially net cleaning entails risks for fish health and welfare and reduces the life-time of the applied coatings.

In multiple studies we assessed the risks of net cleaning: the release of cleaning waste particles and the abrasive treatment of the net surface. Our results show that cnidarians in the cleaning waste can damage the gills of cultured salmon, likely contributing to the dire gill health situations seen at many farm sites. An analysis of the spreading of the cleaning waste indicates that the harmful particles are not confined to the cleaned cage but can be distributed as far as to adjacent farm sites.

In addition, our experiments showed that washing of nets using high-pressure cleaners leads to abrasion of the antifouling coating, damaging as much as 30% of the coating in a single cleaning event and eventually removing almost all the coating during the grow-out season.

To address these risks and to support the sustainable growth of the aquaculture industry, novel biofouling control strategies are needed. To this end, we tested the efficacy of several coatings suggested as more environmentally friendly alternatives to today's copper coatings. However, none of the coatings based on alternative biocides or biocide-free components could compete with classic copper coatings. Thus, net cleaning remains the most important tool for non-biocidal biofouling control. Results from a study assessing novel net cleaning technologies indicates cavitation-based cleaning as an equally efficient but less abrasive alternative to high-pressure cleaning. While this technology has the potential to solve some of the challenges in aquaculture biofouling control, others remain and encourage further research in this area.

Based on the results of our latest research, current knowledge gaps will be discussed to indicate future research needs.

WHAT MAKES A FISH EGG ABLE TO BE FERTILIZED AND SUBSEQUENTLY DEVELOP INTO AN EMBRYO: NEW INSIGHTS FROM CRISPR/CAS9 GENOME EDITING IN MODEL SPECIES

Caroline T. Cheung, Thaovi. Nguyen, Stéphanie. Gay, Amélie Patinote, Emilie Cardona, Violette Thermes, Julien Bobe

INRA, UR1037 Fish Physiology and Genomics, F-35000 Rennes, France
Julien.bobe@inra.fr

Introduction

The control of egg quality is a recurring question and a major issue in aquaculture for both traditional and new aquaculture species. Numerous studies in many different species have stressed the diversity of factors than can possibly impact the ability of the eggs to be fertilized and subsequently develop into a viable embryo. Our understanding of the mechanisms behind egg quality defects, including lack of fertilization and early embryonic failure, remains however still incomplete. In order to better understand the molecular processes that control egg quality, we have initiated a series of experiments to document the importance of various molecular factors (messenger RNAs and non-coding RNAs) for a fully fertilizable and viable egg using a genome editing approach in model fish species

Material and methods

Experiments were fully approved by INRA institutional and CREEA ethics committees and conducted using zebrafish (*Danio rerio*) or medaka (*Oryzias latipes*), two model species with short generation times and daily spawning. Candidate genes for genome editing (i.e. knock-out) were selected due to their predominant expression in the ovary in fish and, in some cases, in other vertebrates, including mammals. This strategy was applied to the following genes: *nucleoplasmin 2a* (*npm2a*), *nucleoplasmin 2b* (*npm2b*), micro RNA 202 (miR-202), *forkhead box R1*(*foxr1,* formerly known as *foxn5*), *OTU deubiquitinase with linear linkage specificity a* (*otulina*), and *solute carrier family 29, member 1a* (*slc29a1a*). Mutations (nucleotide insertions/deletions) in target genes were generated using CRISPR/Cas9 with one or several targets depending on gene size. When possible, homozygote -/- females were generated and used for reproductive phenotyping. Whenever it was not possible to transmit the mutation to the next generation, because of heavily impaired reproductive success, phenotypes were assessed in eggs produced by F0 females after checking that corresponding target transcripts were significantly knocked down

Results

In the case of *otulina* and *slc29a1a*, eggs originating from mutant zebrafish females exhibiting a knocked-down expression of target genes could not be fertilized. Similarly, mutant *npm2a* females produced eggs that were not cellularized, a phenotype resembling previously described unfertilized eggs (Cheung et al., 2018a)two npm2 (npm2a and npm2b. A similar phenotype was observed in miR-202 -/- mutant medaka females that also exhibited a dramatically reduced number of eggs per spawn and were therefore infertile or subfertile (Gay et al., 2018). In the case of *foxr1*, mutant female zebrafish produced eggs that could be fertilized but did not develop or developed abnormally and systematically died within 24h post fertilization (Cheung et al., 2018b)but the role of foxr1 in reproduction is unknown. Evolutionary history of foxr1 in vertebrates was examined and the gene was found to exist in most vertebrates, including mammals, ray-finned fish, amphibians, and sauropsids. By quantitative PCR and RNA-seq, we found that foxr1 had an ovarian-specific expression in zebrafish, a common feature of maternal-effect genes. In addition, it was demonstrated using in situ hybridization that foxr1 was a maternally-inherited transcript that was highly expressed even in early-stage oocytes and accumulated in the developing eggs during oogenesis. We also analyzed the function of foxr1 in female reproduction using a zebrafish CRISPR/cas9 knockout model. It was observed that embryos from the foxr1-deficient females had a significantly lower survival rate whereby they either failed to undergo cell division or underwent abnormal division that culminated in growth arrest at around the mid-blastula transition and early death. These mutant-derived eggs contained dramatically increased levels of p21, a cell cycle inhibitor, and reduced rictor, a component of mTOR and regulator of cell survival, which were in line with the observed growth arrest phenotype. Our study shows for the first time that foxr1 is an essential maternal-effect gene and may be required for proper cell division and survival via the p21 and mTOR pathways. These novel findings will broaden our knowledge on the functions of specific maternal factors stored in the developing egg and the underlying mechanisms that contribute to reproductive success.”,”DOI”:”10.7717/peerj.5534”,”ISSN”:”2167-8359”,”note”:”PMID: 30155373\nPMCID: PMC6109588”,”journalAbbreviation”:”PeerJ”,”language”:”eng”,”author”:[{“family”:”Cheung”, ”given”:”Caroline T.”},{“family”:”Patinote”,”given”:”Amélie”},{“family”:”Guiguen”,”given”:”Yann”},{“family”:”B

obe","given":"Julien"}],"issued":{"date-parts":[["2018"]]}}],"schema":"https://github.com/citation-style-language/schema/raw/master/csl-citation.json"} . Finally, *npm2b* mutant zebrafish females produced eggs that could be fertilized but developed abnormally and systematically died within 24h post fertilization (Cheung et al., 2018a)two npm2 (npm2a and npm2b, a phenotype consistent with our prior observations showing a developmental arrest at mid-blastula transition when maternally-inherited npm2b mRNA were blocked using morpholino injection in the eggs (Bouleau et al., 2014)but this maternal effect has never been demonstrated in nonmammalian species. A link between developmental competence and the abundance of npm2 maternal mRNA in the egg was previously established using a teleost fish model for egg quality. The importance of maternal npm2 mRNA for egg developmental competence remains unknown in any vertebrate species. In the present study, we aimed to characterize the contribution of npm2 maternal mRNA to early developmental success in zebrafish using a knockdown strategy. We report here the oocyte-specific expression of npm2 and maternal inheritance of npm2 mRNA in zebrafish eggs. The knockdown of the protein translated from this maternal mRNA results in developmental arrest before the onset of epiboly and subsequent embryonic death, a phenotype also observed in embryos lacking zygotic transcription. Npm2 knockdown also results in impaired transcription of the first-wave zygotic genes. Our results show that npm2 is also a maternal effect gene in a nonmammalian vertebrate species and that maternally inherited npm2 mRNA is crucial for egg developmental competence. We also show that de novo protein synthesis from npm2 maternal mRNA is critical for developmental success beyond the blastula stage and required for zygotic genome activation. Finally, our results suggest that npm2 maternal mRNA is an important molecular factor of egg quality in fish and possibly in all vertebrates.","DOI":"10.1095/biolreprod.114.119925","ISSN":"1529-7268","note":"PMID: 25009208","journalAbbreviation":"Biol. Discussions and conclusions

Together, our results shed new light on the molecular processes behind fertilization and early embryonic development in fish. Here we reveal the importance of several genes (*otulina, slc29a1a, npm2a,* and *miR-202*) that are required for the production of fertilizable eggs. We also confirm the critical role of maternally-inherited *npm2b* for early embryonic development in consistency with the differential abundance of npm2b mRNA in eggs of varying quality in rainbow trout (*Oncorhynchus mykiss*) (Aegerter et al., 2005)14, and 21 days later. For all 56 collected egg batches, an egg sample was fertilized to estimate egg quality by monitoring embryonic development. Remaining eggs were used for RNA extraction and subsequent real-time PCR analysis. A significant drop of egg quality was observed when eggs were held in the body cavity for 14 or 21 days post-ovulation (dpo and report the key role played by *foxr1* in determining the ability of the eggs to support early development, once fertilized. Further investigations are in progress to understand how environmental factor and/or husbandry practices can impact egg quality through the modulation of the above studied genes.

Together, our observations indicate that the mechanisms defining egg formation involved evolutionary conserved players, not only among fish but also in vertebrates. Complementary investigations have been initiated to further study additional evolutionary conserved ovarian predominant genes, including molecular partners of nucleoplasmin. Finally, the major decrease in egg production and quality observed in KO miR-202 reported here suggests that non-coding RNA, and more specifically miRNA, could be relevant modulator of egg quality in response to environmental cues

Further growing interest on aquaculture production of European perch is still limited by several bottlenecks. Economic production together with high quality and healthy meat depends essentially from artificial diets. Predicting growth rates, feed intake and energy requirements of the farmed animal in different life stages are crucial for the viability of the enterprise.

We tested four different available commercial feeds (3 mm) in a practical approach, three of them declared for percids (feed A, B, D) during grow out from 100 g to 200 g fresh weight in a three month trial in triplicate at an initial density of about 20 kg/m³ (157 fishes per treatment). Crude protein were nearly similar and ranged from 49 – 54%, crude fat was the testing variable with values from 10% (feed C and D), 15% (feed A) and 20% (feed B). Further, D was swimming feed in contrast to sinking feeds A, B and C.

At the end of the experiment we compared survival, final fresh weights, specific growth rate, Fulton's condition factor (K), coefficient of variance, filet quantity and quality (fatty acid analysis) and other relevant parameter

At the end of the experiment mean survival was highest with feed D (98.5%). Remarkable lower survival was overserved for feed A (94.1 %).

Conclusion
Under the tested conditions feed B, declared for percids, showed best results in terms of growth, survival and food quotient. Feed B contained highest value of raw fat (20 %) and was relatively expensive (€/kg feed). In contrast, not explicit for percids declared feed C revealed comparable results to feed B for growth and also good results for survival and FQ. This feed was low in raw fat (10%) and was much cheaper (€/kg feed) and could therefore recommended for economical grow out of *Perca fluviatils*.

LAND-MARK BASED MORPHOMETRIC DISCRIMINATION OF NATIVE AND INTRODUCED PIKE-PERCH, *Sander lucioperca* (L.) POPULATIONS IN EURASIA

Türker Bodur

Department of Aquaculture, Faculty of Fisheries, Akdeniz University, Turkey
turkerb@akdeniz.edu.tr

Introduction

Since pike-perch was distributed widely in Turkish freshwater, native or introduced, the phenotypical characters might be affected by fishing pressure, different environmental conditions and feeding habits. As a first study on morphological discrimination of pike-perch population in Turkey, it is aimed in this study (i) to understand the effect of environmental conditions on pike-perch morphology and (ii) see the differences of morphometric characters in between native and introduced populations in this article.

Material Method

A total 223 S. lucioperca specimens which were collected from six geographically different regions of Anatolia and Europe were analysed (Fig. 1). All specimens were carried to the Laboratory of Fisheries Faculty of Akdeniz University and right body profile of each specimen was photographed under the day light by high resolution digital camera (D560, Nikon, Japan). 18 landmarks were identified by tpsDIG freeware Thirty-five distances between landmarks were calculated by Pythagorean. In order to avoid the effects of different specimens' size on analysis, size-dependent variation was removed in morphometric characters. For the analysis of morphometric characters, MorphoJ software was used for wireframe graphs. Normality, ANOVA, Wilks' λ, Canonical Function Analyses were done by SPSS software programme.

Results

The predicted group membership shows how many individuals are morphologically classified with which populations and 85.10 % of original grouped cases are correctly classified. In this table it can clearly be seen that the least corrected classification was in SASDL (75.00%) population because in total 12 out of 48 individuals have common morphometric characters with other populations. ETLD (94.40%) population was the most correctly classified by morphological characters in wild populations. Outside sample, DEOR showed small similarities with WALM (3.30%), SASDL (10.00%) Turkish samples. According to Wilks' λ value, it was determined that except LM1-18, LM11-13, LM01- 15, LM5-6 characters from head and second dorsal fin out of 34 investigated characters, all other 30 morphological parameters belonging to body and caudal region showed significant differences ($P<0.01$) which explained the discrimination between native and introduced population in study region. Discriminant Function Analysis showed the effect of differences of characters on population discrimination. While ETDL and NALB populations have similar body shape, when two native populations, ETDL and NALB are compared with introduced populations, it has been seen ETDL population mostly discriminate from WALM and SASDL by slightly body depth and head formation but strongly divert from SALE by head length and depth, also caudal peduncle (Fig 2.). Morphologic characters of NALB population distinguished from WALM and SASDL mostly on body depth and fin length but SALE population di fer from NABL considering the head formation**.**

Discussion

The main finding of this study is that introduced SALE population seems strongly differentiated from other introduced populations WALM, SASDL and also native populations NABL and ETDL. It was expected that European population DEOR would be classified far from Turkish native populations but results indicate that DEOR population has slightly connected with WALM and SASDL populations. Fontaine et al. (2015) found at least genetically differentiated groups in Europe and DEOR population was actually in between these two groups (Hungarian and Scandinavian). Since WALM population was introduced from Austria (Çelikkale 1990), its connection with DEOR might be understandable because of the large genetic distribution of riverine populations (Krpo-Ćetković and Stamenkovic 1996). However SALE populations should be siblings of WALM; hence, differences between these two populations seem interesting and show possible different ecological factors and feeding habits affecting morphological structure of pike-perch. In this study, it is clearly shown that two major pike perch populations from Northern Anatolia have discriminated from introduced populations (European origin). In present study it is also clearly seen that one of the two introduced pike-perch populations, Lake Eğirdir, strongly discriminated from other introduced and native populations, which shows that feeding habits, feed availability and fishing pressures have strong effects on morphology of pike-perch populations in study area.

Introduction

The ongoing global push for sustainability has motivated both the greenhouse horticulture and aquaculture sectors to explore the potential of geothermal energy for heating as an alternative to fossil fuels (Badiola et al., 2018; Lund and Boyd, 2016). Greenhouses and RAS experience distinct heat demand fluctuations throughout the year and therefore do not make consistent use of geothermal wells. Geothermal wells on the other hand, need to operate close to full capacity year-round to be profitable. The heat use efficiency of geothermal wells could be improved by combining both food production systems into an aquaponic-based thermal treatment network in which a RAS functions as a sink for the (low temperature) residual geothermal heat coming from the greenhouse, but also utilizes geothermal heat directly whenever greenhouse heat demand is low (Thorarinsdottir and Unnthorsson, 2018).

The EU funded GEOFOOD project aims to analyse in detail how to optimize the design and operation of such aquaponic facilities that use geothermal energy. To that end a predictive model was developed which simulates the energy balances present throughout the thermal treatment network. The model enables the user to compose a sequence of geothermal wells, greenhouses and RAS for which different scenarios can be explored by selecting several types of greenhouse, different crops and fish species as well as climates. When used as a design tool, the model is capable of dimensioning the aquaponic facilities and/or the geothermal well. On the other hand, the model can be employed to analyse the hourly heating requirements of individual components within the thermal treatment network.

Methods and materials

Geothermal aquaponics consisting of a 5 ha tomato greenhouse combined with a RAS for pike-perch has been simulated for three different locations: The Netherlands, Iceland and Slovenia. The objectives of the simulations are to dimension the geothermal well and RAS to optimize for heat use efficiency and to investigate the impact of the local climate conditions on optimal geothermal capacity and RAS size.

The model KASPRO (De Zwart, 1996) has been used to simulate greenhouse heat demand as well as flow and temperature of the residual heat coming from the greenhouse. It is a physical greenhouse climate model coupled with a virtual climate controller, consisting of modules describing the energy and mass balances present within the greenhouse.

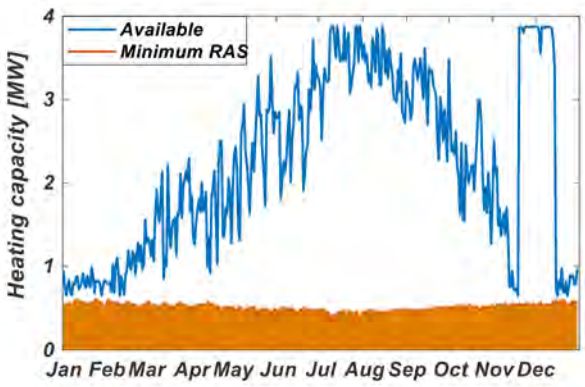

Figure 1. Heating capacity needed by the minimum size RAS (i.e. 6544m^2) and available heating capacity.

(Continued on next page)

The RAS energy model has been newly developed for the GEOFOOD project in order to predict the heat demand of RAS facilities. It is based on the energy balance for indoor aquaculture facilities as described by Timmons and Ebeling (2013). As part of the GEOFOOD project the model will be validated using on-site measurements performed at a new aquaponic facility that has been completed May 2019 in The Netherlands at the research centre of Wageningen University & Research, Greenhouse Horticulture.

Results

For a tomato greenhouse located in The Netherlands preliminary results show that geothermal heat extraction can be increased with 31% by combining it with a pike-perch RAS of 6544m^2. At this size, the RAS runs completely on residual and surplus geothermal heat, without the need of alternative energy sources during peak demands.

However, from figure 1 it can be observed that still a large part of the available heat remains unused. Simulation results also indicate that the RAS facility can be increased from 6544 m2 to 8894 m^2 (i.e. an increase of 35.9 % in fish production capacity) if only at peak demand an alternative heat source may be used, amounting to no more than 5 % of yearly RAS heat demand. In that case the simulated aquaponic system, consisting of a 5 ha tomato greenhouse and 8894 m2 pike-perch RAS, could extract 40 % more heat from the geothermal well than a 5 ha tomato greenhouse. Results for the other locations and the ongoing model validation process will be presented.

Discussion and conclusion

Integration of the newly developed RAS model and the greenhouse model KASPRO into a thermal treatment network enables assessment of geothermal energy use potential within circular food production systems, in particular aquaponics.

In the specific case of the simulated tomato greenhouse within The Netherlands, the results suggest that integrating a RAS facility contributes positively to exploitation of geothermal heating infrastructure.

Though further validation is required, the presented model is not only relevant for the current energy transition in terms of assessing geothermal potential for food production. It could also support efforts to connect established greenhouse horticulture areas with an emerging RAS sector, thereby moving towards more circular food production systems.

Introduction

Recirculation Aquaculture Systems (RAS) use water recycling as the base for an efficient production. Water reutilization demands cleaning techniques to remove accumulating compounds. These include mechanical filtration, biofiltration and a disinfection method. The most common disinfection methods used in RAS are UV and Ozone, both having pros and contras in terms of costs, risks, and application requirements. An alternative to these methods is hydrogen peroxide (H_2O_2), which, even been classified as a green oxidant, has not been commonly used and is hardly criticized due to acquisition, storage and secure manipulation issues. As H_2O_2 dissociates into non-toxic environmentally benign by-products including oxygen, its application offers potential savings in terms of oxygenation in RAS. Moreover, H_2O_2 is used to treat ectoparasitic illness with FDA approved H_2O_2-35% dosages between 50-1000 mg/L for 15-60 min. Minimum concentrations to which stress responses have been observed in salmonids range between 4-170 mg/L while the limits for biofilter function are around 5 mg/L [1-4].

Materials and methods

In the present study, we perform serial experiments in a RAS rearing ~65 kg European seabass (*Dicentrarchus labrax,* weight ranging from 500-800g) to test the best application possibilities for H_2O_2 into a system, with concentrations between 2.4-15.8 mg/L/h. We tested two application positions: the bypass between the protein skimmer and the sump (with higher organic burden), and the flow to the rearing tanks (low organic load). We evaluated the impact on physicochemical parameters with focus on oxygen and nitrogen species concentration and the effect of the application on bacterial community of the different compartments (assessed via total bacterial counts in CFU/ml). Dosage was applied for 4 h on a daily basis and rates of decay of H_2O_2 on the system was assessed with Quantofix Peroxide test sticks (Sigma Aldrich, from 0-25 mg/L and 0-100 mg/L) until total removal. Ozone was switched off during dosage. Smart Digital S-DDA (Grundfos, Germany) dosage pumps were used for a controlled H_2O_2 application to the system (dosing capacity between 2.4 ml/h and 7.5 L/h). Stress levels of the reared fish was assessed using cortisol and glucose as blood markers

Results

With the concentrations used, we accomplish a partial disinfection of the system without reaching levels affecting the bacterial flora of the biofiltratio units or the health of the reared fish. We found a significant reduction of the bacterial load with each of the concentration tested. The best application position was the inlet to the protein skimmer, due to the lowest impact to the bacterial flora of the filter and the reared fish. An economically relevant increase in oxygen level of the system as well as the highest disinfection levels were achieved with 15.8 mg/L/h. In this assay, an artificial oxygen depletion was simulated before applying H_2O_2 to the system, and this was recovered within the first 40 min, even during a feeding period, which normally reduces the oxygen level in the water column. After application, the rates of decay varied from 30 min to 1 h, time after which, no H_2O_2 was detected in the system.

No significant negative effects were found on fish stress markers even when cortisol (Ref: 59.8±49.5 vs. Treat: 62.2±43.5) and glucose (Ref: 131.0±34.9 vs. Treat: 155.1±45.3) levels tended to increase during the experiments using increasing H_2O_2 doses. These markers showed a high variability. During application, the number of fish showing conspicuous low cortisol levels increased.

C. Economic benefits of H_2O_2 application compared to common systems using Ozone disinfection on a daily basis.

Discussion and conclusion

Organic burden in the system, fish stocking density, feeding frequency and biofilter performance were all factors influencing the required H_2O_2 dosage and its rate of decay in accordance to what has been published [2, 5, 6]. In the present study, we found a relatively rapid decay of H_2O_2 remnants, supported by the organic load typically present in a RAS rearing at commercial or semi-commercial scales. We recommend to apply H_2O_2 in positions of the system with high organic burden to avoid affecting biofilter function or promoting nitrite accumulation as previously published [5]. Despite previous results showing negative stress responses of *D. labrax* to H_2O_2 application [7], we did not found critical changes on cortisol or glucose related to the treatment. These authors used smaller fish (weight 120-200 g) and doses of 50 ppm/h, which are higher than in the present study. The stress in *D. labrax* is genetically driven and highly dependent on size/age with individuals having consistent high (439.2 ± 31.1 µg/dl) or low (247 ± 85.1 µg/dl) cortisol concentrations and, as well as glucose, there is a circadian pattern for these parameters within this species [8, 9]. Glucose levels between 100-150 mg/dl have been reported in the literature for *D. labrax* [10]. With appropriate knowledge of system performance and microbiological background, H_2O_2 can be a positive complement to the disinfection spectrum of a RAS. It can be used alternating with common methods to avoid artificial selection of specific microbial groups and can have a positive impact in cases in which parasitic illness are present. Thus, as a disinfection method with a plus for its oxygenation influence, H_2O_2 can enrich the disinfection portfolio of aquaculture facilities.

AMMONIUM REMOVAL BY ION EXCHANGER - EFFECTS ON WATER PARAMETERS, MICROBIAL COMMUNITY AND SEA BASS (*Dicentrarchus labrax*) IN A MARINE RECIRCULATING AQUACULTURE SYSTEM

M. Bögner*, K. Lorkowski, D. Bögner, F. Wilsdorf, G. Jähne, M. Slater

Introduction

Water treatment plays a central role in the successful operation of recirculating aquaculture systems (RAS), because high stocking densities and feeding rates rapidly impair the quality of the limited water body. In RAS, nitrogen load is typically removed by multistep biological filtration whereby the first step is ammonium oxidization to nitrite. This biological degradation is vulnerable to disturbances e.g. changing water conditions and medications of the cultivated species what can lead to an accumulation of toxic nitrogen components in the system water. Ammonium can alternatively be removed from water by using zeolite. In emergencies zeolite can decrease fish mortality by reducing dangerous ammonium concentrations. In the present study a marine RAS, stocked with Sea bass (*Dicentrarchus labrax*), was operated with the bioreactor replaced by zeolite in the RAS water. Water parameters, microbial community and reared animals were determined to evaluate the impact of an alternative ammonium removal method on RAS performance.

Material and methods

Two identical 5m^3 RAS each equipped with 3 rearing tanks, drum filte , ozone- injected protein skimmer and moving bed bioreactor were operated at constant water parameters (temperature: 17.0°C, conductivity: 50.4mS cm^{-1}, pH: 7.9, O2: 97.8%). RAS were stocked in each experiment with 9kg m^{3-1} juvenile Sea bass (102.7 ± 25.3g) and fishes were fed 8 times a day (1.02% body weight per day) during a period of 21 days. These two RAS were controlled in 3 different scenarios: 1) RAS 1 and 2 with bioreactor and ozone, 2) RAS 1 and 2 with bioreactor without ozone and 3) with zeolite and ozone (RAS 1) or without ozone (RAS 2). Nitrogen components and abiotic water parameters in the water were measured daily. At the beginning and the end of each phase bacterial count and the composition of the bacterial community were determined. At the end of each phase the blood of 12 fishes per RAS was collected and analysed for relevant parameters (cortisol, glucose, lactate, ammonium, lysozyme, haematocrit).

Results

During phase 1 and 2 ammonium and nitrite concentration in the tank waters were similar in both RAS (Figure 1). Zeolite treatment (phase 3) led to a large increase in ammonium concentration and a decrease in nitrite concentration when ozone was applied (RAS 1), while without ozone ammonium increase was much lower but nitrite was strongly elevated (RAS 2). Nitrate level in the water increased during phase 3 in both RAS but with a higher slope in the system with ozone. During phase 1 and 2 ozone treatment had minimal effect on the bacterial count in both systems. Numbers of bacterial units increased strongly during zeolite treatment, especially when ozone was not applied (Table I). Zeolith treatment had no effect on stress related blood plasma parameters of the fishes.

Discussion

Zeolite had strong effects on water parameters in both RAS. Ammonium content in the water were elevated without bio- filtration, and probably caused bacterial growth in the RAS leading to high nitrite level in RAS 2 without ozone. An additional ozone treatment could prevent the accumulation of toxic nitrite, because of the spread of the bacterial mass was reduced. Blood parameter data indicate that the zeolite treatment could be suitable to continue the normal operation of a RAS when biofiltration is affected allowing emergency situations to be managed without the need for performance-reducing emergency measures such as stopping feeding or reducing stock biomass.

EVALUATION OF A MEMBRANE-DENITRIFICATION REACTOR (MDR) IN A RECIRCULATION AQUACULTURE SYSTEM UNDER REAL CONDITIONS

A. Boley*, W.-R. Müller*

Introduction

According to the European Commission, recirculating aquaculture systems are appropriate measures to reduce the release of nutrients into the receiving waters (European commission, 2016). Developing and implementing of innovative technological solutions are suggested to achieve the objectives of the strategic guidelines for sustainable development of EU aquaculture (European commission 2013). The removal of nitrate and particles is a crucial factor not only for the environment, but also for animal welfare.

In previous investigations, a combination of denitrification and membrane cleaning was investigated in small membrane denitrification reactors, and then two semi-technical recirculation aquaculture systems (RAS) were installed for feasibility studies of the Membrane-Denitrification-Reactor (MDR) (Boley et al. 2017). In the present study, the integration of the MDR in two commercial RAS systems was investigated and evaluated.

Materials and methods

To demonstrate the functionality under real conditions, the MDR was installed in the water treatment unit of Fischzucht Rhönforelle in Marjoss, Germany (RAS1, s. Fig. 1) and thereafter at AQUA SCHWARZ GmbH in Goettingen, Germany (RAS2).

RAS2 was a smaller system only with biofilte . Two independent systems were used, one with MDR (A) and the other without MDR (B) as reference. Total fish mass increased from 39 kg/tank to 156 kg (A) resp. 164 kg (B) per tank. The fish stock was reduced several times since the biofilter capacity was insufficient. RAS1 was operated with water from a well with low hardness (0.5 mmol/L), in contrast to the water in RAS2 with a very high hardness (5 mmol/L).

For both RAS, measuring devices were installed near to the MDR for the online-measurement of different parameters (s. Fig. 2). Lab analyzes were also carried out.

Results and discussion

The denitrificati n started fast in both RAS, so that after 2 d, the nitrate was completely reduced in the effluent of the MDR (s. Fig. 2). The denitrification rates were low (1…2) mg/(L h), due to a small membrane area, compared to the large water volume inside the MDR (~600 L). The flux through the membranes reached (7…10) L/(m² h), s. Fig. 2. A special feature in RAS2 was the low consumption rate of ethanol, which could be reduced to 1.0 g ethanol/g NO_3^--N without increased nitrate concentrations in the effluent, whereas the stoichiometric consumption is 1.4 g Ethanol / g NO_3^--N. This indicates that additional organic compounds from the fish tank were used for denitrification, because here, in contrast to RAS1, a sedimentation unit was missing. This assumption was also supported by the COD concentrations in the effluent, which were significantly lower than in the influen

Therefore, the NH_4^+-N levels in the MDR effluent in RAS2 increased to 2.7 mg/L, while they remained below 0.1 mg/L in RAS1 with lower organic load. Single Nitrite peak conc. in the effluent of MDR in RAS1 were observed up to 6 mg/L. In RAS2 the NO_2^--N conc. remained low, but when the consumption rate of ethanol decreased to below 1 g Ethanol / g NO_3^--N, the NO_2^--N concentrations in the effluent of MDR increase

(Continued on next page)

A COMPARISON OF GROWTH, MORPHOLOGY, CONDITION, FILLET YIELD, DRIP LOSS AND RIGOR PROGRESSION IN TWO STRAINS OF TURBOT (*Psetta maxima)*

M. Bolton-Warberg, D. O'Connell, A. Wan and R. FitzGerald†

Carna Research Station, Ryan Institute, National University of Ireland Galway, Carna, County Galway, Ireland
majbritt.bolton-warberg@nuigalway.ie

Turbot (*Psetta maxima*) is a high-value whitefish that is much sought after by trade customers and consumers alike. Globally, capture production was almost 6,500 tonnes in 2017, compared to over 57,000 tonnes of farmed production in the same year (FAO, 2019). The main producers are China, the Netherlands, France and Spain, with the majority (80%) coming from China. Globally, turbot production is very small when compared to other marine species but there was rapid commercial growth between 2000 and 2010. More recently, Spanish production has increased and now accounts for more than three quarters of the European production of turbot.

While many of the major bottlenecks have been overcome, there is still some applied research to be undertaken to ensure the upward trend in production is maintained. For example, there are a number of 'strains' (or broodstock) of turbot available to turbot farmers. There is little empirical data that enables direct comparisons to objectively assess the stock performance and product quality for these 'strains'. The main traits associated with improved stock performance, from a commercial perspective, are growth performance and fillet yield, but also, from a consumer perspective, it is important to consider and examine the characteristics of the seafood products themselves including, for example; fillet quality traits, sensory attributes and shelf-life. It is imperative that stocks can be assessed for production characteristics to enable farmers to choose the best stock for their farm.

The primary aim of this experiment, as an initial study with turbot stocks, was to compare growth performance, body form and shape, general body morphometry and some selected product traits, specifically progression of rigor and drip loss, in two commonly available strains of turbot, one originating from Scotland, the other from Denmark. A selection of these results will be presented here.

Introduction

The demand for aquafeed grown exponentially in the last decade and is expected to increase further in the coming years (FAO 2018). The wild fish used for the fish meal and oil, currently used in feed formulated for carnivorous species, will be used in human consumption and less available for aquaculture. Among the potential ingredients of future use in aquafeed, microalgae represent a promising matrix, as characterized by nutritional, nutraceuticals and immunostimulant properties (Camacho-Rodríguez *et al.,* 2017). However the high production cost is a limiting factor for their use. The development of a microalgae-based biorefiner , able to use some by-products and agro-industrial waste to produce biomass would enable to limit the disposal costs sustained by the companies and to lower the production costs of the microalgae. The present research was undertaken to evaluate effect on growth response and fillet quality traits of sturgeon (*A. baerii*) fed with two microalgae freeze-dried biomass *Nannochloropsis gaditana* and *Scenedesmus almeriensis* grown in Sinthetic Medium (SM) or in diluted Pig Manure (PM) and included in partial substitution of dietary fish meal and oil

Materials and methods

Four complete diets were formulated to be grossly iso-proteic and iso-lipidic. A control diet (C) was prepared using a blend of conventional animal and vegetal protein sources. The test diets coined respectively *N. gaditana* grown on Synthetic Medium (NSM), *N. gaditana* grownoin pig manure (NPM), *S. almeriensis* grown on Synthetic Medium (SSM) and *S. almeriensis* grown on Pig Manure (SPM) were prepared by replacing the 10% of protein and lipid supplied by the blend of conventional protein and lipid-rich ingredients with microalgae. All the ingredients are mixed and pelleted by a cold extrusion process (70°C). Each diet were randomly assigned to tank and tested in triplicate according to a monofactorial design. Microalgae dried biomass and diets were analized microbiologically and verified for nutritional quality. To carried out the feeding trials 240 juvenile *A. baerii* (average 12.8±0.3g each) were randomly allocated among 15 circular tanks (16 fish/tank) in RAS system under controlled rearing conditions (temperature, 19°C, DO 9.6 mg/L, artificial daylenght, 12h). Diets were offered in two daily meals with a fixed feed ratio (3% body mass) over 6 weeks and each group were weighted every week under moderate anaesthesia. At the end of the trial, survival rate (%), Final Body Weight (FBW), Specific Growth Rate (SGR), Feed Conversion Ratio (FCR), Feed Intake (FI), were evaluated. Furthermore, nine fish per feed treatment were analized to determine the biometric indeces, fillet proximate composition and oxidation parameters (SOD, CAT, GPX, 8-isoprostanes). Data were subjected to ANOVA and differences tested by the Tukey's test ($P < 0.05$).

Table I Proximate composition of microalgae biomass included in the experimental diets

	Water (%)	Protein (%)	Lipid (%)	Ash (%)	Carbohydrate (%)
N. gaditana on PM	4.7	48.4	18.6	23.8	4.5
N. gaditana on SM	4.5	35.8	14.5	32.8	8.2
S. almeriensis on PM	3.4	33.8	8.4	13.7	29.1
S. almeriensis on SM	8.0	29,1	2.1	25.1	18.5

(Continued on next page)

Results

The macronutrient composition of the dried micoalgae biomass are reported in Table I.
Microbiological analysis of microalgae biomass showed no difference in TBC (Total Bacterial Count) among the different thesis (average 5.9±0.07 log CFU/g). *E. coli* were found below the detection limits of the method (< 2 log CFU/g) in *N. gaditana* grown on PM and *S. almeriensis* grown in both SM and PM, while its value was 3log CFU/g in *N.gaditana* grown on SM. Enterobacteriaceae resulted respectively 2.7 and 2.0 log CFU/g in *N. gaditana* and *S. almeriensis* grown on SM and under detection limits of the method (< 2 log CFU/g) in *N. gaditana* and *S. almeriensis* grown on PM. *Salmonella* resulted absent in all the microagae biomass. All the diets used in feeding trial resulted similar for their proximate, fatty acid composition and microbiological quality (data not reported). Dietary treatments significantly affected FBW that resulted similar in the groups C (44.2g), NSM (44.7g) e NPM (43.9g), while it was significantly lower ($P<0.05$) in the SSM (40.8g) and SPM (40.5g) groups. However, did not result in significant changes in survival rate, SGR, FCR and of the biometric index (K), nor fillet composition. Also oxidation parameters (SOD, CAT, GPX, 8-isoprostanes) of fillet were not significantly a fected by dietary treatments ($P>0.05$).

Discussion and Conclusion

Very few data are available on the use of microalgae biomass in acipenserids diet. Spirulina meal integrated with plant oils was found to be a good alternative to replace fish oil in white (*A. transmontanus*) and siberian (*A. baerii*) sturgeon diet (Palmegiano *et al.,* 2008; 2002). The data observed in this study confirm the potential use of the microalgae *N. gaditana* and *S. almeriensis* in the siberian sturgeon diet, in fact all the experimental diets tested, both based on microalgae grown on SM and on PM ensure a balanced and complete level of the nutrients, suitable for the growth of sturgeon juveniles and nutritional quality of the fillet, analogous to the control group fed with a fish meal/oil-based diet. Moreover the use of agrozootenic by-products, such as pig manure, for the growth of microalgae, appears to be a good alternative to common fertilizers, to reduce production costs.

LIGHT-ENHANCED SHELL FORMATION IN THE FLUTED GIANT CLAM, *Tridacna squamosa*, INVOLVES LIGHT-DEPENDENT EXPRESSION OF NA^+-DEPENDENT SECONDARY ACTIVE TRANSPORTERS IN ITS CTENIDIUM

Giant clams live in symbiosis with phototrophic zooxanthellae and strive in nutrient-deficient tropical waters where light is available. They conduct light-enhanced shell formation that involves the deposition of calcium carbonate (calcification) onto the inside surface of the shell valve following the reaction of $Ca^{2+} + HCO_3^- \Leftrightarrow CaCO_3 + H^+$. Hence, light-enhanced shell formation necessitates the increased supply of Ca^{2+} to and removal of H^+ from the extrapallial fluid, which is the site of calcification, to promote a more rapid precipitation of $CaCO_3$ as aragonite. Indeed, there is a significant increase in the pH of the extrapallial fluid in the fluted giant clam, *Tridacna squamosa*, exposed to light. H^+ could be transported from the extrapallial fluid into the shell-facing epithelial cells of the whitish inner mantle through plasma membrane Ca^{2+}-ATPase per se or as NH_4^+ through an unidentified transporter. Subsequently, the excess H^+ could be shuttled through the hemolymph to the ctenidium (gill) for excretion. The ctenidium of *T. squamosa* expresses homologs of Na^+/H^+ exchanger 3 (NHE3-like) and vacuolar-type H^+-ATPase subunit A (ATP6V1A) that have an apical localization in ctenidial epithelial cells. With illumination, the gene and protein expression levels of these two H^+ transporters increase significantl , in support of increased H^+ excretion during light-enhanced shell formation to maintain acid-base balance. In addition, the ctenidium of *T. squamosa* expresses a homolog of Na^+/Ca^{2+}-exchanger 3 (NCX3-like), the gene and protein expression levels of which are also up-regulated by light. As NCX3-like is localized to the basolateral membrane of the epithelial cells of the ctenidial filaments, there could be an increase in the transport of Ca^{2+} from the ctenidial epithelial cells to the hemolymph, and the absorbed Ca^{2+} is shuttled to the extrapallial fluid in support of light-enhanced shell formation. As both NHE3-like and NCX3-like are Na^+-dependent secondary active transporters, any increase in their activities through upregulation of expression levels would disrupt the Na^+ gradient across the plasma membrane, which must be ratified. Indeed, the protein abundance of Na^+/K^+-ATPase (NKA) α-subunit (NKAα) is upregulated in the ctenidium of *T. squamosa* during light exposure, indicating a possible increase in NKA activity to maintain the transmembrane Na^+ gradient. Interestingly, NKAα has an atypical apical localization in the ctenidial epithelial cells of *T. squamosa*, which could be related to the needs to absorb K^+ from the external seawater to maintain K^+ homeostasis due to phototrophy without food intake. Although both giant clams and scleractinian corals harbor zooxanthellae and conduct light-enhanced calcification, they have different complexities, and it is unsurprising that light-enhanced shell formation in the more advanced giant clams involves the cooperation of multiple organs. To date, many species of giant clams are either critically endangered or vulnerable. Our results provide a deeper understanding on the mechanisms of light-enhanced shell formation in giant clams, which may furnish insights into better ways to enhance their growth during mariculture for reseeding purposes.

CAN THE INOCULATION OF COMMERCIAL NITRIFYING BACTERIA IMPROVE BIOFILTERS PERFORMANCE IN THE M*acrobrachium amazonicum* LARVICULTURE?

M.V. Boock*, H.P. Barros, H.L.A. Marques, M.S.N. Galvão, C.P. Graciano, R.H. Ferreira

*UPD Pirassununga/Instituto de Pesca/APTA/SAA-SP, Rua Virgílio Baggio, 85, ZIP Code: 13.641-004
E-mail: mvboock@yahoo.com.br

Introduction

The high stocking densities used in *M. amazonicum* larviculture may accumulate nitrogen toxic metabolic compounds, reaching high values (Hayd et al., 2014). An efficient biological filtration of nitrogen compounds is essential for getting satisfactory survival rates in the freshwater prawns' larviculture. Nowadays, the lack of commercial hatcheries is one of the main bottlenecks for the development of freshwater prawns' farming in Brazil. The objective of this study was comparing the performance of one artisanal model of biofilter commonly used on commercial hatcheries and a commercial one (canister filter), both inoculated with commercial nitrifying bacteria, aiming to determine the most efficient and the easiest to manage.

Materials and Methods

The study was run in the Freshwater Prawn Laboratory APTA/Pirassununga, Brazil. The treatments were Without Filtration Without Inoculation (WFWI); Without Filtration Inoculated (WFI); Canister Filter Inoculated (CFI); Dinamic Filter Inoculated (DFI), carried out in a complete randomized design with five replicates per treatment

The tested commercial nitrifying bacteria (N-Control) were previously dissolved in brackish water at salinity of 10g L^{-1} and daily added into the biofilters (treatments CFI and DFI), or directly into the WFWI treatment tanks, using the recommended doses (6mg L^{-1}), according to the producer. The larvae of *M. amazonicum* were collected from the hatching tank, counted, acclimatized, and stocked (49 larvae L^{-1}) in 20 L black rectangular plastic tanks. The water variables pH, dissolved oxygen (DO) and temperature (T) were monitored daily using an Alfakit AT-355 pH meter and an YSI Pro-20 oximeter, respectively. The salinity was kept between 10 and 11.

Water samples of all tanks were collected twice a week for determination of ammonium (NH_3), nitrite (NO_2) and nitrate (NO_3) dissolved in the water. The analyses were made by a certificated company (Aquali Assessoria e Análises Ltda). The production variables were mean weight (MW), survival (S) and days of larviculture (DL). Means were subjected to one-way ANOVA and compared by Tuckey Test ($p<0.05$). When the premises of normality or homoscedasticity, were violated, the non-parametric Dunns Multiple Comparison - Kruskal-Wallis Tests ($p = 0.05$) were applied. The software utilized for performing statistical analysis was the Toxstat, version 3.0.

Results

There were no significant differences in water variables pH, DO and T among treatments (Table I). For the nitrogen compounds, there were significant differences among the CFI and the other treatments (Table I), but no differences were detected between the treatments WFWI and WFI. According to the survival data presented in Table II, there were differences among the control (WFWI and WFI) and inoculation (CFI and DFI), due to the greater concentrations of nitrogenous compounds present in the control treatments.

Discussion and conclusion

The variables pH, DO and T ranged within the stated water parameters for hatchery of *Macrobrachium* sp according to Moraes-Valenti and Valenti (2010).

The treatment CFI was the most efficient filte , presenting the minor value to the variable nitrite. Although the survival of the treatment CFI were similar to the DFI treatment, the canister filter presented a faster assembly, easier handling and, consequently, it could means a reduction of labor costs in hatchery commercial operation. This hypothesis, however, needs to be confirmed by further economic studies

Despite the treatment WFI had presented high mortalities, we noticed that some larvae survived until the lasts larval stages. This fact indicates that the addition of commercial nitrifying bacteria directly in the larvicuture tanks, without any filtration could be a potential new hatchery system.

(Continued on next page)

Table I. Average values (± standard deviation) of pH, dissolved oxygen (DO), temperature (T), ammonium (NH_3), nitrite (NO_2) and nitrate (NO_3) for the treatments: Without Filtration Without Inoculation (WFWI); Without Filtration Inoculated (WFI); Canister Filter Inoculated (CFI) and Dynamic Filter Inoculated (DFI);

	Treatments			
Variables	**WFWI**	**WFI**	**CFI**	**DFI**
pH	7.76 ± 0.02	7.74 ± 0.02	7.76 ± 0,01	7.76 ± 0.02
DO (mg L^{-1})	4.20 ± 0.19	4.33 ± 0.27	4.25 ± 0,17	4.35 ± 0.25
T (°C)	28.81 ± 0.62	28.98 ± 0.46	29.01 ± 0.27	29.10 ± 0.62
NH_3 (mg L^{-1})	0.27 ± 0.23	0.41 ± 0.24	0.21 ± 0.06	0.28 ± 0.12
NO_2 (mg L^{-1})	0.73 ± 0.40^{ab}	1.26 ± 0.70^{a}	0.13 ± 0.03^{c}	0.36 ± 0.55^{b}
NO_3 (mg L^{-1})	1.70 ± 0.86	2.15 ± 0.74	1.19 ± 0.09	1.66 ± 1.45

Subscribed different letters in the same roll indicate significant differences (ANOVA, followed by Tukey-test, $p<0.05$).

Table II. Average values (± standard deviation) of mean weight (MW); survival (S) and days of larviculture (DL), for the treatments: Without Filtration Without Inoculation (WFWI); Without Filtration Inoculated (WFI); Canister Filter Inoculated (CFI) and Dinamic Filter Inoculated (DFI).

	Treatments			
Variables	**WFWI**	**WFI**	**CFI**	**DFI**
MW (mg)	0.94 ± 0.03	0.91 ± 0.04	0.90 ± 0.06	0.91 ± 0.04
S (%)	7 ± 2	5 ± 3	44 ± 8^{a}	46 ± 15^{a}
DL (un)	33 ± 2	31 ± 5	28 ± 4	28 ± 5

Subscribed different letters in the same roll indicate significant differences (ANOVA, followed by Tukey-test, $p<0.05$).

Introduction
Aquaculture in Europe is diverse in its products and producers, but many parts are maturing with the involvement of major international companies and increasing technical and managerial sophistication of production systems and market chains. The industry is having to pay closer attention to recruitment and career development as well as skill development either internally or through external training and education organisations in order to compete and grow in response to emerging opportunities and challenges.

Institutional provision for aquaculture education and training in Europe
There are in the region of 100 education and training institutions in the EU and Associated States that have at least some provision for aquaculture sector training. Most formal provision is at graduate or postgraduate level although significant vocational programmes exist in countries such as Norway and France. So far there is little development of aquaculture-specific professional bodies with independent accreditation systems as exist in other sectors

Industry and private sector responses to training needs
The availability of on-the-job training within the aquaculture sector depends to a considerable degree on the economic status of the industry. The salmon industry is relatively consolidated, and individual companies have substantial internal programmes for staff training and development. There are also private companies providing specialist training especially for safety or certification compliance related issues. Online provision is still limited

EU Policy context and support actions
The European Commission supports the aquaculture sector particularly through policies and actions administered through the Directorate General for Maritime Affairs and Fisheries (DG Mare). However, to understand the wider context and support for skills and career development requires consideration of the work of the Directorate General for Employment, Social Affairs & Inclusion (DG EMPL), the Directorate General for Education, Youth, Sport and Culture (DG EAC) and the Directorate General for Research and Innovation (DG RTD). Each of these DGs have actions relevant for skills development in the aquaculture sector and work together to some extent, for instance through the Blueprint for Sectoral Cooperation on Skills. Funding provided through these DGs is supporting a range of EU projects including BlueEDU (Erasmus+ Sector Skills Alliance for cage-based aquaculture) which provided some of the analysis for this presentation.

Future opportunities
Several EU funded projects are piloting new approaches including blue careers centres (e.g MENTOR), employment of industry-based tutors (e.g CETBC), development of e-Learning courses (e.g. SEAFOODtomorrow & AQUAEXCEL[2020]) and collaborative approaches to creating and sharing learning materials (e.g. AquaCase). It is important that lessons are learned from these and incorporated into future policy and support. The long established ESCO (European Skills, Competences, Qualifications and Occupations) initiative increasingly provides a solid framework for serious strategic planning on skills and career development within the aquaculture sector. This could in the future include outreach on career opportunities; recognition and accreditation of knowledge and skills through national or independent qualification frameworks; enabling flexible and lifelong learning including through distance and work-based programmes; and greater cooperation on curriculum and learning materials for relevance and effectiveness. The industry has the greatest stake in this but need to work with the education and training sector and other stakeholders (e.g. through EATIP and its Mirror Platforms) for greater momentum and impact on industry metrics such as productivity and business growth.

We explored potential antibiotic effect of Marennine, a blue pigment produced by *Haslea ostrearia* microalgae, on the pathogenicity of *Vibrio splendidus.* These bacteria are Gram-negative marine species often considered as an eminent threat for bivalve hatcheries. Here we demonstrate that in larval rearing conditions, larva of *Mytilus edulis* and scallop *Placopecten magellanicus* showed significant mortalities exposed to high concentrations of *V. splendidus*. However, in the presence of Marennine extracts, the pathogenicity of the bacteria was suppressed. In an attempt to explore the mechanism of such effects we used Nuclear Magnetic Resonance spectroscopy to explore interactions of the pigment with intact viable *V. splendidus* at a molecular level. Our hypothesis was that Marennine interacts with the outer membrane.

Purified Marennine was exposed to ^{2}H-labelled bacteria in artifi ial sea water and in controlled conditions. NMR results showed that Marennine affects fatty acyl chain fluidit . This effect was more striking when the membrane was already fluid, during the limited nutrient conditions like the stationary phase of bacterial growth. The results suggest that Marennine is a disruptive agent of the membrane dynamics for *V. splendidus*, and that its action mechanism is compared to Polymyxins, highly regarded antibiotic family, used in aquaculture and known to interact with the outer membrane of Gram-negative bacteria.

ALTERNATIVE METHODS FOR MONITORING BENTHIC ORGANIC ENRICHMENT EFFECTS AND APPLICABILITY ACROSS A RANGE OF ENVIRONMENTAL AND AQUACULTURE CONDITIONS

L. Brager[1]*, P. Cranford[1], D. Wong[1], B. Law[2]

Introduction

Increasing organic matter inputs to sediments have a known effect on benthic communities due largely to oxygen depletion and consequent toxic sulfide production. Total dissolved (free) sulfide (TFS) concentrations in sediment are widely measured as a practical indicator of benthic organic enrichment effects and are used in eutrophication studies and aquaculture management frameworks in several countries as a proxy for benthic community biodiversity, including Canada. However, the need for an expanded range of performance indicators that are of use in managing effects from BOD matter effluents in soft-bottom environments is recognized to increase confidence in regulatory decisions. Previous work developed accurate and practical alternative protocols for measurement of dissolved oxygen (DO) and determination of TFS in the sediment pore-water to address issues that currently exist within the traditional ion-selective electrode (ISE) method for measuring TFS in sediment slurries (Cranford et al. 2017). The applicability of these methods, as well as spatial and temporal trends of pore-water sulfides, are being assessed across a range of environmental (seabed, water depth, hydrodynamics) and aquaculture production levels, and compared with the ISE sulfide method at multiple locations across Canada

Materials and methods

Sediment samples were collected along organic enrichment gradients using either core or grab devices at n=7 finfis and n=2 shellfish sites across Canada in 2016, 2017 and 2018. Sediment pore-water was extracted from 1 and 2 cm depth below the sediment-water interface and immediately analyzed for dissolved oxygen (DO) and TFS using the UV spectrophotometric method (UV; Cranford et al. 2017). Replicate pore-water samples were collected and fixed for later analysis by the methylene blue microplate method (MB, Wong, in preparation). Sediment plugs from the top 2 cm were also collected and analyzed for TFS using the traditional ISE method according to the current regulatory monitoring protocols for the region, in addition to samples for measurement of grain size, porosity, and organic content.

Results and discussion

The new methods (UV and MB) for measuring TFS in sediment pore-water have been validated in a range of environments and production levels, and show strong correlation with each other (Fig. 1A). Comparability of pore-water TFS with ISE TFS is more scattered and inconsistent, indicating site-specificity (Fig. 1B).

Spatial and temporal trends in pore-water DO and TFS confirm known organic enrichment patterns with respect to aquaculture inputs. Spatial variability in TFS is inherent with increasing impact across all methods used for determination. The magnitude of organic enrichment effects vary with seabed type (among other factors). Pore-water TFS measurements show a localized impact (Fig. 2A), while DO can detect impacts at a greater distance and is more sensitive to the initial stages of biochemical oxygen demand (BOD) stress on the benthos (Fig. 2B). Temporal variability in the alternative indicators are consistent with expected production level trends, and demonstrate the sensitivity of these new metrics for detection of both increasing impact levels and recovery during a fallow period (Fig. 2).

Final steps of this ongoing research will be to quantify the empirical relationships between these new alternative indicators and the benthic community biodiversity as the scientific basis for proxy use as a management tool

Introduction

The existence of small-sized plastic waste in the marine environment and its potential impact on aquatic life has recently become a major concern due to the large quantity of plastic debris released in coastal areas. Once in the water, large plastic debris can be fragmented, through ultraviolet photodegradation, biodegradation, and chemical degradation processes to form smaller-sized plastics, including microplastics (< 5 mm) and nanoplastics (< 100 nm) (NPs) (Koelmans et al 2015). With a decrease in size, plastic particles become more bioavailable to aquatic organisms, and potentially more hazardous. In previous studies, NPs have been reported to induce oxidative stress, immune dysfunction, teratogenic effects, and altered locomotion (Besseling et al 2014, Lu et al 2016). Furthermore, altered lipid metabolism and histopathological changes in liver (Lu et al 2016) of fish exposed to plastic particles have been reported. *Dicentrarchus labrax* (sea bass), a marine fish species and a top predator is a common and valuable aquaculture species in the Mediterranean area. This species may be exposed to NPs via water and food web and constitute a potential source and risk to human health. For these reasons, the goal of this study was to evaluate the effects of NPs on *D. labrax* at different levels of biological organization.

Material and methods

Juvenile *D. labrax* specimens (14.6 ± 2.4 cm length and 21.4 ± 6.5 g weight) were obtained from an aquaculture facility (Spain) and acclimatized for 30 days in 1000 L aquaria, with aerated ASW (salinity 30), 19 °C and natural photoperiod (14 h light: 10 h dark). Following the acclimatization period, fish were randomly distributed in the following the experimental groups: 0 mg/L (control), 0.02 mg/L, 0.2 mg/L and 2 mg/L NPs. Each experimental condition consisted of 2 tanks with 3 animals per tank, containing 20 L of experimental media. Animals were exposed to NPs for 96 h, generally following OECD guideline 203 (OECD, 1992), and kept in the conditions described for the acclimatization period (ASW, 19 °C, 14 h light: 10 h dark). At the end of the exposure, skin mucus, blood and liver were sampled and processed for further analysis. Molecular were assessed in liver and relevant biochemical markers concerning metabolism, oxidative stress and general health status were studied in plasma and skin mucus.

Results

Concerning molecular responses (Fig. 1), transcriptional levels of genes associated with lipid metabolism presented a global upregulation after exposure to NPs. Peroxisome proliferator-activated receptors', *pparα* expression was significantly increased after exposure to 2 mg/L NPs, whereas *pparγ* mRNA levels presented a significant upregulation after exposures to 0.2 mg/L and 2 mg/L NPs. The expression levels of *pparβ* and *hadh* were not significantly different from control. The mRNA levels of *nd5* were increased after exposure to NPs (in animals of all tested concentrations). Regarding biochemical responses assessed in plasma, esterase activity (EA) was significantly decreased when compared to control after exposure to 0.02 mg/L, 0.2 mg/L NPs. In skin mucus, significant differences with respect to control were found in alkaline phosphatase (ALP) levels after exposures to 0.2 mg/L and 2 mg/L NPs.

Discussion and conclusions

Overall, results showed that NPs activate transcriptional machinery in the liver of *D. labrax*, leading to increased expression of genes related to lipid metabolism. Peroxisome proliferator-activated receptors (PPARs) participate on the fatty acids signals as key regulators of lipid metabolism. The peroxisome proliferation has been proposed as a biomarker for environmental pollution assessment, as increases in the size, number and volume of peroxisomes in aquatic organisms exposed to contaminants have been documented in marine species. Alterations in mRNA levels of *ppara*, *pparγ* and *nd5* after exposure to NPs suggest an interference with the ability of fish to mobilize energy reserves. Regarding biochemical parameters, decreased EA levels were found in plasma after exposure to 0.02 and 0.2 mg/L NPs, and levels of ALP in skin mucus also decreased significantly following exposure NPs, at 0.2 and 2 mg/L. Both enzymes could play an important role in sea bass innate immunity, and their decreased levels suggests an impairment of the immune system's function following exposure to NPs.

Amoebic gill disease (AGD), caused by *Paramoeba perurans*, is a major health issue for the global Atlantic salmon (*Salmo salar*) aquaculture. Even though the cases in Norway become more or less stable in the last years, AGD remains a persistent and serious gill health challenge. Hydrogen peroxide (H_2O_2) is the commonly used chemotherapeutant for AGD. However, the treatment resolution between lab-based and field-based experiments is often weak and a very high concentration of H_2O_2 is required. Peracetic acid (PAA) is being proposed as an alternative chemotherapeutant to H_2O_2. PAA is one of the most commonly used disinfectants in aquaculture because of its high treatment efficac . Earlier reports demonstrated that PAA has a far more antimicrobial effect than H_2O_2, and its effective dose against various pathogens is relatively lower than H_2O_2. In this study, we explored *in vitro* the anti-parasitic activity of PAA against *P. perurans*. We first evaluated several staining techniques for viability test to be employed in the *in vitro* exposure systems. Out of the four staining techniques (*i.e.*, MTT, Neutral Red, Resazurin, WST-1) tested, WST-1 assay was selected because of its stability and discriminatory potential. Preliminary results of the *in vitro* microplate-based exposure revealed that *P. perurans* were susceptible to PAA after a 30-min exposure at 2.4 ppm concentration. In a parallel study, we have documented that exposing salmon to PAA at similar concentration did not result to compromising health concerns. The microplate-based WST-1 assay for viability was complemented with Neutral Red-based staining, to provide a more quantifiable data of the susceptibility of *P. perurans* to PAA. PAA compromised the cell membrane of the amoeba thereby killing them, as supported by the loss of uptake of the Neutral Red dye in PAA-exposed amoeba. This observation corroborated the microplate-based assay of the killing potential of PAA against *P. perurans*. We are currently running several *in vitro* experiments to investigate how different factors (*i.e.*, dosage, temperature, starting parasite concentration and light) affects the anti-parasitic activity of PAA against *P. perurans*. Protocols will be standardised, and methods optimised continuously in the working process.

REMOTE MONITORING OF CARDIOVASCULAR PERFORMANCE TO GAUGE STRESS RESPONSES OF RAINBOW TROUT (*Oncorhynchus mykiss*) IN AQUACULTURE

J. Brijs[1]*, E. Sandblom[2], M. Axelsson[2], K. Sundell[2], H. Sundh[2], A. Kiessling[2], C. Berg[1]and A. Gräns[1]

Introduction

The welfare of farmed fish has become of increasing concern for consumers, producers, interest groups and authorities. To improve the welfare of fish, it is necessary to identify and quantify the severity of stressful farming practises early enough so that an intervention can take place before detrimental effects occur. The rapid development and miniaturization of bio-telemetry systems and bio-loggers presents a solution, as they allow us to remotely record physiological stress responses in fish over long uninterrupted periods. The remote measurement of cardiovascular variables such as heart rate and gut blood flow provide exciting avenues for determining and quantifying stress responses of fish, as these physiological parameters are affected by most behavioural responses, as well as most environmental and anthropogenic perturbations. By exploiting this technology, the aim of the present study was to investigate whether *in vivo* monitoring of heart rate and gut blood flow in freely swimming fish could be reliably used as an indicator of stress and as a tool for assessing the welfare of farmed fish during common aquaculture practises before and during harvest.

Materials and methods

20 rainbow trout (body mass: 2082±113 g) were surgically implanted with DST milli-HRT bio-loggers (*i.e.* measures heart rate and body temperature, Logger version 8, STAR-ODDI, Iceland) and 4 additional rainbow trout (body mass: 2941±166 g) were implanted with multivariate bio-loggers (*i.e.* measures heart rate, gut blood flo , activity and body temperature, Transonic EndoGear3, Transonic Systems Inc., USA). The surgically implanted individuals were then transported by well-boat and transferred to a sea cage containing ~5000 conspecifics where they remained for 16 days during which the bio-loggers were continuously recording. After these 16 days, the trout were transported by well-boat from the sea cage to the slaughterhouse. During this procedure, trout were subjected to a series of common aquaculture practices such as light crowding, severe crowding, brailing, well-boat transportation, held in a stationary well-boat, held in a holding cage by the slaughterhouse, and then finally brailing directly followed by CO_2 stunning. During this period the bio-loggers were continuously recording. Un-instrumented trout were also captured with dip nets at each of the abovementioned steps and sampled for blood via caudal puncture. Blood samples were subsequently analysed for plasma cortisol, haematocrit, haemoglobin concentration, red blood cell count, and electrolyte concentrations.

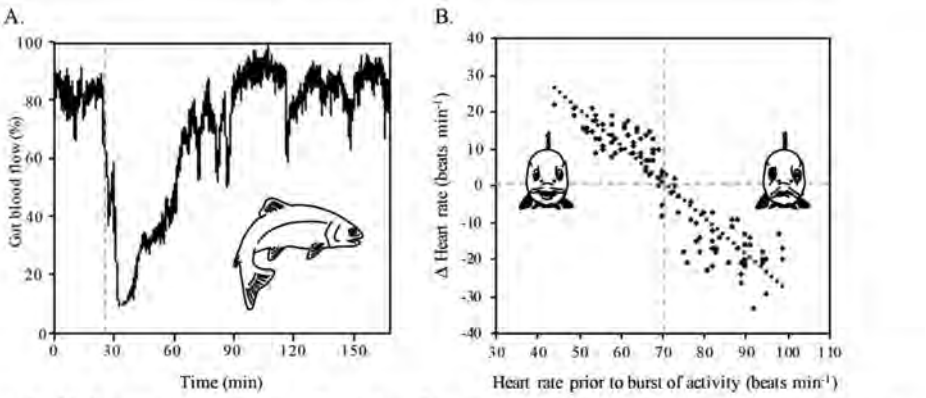

Figure 1: A) A representative trace displaying the consistent gut blood flow response to an acute stress event (dotted line). B) Chronically stressed fish display bradycardic heart rate responses in response to acute stress events or spontaneous bursts of activity, whereas relatively unstressed fish display tachycardic heart rate responses. Data from Brijs *et al.* 2018 and Brijs *et al.* submitted.

(Continued on next page)

Results

Life in the sea cage: After the initial release into the sea cage, heart rate and gut blood flow of trout were significantly elevated and it took ~7 days for heart rate and gut blood flow to stabilize. During this time, when fish experienced an acute stress event or a spontaneous burst of activity (*i.e.* during the daily approach of the feeding boat and subsequent feeding event), transient reductions in both gut blood flow and heart rate were observed. However, once fish had recovered, acute stress or spontaneous activity instead transiently increased heart rate while gut blood flow still decreased. Interestingly, a clear circadian rhythm in heart rate emerged in the recovered trout (*i.e.* average circadian fluctuation in heart rate of ~25 to 27 beats min^{-1}).

Final journey before slaughter: Stressful handling practises (indicated by elevated plasma cortisol levels) such as crowding and transportation significantly elevated heart rate whilst transiently reducing gut blood flo . In contrast, other stressful practises such as air exposure during brailing triggered significant reductions in both heart rate and gut blood flow until the trout were released back into oxygenated water, whereupon heart rate significantly increased. Repeated stress induced by multiple handling practises clearly had a cumulative and long-lasting effect, as both heart rate and gut blood flow peaked at the end of the day of transporation and remained elevated up until slaughter the following day.

Discussion and conclusion

Acute stress induced by common farming practices, as well as intense voluntary activity, consistently resulted in relatively rapid and substantial decreases in gut blood flow of farmed trout (see figure 1A). However, in contrast to reductions in gut blood flow caused by voluntary activity, recovery from stress-induced reductions involved a substantial and prolonged increase in gut blood flo . This may be necessary to repair stress-induced damages to the gastrointestinal tract. Long-term recordings of heart rate clearly demonstrated that heart rate responses to acute stress or intense activity differ depending on the physiological state of the animal (see figure 1B). Stressed fish (*i.e.* elevated mean heart rates >70 beats min^{-1}) tended to exhibit decreases in heart rate in response to acute stress or intense activity, whereas fish with mean heart rates <60 beats min^{-1} exhibited markedly increased heart rate responses. Therefore, although both parameters are useful indicators for stress in fish, researchers utilising heart rate as an indicator of stress need to be aware of the physiological and behavioural constraints that affect heart rate and thoroughly evaluate the range of heart rates normally exhibited by their model species. In conclusion, the present study demonstrates that the application of bio-loggers provides a powerful tool for the further development of management protocols aiming to pinpoint stress and improve welfare of farmed fish, which in turn may have ethical and economic benefits for the aquaculture industr .

SPAT MORTALITY IN FARMED BLUE MUSSELS (*Mytilus edulis*) IN SCOTLAND

C. C. Broughton[1]*, J. Bailey[1], D. Green[1], M. Weidmann[1], S. Carboni[1]

[1]Institute of Aquaculture, University of Stirling, FK7 4LA Stirling, Scotland, United Kingdom
E-mail: c.c.broughton@stir.ac.uk

Introduction

The industry for blue mussels (*Mytilus edulis* (Linnaeus, 1758)) has been a growing sector in Scotland for the past ten years, and relies heavily on the wild collection of seed (spat) for the on-growing product. There are several external risks that could impact mussel production, especially unreliable spat resources and poor water quality, pollution, bio toxins and infectious diseases (Bower et al., 1994). In recent years, problems involving spat availability and mortality have occurred impacting the mussel industry to the extent of possible closures of some businesses. One site in particular has been experiencing a severe case of spat mortality in the winter months for the past decade. Interestingly, it is only in the winter months where the mortalities have been observed and only the spat is affected, whereas older mussels from the previous season seem to remain in a healthy state. The investigation of this mortality case involves an experimental design which observes the mortality on a fortnightly basis by deploying lantern nets from the grow out lines in the affected site and in one control site.

Materials and methods

20 lantern nets, each stocked with 1000 individuals, were deployed across the affected site and 10 nets were deployed across a control site in a different body of water, which has not been experiencing any mortality, late October of 2018. The collection and counting of dead spat occurred after stocking, for a period of 11 weeks. Live and moribund samples, and eventually some survivors, were collected at each time point for analyses including histopathology, bacteriology, virology, gene expression and DNA sequencing. Temperature and salinity were monitored in the proximity of the experimental nets at both affected and control sites. Additionally, water samples for heavy metal analysis by Ion Coupled Plasma Mass Spectrometry were collected at each time point.

Results and discussion

Preliminary results confirm that spat mortality was significantl higher in the affected site compared to the control site, reaching 68.3 percent over four time points within the 11-week period. Most mortalities were observed at T1 and T2 reaching 54.9 percent (30d post stocking) after which the mortality rate then subsided at T3 (62.7%), 44d post stocking, contrasted by a 0.9 percent maximum mortality at the control site. Gene expression analysis of the spat collected during the mortality and the survivors collected at the end of the mortality period may determine whether there is a difference in response, indicating susceptibilities or compromised immunity. These results will be related to the monitored environmental parameters, histopathology examination, and heavy metals concentrations.

EVALUATING THE EFFECTS OF FARMING REARING TOOLS ON THE QUALITY ASPECTS AND GROWTH OF THE PACIFIC OYSTER *Crassostrea gigas*

G. Brundu*[1], B. Loi[1], A. Chindris[1], P. Graham[12], D. Bernabè[1], and G. Giménez Papiol[1]

Introduction

According to farmers and buyers, the main characteristic that defines the marketability of an oyster is the shell shape. A good oyster has a teardrop shape (thick, deep and wide) and it must be without epibionts and blisters (Doiron, 2008). Various factors are able to influence the shell shape of the oysters, among which the rearing tool adopted. The aim of this study is to evaluate the effects of the innovative Ortac farming system on the quality aspect of the Pacific oyster *Crassostrea gigas* (Thunberg, 1793) (shell shape, weight meat percentage, backward shape, epibiosis and blisters) and growth rate (weight and length). Results obtained with ortac were compared with those obtained with the traditional floating bag

Materials and methods

The experiment was conducted in a shallow lagoon located in the central-western coast of Sardinia Island (Western Mediterranean, Italy). A total of 2,400 triploid *C. gigas* spat (6±0.1g fresh weight, 40.5±0.3mm length, mean±SE) were seeded in 12 rearing tools (200 seed per tool): 6 floating bags (hereafter bag) and 6 ortacs (hereafter ortac). Oysters were reared for fourteen weeks (from September to December 2018) continuously immersed in the water during the whole experiment. At the end of the experiment, five random individuals per tool were measured for wet and dry weight of meat and shell, as well as length, width and depth. Weight and biometrics were used to calculate the shape score, an indicator of the quality shape of the oysters ((length/width)/(depth/length), Rankin et al., 2018), and the weight meat percentage of the animals (percentage of dry meat weight (g)/dry shell weight (g), Davenport and Chen, 1987). The backward shell curvature (i.e. unfavorable for holding the meat, Rankin et al., 2018) of all the animals per tool, as well as the percentage of oysters hosting epifaunal organisms (serpulids and barnacles) and the presence of blisters in the shell, were recorded. The wet weight and shell length of thirty random individuals were measured every two weeks, and mortality rate was checked in comparison to the starting number of animals. All data were analyzed by Statistica 6.1 StatSoft,Inc. (2004).

Results

The tool influenced both the quality and the growth of the animals. Oysters grown in ortac resulted in a poorer shape score, a lower weight meat percentage, a higher percentage of backward and blisters, and a lower percentage of animals free of epibionts (Tab. I). Regarding the growth rate, the bag showed a higher ($p < 0.05$) wet weight from week 8 (32.3±0.4g) to week 14 (32.4±0.4g) than in ortac (26.8±0.5 and 28.3±0.4g at week 8 and 14, respectively). The length increased significantly from week 0 to week 8, without significant d ferences between tools (Fig. 2).

Discussion and conclusions

According to our study, the rearing tool affects both the quality aspect and the growth of *C. gigas*. In the past, mortality and growth were considered the main selective breeding traits in oyster aquaculture (Mahon, 1983), while nowadays, as a niche market product, the appearance of the oyster is commercially important and shell quality is the first feature affecting buyers (Brake et al., 2003). No mortality was observed in our study, and oysters grow faster when reared in the bag (i.e. higher weight from week 8 to week 14). Better results with bag were obtained also in the quality aspect (i.e. low shape score, high weight meat percentage, low percentage of backwards and blisters), except for episiosis, since a lower shell colonization by barnacles and serpulids was obtained with ortac. Ortac is an innovative tool able to improve the growth rate and the shell quality of the oysters (Flynn, 2013) in oceanic conditions. Results obtained in our study demonstrate that, when grown in Mediterranean lagoons and by using ortac, *C. gigas* has a worse quality aspect and a lower growth performance than in bag. We hypothesize this is due to the different environmental conditions of Mediterranean Sea in comparison to the oceans, mainly the lower water movement (i.e. tides, currents and waves). The adoption of more accurate husbandry practices and/or adjusting the ortac farming system to Mediterranean features could improve the efficiency of the tool, in terms of quality aspect and growth.

Introduction

In Europe, the demand for shellfish products is constantly expanding and the Mediterranean Sea could offer potential locations for expansion. In Italy, Sardinia records the greatest national productivity of the Pacific oyster *Crassostrea gigas* (Thunberg, 1793), about 60% of total production accounted to just five oyster farmers operating in small coastal lagoons (FAO, 2019). Since Sardinia has many areas covered by shallow coastal lagoons that could represent potential sites for oyster farming, the Sardinia Region funded the OstrInnova project. The general objectives of the project were to increase the oyster production, by identifying new potential farming sites and assessing the productivity by implementing a bio-energetic growth model. One of the main outcomes of the project was a pilot scale bivalve's hatchery at the International Marine Centre - IMC facilities (Oristano, Italy). This was designed for research and technology transfer on the production of shellfish. The hatchery, together with the knowledge and skills required for its management, represents an after-OstrInnova asset, available for the development of shellfish production and research in Sardinia.

Materials and methods

In the OstrInnova project, shellfish producers, universities and research centers from Sardinia and UK were involved. An expert in shellfish production and research was involved for the hatchery design, this was made taking into account the location and the existing facilities. OstrInnova was launched on April 2016, and from the beginning of the project the IMC staff was trained on shellfish production techniques. During the training period, a 2-months stage in a leading research institute (Cawthron Institute, New Zealand) on shellfish research and production was done by a member of the IMC staff, aiming to improve the expertise in bivalve's hatchery protocols. The pilot scale hatchery, built during summer-autumn 2018, allows research at different scales for each developmental stage of shellfish species and is useful for investigating on the reproduction and rearing of diploid and triploid oysters.

Results

The pilot scale hatchery is composed by four units, phytoplankton production, broodstock conditioning, larval rearing and post-larval stages. The phytoplankton production unit is provided with nine polyethylene photobioreactors of 200-300 l capacity each one. The photobioreactor are equipped with a lighting systems consisting of 40W cool-white fluorescent tubes. The system is supplied with CO_2 and equipped with a blower and a micro filtration system for the air. In order to facilitate the distribution of phytoplankton and to minimize potential contamination from the outside, a system of pipes and a volumetric pump were set up to connect the photobioreactors to the different hatchery units. The broodstock unit includes six 150 l slope bottom customized tanks and a spawning table equipped with a chiller/heater unit. This design allows the maintenance of six separate broodstock tanks, with a maximum capacity of 300 adults. The larval rearing unit includes two separate systems, one static and one flow-through. The first system consists of nine cylindrical tanks with conical bottom, with a capacity of 180 l each. The second one is composed by twenty 5 l polymethyl-methacrylate transparent cylindrical containers that works as a flow-through system. The post-larval stages unit is composed with i) a settlement unit (3 tanks), ii) a micronursery made of 20 upwellers, and iii) a nursery tank operating either in downwelling or upwelling. For biosafety reasons, each system is equipped with a filtration system (sand or cartridge filter), UV sterilizer, chiller/heater and protein skimmer.

Discussion and conclusions

Sardinia is the highest oyster producer in Italy, and this production is completely focused on triploids Pacific oyster *C. gigas*. Due to the absence of oyster hatcheries in Sardinia, and that in Italy exists only an oyster hatchery located in Ferrara which produces just diploid oysters for local farmers, the total amount of *C. gigas* spat seeded in the region comes from French hatcheries. Taking into account the current and potential shellfish production in Sardinia, the government has started to invest on the improvement and development of this industry. In this line, the pilot scale hatchery built at the IMC laboratories has not the purpose to produce *C. gigas* for farmers but to improve the scientific research about reproduction

(Continued on next page)

and rearing of triploid individuals, increase knowledge and skills, and develop and transfer the required technology to the productive sector. This strategy is aimed not only to *C. gigas* but also to other shellfish species of interest, such as *Ostrea edulis*. On the basis of the information obtained during the OstrInnova project, the future production of shellfish in Sardinia is focused on the rearing of the European flat oyster *O. edulis* as an alternative species to the Pacific oyster. For this reason, and considering that along the Sardinian coasts exist well-established natural populations of *O. edulis*, one of IMC's research lines on shellfish production will be focused on the reproduction and rearing of this species. Research on *O. edulis* will have a local impact and can contribute to the global production of the species and to the restocking efforts invested in other areas. Shellfish production in Sardinia is a regional development strategy that can contribute to local and global challenges.

Acknowledgements

The project "OstrInnova - Valorization of the oyster sustainable production in the shellfish rearing system of Sardinia" was fund by Sardegna Ricerche. Special thanks to Julien Vignier, aquaculture research scientist of Cawthron Institute (Nelson, New Zealand), for hatchery design, help, suggestion and hosting for training.

PRODUCTION POTENTIAL OF BLUE MUSSEL (*MytiluS* SPP.) FARMING ALONG THE SALINITY GRADIENT OF THE GERMAN BALTIC SEA

Anna-Lucia Buer*[a], Lukas Ritzenhofen[a], Marie Maar[b], Gerald Schernewski[a]

Introduction
Aquaculture production is globally increasing (80 mio t in 2016) but production in Europe contributes to only 3% while Asia dominates with 85% (EEA 2018). For shellfish aquaculture (mainly *Mytilus* spp.) production in Europe even decreased from 190,000 t in 2000 to 155,000 t in 2016. To support blue growth in Europe, the EU Blue Growth Strategy (COM(2012) 494/F1, EC 2012) was developed, including the expansion into areas, with sub-optimal growing conditions for *Mytilus* spp. as the Baltic Sea (Beyer et al., 2017). Mussel cultivation is an extensive aquaculture without additional feeding, avoiding an input of extra of nutrients. The blue mussel is distributed in most parts of the Baltic Sea and juvenile mussels (spat) settle naturally if collector material is provided. By its filter feeding behaviour, it removes particles and binds nutrients in biomass. When harvested, it can then support nutrient removal in that waterbody (Petersen et al., 2014)Denmark where biological and economic parameters related to nutrient removal was monitored throughout a full production cycle (1yr. The limiting factor here is the decreasing and highly variable salinity, which hampers growth of *Mytilus* spp. To further investigate the potential of blue mussel farming and nutrient extraction in the Baltic Sea, where tradition is scare, several studies have been conducted or are ongoing in many member states. We focused on the southern Baltic Sea, where along the German coast a salinity gradient from 1 to 24 psu is covered. We compare growth rates of four mussel farm trials in German coastal waters to estimate production potential and nutrient removal depending on salinity. Furthermore, a Dynamic Energy Budget (DEB, Maar et al., 2015) model based on environmental parameter (salinity, temperature, chlorophyll a concentrations) is verified with measured growth data to predict mussel growth under varying conditions in di ferent areas.

Material and methods
Test mussel farms in the longline system were set up in Kiel, Nienhagen, Greifswald Bay (GWB) and Wieker Bay (WB) at salinities ranging from 7 to 17 psu and growth data of the first 12 to 16 months collected. Results were entered into the growth model (DEB) combined with environmental monitoring data and growth potential at twelve different locations along the German Coast estimated covering a wide salinity range. Based on modelling results, potential usages of the biomass yield after 6 and 18 months and the economic feasibility was investigated.

Results and discussion
Kiel Bay and Nienhagen show fast growth, nearly comparable with North Sea mussels (Walter and De Leeuw, 2007)with 11 000 to 64 000 individuals per meter collector. The shell length of suspended mussels increased in their first summer at an average of 1.2 mm per week. Between the end of August until the end of September a mean of 2 to 9 kg mussels per meter equalling 4500 to 20 300 individuals per meter were harvested. Relayed on bottom cul- tures the mussel seed continued to grow and could be marketed as consumption mussels after their second summer. Kurzfassung Seit 2001 ist die Langleinenkultur von Miesmuscheln (Mytilus edulis. Nonetheless, modelling predicts far slower growth in Nienhagen and hereby highlights the dependency on environmental parameters such as temperature and chlorophyll followed by annual divergences in mussel growth. A continuous yield is important for economic feasibility as well as fast growth and a market size of min. 5 cm after 18 months which can only be reached in areas of a salinity of 11 psu or more. If aiming for small size mussels, a compensation fee is necessary for the removal of nutrients to make mussel farming economically attractive in regions of low salinity.

Introduction

Regrouping, loading and transport are common sources of stress in farm. This is also true for fish. Well-boat transport and loading are very stressful for fish such as salmon (Delfosse, 2017; Iversen *et al.*, 1998). Composed of *Melissa officinalis* and soluble magnesium, a natural product is used to reduce aggressiveness and to improve animal welfare. A previous study set up in fishes shown a decrease of stress in fish at a recommended dosage of 0.25ml/l. (Labalett *et al* 2018).

The aim of the present study is an assessment of environmental safety of this solution by studying biological biomarker. The toxicity of this product was evaluated using bioassay. The mortality of two copepods (*Daphnia Magna* and *Tisbe Longicornis*) and the growth rate inhibition of marine micro-algae (*Selenastrum Capricornutum* and *Dunaliella tertiolecta*) were analyzed at different dosages in order to evaluate the eventual toxicity of this natural product.

Material and method

The methods used to measure the livability or growth population inhibition were different. Growth population inhibition test was done on 50 ml with a density of 10,000 cells by ml, the culture of *S. capricornutum* and *D. tertiolecta* was continuously exposed to light and mixed twice a day. Three replications and six different dilutions were applied, the initial solution containing sea water and nutrients for the right development of the organism. The dosages applied were 0; 0.625; 1.25; 2.5; 5; 10 ml/l of *Melissa officinalis* combined with magnesium (Durelax® Liquid, Norfeed, France), the micro-algae were exposed to each dilution. The cellular density was measured 48h after the start of the trial.

The objective of the second test was to measured the incidence of the natural solution on two copepods, *D.magna* and *T.longicornis* livability. Juveniles copepods were used in this trial. *Daphnia Magna* was used after 24 hours of clutching. *T.longicornis* were chosen according to their size (125-250 µm). Four replications by treatment and seven different dilutions were done: 0, 0.25; 0.5; 1; 2;4;8 ml/l of water. The mortality was measured after a time exposure of 96 hours.

Results and discussion

No mortality on *D.magna* or *T.longicornis* was observed showing the safety of the product even at doses 32 times the recommended dosage.

There was no growth inhibition concerning *D.tertiolecta* even at doses 40 times the recommended dosage. However, we observed a significant speed growth reduction of *S.capricornutum* for dosages from 10 times the recommended dosage compared to the control.

At the recommended dosage 0.25ml/l and up to 10 times the recommended dosage there is no incidences on sensitives biomarker species . This combination of *Melissa officinalis* and magnesium could show great potential of use for aquaculture

Introduction

With many capture fisheries already being fished above sustainable limits (Froese et al., 2018), the only way to produce more fish, is through aquaculture (World Bank, 2013). However, in view of food production having a major environmental impact, e.g. to climate change through greenhouse gas (GHG) emissions (Steinfeld et al., 2006), assessing the impact of the production chain is crucial to ensure a sustainable growth of the sector by understanding how to limit or prevent environmental impacts. Globally operating certification schemes, such as the Aquaculture Stewardship Council (ASC) set limits on these impacts for participating farms. The ASC was established in 2010 in order to provide certification for farmed fish based on standards of best practice defined through multi-stakeholder dialogues. Because climate change is a global problem and the biggest of the environmental factors to be addressed, the ASC promotes efficient and sustainable energy use and requires their farms to monitor energy use on the farm sites and feed use (Aquaculture Stewardship Council, 2019).

The ASC currently has nine certification standards available, of which salmon is the most important one in Europe in terms of production volumes and value (European Commission, 2017). At present, ASC has 27% of global salmon farming under certificati n, which is about 40% of all ASC-certified farms (Roebuck and Wristen, 2018). The ASC strives to lower GHG emissions from these certified farms by lowering the energy use. Therefore, the aim is to investigate and evaluate the environmental impact in terms of GHG emissions from energy use and feed at ASC-certified salmon farms sites.

Materials and methods

For this study GHG analysis will be performed using data available from ASC-certified farm sites to evaluate energy use and associated GHG emissions (CO_2-equivalents (CO_2e)) and GHG emissions resulting from feed from grow-out sites of Atlantic salmon production. GHG will be assessed using one tonne of live-weight salmon as functional unit for the assessment, limited to the grow-out site of salmon, as data from smolt production will not be used and chain of custody is not available. This data will be compared as far as possible to secondary data from non-certified farms obtained from literature resources. Comparisons within certified data will made in regard to companies and countr .

Data submitted from a total of 176 salmon farming sites contain quantity and type of energy used on each farm site per production cycle and the calculated GHG emissions in CO_2e thereof. Moreover, farms also provided data on GHG emissions from feed (CO_2e) calculated by themselves multiplying the specific GHG emission factors per kilo of feed provided by the feed manufacturer by the amount of feed used per production cycle on the farm site. Since data for GHG emission related to energy use are required to be submitted per year, conversions will be applied in order to have the same time period for all indicators when needed. Data could be accessed through the database of ASC, being submitted for each farm site in order to obtain ASC certification

As there is no uniform format for data submission in place, differences in detail of the received data were present. Therefore, submitted data was classified in terms of detailedness and completeness as ‘poor’, ‘medium’ or ‘good’. Classification ‘poor’ was given for farm sites that just provided the resulting values for each indicator without further detailing or when data was missing. Whereas, ‘good’ meant a detailed report including all necessary background information and sources. And ‘medium’ covered all the basic required data points but certain factors were left out. Poor quality was excluded from further analysis, leaving 89 farm sites for assessment. As farms are allowed to use different sources for the calculation of emission factors, difference in these will be investigated and GHG emissions will be recalculated with one standardized value for all of them.

An overall comparison of GHG emissions from energy use as well as feed of all farm sites will give an indication of the ranges of the farms under certification

(Continued on next page)

Results / Discussion

The results of this study will be used as a first step to evaluate the current practice of ASC-certified farms on GHG emissions. This might help to alter the requirements on these indicators to further drive reduced energy use and GHG emissions or to help in the improvement of data collection.

This abstract will be adapted as soon as the results are available.

Introduction

The optimization of feeding management is essential to improve the key performance indicators such as growth rates, feed efficienc , mortality and quality traits of the Mediterranean aquaculture. Optimal feeding frequencies under farming condition may contribute to maximise feed utilization reducing wastes and production costs. Several effects of the feeding frequency on performances have been observed in different fish species mainly depending on the fish size and on the interactions between feeding frequencies and type of administered diets (Yúfera et al., 2014; Enes et al., 2015; Guo et al., 2015; Zeytin et al., 2016). This study was undertaken in order to assess the effects of different feeding frequencies on growth, feed digestibility, somatometric indexes, fish plasma biochemistry, and digestive condition of gilthead sea bream fed different fishmeal and fish oil dietary levels with the final aim to provide guidelines designed for the daily management of feeding practices under farming condition.

Materials and methods

Two isoproteic and isoenergetic experimental extruded diets with different FM and FO dietary level (FM/FO 30/15 and 10/3, A and B, respectively) were formulated using practical aquafeed ingredients. Each diet was randomly assigned to fish groups of 60 individuals (initial weight: 88.3 ± 2.4g) each submitted to a different feeding frequency (1, 2, 3 meals day^{-1}) in triplicate: (1) a daily meal at 8.30am, (2) two meals a day at 08.30 and 16.00 and (3) three daily meals at 08.30, 12.30 and 16.00 respectively, over 109 days. All the fish received the same total daily feeding ration that was determined based on the feed ingested by the group 1 which was fed close to satiation (90-95% of the satiation level). At the end of trial growth, feed utilization, feed digestibility, digestive enzyme activity, gut histology and plasma biochemistry were measured. Data were analysed by a two-way ANOVA followed by a Tukey's multiple comparison test.

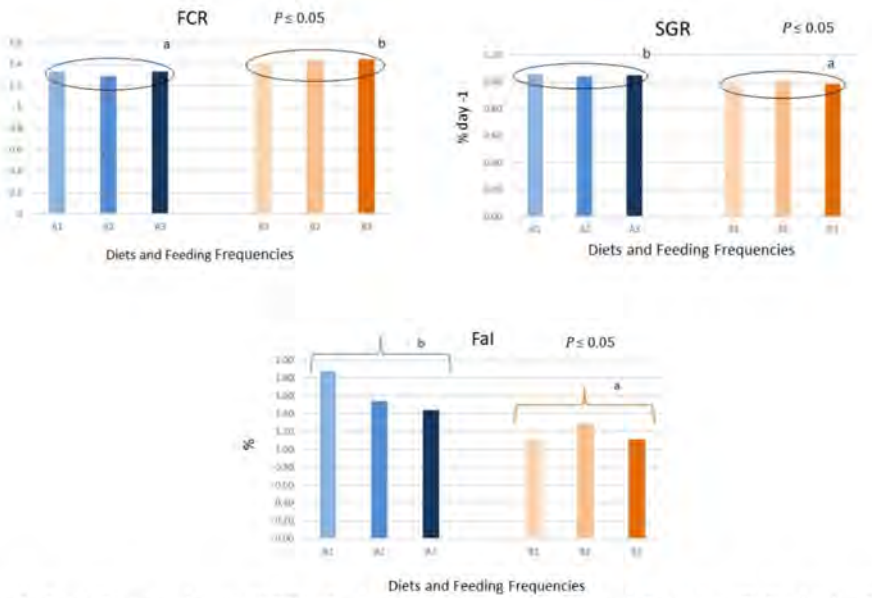

Fig.1. Specific growth rate (SGR), feed conversion rate (FCR) and fat index (FaI) obtained at the end of the trial under different feeding frequencies (1, 2, 3 meals) and fed high (A) and low (B) fishmeal and fish oil dietary level. Different superscript letters a, b denote significant differences among diets.

(Continued on next page)

Results

At the end of the trial, no significant differences ($p > 0.05$) due to the different feeding patterns were observed in terms of final body weight, specific growth rate (SGR), voluntary feed intake (VFI), feed conversion rate (FCR) and no significant differences were found in the viscerosomatic index (VSI), hepatosomatic index (HSI), condition factor (CF) and fat index (FaI) values between different feeding frequencies. SGR and FaI values were slightly higher in diet A compared to diet B while FCR showed lower values (Figure1).

Discussion and Conclusion

The results showed that it is possible to obtain an equivalent growth performance and feed utilization regardless of the number of the meals daily administered under both high and low FM and FO dietary level. No effect on fat deposition was determined by feeding frequencies even if a tendency toward lower values were observed in the 3 meals group fed high FMFO level. Based on the present results frequent feeding do not support an increase in feed utilization during the on-growing of sea bream and this could be a useful indication to plan feeding activity at farm level which maximize growth and costs of feeding procedures.

Seafood production through aquaculture is in a unique position to contribute to healthy and sustainable diets and help to tackle the rising burden of chronic noncommunicable diseases and malnutrition in the UK, if environmental sustainability challenges and barriers to consumption are adequately addressed. Diversifying production, especially towards species of higher environmental sustainability, such as seaweed, mussels and sea urchins, and in particular through Integrated Multi-Trophic Aquaculture (IMTA), could serve a significant purpose towards bioremediation, while also allowing for product diversification and increased public acceptability of the industry. However, continued challenges to the commercial implementation of IMTA have hindered investment.

The Diverseafood project addresses barriers to the diversification of aquaculture systems in the UK, notably the development of economically attractive business models, a suitable regulatory framework and the consumer market of IMTA produced seafood, while evaluating the contribution of IMTA to the nutritional value of aquaculture-produced seafood and to the environmental sustainability of the sector. One key challenge is that current IMTA systems do not consider the economic value of the bio-mitigation services provided by extractive species or the value they might represent in terms of social licence to operate. This work will identify the value of provisioning, regulating and socio-cultural ecosystem services associated with IMTA by developing the first bioeconomic model for IMTA to value diversification and nutrient removal and analysing the effect of IMTA practices on the social licence for companies to operate.

This research will evaluate the impact of a transition from salmon monocultures to IMTA systems on the value of provisioning, regulating and socio-cultural ecosystem services. The project will develop a bioeconomic model of growth and harvest based on existing IMTA optimisation models of multispecies productivity and studies that examine the economics of IMTA. Data requirements include farm layout, investment and operating costs, sale prices, cultivation (species, harvest weight, culture period, mortality), environmental drivers (water temperature, salinity, total particulate matter, etc.) and culture practice (stock density, feed applied, etc.) and will be sourced from previous experiments and existing literature.

The bioeconomic model will couple an economic value function with the dynamics of a conventional monoculture salmon farm and then add in co-cultured groups (bivalves, seaweeds). The main difference between the monoculture and the IMTA system formulations is that these versions will include extra terms for the revenue and costs from the addition of co-culture groups (impact on provisioning services), as well as extra bio-mitigation terms in the equation of motion (impact on regulating services). Thus, it will consider two elements that can potentially add to economic welfare using diversified systems, (i) increased profitability and reduced risk through diversification, and (ii) nutrient remova

Several interesting aspects of the management of an IMTA system operation in contrast to monoculture will be analysed. We will begin by introducing a fixed site area for the operations, which amounts to imposing an additional constraint in the optimization problem. This expanded model will be used to consider the current regulatory regime in Scotland that involves the use DEPOMOD/AUTODEPOMOD models by the Scottish Environment Protection Agency (SEPA) (Ecasa Toolbox 2007) to regulate aquaculture discharges. The case of a nutrient tax will then be considered, showing how this leads to different management and welfare implications and, finall , extend the analysis to consider the often-discussed notion of a “nutrient credit”. The model will provide a useful quantitative tool for the aquaculture industry, regulatory bodies, and the scientific community to understand how diversified aquaculture systems can support an environmentally sustainable and economically profitable expansion of aquaculture. The recognition of both provisioning and regulating ecosystem services and their association with a system of nutrient trading credits, which still has to be put in place at a national or international level, can represent financial incentive tools to encourage producers to contemplate alternative diversified aquaculture systems as viable options to their current practices

(Continued on next page)

With few ecological-economic assessments of IMTA vs. monoculture done to date (e.g. Shi et al. 2013, Nobre 2010), the development of a bioeconomic model will help create financial and regulatory incentives for governments and the industry to jointly invest in IMTA systems and for companies to improve operating practices. It will also be used to support the analysis on establishing and implementing a scheme for the payment of credits or other incentives for bio-mitigating services.

Public perception is considered one of the limiting factors to the expansion of aquaculture, as it translates not only in seafood purchasing and consumption attitudes, but also on the shaping of public support for the industry and social licence to operate. However, to build social approval it is essential to understand perception and attitudes and their underlying factors, and use this to improve how businesses, third sector and regulators operate and engage with the public.

Though several studies have focused on analysing consumers' knowledge and consumption habits, the stated preference for aquaculture or wild-caught seafood products, the relevance of key topics (e.g. welfare), trends in media coverage in European countries; literature remains scarce on the determinants of public perception of aquaculture and associated attitudes, as well as contrary or supporting arguments, with studies on social licence to operate in aquaculture just recently starting to populate the literature. There is also limited evidence that informing the public by itself is an effective strategy to raise acceptability or to increase consumption and there is high uncertainty on what should be communicated to the public or communities and how this engagement should occur. The role of others, such as corporate social responsibility or certification, in shaping the image of aquaculture also remains poorly explored.

A systematic literature review was conducted on perception and attitudes towards aquaculture at European level and used to inform subsequent focus groups with public and communities and stakeholder interviews exploring communication in aquaculture. Focus groups were designed to investigate seafood purchasing and consumption behaviour, as well as public perception and attitudes to aquaculture production and products; with a total of 6 focus conducted (6-8 participants each) with different groups of UK consumers (low-frequency, high-frequency), non-consumers (general, vegan) and communities living in proximity of operating aquaculture facilities (older members, younger community members). A series of in-depth interviews were also be conducted with different UK stakeholders (producers, processors, retailers, third sector and regulators; 3-4 per group) to identify perceived public perception issues, communication challenges and pathways for improved engagement. This research aims to support the development of best communication practices, improve public engagement with the aquaculture sector and sustainable seafood production and consumption.

ANTIMICROBIAL ACTIVITY OF *Nannochloropsis* spp. AGAINST FISH PATHOGENS

I.T. Çağatay*, M. Özbaş, N.A. Satı and H.E.Yılmaz

Akdeniz University, Faculty of Fisheries, Antalya, Turkey
E-mail: tulaycagatay@akdeniz.edu.tr

Introduction

Microalgae are the primary sources of many bioactive compounds like proteins, carbohydrates, lipids, vitamins and enzymes. It is considered a promising organism for industrial and biotechnological applications because of its ability to accumulate high levels of polyunsaturated fatty acids (Durmaz, 2006). Microalge are used in food additive for human or animal nutrition, pharmaceutical industry, organic fertilizer, biofuel production, drug therapy and antimicrobial, antifungal agent for human pathogens (Spolaore, 2006; El-Sheekh et al., 2006; Dussault et al., 2016).

One of the most important bacterial diseases that cause economic losses in aquaculture is rainbow trout fry syndrome caused by *Flavobacterium psychrophilum*, affecting hatchery reared rainbow trout fry and fingerlings. Synthetic antibiotics and vaccine are used in treatment and cure however, accumulation and resistance to these drugs by aquatic-environment are increasing problems. Therefore, finding alternative agents for pathogen control are crucial for Turkish aquaculture sector which has around 240 thousand tons production capacity cultured.

Materials and Methods

Walne media was used to culture *Nannochloropsis* spp. in 1 lt glass bottles were ventilated and incubated at 26 °C, in daylight, for 9-15 days (Rippka et al., 1988). *F. psychrophilum* were grown according to Austin&Austin, (2007). Ethanol and methanol solvents were used as a extraction. Disk diffusion method was used to determine the algal antimicrobial effect on *F. psychrophilum*. At the end of the incubation period at 22-25°C for 24 hours, the presence of antimicrobial activity was determined according to the inhibition zones formed around the discs.

Results

In this study, the antimicrobial activity of *Nannochloropsis* extracts were tested for *F. psychrophilum* that was found to be sensitive to both ethanol and methanol. The antimicrobial activity of the methanol extract formed against *F. psychrophilum* was 15.0±0.4 mm, while the ethanol extract had a lower zone diameter and was measured to be 9.0±0.5 mm. As a result, it was observed that *Nannochloropsis* spp. showed quite high antimicrobial activity against *F. psychrophilum* (Figure 1).

Discussion and Conclusion

F. psychrophilum have shown antimicrobial activity positively as the inhibition zones were 9-15 mm respectively. Higher antimicrobial activity was observed in the extracts obtained with the methanol extract. It has been observed that the extracts obtained from sea and fresh microalgae have antimicrobial activity on human pathogens (Özdemir et al., 2004; Abo State et al., 2015). However, a few studies have examined the antimicrobial activity of some algae against some fish pathogens. Bhuvaneswari et al. (2013) studied the antimicrobial effect at the molecular level of the cyanobacteria *A. platensis* against *A. hydrophila* and *E. tarda*. In the light of these results, *N. oculata* extracts should be performed and used fish disease prevention studies and/or feeding trials as an alternative environmental friendly, low costs chemotropic reagent for aquaculture that will open new horizons for green and sustainable aquaculture.

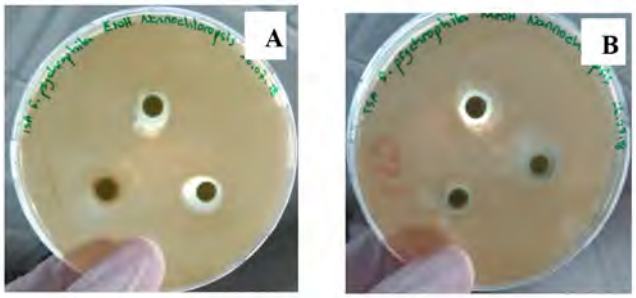

Figure 1. Zones show antibacterial effects of *Nannochloropsis spp.* extracts on **A)** *F. psychrophilum* (ethanol) **B)** *F. psychrophilum* (methanol).

QUANTIFYING THE CONSEQUENCES OF DELOUSING ON FISH WELFARE IN SALMON FARMING

W. Caharija*, B. Venås, M. B. Schrøder, L. M. Sunde

SINTEF Ocean, Sealab, Brattørkaia 17 C, 7010 Trondheim (Norway)
E-mail: Walter.Caharija@sintef.no

The ability to delouse salmon cages efficiently when sea-lice counts exceed legal limits is critical, as uncontrolled outbreaks of sea-lice may lead to impaired fish welfare and health and have severe consequences for wild salmonids in the environment near the farm (Bjørn et al., 2001, Igboeli et al., 2014). Today, the most common delousing methods are non-medicinal treatments such as freshwater, thermal or mechanical delousing (Lekang et al., 2016), while chemical methods such as immersing the fish in closed/semi-closed volumes containing anti-louse chemicals have been abandoned since sea-lice populations have undergone a survival-driven genetic selection for resistance against these substances (Aaen et al., 2015). All the current non-medicinal treatments consist of the following two steps: **crowding** the fish at higher than normal densities, and **pumping** the fish from the cage, through a barge or ship that contains the delousing treatment system, and back into a different section of the cage or into a new cage (Føre et al., 2018b). **Both phases are extremely dangerous for the fish well-being. Crowding** may subject the fish to lowered welfare and lead to detrimental health and increased mortality since crowding at very high concentrations may induce mechanical damage, and increased stress levels to the fish (Erikson et al., 2016). **Pumping and delousing** expose the fish to mechanical stress due to low pressure, turbulent flo , confined space, thermal shocks, collisions with pipe walls and metal walls and presence of rotating equipment such as impeller pumps or brushes (Svendsen et al., 2017).

Although delousing is the riskiest fish treatment operation in the production cycle for farmed salmon, **there exist no knowledge-based and objective methods** for handling these challenges and the present industry practice in parasite management is founded in **experience-based reasoning, and manual monitoring and operation** (Føre et al., 2018a). This practice typically entails that operators first observe the fish via direct visual observation or underwater cameras and then interpret this information primarily based on their subjective experience, yielding a subjective perception of the current lice level and state and condition of the fish. These interpretations are then used as a foundation for making decisions concerning crowding and pumping, making the delousing process prone to **huge variations in fish mortality and stress**, both between operation crews and delousing units (Lekang et al., 2016).

Inspired by the core principles of **Precision Livestock Farming** (Berckmans, 2004), researchers at SINTEF Ocean have coined the **Precision Fish Farming** concept whose aim is to apply control-engineering principles to fish production, thereby improving the farmer's ability to monitor, control and document biological processes in fish farms, including the fundamental **delousing process** (Føre et al., 2018a). In relation to salmon delousing and within the Precision Fish Farming framework, the SINTEF Ocean scientist have been **investigating the consequences that crowding, pumping and delousing have on fish welfare** since non-medicinal delousing treatments were introduced by the salmon farming industry in Norway. Among several activities, the projects called **CROWDGUARD** and **KVALISYS** are the most relevant. The **CROWDGUARD project** (RCN project no 282371) develops technology for quantificat on and documentation of fish welfare related states during **crowding** focusing on sensor platform, instrumentation and communication, operational testing and data collection, data processing, analysis and validation. The goal of CROWDGUARD is to take control over the crowding situation and the biomass density to ensure that the fish is not exposed to excessive physical loads.

The **KVALISYS project** (FHF project no 901397) aims at quantifying the mechanical loads inflicted by **pumping and delousing** equipment to Atlantic salmon by employing a new generation of passive data loggers – "sensor fish". The scope of KVALISYS is to establish a standard methodology and an accepted baseline to compare different pumping and mechanical delousing systems. This may yield concrete guidelines and suggestions on how to design pumps for fish as well as delousing units.

The two projects, CROWDGUARD and KVALISYS address specific aspects of delousing operations, either by making some quantities observable and measurable (i.e. mechanical loads, stress level or biomass density), either by improving single machinery components such as pumps, or by applying feedback control exclusively to one single phase of the overall process. The hereby presentation will show the latest activities and results within the **CROWDGUARD** and **KVALISYS** projects.

SHELFISH FARMING IN OPEN SEA WITH ADVANCED CONCRETE RAFTS

J.A. López, H. Coll, F. Galán, E. Camacho

Research & Development Concretes SL, Street Rodanes 52, Vilamarxant, 46191, Spain
E-mail: ecamacho@rdconcrete.com

Introduction

Approximately 85% of the mussel aquaculture around the world is suspended and off-bottom culture (McKindsey et al. (2011)), including among the techniques the floating raft system, the used in Spain to produce 40% of the EU mussel. Since its origins in Galicia to our days, the rafts have been built with eucalyptus wood. This imply a short lifetime, the need to use paints for protection and a high carbon footprint. In 2015 the company RDC developed a 540 m^2 precast raft made of Ultra-High-Performance Fiber-Reinforced-Concrete (UHC), an extremely compact and durable composite (this project received funding from the EU's Horizon 2020 research and innovation programme under grant agreement No 738777, SELMUS, SME Instr. Phase 2). Four years after the idea, there are more than 5.000 m^2 under operation and proving high resiliency and very low maintenance costs.

Considering the UHC raft performance, a new design is under development to enable it to cover other needs (project OpenMode-863562, co-funded by the European Maritime & Fisheries Fund (EMFF)). This new generation is adapted for open waters, connectable and sensor-equipped, allowing intensive harvesting in new areas, adapting the modules to the farm needs and facilitating their transport and assembling. The project will test these capacities with eight pilots floated in five countries across three EU sea basins

The problem of the traditional mussel rafts

Wooden rafts for mussel farming are used in Spain since 1900 due to their reduced purchase cost, lightness and flexibilit . The intensive system is feasible due to the upwelling-downwelling dynamics on the continental shelf (Figueiras et al. (2002)). The structure can carry up to 500 ropes and produces nearly 60 tones/year. However, its use has three type of disadvantages: 1) Economic: It has low durability (≈12 years) and needs periodic investment in maintenance which undermines the sector's profitabilit . 2) Industrial: each raft is built manually through a high-risk job in the inter-tidal zone using hammers. Replacing the damaged elements is a slow work. 3) Environmental: it implies intense deforestation. The degradation of the wood and the products used to protect it cause water pollution.

The 540m^2 UHC raft

The modular raft designed in 2015 was made of UHC (Utility Model ES1147609U), an innovative material which permeability is nearly 1,000 times lower than concrete, is five times more flexible than steel (elastic modulus) and its strength is six times higher than for wood. With the same area than the traditional raft (20x27 m), it is formed by three frames where six steel floaters are connected, and 10 secondary beams perpendicular to the first. Its lifetime is expected to exceed 30 years. The first prototype was precast in 2016 for the Technology Center AZTI. In October 2019 there are already ten units harvesting mussel and oyster in both basins of the Spanish coast. The continuous monitoring systems and cameras are proving the robustness and resiliency of the rafts, which are already demanded by the Galician farmers because they have proven to minimize the operating expenses.

The product is aligned with the EU Blue Growth strategy, as: 1) it boosts the shellfish aquaculture competitiveness. 2) It improves maritime spatial planning and integrated maritime surveillance concentrating the farms on controlled and visible modules. To reach a similar production some regions use a tangle of kilometers of submerged ropes (long-line method) and plastic elements.

The OpenMode project: Towards a global and sustainable impact in shellfish farmin

The 540m^2 UHC raft is useful in semi-opened waters with very high production capacities, and the special transport required for the precast elements is complex and expensive. The project OpenMode aims to build on the progress achieved up to now adapting the UHC rafts for open waters. For this, they need to be: 1) Modular: The length of its beams will be 12 m to be exportable in 40' containers, so that an EU-produced hi-tech solution can be competitive in any country. The smaller size will also reduce the stresses under intense swell. The simple packing and assembling facilitates its reuse. 2) Connectable: Elements can be connected onshore or offshore to form larger structures (12x24 m, 12x36 m…), with a type of connection that depends on the swell and application. The module configuration will facilitate the adaptation to other BG sectors. 3) Sensor-equipped: A remote system will send weather, marine, water and structural parameters to support the decision taking and minimize costs, risks and environmental impacts of visiting the platforms.

(Continued on next page)

The project will float eight 140 m^2 pilots before 2021. Four of them to test the connection systems in the Bay of Biscay (Atlantic basin), one in the North Sea with the support of the Technical University of Denmark to scale-up the compensation policies, two in the Dalmatian coast to increase the productivity and face their problems with the predatory fishes, and one in Malta to explore the possibilities to combine the structure with solar energy. There are specific tasks dedicated to BIM, maritime safety, Life Cycle Assessment, User Experience, trainings and optimization of harvesting through Big Data analytics.

Introduction

The lack of suitable sites for aquaculture is one of the factors limiting the development and growth of European aquaculture (COM 229/2013). The national Multiannual Strategic Plans for Aquaculture prepared by Member States (MS) in 2014 (Reg. 1380/2013/EU) foresee the commitment in improving spatial planning to identify marine areas to be allocated to aquaculture by 2020. In 2014 entered into force the Directive 2014/89/EU establishing a EU framework for Maritime Spatial Planning (MSP) for a sustainable coexistence of uses and, where applicable, the appropriate apportionment of relevant uses in the maritime space. The MSP directive includes aquaculture among the innovative economic sectors to be considered to promote the Blue Growth and the sustainable development of maritime sectors. MS are responsible and competent for designing and set up maritime spatial plans, which identify the spatial and temporal distribution of relevant existing and future activities and uses in their marine waters. Italy implemented the MSP directive with a national decree in 2016 and the following guidelines of the Ministry of Infrastructures and Transport in 2017. The objective of this study is to develop aquaculture suitability maps in Italian seas to facilitate the allocation by regional governance of marine areas for aquaculture development and for further detailed local studies for site selection for shellfish and fish farming activities in coastal and offshore areas.

Materials and methods

Primary tools used for spatial planning are the Geographic Information System software, which allow the management and analysis of geo-referred datasets related to multiple kinds of information, such as infrastructural, social and environmental, returning readily interpretable, highly visual maps (Malczewski, 2010). The IT-AQUA GIS was build using the ESRI ArcGis 10.3 Geographic Information System and the data have been mostly sourced from many Open GIS Consortium Web Feature Services (OGC WFS) Geoportals. The scientific literature on geospatial analysis used for the identification of Allocated Zones for Aquaculture (AZAs) was reviewed (Aguilar-Manjarrez et al, 2017) and relevant data layers, at national scale, representing potential constrains to aquaculture development were selected. The principles and criteria for the identificatio of the categories of constraints and interactions, the list of constraints and the relative "respect zone" have been discussed in two round meetings within the Italian Aquaculture Platform (ITAQUA, Ministry of Agriculture). The most relevant stakeholders involved were Regional and local Competent Authorities, Central Authorities (Ministries of Environment, Health, Research, Economic Development), Producer's Associations, aquaculture companies, cooperatives and scientific experts, who validated the process for the identification o AZAs in the Italian Regions.

Environmental data, as Natura 2000 network sites, Marine Protected Areas (MPAs), natural benches of bivalves, have been sourced from ISPRA repository, from the National Geoportal of Ministry of the Environment and from Regional Resolutions. Infrastructural data as pipelines and submarine cables, military polygons, wrecks and hydrocarbon exploration, extraction areas, etc., have been sourced from the General Management of Environmental Safety and Mining and Energy Activities (DGS UNMIG) and from the Hydrographic Institute of the Italian Navy. General interaction as sea routes, boating, sport fishing, tourist settlements, etc., have been sourced from the Opendata of the Italian Public Administration (dati.Gov.it) and from Ordinances and Decrees of the Port Authorities. Aquaculture licensed sites have been sourced from the repository of the State maritime property register, and further validated and updated.

Results

Data was harmonised according to the Infrastructure for Spatial Information in the European Community (INSPIRE) directive and then compiled into a geodatabase which comprised, 12 environmental, 13 infrastructural and 9 other human interaction geospatial layers (constraints). A constraint - free area layer was then calculated and identified using a simple boolean overlay of the identifi d constraints. Where appropriate, a buffer (Respect Zones) was added to the constraint layers.

(Continued on next page)

The IT-AQUA GIS geodatabase, containing all the layers of constraints, has been then used as background dataset to perform a case study in the Latium Region, where the process of identification of zones have been started following the Guidelines for the identification of AZAs drafted by ISPRA to facilitate the planning and management of of marine waters for aquaculture use at regional level and the integration of aquaculture activities within the Regional plans for MSP by 2020.

Discussion and conclusion

The purposes of the identificati n and allocation of zones suitable for aquaculture, through the establishment of AZAs and within the wider MSP process, are multiple and encompass, among others, the minimization of multi–use conflicts, the reduction of environmental impacts, the optimization of production cycles, the streamlining of the licensing procedures, the increasing of confidence of investors. Furthermore, the involvement of a number of stakeholders in the decision making process strives to include different coastal users in the identification of the AZAs increasing the social acceptance of aquaculture in the region (FAO, 2010).

Acknowledgments

The case study was funded by Lazio Region (AZA-Lazio project, EMFF Art. 51).

Introduction

Sulphur-containing amino acids (SAA), which include methionine and cysteine, allow normal growth and functioning of fish. Methionine is an essential amino acid and cannot be synthesized *de novo* in sufficient quantities to meet metabolic requirements. In fish, cysteine has the potential to spare 33 to 60% of methionine requirement (Abidi and Khan, 2011; Harding et al., 1977; Moon and Gatlin, 1991). The relatedness, interactions and sparing effects of SAA imply that quantifying the requirement of a species for one essential SAA must be done within the context of other SAA present in the diet. The objective of this study was to quantify the dietary methionine requirement and sparing effect of cysteine in juvenile Yellowtail Kingfish (YTK)

Materials and methods

YTK (mean weight 52.6g) were fed one of ten diets, containing five incremental levels of methionine, ranging from 7.9 to 25.2 kg^{-1}, crossed with two levels of dietary cysteine (i.e. 5.5 or 13.9g kg^{-1}). All diets were isonitrogenous (≈600g crude protein kg^{-1}), isoenergetic (≈22MJ gross energy kg^{-1}), and prepared using practical raw ingredients. YTK were held at 22°C for 8 weeks and fed twice daily to satiation.

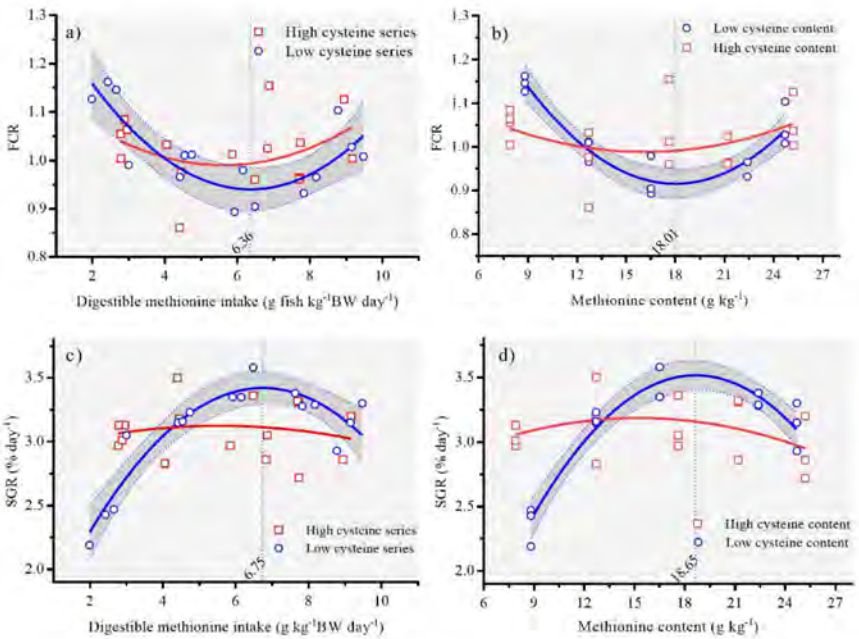

Fig. 1. FCR response relative to digestible methionine intake (a) and dietary methionine content (b); SGR response relative to digestible methionine intake (c) and dietary methionine content (d). Regression models for fish fed diets low (blue) and high (red) in cysteine. Grey bands indicate the 95% confidence interval for low cysteine series. Dotted, vertical lines indicate the optimal methionine intake (a,c) and dietary specification (b,d) for YTK fed diets containing low level series of cysteine.

(Continued on next page)

Results

Applied models indicate that the maximum growth and feeding efficiency of YTK occurs at a digestible methionine intake of 6.75 and 6.36g kgBW^{-1} day^{-1} respectively, at an average digestible cysteine intake of 1.73g kgBW^{-1} day^{-1} (Figure 1). Furthermore, the continuing increase in methionine intake caused a reduction in SGR and a worsening in FCR. YTK fed the diets containing the higher level of cysteine, recorded high variability in both SGR and FCR and no specific methionine requirement could be established. Generally, YTK fed the diet higher in cysteine performed more poorly relative to YTK fed the diet lower in cysteine.

Discussion and conclusion

The dietary crude level of total sulphur amino acids (TSAA; methionine+cysteine) is approximately 24.3g kg^{-1} diet which equates to a daily digestible intake of TSAA of 8.4g kgBW^{-1} d^{-1}. Based on the SGR response of YTK, cysteine can spare at least 48.2% of the dietary methionine requirement in YTK, considering molecular weight and digestibility. The decline of SGR in YTK past the optimum methionine intake, indicates a maximum methionine threshold, possibly induced through the buildup of excess methionine derivates via transamination or transulfuration pathways. The results suggest the dietary specification of methionine, currently relied on in commercial aquafeeds for YTK, may be inadequate. This study provides new data on the SAA requirements of juvenile YTK and will facilitate the formulation of better diets for this species.

DETERMINATION OF CARRYING CAPACITY IN INLAND WATERS AND VARIOUS MODELS

İsmail Berat Çantaş[1*]., Önder Yildirim[1]

[1]Department of Aquaculture, Faculty of Fisheries, Mugla Sitki Kocman University
email:ismailcantas@mu.edu.tr

INTRODUCTION

The amount of inland water aquaculture, their environmental impacts and potential must be revealed for the sustainability of aquaculture and the efficient use of water resources. However, development of inland aquaculture sector is under the responsibility of researchers, public institutions, non-governmental organizations and cultivators working in this field by ensuring the sustainable use of the water body without limiting other uses. Use of models to estimate the environmental impact of inland water aquaculture or, in other words, determination of the carrying capacity of inland waters should be considered as the first stage for the development of accountable sustainable fisher . In all of the fish farming methods, fish feces and wastes from inedible feed accumulate in the environment (Beveridge, 1984). Effects of fish farming on aquatic environment depend on the method and application of aquaculture, the feed quality, the stock amount and the hydrography of the area for cultivation (Wu, 1995). Carrying capacity is a scientific term that tolerates a harmful effect of accumulated concentration of a substance on an ecosystem in a given aquatic environment.

While one portion of solid organic material containing mainly carbon and nitrogen entering the receiving water body from the fish screens (approximately 15%) are remained in the water column as suspended solid, some of them are consumed by fishes outside the cage. In addition, an important portion of them are accumulated in the sediment and causes organic enrichment of benthic system, and significant changes in benthic macrofauna and sediment chemistry (Ackefors and Enell, 1990).

Beveridge (1984) model and MOM system (Modeling-Ongrowing fish farm monitoring) are used as the determinants of the carrying capacity.

MODELLER

BEVERIDGE MODEL

Various models can show us that how much fish can be grown by phosphorus entering the ecosystem from feeds and other sources and without deteriorating the environment in dam lakes carrying out intensive fish farming (Beveridge, 1984)

MOM

There is a need for systems where modeling and monitoring programs and environmental quality standards are existed together in order to prevent excessive use of the aquaculture area and to make the use of resources sustainable. The monitoring program consists of three types of research (A, B and C). A-research type is based on simple measurement of the sedimentation rate of organic material on the ground of cage companies; B-research type is performed in the local active zone, which includes three groups of parameters. In the C-research type, the focus is on the structure of benthic communities in the central and local active zones (Hansen et al. 2001). The parameters used include biological (macrofauna existence), chemical (pH, redox potential) and sensory (gas discharge, color, odor, viscosity, deposit thickness) parameters. Mom model is shown below according to Hansen et al. (2001).

DISCUSSION AND CONCLUSIONS

It is very important to calculate the carrying capacity in order to ensure sustainable aquaculture and reduce the pollution caused by the aquaculture. Knowing how much fish you can grow before starting inland water aquaculture is important to ensure making production here for many years, and also the capacity estimates for aquaculture should be made. In addition to existing models with carrying capacity of aquaculture, it is possible to develop new models and obtain more effective and wide-ranging parameters. Future studies should be designed so as to obtain instantaneously the past, current and future values of the carrying capacity of aquaculture.

DETERMINANTS OF FISHERY AND AQUACULTURE PRODUCTS CONSUMPTION AT HOME IN THE EU28

Javier Cantillo*, Juan Carlos Martín, Concepción Román

Universidad de Las Palmas de Gran Canaria, Institute of Tourism and Sustainable Economic Development. 35017. Las Palmas de Gran Canaria (Spain)
*E-mail: javier.cantillo101@alu.ulpgc.es

Introduction
The European Union is the world's largest market for fishery and aquaculture products in nominal terms. Given the importance, the European Commission aims to balance distinct stakeholders in the Common Fisheries Policy. For this reason, a better understanding of the EU internal market is needed, and a survey of 27732 EU residents was carried out to analyse the fishery and aquaculture EU market (European Union, 2018). The data provide the base for the estimation of two ordered probit models and the estimation of the marginal effects for different consumption frequencies. The models aim to determine the main determinants of fishery and aquaculture products consumption at home for the EU residents. The results of the survey show that home is the most common place to consume this kind of products, with around 70% of people in the EU28 consume fishery and aquaculture products at home at least once a month (European Union, 2018). To our best knowledge, in the current literature, there is not a similar approach that considers such an extensive sample which is representative of the EU28. The results provide important insights for different stakeholders such as policy makers, nutritionists, fishery and aquaculture associations and marketing manage .

Materials and methods
The database used for the estimation of the models was obtained from the Special Eurobarometer 2018 (European Union, 2018), which includes questions that analyse the internal market for fishery and aquaculture products of the EU. For the present study, we focus on the responses for the frequency of consumption at home for fishery and aquaculture products (dependent variable) and correlate them with variables related to attitudes of respondents, socioeconomical and demographic factors (independent variables). Two ordered probit models were estimated, one of them including the standard deviations of the independent variables involved (heteroscedastic model). The marginal effects for the different consumption patterns at home were estimated for both models. The methodology was selected considering that the ordered probit models are an appropriate analytical framework when survey responses are ordinal (Kumar et al., 2008; Thong and Solgaard, 2017).

Results
Preliminary results indicate that the largest marginal effects on home consumption frequency depends on how clear and easy to understand is the information accompanying the fishery or aquaculture products. In fact, understanding clearly or to some extent that information would increase by 40% and 27% respectively the probability to consume products at least once a week.

Other important aspect that determine home fish consumption frequency is the attitudes regarding the main reasons to buy or eat fishery and aquaculture products. Particularly, it was found that considering important that they are healthy, taste good and less expensive than other food, would increase the probability to consume them at least once a week by 20%, 18% and 18% respectively; while other reasons such as being easy or quick to prepare, quick and easy to digest, would increase the probability by around 11% each one.

It was also found that consumers who have a clear preference for wild products, tend to consume the products more frequently. Similarly, older generation of residents, especially those older than 45 years are more eager to consume fishery and aquaculture products more frequently at home. On the other hand, the attitude toward the importance of the cost of the product was found to be not significant in general

Discussion and conclusions
The results provide valuable information for producers, retailers and authorities Particularly, they give important insights to establish common policies for the EU28 countries, by using a generous database that enhances the credibility of the results. Results indicate that there is a great possibility of increasing the consumption of fishery and aquaculture products at home in EU28 by just providing clearer and easier information to understand about the products, specially, keeping in mind, that around 25% of respondents from the Eurobarometer survey indicated that the information accompanying fishery

(Continued on next page)

and aquaculture products is not clear or easy to understand (European Union, 2018). This strategy is also supported by several studies in the literature, that conclude that giving quality information to consumers, enhances the product attributes (Bronnmann & Hoffmann, 2018; Kumar, 2018). Following this, additional studies are required to understand how the information can be provided in a clearer and easier way, and which is the information needed by consumers, in order to develop a common policy regarding the minimum requirements of the information accompanying the products, so in a way it can be standardized.

Regarding to the importance of certain attitudes than increase fish consumption frequency at home, producers need to focus on alternatives than enhance the healthiness and the taste of the products; while also provide products that are easy and quick to prepare, which are currently not as common in the market as for other food categories. Moreover, the fact that those who have a clear preference for wild products have a higher probability of frequency of consumption, is a clear sign to aquaculture producers and authorities, alerting them about the need to keep looking for strategies that offset the negative image that aquaculture products currently have. Similarly, given that younger people have a lower frequency of consumption at home in comparison to older people, is important to identify how through some marketing strategies such as product differentiation or online shopping, this can change.

Finally, it is important to notice that since the attitude towards the importance of the cost is not significant for fish consumption frequency at home, producers should risk on looking for higher quality products that might be more attractive to consumers despite their higher costs. However, prior to this, studies that evaluate the willingness to pay for these new products should be performed to understand their feasibility, since consumers who consider that one of the most important reasons to buy these products is that is less expensive than other food, tend to have a bigger consumption frequency.

IDENTIFICATION OF EPITOPES TARGETED BY IMMUNE RESPONSE AGAINST SALMON PANCREAS DISEASE VIRUS IN NORWEGIAN SALMON AQUACULTURE

Yanran Cao *, Anne Stene, Beate Julie Thu, Anne Synnøve Røsvik

Department of Biology Science, Faculty of Natural Sciences, Norwegian University of Science and Technology, Ålesund, Norway
E-mail: yaca@ntnu.no

Background Pancreatic Disease (PD) is one of the globally important viral pathogens in salmonid aquaculture. Sick fish have extensive pancreatic damage and inflammation of the heart and skeletal muscles, which can cause major financial losses due to poor growth and reduced slaughter quality. PD is caused by a virus called Salmonid alphavirus (SAV) or PD virus. In Norway, there are two of six known subtypes of SAV (SAV2 and SAV3) (Hjeltnes, Bang et al. 2018). Vaccination has already proven to be an important tool and the humoral immune response is a major factor helping fish to survive SAV infection (Mérour and Brémont 2014). Commercial vaccines against PD are available, while the efficacy of vaccine has been debated (Hjeltnes, Bang et al. 2018).

Object E2 protein is an envelope protein of SAV, which supposed to be the carrier of neutralizing epitopes and represents a promising target for subunit vaccine against SAV. In our previous study, we demonstrated humoral responses against E2 protein in farmed salmon post natural SAV infection (Cao, Stene et al. 2017). The aim of this study is to further identify linear B-cell epitopes recognized by these anti-E2 antibodies and map to their structural localization.

Method Atlantic salmon reared in sea cage culture at the north western part of Norway was used in this study. Twenty salmon plasma samples were identified as serologic positive against E2 protein (provide by Dr. Tøndervik, SINTEF Norway) and against SAV3 virus (provide by Dr. Aas-Eng, Pharmaq AS) (Cao, Stene et al. 2017). The overlapping peptides (10 mers with an offset of 3) from Mimotopes were designed for screening linear antibody epitopes using an enzyme-linked immunosorbent assay (ELISA) (Hammarlund, Lewis et al. 2005). A western blot (WB) assay was applied for the verification of specific binding. To identify the structure of E2 protein and epitope on the molecular, the in silico tools special for designing peptide-based subunit vaccines and immunotherapeutics against various pathogen-causing diseases were applied (Dhanda, Usmani et al. 2016).

Results The serologic positive plasma were examined for the fine specificity of the antibody responses. Several linear epitope recognized by the plasma antibody were identified and spontaneous responses most frequently recognized two specific E2 epitope, namely E2127-136 and E2214-223 , which is in accordance with the results calculated with the B cell epitope prediction program BepiPred-2 (Jespersen, Peters et al. 2017). Using BepiPre-2, we calculated the location of linear B-cell epitopes and demonstrated that the sequence DGTRH in E2127-136 and KSADSA in E2214-223 both have random coil-structure, which represent the potential epitope regions (Li, Liu et al. 2013). Furthermore, both sequence have relative surface accessibility as show in the structure model produce by SWISS-MODEL program (Waterhouse, Bertoni et al. 2018) (Figure 1)

Conclusion In this study, we identified and characterized two linear epitope motifs in SAV virus E2 protein. These results further our understanding of the epitope distribution of SAV E2, and provides critical knowledge that will aid in the understanding of SAV infection and immunity, vaccine design, and pre-clinical efficacy studies. Results from this study provide also information for the development of peptide-based immunodiagnostic tests to detect SAV in serum.

RESTORATIVE AQUACULTURE WITH OFFSHORE STRUCTURES

M. E. Capron, M. D. Chambers, J. R. Stewart, K. Lucas, Z. Moscicki, C. Sullivan, S. A. Krueger-Hadfiel

OceanForesters, 2436 E. Thompson Blvd., Ventura CA 93003 USA
mailto:MarkCapron@OceanForesters.com

Introduction
Flexible floating reefs, pictured at right, support a new off-shore aquaculture ecosystem where the essential inputs are sunlight, and ammonia or nitrate, and phosphate. This new ecosystem supports a free-range fishery more sustainably and at lower cost than traditional ocean fish pens.

Existing wild fisheries production should increase due to increased habitat and food suppl .

OceanForesters assembled a team that received funding from the U.S. Department of Energy Advanced Research Projects Agency-Energy (ARPA-E) through the University of Southern Mississippi to design these aquaculture systems that could eventually produce inexpensive biofuels.

Nutrient Recycling
In ocean forestry, nutrient conversions, per the figure at right, combine with photosynthesis to add carbon to inorganic nutrients creating food for animals. As a result, the flexible artificial reef can have an optimally balanced suite of products including macro-algae, shellfish, finfish and other seafood. Operation using recycled inorganic nutrients and sunlight is much less expensive and more easily scaled than when using fishmeal.

Chambers, et al. (2014) observed that the macroalgae and shellfish absorbed more nutrients than the fish emitted, thus cleaning up excess nutrients in the Piscataqua River.

Economic Analysis
Because our natural-like ecosystem produces its own food for free-range fish, it eliminates the need for fishmeal to feed penned fish. A rough comparison of economics is that our expensive structure may cost $1000 per ton of seafood but it could save as much as $2000 for fishmeal per ton of fish.

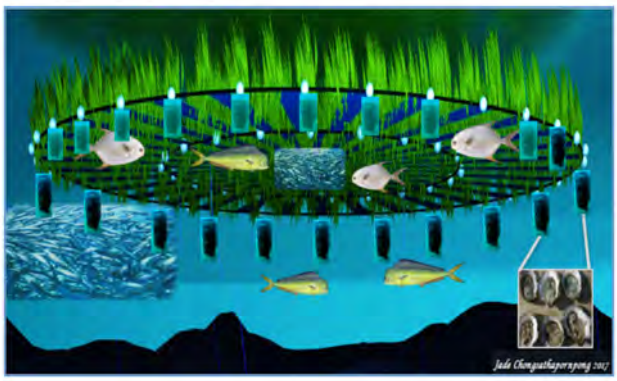
We are also working with CleanCarbon Energy to develop a new hydrothermal liquefaction system that could eventually produce biocrude oil for as low as $70 per barrel, because income from our seafood sales offsets the cost of a structure designed to submerge to the seafloor to survive a Category 5 tropical storm

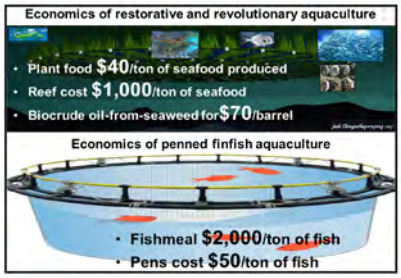
Application to Jamaica
Roughly 80 square kilometers of seafloor off Alligator Pond (west of Kingston) could ultimately support 1,000 hectares (fifty 20-ha reefs) of OceanForesters' hurricane-surviving floating flexible reefs. Restorative aquaculture of conch on fifty reefs could sustainably produce over 10,000 tons of conch per year.

The total of all production from the fifty reefs (conch, lobster, crab, oyster, sea cucumber, sea urchin, kingfish, jack, mackerel, whiting, bonito, and other free-range finfish may be as high as 150,000 tons per year. If the average export value is $2.5/kg, the total value of exports could be over $300 million per year.

High reef productivity can start with commercial fertilizers. Sustainable operation requires recycling inorganic nutrients from Jamaica's municipal wastewater. Pasteurized nutrients from people are brought to the reef for recycling. Recycling of people wastes also addresses other United Nations Sustainable Development Goals, creates more local jobs, and ensures local control and availability of the essential fish-growing nutrients. Ocean forests will also clean up excess ocean pollution from offshore runoff, thus improving water quality and increasing tourism.

(Continued on next page)





Benefits

Floating reefs, like natural ones, produce abundant shellfish and finfish put local fishers and seafood processors back to work, remediate ocean pollution, and increase ocean biodiversity through natural nutrient recycling. The system uses the natural recycling of nutrients (see diagram to the right) in which shellfish eat plankton and other organic nutrients while their wastes are food for the seaweed, which in turn provides food and habitat for finfish which are naturally attracted to the reef.

Benefits include: increasing food supplies, cleaning up dead zones, reducing ocean acidification, and eventually producing enough biofuels to replace all fossil fuels, while capturing sufficient C_2 to reverse climate change.

Introduction

MicroRNAs (miRNAs) are small noncoding RNAs (~22 nt) that hold important post-transcriptional regulatory roles in most biological processes. The most striking characteristic of miRNAs is their high stability in extracellular spaces including biological fluids, which allows their utilization as noninvasive biomarkers. Several reports have highlighted the potential of circulating miRNA (c-miRNA) as predictive and diagnostic markers of biological process related to nutrition, reproduction or pathology (Turchinovich et al, 2012).

MicroRNAs have been less studied in fish than in mammalian species but knowledge in this area is continuously growing, especially in rainbow trout (Onchorynchus mykiss), which represents a key sector of aquaculture production. MiRNAs seem also to play important roles in the development and physiological processes in fish (Wienholds et al, 2005; Bizuayehu et al, 2012). A recent study reveals that miRNA are present in the blood of rainbow trout and are subjected to postprandial regulations in blood as in other tissues. As significant correlations were found between circulating miRNAs and expression of genes in liver, the authors suggested that circulating miRNAs could be good indicators of metabolic pathways in rainbow trout (Zhu et al, 2018).

In this context, the aim of the present study was to perform an extensive profiling of wide plasma and ovarian fluid miRNAs in female rainbow trout and assess the impact of moderate (i.e. 20%) feeding restriction, during oogenesis process, on c-miRNAs, in order to evaluate the potential of c-miRNAs to be used as non-invasive biomarkers of metabolic and physiological status of the fish during the reproduction cycle

Materials & methods

For that purpose, two feeding strategies were implemented during the last five months before the reproduction. Females were either fed (1) ad libitum or (2) 80% of the ad libitum (restriction). During the trial, two artificial photoperiods were applied to trigger reproduction during summer and plasma sampling was carried out at different times during oogenesis process. Ovarian fluid was sampled during spawning period.
To investigate the abundance of circulating miRNAs, small RNA libraries were generated and sequenced using Illumina small RNA deep sequencing. Validation by RT-qPCR was carried out.

Results & discussion

More than 500 microRNAs were successfully detected in the plasma and ovarian fluid of female rainbow trout. Some miRNAs were exclusively detected in the ovarian fluid whereas others were only found in the plasma. Circulating miRNAs only found in ovarian fluid showed significant different abundance according to feeding level (ex: mir 202, mir2928…). Inversely, some c-miRNAs specific of the plasma have seen their abundance significantly changed during the oogenesis or depending of feeding level (ex: miR 206, miR122, miR10…).

Conclusion

To conclude, the present study demonstrates for the first time that trout plasma and ovarian fluid contain large amounts of miRNAs. Some of them are significantly affected by oogenesis stage and/or feeding rate suggesting that c-miRNAs could be considered as promising non-invasive biomarkers of nutrition and reproduction for further application in the research or aquaculture areas.

Introduction

Faecal material discharged from open ocean salmon fish farms generates a direct impact to the bottom dwelling communities, modifying both population structure and diversity via organic enrichment. Therefore, accurate modelling of such particles is critical for the planning and licensing of fish farming locations in Norway. To attain such accuracy, particle transport models should include relevant small-scale processes that influence particle movement, such as particle resuspension and re-entrainment into the water column. Approaches to simulate such phenomena tend to overlook the role of bottom substrate on the onset of particle resuspension, assuming the same value of critical shear stress to be applicable for all bottom types even when there is evidence against it in the body of knowledge (e.g. Law et al. 2016).

We performed controlled lab experiments using tubular flow raceways to determine near-bed flow conditions necessary to resuspend fish faeces over the most common bottom types in existing aquaculture locations in Norway. These novel parameters will help to expand existing modelling tools for the Norwegian salmon fish farming industr .

Materials and methods

Faecal pellets were collected from a research pen holding near 2 kg individuals of Atlantic Salmon in Masfjorden (Norway). A total of 42 experiments were performed, with faecal pellets being placed in a tubular raceway equipped with a propeller to induce step-wise increases in mean-flow velocity and a bee-hive panel to generate quasi-homogeneous turbulence in the system. Different bottom substrates were placed in the flume according to a randomized experimental design. A Nortek Vectrino ADV was used to record 3D velocity components near the bed while two (2) downward looking GoPro Hero 5 cameras were used to record the experiments. Mean flow conditions for faeces resuspension were extracted from the synchronized videos and velocity records, while a second moment statistic method based on the turbulent kinetic energy was used to derive bottom shear stresses and shear velocities. Influence of substrate and the time the faecal material was let to sit in the flume (particle age) was analysed using parametric ANOVA.

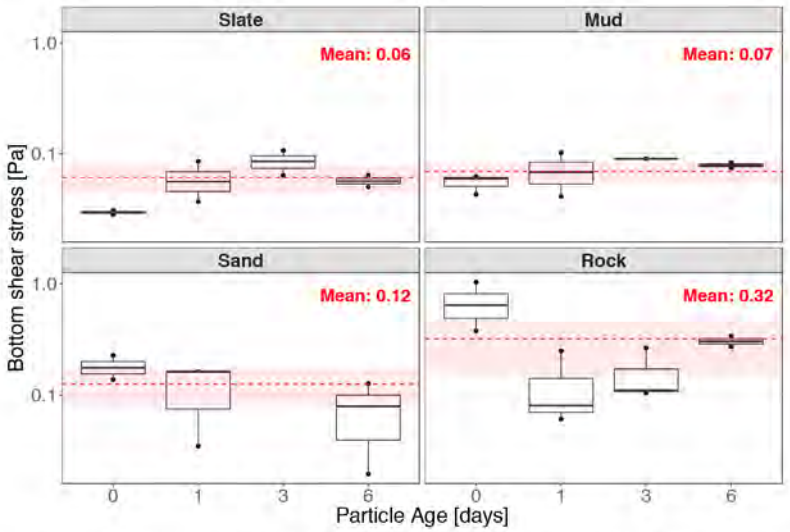

Fig. 1. Critical shear stresses required to resuspend Atlantic Salmon faecal pellets over different bottom substrates

(Continued on next page)

Results

Tests indicated there is a significant effect of the substrate type on the shear stress required to onset the resuspension of faecal material once it has been deposited on the sea bottom (Fig. 1). Faeces sitting on smooth regular surfaces such as muds or rock slates were resuspended when exposed to fairly low bottom shear stresses, in the order of 0.06-0.07 Pa. Slightly higher values of shear stress for the muddy substrates can be associated to the build-up of bedforms between sequential tests and interactions between the cohesive material and the organic particle.

Particles laying on sandy bottoms required a higher level of shear in order to be resuspended from the bottom when compared to the smooth substrates group. Post-Hoc analyses showed no significant difference between sandy substrates and smooth surfaces, but a strong difference between the aforementioned groups and exclusively rocky substrates (i.e. pebbles, boulders) can be observed. Particles sitting on rocky substrates, which are typical for some fiord systems in the Norwegian coast, are mobilized until they fall into fractures and gaps between rocks, once trapped they need to be exposed to very high shear to leave the cracks and be re-entrained into the bulk of the flo .

Discussion and conclusions

Our results indicate there is a clear effect of substrate type on the bottom shear stress required to resuspend faecal material from salmon holding aquaculture pens once they have reached the seafloo . These results validate previous evidence by Law et. al (2016) who observed differential shear requisites according to surface type using a Gust Microcosm Erosion Chamber, but who still required further testing in larger scale flumes which could reproduce field conditions more accurately. As a natural continuation of this work, the differential critical shear stresses obtained will be implemented in a particle tracking model and compared to the constant-value approach introduced by Cromey et al. (2002) and currently used in most fish farm particle resuspension modules. By validating these upcoming results against available field data in different fish farm locations in Norway, we will be able to assess the required level of model complexity for future aquaculture-related particle dispersion studies.

Introduction
Sustainability of marine aquaculture is nowadays dependent on finding alternative cost-effective lipid sources that can replace fish oil. Potential alternatives should provide high energy lipid but also meet fish n-3 LC-PUFA requirements. While poultry oil (PO) is considered a good non-protein energy source, some algae oils, particularly from microalgae, can provide high n-3 LC-PUFA contents. However, algae oils are frequently expensive and with limited availability. Therefore, the objective of this study was to evaluate the combination of PO with two different microalgae oils as replacers of FO in diets for gilthead seabream (*Sparus aurata*) fingerlings, under two different dietary fish meal (FM) levels and a cost-effective approach.

Materials and methods
Seven isoproteic and isolipid experimental diets (50% CP and 17.5 % CL) were formulated under two different fish meal (FM) contents (15 and 7.5%). A positive control was formulated with 15% FM and 5% FO. For each dietary FM content, FO was replaced by a combination of poultry oil and one of two microalgae oils that were named as algae oil (POALG) or DHA oil (PODHA). A negative control replacing FO by exclusively PO was also formulated for each dietary FM content. Experimental diets were assigned to triplicate groups of gilthead fingerlings (IBW 2.5±0.01g) allocated in 250 l tanks, at a stock density of 0.55 kg m^{-3}. Fish were fed manually 3 times a day, 6 days per week for 74 days. Temperature along the trial was 23.1±0.3ºC and dissolved oxygen was maintained above 6.0 mg l^{-1}. Fish were individually weighed and measured at day 1, 30, 45, 60 and 74 of the feeding trial. Besides, at the end of the trial, whole-body samples were collected for biochemical analysis. A one-way ANOVA was applied to analyze differences ($p<0.05$) in the different lipid sources with the same dietary FM content, while t-Student test was applied to detect differences ($p<0.05$) between each lipid source but with different % FM.

Results
Results showed that fish fed POALG and PODHA presented similar growth performance than fish fed FO, but better growth than those fed on only PO, for both dietary FM contents. Besides, fish fed 7.5% FM diets presented lower growth than fish fed their homologous 15% FM diet, except for fish fed PO whose growth was similar regardless the content of FM in the diet. Furthermore, fish fed the most extreme diet (7.5% FM and PO) presented the highest mortality during the trial. Fish fed 15% FM and POALG showed similar FCR and LER than fish fed FO, but higher than fish fed PODHA or PO. Besides, whole-body fatty acid composition showed that fish fed POALG or PODHA showed EPA+DHA contents than fish fed PO. Contrary to growth performance, whole-body FA was not influenced by the dietary content of FM, with fish fed either 15 or 7.5% presenting similar FA composition.

Discussion and conclusions
The results of the present study indicate that both combinations of PO with the two microalgae oils tested were efficient total replacers of FO at both dietary FM contents. However, the substitution levels used were insufficient to eliminate the effect of the decrease from 15% to 7.5% FM in the POALG and PODHA diets on fingerlings growth and feed utilization, even when fatty acid composition was similar between the diets and fish composition after the feeding period. These results suggest that some other factors independently from dietary fatty acid composition could be affecting growth performance and feed utilization of fish fed 7.5% FM diets.

IMPAQT – AN INTELLEGIENT MANAGEMENT SYSTEM FOR INTEGRATED MULTI-TROPHIC AQUACULTURE

Joanne Casserly & Frank Kane

Marine Institute, Rinville, Oranmore, Co. Galway, Ireland
Email: joanne.casserly@marine.ie

Introduction

European aquaculture is met with many challenges in the face of increasing demand for its products. Global estimates forecast that aquaculture will supply over 60% of the fish intended for direct human consumption by 2030, beyond this aquaculture will dominate global fish supply (World Bank, 2013). With fish stocks approaching maximum sustainable yields, aquaculture production must increase in order to meet the demands for the 70% more protein required by the predicted world population by 2050 (Anon. 2017). In Europe the demand supply gap for fish derived protein continues to increase. The EU is the world's largest importer of fisheries and aquaculture products, importing 70 % of the EU consumption (EUMOFA, 2018). Aquaculture is one of the pillars of the EU's Blue Growth strategy and its development can contribute to the Europe 2020 strategy (Anon, 2013). The FAO's Blue Growth Initiative, also focuses on innovation, integration and the adoption of a multi-sectoral approach, to maximize ecosystem services while providing social and economic benefits.

Integrated Multi Trophic Aquaculture (IMTA), is acknowledged as a promising solution for sustainable development of aquaculture. The concept of IMTA is to farm species of different trophic levels, complementary to each other, so that the wastes and by-products of one species become the feed, fertiliser and energy source for another. As yet, IMTA is not widely adapted at a commercial level. It has been only tested at a very small scale in Europe and the management of large-scale areas remains challenging. Culture of extractive species with fed species in the same aquaculture sites is encouraged, and this practice is shown to remove waste materials from fed species and lower the nutrient load in the water (FAO,2018).

Methodology

IMPAQT aims to promote the eco-intensification of aquaculture by demonstrating the eco-efficiency and minimization of environmental impacts, enabling socio-economic benefits and ecosystem services, and promoting the transition towards a circular economy business model. IMPAQT will develop and deploy novel sensors and data sources, together with smart systems required for long-term autonomous monitoring in the field. IMPAQT also aims to provide an advanced IMTA model for users, which yields spatially explicit information on how the different farm components interact with the environment on the scale of an ecosystem and that can be used for planning decisions by both farmers and regulators.

Results

This integrated management system, operating at the scale of an IMTA farm and comprising analysis and decision support functionalities, will be enable enhanced operational decisions for animal welfare, production optimization, environmental protection and food-quality assessment.

This project has received funding from the EU H2020 research and innovation programme under Grant Agreement No 774109.

PROBIOTIC *P. acidilactici* MA18/5M ENHANCES SHRIMP GROWTH AND ANTIOXYDANT DEFENCES: BENEFICIAL EFFECTS AND POSSIBLE PHYSIOLOGICAL MECHANISMS

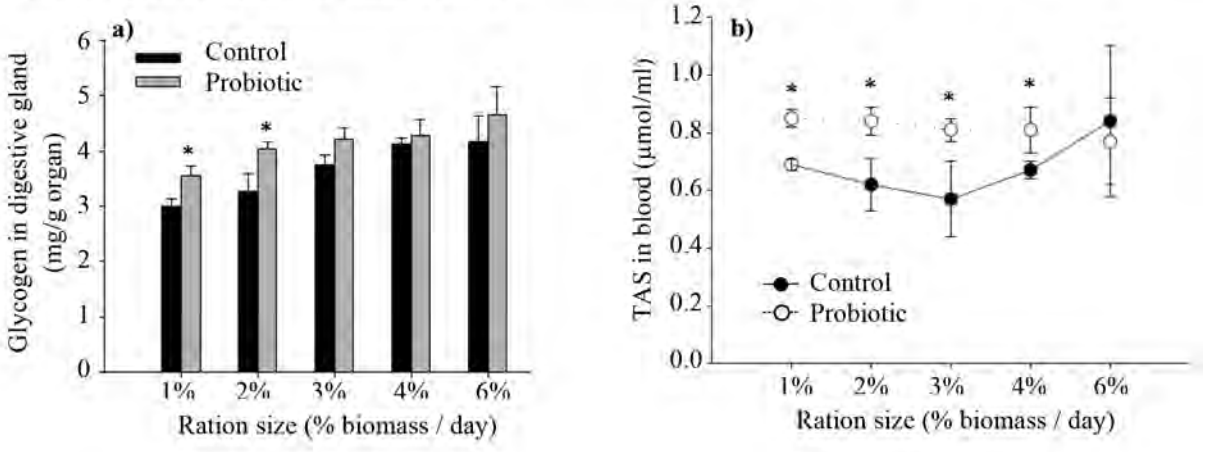
High metabolic activity, increased environmental stress and infectious challenges are few conditions known to increase the intracellular production of reactive oxygen species (ROS) hence the need for higher antioxidant defense to protect cellular and animal integrity. Accordingly, the beneficial effects of in-feed antioxidants to sustain animal health and performance start to be recognized across the livestock industry. There is less notoriety about the potential link between (dietary) carbohydrates metabolism and the antioxidant system, particularly as a mechanism by which probiotics can positively influence the animal s oxidative status.

A controlled feed-intake trial documented the positive influence of the well know probiotic *P. acidilactici* MA18/5M on the growth, carbohydrate digestibility, glycemia and antioxidant status of peneid shrimp (**Fig**). The positive effect of probiotic on the shrimp antioxidant status was further confirmed under semi-commercial conditions as well as when exposed to a controlled vibriosis challenge where enhanced survival was also documented. As supported by knowledge in other species, it is hypothesized that enhanced carbohydrate utilization as a result of *P. acidilactici* would decrease cellular oxidative stress level via the direct ability of glucose to scavenge OH-radicals or by fueling the pentose-phosphate pathway generating NADPH. NADPH is indeed a key player against oxidative stress and free radicals propagation in particular.

Together, this shades light on a scarcely explored mechanisms by which the probiotic *P. acidilactici* MA18/5M can enhance shrimp health status and growth via its nutritional benefits.

Fig: Positive effect of *P. acidilactici* MA18/5M on **a)** carbohydrate utilization and **b)** blood Total Antioxidant Status (TAS)



SEA URCHIN RECRUITMENT: THE EFFECT OF DIATOM BASED BIOFILMS ON *Paracentrotus lividus* COMPETENT LARVAE

Introduction

In Europe, sea urchin *Paracentrotus lividus* aquaculture still faces certain constraints which have to be solved for a sustainable and cost-effective industry. Settlement, metamorphosis and post-metamorphosis survival rates are still not high enough to produce juveniles in hatcheries at an industrial-scale (Carbonara et al., 2018). It seems that the most successful metamorphosis-inducing signals are microbial biofilms (Hadfield and Paul, 2001). Recent studies have shown the metamorphosis induction effect of benthic diatoms on *P. lividus* (Rial et al., 2018; Zupo et al., 2018) and the potential to regulate developmental transition in sea urchins of neurotransmitters as histamine (Swanson et al., 2012) and Gamma-Aminobutyric Acid (GABA) (Rahman and Uehara, 2001). The main objective of the present study was to compare the effect of these different inducing cues on the metamorphosis of *P. lividus* and to identify those that could be of easy and cheap application.

Materials and Methods

Sea urchins competent larvae were exposed to the following treatments: *Nitzschia laevis* biofilm (NL), *Halamphora coffeaeformis* biofilm (HC), Mix biofilm of both *N. laevis* and *H. coffeaeformis* (MIX), Natural biofilm sampled from refining oyster ponds (NATURAL), Broken oyster shells 10 g (SHELL), Histamine 10^{-6} M (HIS), GABA 10^{-3} M (GABA), GABA 10^{-3} M + Mix biofilm of both *N. laevis* and *H. coffeaeformis* (GABA+MIX) and a negative control of filtered seawater (FSW). All experimental treatments were carried out in four 80 mm diameter Pyrex® Crystallizing Dishes filled with 100ml of filtered seawate .

Every 24h metamorphosis rate was recorded in each treatment. The first four treatments providing a metamorphosis rate of more than 90% were transferred into tanks filled with aerated filtered seawater in order to assess survival of early juveniles. At 10 days post-metamorphosis (DPM), survival was assessed by counting living juveniles on each treatment.

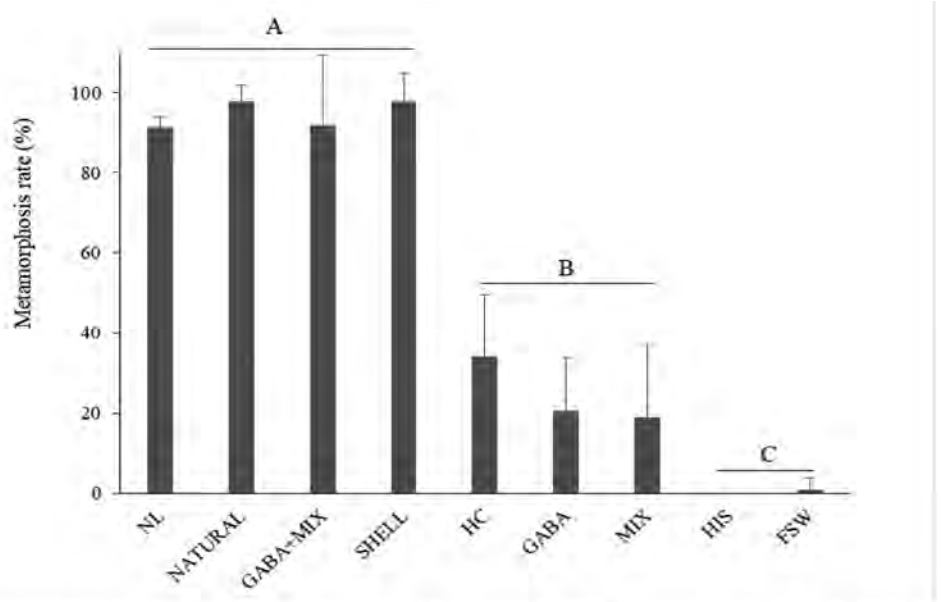

Figure 1 *Metamorphosis rate (%) of P. lividus larvae after 72h exposure to the different treatments. NL = N. laevis, NATURAL = natural biofilm, GABA+MIX = GABA+N. laevis+H. coffeaeformis, SHELL = broken oyster shells, HC = H. coffeaeformis, MIX = N. laevis+H. coffeaeformis, HIS = histamine, FSW = filtered seawater. Data are expressed as mean ± sd.*

(Continued on next page)

Statistical analysis of results were carried out using SigmaStat® 9.0 software. One-way ANOVA tests or Kruskal-Wallis tests were realized. Student-Newman-Keuls *a posteriori* multiple comparisons tests were carried out when significant differences ($P < 0.05$) were observed between treatments.

Results

After 72h of experiment, we can divide the treatments in three groups according to their effects on metamorphosis rate: group A - NL, NATURAL, GABA+MIX and SHELL, group B – HC, GABA and MIX, and group C - HIS and FSW. The sea urchins larvae in group A showed significantly higher metamorphosis rates than in groups B and C ($P < 0.001$). Significant differences were also found between larvae in groups B and C ($P < 0.05$). Between treatments in the same group there was no statistical difference (Figure 1). Sea urchins of the group A were those transferred to the tanks for survival assessment. Survival 10 DPM was higher than 60% for the four treatments. No difference was found between them.

Discussion and Conclusion

In this study we demonstrated that the transition from planktonic larvae to benthic juvenile could be promoted through diatom-based biofilms. As no difference was found between survivals in the NL, NATURAL, SHELL and GABA+MIX treatments, these represent efficient metamorphosis inducers for *P. lividus* larviculture. However, in order to promote practical and easy solutions for farmers, this study suggests to use preferably *N. laevis* biofilms or the treatments coming from the oyster ponds (i.e. natural biofilms or oyster shells). Monospecific diatom biofilms, as *N. laevis,* provide advantages for the industry: their growing is simple all around the year and they allow an easier quality control in terms of growth rates and nutritional profile in an industrial production cycle. In another way, using natural biofilms and oyster shells from the oyster ponds could represent a practical and sustainable source of metamorphosis inducing cue for oyster farmers.

Introduction

Integrated Multi-Trophic Aquaculture (IMTA) still faces considerable controversy over its advantages in the ecological, social and economic levels (Troell et al., 2009)”container-title”:”Aquaculture”,”page”:”1-9”,”volume”:”297”,”issue”:”1”, ”source”:”ScienceDirect”,”abstract”:”The marine aquaculture sector is growing rapidly. Offshore aquaculture installations have been drawing increasing attention from researchers, industry and policy makers as a promising opportunity for large-scale expansion of the aquaculture industry. Simultaneously, there has also been increased interest in both land-based and nearshore aquaculture systems which combine fed aquaculture species (e.g. finfish This study is concerned by the question of the sustainable aquaculture technical feasibility and searches to provide an alternative source of seaweeds to sea-urchin farmers in order to promote a French oyster aquaculture diversification.

The specific objective of the experiment is to determine *Palmaria palmata* growth rate and yield when cultivated in an IMTA system with effluents from oysters *Crassostrea gigas* and sea urchins *Paracentrotus lividus*. This assay is still in course.

Materials and Methods

Seven to ten cm long thalli of *P. palmata* are maintained by vegetative propagation in air-agitated tumble in triplicate tanks and stocked to a total biomass of 2g/L (Chow et al., 2001). Algae tanks are submerged in a thermoregulation pond in order to maintain temperature at 13°C. They are exposed to 120 µmol.photons m^{-2} s^{-1}. Growth of algae is being measured every week (weight and surface gain) and expressed in yield (g DW m^{-2} d^{-1}) according DeBoer and Ryther (1977) and in specific growth rate (% d^{-1}) according D’Elia and DeBoer (1978)and showed transient rates of NH4+ accumulation which did not greatly exceed the capacity to incorporate N in steady-state growth. NH4+ was preferred over NO3−even in plants preconditioned on NO3−as the sole N. source, NO3− uptake was suppressed at 5µM [NH4+], but simultaneous uptake occurred at unsurpressed rates at lower concentrations. Potential for N accumulation was greater via NH4+uptake than via NO3−uptake. Changing capacity for NH4+ uptake with N content appears to be a mechanism whereby excessive

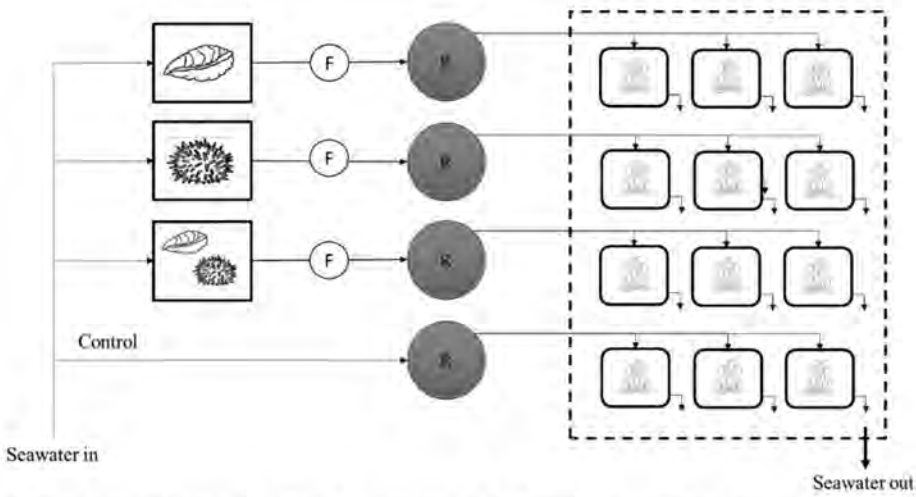

Figure 1 Experimental design. F = filter; R = reserve tanks. Dropped lines design the thermoregulation pond.

(Continued on next page)

accumulation of N was avoided by N-.satiated plants but a large accumulation was possible for N-depleted plants.”,” DOI”:”10.1111/j.1529-8817.1978.tb00297.x”,”ISSN”:”1529-8817”,”language”:”en”,”author”:[{“family”:”D’Elia”,”given”:”Christopher F.”},{“family”:”DeBoer”,”given”:”James A.”}],”issued”:{“date-parts”:[[“1978”,9,1]]}}],”schema”:”https://github.com/citation-style-language/schema/raw/master/csl-citation.json”} . Nitrogen uptake efficiency (NUE) and nitrogen uptake rate (NUR) are also measured weekly. Excess algae resulting from growth is removed every week and initial density restarted.

Oyster culture contain individuals at a density of 43 kg/m^3 in tanks filled with filtered sea water (FSW). They are fed with 2 x 10^9 to 3 x 10^9 cells per day of cultures of *Dunaliella tertiolecta* or *Skeletonema* sp. The sea urchin culture contain individuals at a density of 23 kg/m^3 in tanks filled with FSW and they are fed *ad libitum* with *P. palmata* or *Ulva* sp. collected from natural populations. Linear and specific growth rates of the animals are assessed every week.

Oysters, sea urchins and algae are reared in an open through-flow system (Figure 1). Sea water effluent from animals is filtered, accumulated in reserve tanks and passed at a constant flow (30% per day) on to the tanks with algae. Additionally triplicate algae control tanks without animal effluent are used in order to study the growth of algae without providing nutrients.

Results

First results show a macroalgae mean growth of 30% and a mean NUE of 95%. However, several problems have induced a high variability within results and a bias that must be taken into account: a development of microalgae and epiphytes in the algae tanks and a cross contamination between them. Moreover, four weeks after the start of the experiment, a high mortality rate (20-40%) has been observed in the sea urchin culture due to a low water exchange rate. For these raisons, some adjustments have been made on the experimental design in order to reinitialize the acquisition of data. This assay is still in course.

Discussion and Conclusion

Land-based IMTA systems have already been demonstrated to be technically feasible (Troell et al., 2009). However, in Europe, most of the IMTA systems are based on fish farms with fishes as main link. Only few studies based IMTAs on invertebrates, seaweeds or microalgae (Jacquemin et al., 2018). Due to an anecdotal fish production in our region (non-traditional activity, poor image of farmed fish by consumers), the present work has proposed an innovative study of an IMTA focused on fed invertebrates and seaweeds as extractive species. It seems that ammonium-nitrogen concentrations produced by the invertebrates are high enough to allowing macroalgae growth. However, higher water exchange rates have to be tested in order to improve sea urchin survival without compromising the ammonium-nitrogen concentration available for algae.

Introduction

Some byproducts of the dairy industry, such as exhausted whey and buttermilk, represent a problem both from an economic point of view, as the dairies have important disposal costs, and from an environmental point of view, due to their high microbial and COD content. The traditional treatment technologies are particularly expensive and of hard management. In this respect a possible solution may be given by microalgae, as a sustainable biotechnology able to assimilate the nutrients present in the dairy byproducts, which permits not only to reduce the COD load in the byproducts, but also to obtain biomass that can be valorized in various sectors of commercial interest (nutraceuticals, pharmaceuticals, cosmetics, food and feed supplements, bioplastics and phytobiostimulants).

Materials and methods

A cyanobacterial strain of *Arthrospira platensis* (21.99), purchased from the Culture Collection of Algae at Göttingen University (Germany), was grown in semi-batch cultures in 100-liter column photobioreactors. The culture broth was composed in exhausted whey (EW) diluted with Zarrouk medium (Zarrouk, 1966), commonly used as standard medium (SM) for *A. platensis*, in ratio 1:4. The exhausted whey came from a big dairy factory located in the Po Valley (Italy). Simultaneously a control trial in which *A. platensis* was cultured on SM as such without addition of any byproduct was carried out for comparison. The trials, conducted in duplicate, lasted 25 days in controlled conditions, at temperatures of about 25-27° C, a light intensity of 30 $\mu E\ m^{-2}\ s^{-1}$ and with a Hydraulic retention time (HRT) of 12 days.

The parameters measured were dry biomass, total nitrogen (N_{tot}), nitric nitrogen ($N\text{-}NO_3$), orthophosphate-phosphorus ($P\text{-}PO_4^{3-}$) and Chemical oxygen demand (COD).

A. platensis biomass was regularly harvested, freeze-dried, analyzed microbiologically and characterized for macronutrient and fatty acid composition.

Results

The nitrogen removal with *A. platensis* grown on medium supplemented with EW was absolutely efficacious, as $N\text{-}NO_3^-$ concentration was almost completely uptaken after few days, also thanks to the presence of a relevant microbial community that competed with *A. platensis* for the consumption of nitrogen. Nevertheless, inorganic nitrogen for growth of *A. platensis* was always available, as the microorganisms themselves were able to convert the fraction of organic nitrogen present in the whey into $N\text{-}NO_3^-$, resulting in a highest N_{tot} removal of 84%. This phenomenon also permitted a COD reduction of 96%. With regard to harvested biomass, the average value obtained was 0.85 g/l dw, compared with control that reached an average value of 0.67 g/l dw. The macronutrient composition of the dried *A. platensis* biomass, control and test, is reported in Tab I.

The fatty acid analysis showed a high difference in n-3 composition between control (traces) and test (29.72 g/100 g dw) ($p>0.05$). Microbiological analysis showed no difference in TBC (Total bacteria Count) between test and control (average: 5 ± 0.07 log CFU/g). Enterobacteriacea and *E. coli* were found below the detection limits of the method (< 2 log CFU/g). *Salmonella* and Sulfite-reducin *Clostridia* spores resulted absent.

Tab I: macronutrient composition.

	Water (%)	Protein (%)	Lipid (%)	Carbohydrate (%)	Ash (%)
A. platensis EW	11.30	35.91	2.59	5	34.02
A. platensis CW	8.05	47.43	5.26	9.7	24.80

(Continued on next page)

Discussion and conclusion

A. platensis proved to grow slightly better in experimental medium than in the control, thanks to presence of microbial community naturally present in the whey and with which it integrated in a symbiotic equilibrium: Cyanobacteria (as well as other microalgal strains) produce through photosynthesis oxygen, that can be exploited by microbes that provide CO_2 and nutrients that improve photoautotrophic growth of microalgae (Subashchandrabose et al. 2011). The most important result of this work is the reduction of COD in the mixture whey-SM by over 90%, until values that are compatible with the law-limits concerning emissions of wastewater into the sewerage system (0.5 g O_2/l). The microbiological analysis and biochemical composition show that the microalgal biomass grown on exhausted whey has excellent nutritional values, potentially useful as feed in aquaculture. Further studies should be carried on, in other types of PBRs, in order to verify the feasibility and reliability of these systems in producing *A. platensis*.

Introduction

Food allergies represent a serious public health problem worldwide and fish, being one of the highly consumed foods worldwide, represents a group that limits more people in their food choices, essentially among the young population. Parvalbumin, which is a stable white muscle protein involved in the processes of contraction and relaxation of fish muscle, have been identified as the main responsible proteins of allergic reactions by the consume of fish, including farmed fish. Creatine is used parallelly as a molecule to enhance bioenergetics by increasing efficiency of Ca2+ uptake and to modulate the expression of parvalbumin. Therefore, the supplementation of fish diets with creatine aimed at reducing the expression of fish allergenicity factors and increase flesh quality, is of higher interest and beneficial in terms of food safety and human health. The present study was conducted to produce a low allergenic fish species using enriched diets diets for Atlantic seabass (*Dicentrarchus labrax*) supplemented with different percentages of creatine (0%, 2%, 5% and 8%). Its effects on muscle quality, physiological stress, proteome and parvalbumin modulation were analyzed.

Methodology

Triplicate groups of 20 seabass (initial body weight: 186,17 ± 0.83g) were randomly distributed in 500-L tanks under standard rearing conditions. Fish were hand-fed ad libitum twice a day during 91 days, with four agglomerated diets formulated at different concentrations regarding creatine concentration (CTRL; Crea2%; Crea5%; Crea8%). Fish were then euthanized and sampled for i) growth performance evaluation, ii) nutritional status by body composition analysis and iii) stress levels. Comparative proteomics was used to look into changes in muscle tissues at protein level and to assess the effects of fish dietary creatine on alle gen parvalbumin modulation.

Results

After 12 weeks of trial, growth performance was similar between diets. Hepatic visceral indicators, body proximate composition and metabolites fingerprinting were not affected by the creatine dietary levels. Nevertheless, higher cortisol levels were found in fish fed with higher dietary creatine concentrations. Muscle proteome is differently expressed in fish fed with 2% dietary creatine.

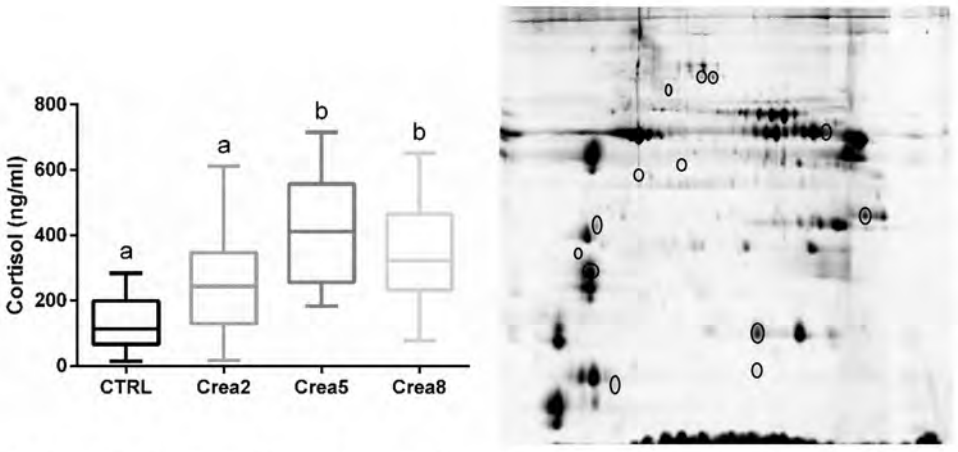

Fig. 1. Left) Fig. 1. Cortisol (nM) concentration in plasma of *D. labrax*. Values are means (n=18) and error bars represent standard error of the mean (SEM). Different letters represent significant differences (one-way ANOVA followed by post-Hoc Tukey, p<0.05); Right) 2D gel of *D. labrax* muscle on a 12.5% polyacrylamide gel and a pI range from 3-7.

(Continued on next page)

Discussion and Conclusion

Our findings suggest that the dietary supplementation of creatine do not constitute a valuable nutritional approach towards either productivity parameters or lowering allergenicity of fish, but could, however, impact its quality. Nevertheless, proteomic technology demonstrates to be valuable for the dietary nutrients/compounds standardization limits, which don´t disturb the biological processes in fish. Such findings can impact fish safety and the aquafeeds industry, to making aquaculture more resilient and competitive.

IN VITRO PROTEIN HYDROLYSIS OF NOVEL AQUAFEEDS INGREDIENTS BY THE DIGESTIVE ENZYMES OF RAINBOW TROUT (*Oncorhynchus mykiss*)

R. Cerri[1]*, A. J. Vizcaíno[2], A. Galafat[2], M. I. Sáez[2], F. J. Alarcón[2], G. Cardinaletti[1], R. Ballestrazzi[1], F. Tulli[1]

Introduction

Interest in identifying novel sustainable ingredients in aquafeeds such as insect and microalgae biomass meals increased in recent years. A number of experiments have evaluated their potential as dietary protein sources in the diet of several fish species, however, to our knowledge, little research has been carried out on the way digestive enzymes of fish hydrolyze their protein and contribute to their protein digestibility (Tibbetts *et* al. 2017, Vizcaíno et al., 2019). Digestibility of proteins is obviously a basic factor to establish the nutritional value of a protein-rich ingredient in particular for carnivorous fish species. Nevertheless, determination of *in vivo* digestibility requires long time frames, specialized facilities, high labor costs and ethical control. In this regards, *in vitro* assays can be used as preliminary alternative tests in order to evaluate the quality of protein-rich ingredients for aquafeeds, based on the extent of protein degradation and the amount of free amino acids released by proteolytic enzymes extracts obtained from a given fish species (izcaíno *et al*., 2019).

The present study was aimed at evaluating the *in vitro* degradability of the protein fraction of novel ingredients such as microalgae dried biomass (*Tetraselmis suecica, Arthrospira platensis*) and insect meals (*Hermetia illucens, Tenebrio molitor*) compared to that of a fish meal as a reference, using rainbow trout enzyme extracts

Materials and methods

The reference fish meal as well as all test ingredients were obtained from commercial farms. Crude digestive enzyme extracts were obtained from fifteen rainbow trout (1,0 kg average body weight) reared at the facilities of the University of Udine and fed for one month a commercial diet not including the novel ingredients. Fish were euthanized 6 h after the last meal using an overdose of anesthetic according to EU Directive 2010/63/EU. Total alkaline protease activity was determined using 5g l^{-1} casein in 50 mM trisHCl buffer (pH 9.0) as substrate (Alarcón *et al.*, 1998). The *in vitro* protein hydrolysis of the different ingredients was carried out according to the methods described by Alarcón *et al.* (2001) using five jacketed reaction vessels connected to a circulating water bath in order to maintain a constant temperature (37°C) and continuous agitation. For each assay, a known amount of each ingredient, providing 160mg crude protein, was suspended in 50mM Tris HCl buffer pH 9.0. After 15min stirring, the addition of a previously calculated volume of rainbow trout digestive enzymatic extract comprising 3040U of total alkaline proteolytic activity started the enzymatic reaction. A control assay with fishmeal as reference protein source was carried out. Protein degradation was monitored at different times by electrophoretic techniques using sodium dodecyl sulphate polyacrylamide gel electrophoresis (SDS-PAGE) to obtain a quantitative coefficient of protein degradation (CPD) (Vizcaíno *et al*., 2019). In addition, total amino acids released by digestive enzymes were also quantified using L-leucine as substrate (Church *et al*., 1998).

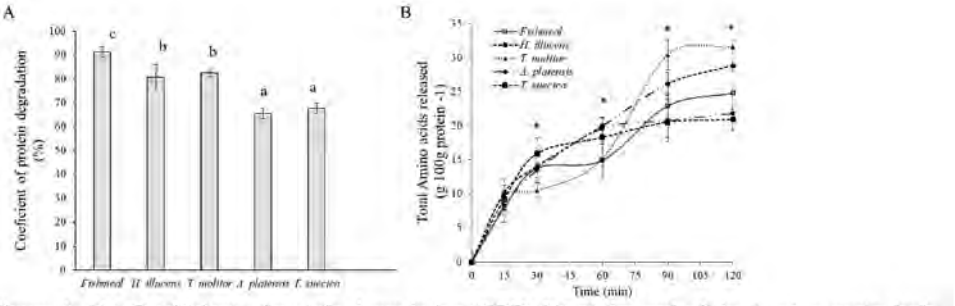

Figure 1. (A) Coefficient of protein degradation (CPD, %) at the end of the *in vitro* proteolysis. Different letters symbolize significant differences among ingredients tested ($p<0,05$). (B) Concentration of free amino acids released (g 100 g $protein^{-1}$) during the *in vitro* proteolysis. Asterisks symbolize statistically significant differences among ingredients for each sampling time ($P < 0.05$).

(Continued on next page)

Results and discussion

Overall, the results obtained have shown an efficient protein hydrolysis of the different tested protein sources. Densitometric analysis revealed that more than 60% of proteins or polypeptides of raw ingredients visualized in the polyacrylamide gels were hydrolysed by rainbow trout digestive proteases. The CPD values (Figure 1A) were higher in Fish meal (90%) and just slightly but significantly lower in *T. molitor* and *H. illucens meals* (*nealy 80%*), while in case of the microalgae meals, they were similarly lower and around 60%, a fact demonstrating high proteolysis capability by rainbow trout digestive proteases.

In turn, the quantification of free amino acids released by digestive enzymes can be used to estimate the bioavailability of dietary protein. At the end of the *in vitro* assay, fish digestive proteases were able to release from 20% to 31.6% of total amino acids contained in the protein of the different raw sources (Figure 1B). The amount of free amino acids released after 120 min of the hydrolysis of insect meals (*T. molitor* 31.6g 100g protein^{-1} and *H. illucens* meals 28.9g 100g protein^{-1}) are both significant y higher ($p<0.05$) than fish meal (24.8g 100g protein$^{-1)}$, instead microalgae dried biomass (*T. suecica* 20.9g 100g protein^{-1} and *A. platensis* 21.7g 100g protein^{-1}) are significantly lower ($p<0.05$) than the value obtained from the degradation of the ingredient used as control. Probably this is caused by the presence of the wall that limit the availability of the protein to be degraded.

Conclusion

Insect meals exhibit slightly lower coefficient of protein degradation and higher amount of free amino acids released than fish meal. Overall, the extent of protein hydrolysis and the concentration of free amino acids released reveal that the microalgae and insect biomasses tested here can be used as potential protein ingredients in practical diets for rainbow trout. Despite this, further research to improve understanding of the factors that determine microalgae protein bioavailability and the biological effect on fish

AN AUTONOMOUS UNDERWATER VEHICLE FOR AUTOMATED INSPECTION OF AQUACULTURE NET PEN CAGES

Introduction

An Autonomous Underwater Vehicle (AUV) is presented, as a useful tool with advanced capabilities that can be used to automatically inspect the net structure of aquaculture net pen-cages for possible dysfunctionalities, such as net holes of various shapes and sizes. For the acquisition of underwater image data and the inspection of the installation, a methodology to efficiently navigate the AUV under real operational conditions has been implemented. The navigation procedures and the required data collection are performed without the intervention of a human user, using real-time processing and assessments. The automated fish net consistency inspection is based on video data recorded from the entire net pen-cage area and is performed off-line.

The system

The AUV is based on the BlueRobotics' BlueROV2, the technical details of which are available from the manufacturer. Existing open-source navigation and guidance software have been enhanced with underwater capabilities, while the AUV is considered as IoT-enabled in the sense that all relevant communication and data-exchange (e.g. images and video, sensor data etc.) are performed through Internet Protocol (IP) networks. To cope with lack of GPS or similar systems underwater, computer vision techniques that facilitate correct positioning within the cage are utilized. The AUV monitoring system comprises of three subsystems: a) AUV, consisting of the vehicle, its sensors and the internal processing/control unit, b) Off-line Processing and Communications, and c) Energy Provision and Management, containing the energy sources and the charging docking station.

Operation

For the location and navigation of the AUV inside the fish cage, the proposed solution involves a combination of inertia and magnetic sensors with a real-time optical recognition system enhanced with photogrammetry fundamentals applied to reference targets attached to the net at known depths and bearings. To achieve the required communication speeds with the land base, the AUV docks to a surface-based station that has direct link to the internet. Through this link, the time-tagged and position-tagged hi-res video is uploaded to a surface-based server for further image processing and fish-cage net dysfunctionality detection. The same docking station is used for the inductive charging of the AUV batteries.

One of the main aspects of the monitoring is net inspection assessments, mainly focused on the detection of possible problems existing at the underwater net infrastructure, like holes or 'broken' patterned structure that may appear on the nets. Since AUV provides video data of the net, appropriate advanced image processing techniques are used for the calculation and extraction of all the parameters that can accurately describe the subjects under consideration and alert properly.

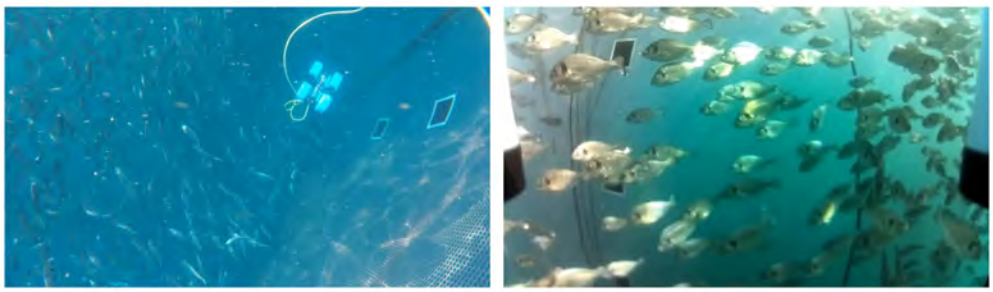

Fig. 1. AUV trials in aquaculture net-pen cages at the HCMR pilot farm

(Continued on next page)

Trials and Results

The AUV has been successfully tested in a real aquaculture environment, within a squared section fish-cage (6m × 6m × 8m). Test-missions and trials were conducted in various lighting conditions and depths, with and without fishes in the cages and under different conditions.

Introduction

Over the last decade, sources of vegetable proteins (VM) and oils (VO) have been increasingly used to replace fishmeal (FM) and fish oil (FO) in feed for marine finfis (Jobling, 2016). The vegetable proteins as substitutes of fish meal present various challenges, due to the quality and the protein concentration from plant sources that are generally lower than FM, and the lower palatability of most plant protein (PP) meals (Drew *et al*., 2007). The present study aimed to evaluate the effect of a digestion enhancer, algae sulphated polysaccharides (MSP®LIPID) on diets with partial FM substitution by PP on growth parameters, body composition, and digestibility in European seabass. Attention has been focused on seaweeds as a rich source of bioactive compounds and their polysaccharides as antioxidants to prevent oxidative damage in living organisms (Hassan *et al*., 2011). The algae sulphated polysaccharides activate the enterocytes and hepatocytes and this initiates several mechanisms (Qi *et al*., 2012). First, the bile acid secretion is increased. The release of the bile by the gall bladder allows the digestive organs to exclude rejected toxins, thus improving the detoxification of the liver, blood, and kidneys. The stimulation of bile secretion and excretion leads to obtain smaller lipid micelles formation which improves the efficiency of the lipolytic enzymes (Hassan *et al*., 2011). Also as the enterocytes and hepatocytes are activated in a way that some enzyme are stimulated these two actions help to improve digestive system and nutriment assimilation (Qi & Sheng, 2015).

Materials and methods

Three isoproteitic, isolipidic and isoenergetic diets were fed to 3 groups of European seabass in triplicate. Groups A were fed the control diet containing 18% fish meal, group B fed a diet in which fish meal was substituted at 33% by PP and group C in which a digestion enhancer (MSP®LIPID) was added in the fish meal substituted diet (Table I). Three hundred and sixty fish (14.4±0.06g) were randomly distributed in nine 500 l tanks, at 19 °C, and fed three times a day, 7d a week, until satiation for 95d initially with 2 mm pellets and after xx g bodyweight 3 mm pellets. The growth parameters and the apparent digestibility coefficients (ADC) were calculated according to the following formulas:

Feed Conversion Ratio (FCR)=feed intake/weight gain

Specific growth rate (SGR) (%day 1) = 100x(ln final body weight−ln initial body weight)/days

Daily Growth Index (DGI)=[(final weigh $^{1/3}$ − initial weight$^{1/3}$)/days]×100

Average daily gain (ADG)=Weight gain(g)/days

Hepatosomatic index (HSI)=100×weight of the liver/whole body weight

Viscerosomatic index (VSI)=100×weight of digestive tract/whole body weight

ADC=100–100x[(marker in the diet/marker in faeces)x(nutrient or energy in faeces/nutrient or energy in the diet)].

Results

By the end of the growth trial, no significant differences were observed for weight gain and SGR among sea bass fed diets A, B and C. All groups had excellent growth rates (SGR above 1.1%/day) relative to water conditions. In addition there were no significant differences in feed conversion ratio between groups, which had a value of 1.3 - 1.4. Replacement of fish meal by plant protein ingredients did not affect DFI which was at 1.1-1.2% bw/day. The whole-body proximate composition was representative of the size of fish tested and did not reveal differences between treatments (Table II). The use of the digestion enhancer proved to be beneficial as it improved the protein ADC significantl , and increased numerically all other digestibility values, however without statistical significance (able III).

Discussion and conclusion

Although commercial diets for sea bass contain high levels of FM, it has already been shown that young sea bass can accept dietary protein-based diets almost devoid of FM without affecting the growth and use of feed (Kaushik *et al*., 2004). The results of this work support these results and show that a 33.3% substitution of FM in a 18% fishmeal diet -during a 95 day trial- is possible without affecting the growth performance and body composition of the seabass, the whole-body composition and feed digestibility, with zero mortality rates (Kaushik *et al*., 2004; Tibaldi *et al*., 2006). Under the present experimental conditions the inclusion of PP also did not affect feed intake. The addition of algae sulphated polysaccharides showed a tenedency of a beneficial effect as far as protein digestibility is concerned. Algae polysaccharides may have an impact on a number of biological processes such as reducing oxidative stress and provide antihyperlipidemic benefits by increasing the activities of antioxidant enzymes and limiting lipid peroxidation (Hassan *et al*., 2011). Furthermore, they exert therapeutic effects on metabolic diseases (Qi & Sheng, 2015).

Introduction

The rapid increase of intensive aquaculture has resulted in the accumulation of nutrients which can disturb the sustainability of aquatic ecosystems, degrade the water quality and cause eutrophication. One potential way is the increased use of land-based recirculating aquaculture systems (RAS). Such systems allow more effective control of culture conditions, and through filtratio , minimize many negative impacts on the surrounding environment (Martins et al., 2010). Integrated Multi-Trophic Aquaculture (IMTA) gives a new prospective to the preservation of the environment. Through the combination of different species that interact and use each other's by products as a source of nutrients, IMTA can contribute to the bioremediation of seawater and provide economic and environmental sustainability (Granada et al., 2009). *Ulva* has been successfully integrated into mid- to large-scale animal mariculture systems, showing high growth rate (Troell et al., 2003; Neori et al., 2004). A good potential for profitability has been estimated for integrated sea bream - *Ulva* farms (Neori et al., 2004). In this study, European sea bass (*Dicentrarchus labrax*) and *Ulva* sp. were cultured in indoor RAS with biofilm filtration in an effort to optimize growth performance and quality of both species. Two different trials were performed where dietary fish oil was replaced by vegetable oils (rapeseed and palm oil) at the first trial, and at the second, pellets containing sardine oil were used for the fish nutrition. The cultivation of sea bass and *Ulva* in IMTA-RAS is a case study of the project IMTA-EFFECT (Integrated MultiTrophic Aquaculture for EFFiciency and Environmental ConservaTion) in the frame of EU ERA-NET project, aiming to evaluate IMTA-RAS performance using alternative diets to finfis and to contribute to food web modelling through fatty acids characterisation.

Materials and Methods

In each trial, two identical RAS units with separate biofilters (bacteria compartments) and similar fish biomass were used. In one unit (*Ulva*-Ras), water compartments and sea bass (fish compartments) were grown in separate tanks (3 tanks per species) in order that the water from upper tanks to insert into the fish tanks and thereafter to flow in a lower biofilter (bacteria compartment). The waste water treated by the biofilm pumped into the water tanks. Rearing conditions were similar in both RAS units in terms of water flow rate, salinity, oxygen, photoperiod and light intensity. Fifty fish were placed in each tank. Fish were fed extruded pellets at apparent satiation twice a day (except week end). Dietary fish oil was replaced by a mixture of rapeseed oil and palm oil (1:1) at the first trial, whereas pellets containing sardine oil were used at the second diet. Sea bass were reared for 12 weeks. Body weight (W) and length (L) (standard and total) were measured at the beginning and the end of each trial. FCR, SGR and Condition Factor ($K=W*L^{-3}*100$) were calculated for each trial. *Ulva* was collected from the Saronic gulf, sorted and cleaned with seawater and weighted after drying in open air. Unattached thali were transferred to the upper level tanks of *Ulva*-Ras and were kept suspended by air diffusers situated at the bottom of the tanks. *Ulva* was kept at densities of 0,5-1 kg $m^{-2.}$ S. *Ulva* was harvested weekly (2nd trial) or biweekly (1st trial) and replaced. Samples were collected at the beginning and the end of the growing period of each species for chemical composition and fatty acid analyses.

Results

In both trials Body Weight Increase (BWI), Specific Growth Rate (SGR), Feed Conversion Rate (FCR) and mortality did not show significant differences between Control and *Ulva*-RAS. Sea bass in *Ulva* containing units (UF) showed a higher feed intake during the 1st trial, while lower in the 2nd trial compared to control fish (CF). Condition Factor (K) was higher in *Ulva*-RAS in both trials. Sea bass chemical composition showed significant differences, between fish UF and CF in both trials regardless feed intake. In both trials, moisture was significantly ($P<0,05$) higher in CF than in UF groups, whereas ash and lipid were significantly higher in UF than in CF groups in both trials. Protein content was significantly higher in UF than in CF groups only at the 1st trial. Fatty acid profile analysis of sea bass showed significant differences in the content (% total lipids) between UF and CF groups. After single or bi-week, culture in indoor RAS *Ulva* showed an increase in Nitrogen and Phosphate content.

(Continued on next page)

Conclusions

Ulva cultured in indoor RAS did not increase its biomass, however chemical composition analysis, shows improved quality, due to the decreased carbohydrates and the higher protein content. Fish in *Ulva*-RAS show an increased Condition Factor (K), higher lipid (% wet weight) and increased EPA & DHA (g/100g) content compared to control. High lipid content in cultured fish is often associated to physiological disorders (e.g dietary EPA and DHA deficiency) or increased feed intake. On the other hand, it may be an indicator of a good physiological condition. For fish in Ulva-RAS, feed consumption increased when fed VO-diet and decreased with FO-diet compared to control fish. However, increased lipid content was observed in both diets, regardless of dietary EPA and DHA content or feed intake. Although *Ulva* was not a dietary component in this study, the results support the previously reported hypothesis that supplementation of fish diet with algae is associated with activation of fish lipid metabolism and good physiological status (Nakagawa et al., 1987). More research is required to reveal the effective substances due to *Ulva* presence in fish culture. Nevertheless, taking into consideration the results of the chemical composition, we can assume that the co-culture of sea bass and *Ulva* could result in a higher nutritional value for both species.

Optimal gut health is a key component in improving feed utilization, for better fish growth and health, reduced production costs and for minimizing the environmental impact of Atlantic salmon industrial production. There is a dearth of knowledge on gut health of farmed fish stock. This is being addressed in the GutMatters project, funded by the Norwegian Seafood Research Fund (FHF), in a national survey to investigate the prevalence of gut health disorders and their incidence during a production cycle in sea farmed Atlantic salmon.

In the survey that ran from October 2017 to November 2018, 6 sea farming sites along the Norwegian coast were monitored starting from smolt transfer to harvest fish size (>4 kg) (sampling 3). At each of 3 samplings per site, fish weight and length; plasma; gross pathology observations of the fish, intestinal mucosa and liver; intestinal, liver, and other samples for histology, qPCR, microbiota, metabolomics, and digestive enzyme activity were analyzed from 20 fish. Additionally, site physicochemical data, fish genetics, population records, feeding regimes, growth and health history data were also collected. Results from the preliminary gut health assessment from gross pathology and intestinal histopathology will be presented.

Histopathology revealed enterocyte steatosis, indicating a lipid transport disorder, in the pyloric caeca and occasionally the mid intestine was a noticeable finding whose prevalence and severity appeared to increase in warmer periods of the yea .

Inflammatory changes, resembling the salmonid soybean-meal-induced distal intestinal enteritis, were also observed in some fish from all participating sites. A trend of a general increase in occurrence and severity of the enteritis over time was noted for most of the sites.

In conclusion, the gut health of some fish from participating farms was hampered by enterocyte steatosis and enteritis. More survey results and follow-up plans for the GutMatters project will be presented.

COMPARISON OF EXPRESSION LEVEL OF GLUCOCORTICOID RECEPTOR (GCR) GENE IN ORIENTAL WEATHERFISH (*Misgurnus anguillicaudatus*) ACCORDING TO REARING DENSITY

K.T. Cho

Gyeonggi Province Maritime & Fisheries Research Institute, Yangpyeong-gun 12513(South Korea)
E-mail: ktcho8977@gg.go.kr

Introduction

The oriental weatherfish (*Misgurnus anguillicaudatus)* is considered as popular food with high level of nutrition value and high medical function in Asian countries for a long time. It is anticipated that commercial farming for *M. anguillicaudatus* will come into the spotlight and increase requirement of research in aquaculture field in Korea, though it has a problem which occurred mass mortality at early stage without any special reason. It is assumed that stress due to rearing density is one of the reasons. Cortisol and Glucocorticoid receptor (GCR) are relative with level of stress in fish, and inversely proportional when stress factor activated them. Stress tolerance and effect can be determined by the GCR gene level (Wendelaar Bonga, 1997). The purpose of this study is to confirm quantitatively difference with expression level of GCR gene in *M. anguillicaudatus* depending on different rearing density.

Materials and methods

We produced fingerlings of *M. anguillicaudatus* by artificial reproduction in 10L plastic tank. We made 3 groups of different rearing density (3,000; 6,000; 15,000 fish/ ^{2}). We provided live feeds (rotifer, Artemia) or commercial feed, and other environments were suitable for fish. We sampled 3 individual in each tanks (n=3) at 0, 5, 10, 12 days after hatch out(0d, 5d, 10d, 12d). mRNA was extracted from each sample by Trizol method, and synthesized cDNA for quantitative Real-time PCR (RT-PCR). RT-PCR was performed using SYBR green PCR Master Mix (Life technologies, USA) and GCR gene-specific primer set. The PCR were performed as follows: 10min at 95°C; 40 cycles of 15sec at 95°C, 1min at 60°C. The data from RT-PCR (C_T value) was analyzed by $2^{-\Delta\Delta CT}$ method, and statistical analysis was performed using the SPSS Version 10 (SPSS Inc., USA).

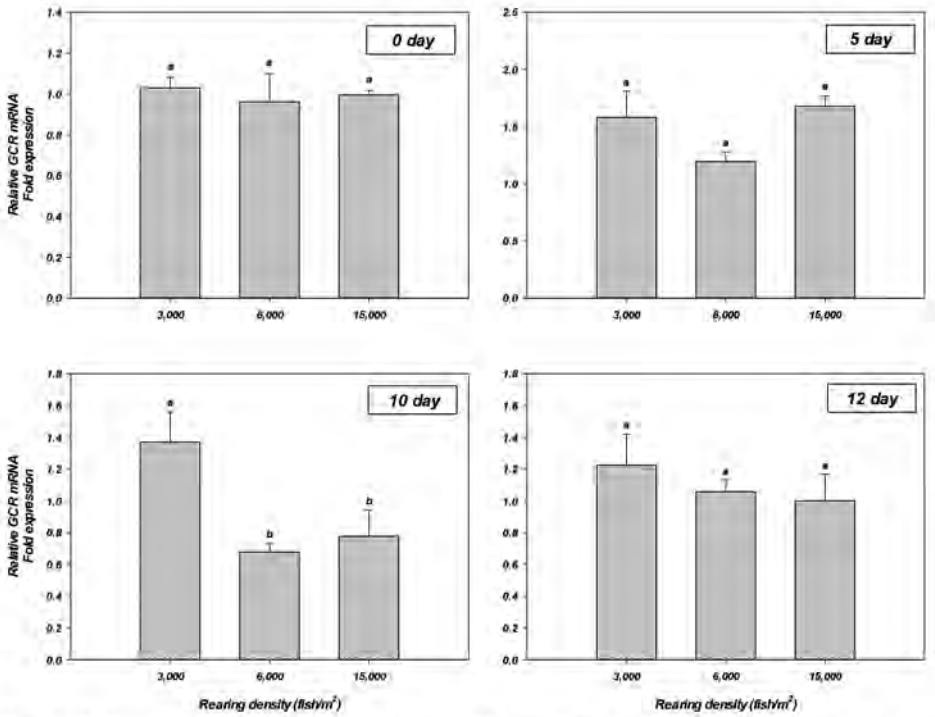

Fig. 1. Relative fold expression of *M. anguillicaudatus* GCR gene according to rearing density. The letters upper the bar within each group marks significant differences by duncan's multiple range test (P<0.05).

(Continued on next page)

Results

The Expression of GCR gene of 10d sample decreased at 6,000 group, and it was significantly difference at 6,000/15,000 group (Fig. 1) ($P<0.05$). Samples of 0d, 5d was not significant y different ($P>0.05$). In the comparison according to the rearing density, 6,000 group was significantly di ferent expression level of GCR gene at 10d.

Discussion and conclusion

We demonstrated that the relationship between stress of fish and rearing density in this study. We produced fingerlings of *M. anguillicaudatus* in different density, and determined expression level of GCR gene from individual samples using Real-time PCR. Expression of GCR gene was same until 5d after hatching in all group, than significantly decreased at 10d in 6,000/15,000 group (Fig. 1). As a result about rearing density, 6,000/15,000 group was significantly decreased at 10d, but 3,000 group was not. This result demonstrated that rearing density over 3,000 fish/ ^{2} affect the fish stress in artificial reproduction of *M. anguillicaudatus*. It was similar to the previous study that stress in fish affect by high rearing density (Witeska et al., 2005). Occurring stress in fish for many factor (environments, pathogen, etc.), Secreted cortisol combines with GCR, and cortisol-GCR complex react to stressful situation (Park et al., 2011). Previous studies reported that down-regulation of GCR expression content with elevated cortisol concentrations (Park et al., 2011; Terova et al., 2005). As a result, we confirmed that stress due to rearing density may cause the mortality of fish, and established the adequate rearing density of *M. anguillicaudatus* for aquaculture.

Introduction

The marine aquaculture cage systems use more intensive energy in the limited area than natural ecosystems to increase the productivity. In particular, it is known to change the marine environment around farms (aquaculture areas) due to the large and dense facilities and intensive food supply (and excretion). In this study, we investigate the change of characteristics of seawater movement according to the increase of facilities and discuss the effects on the aquaculture environment in terms of geochemical process.

Materials and methods

To analyze the variability of the water movement, geochemical process and environmental characteristics around the abalone marine aquaculture area, seasonal hydrographic survey were carried out and time series datasets of hydrodynamic were collected in the study area simultaneously.

Results

According to the preliminary results from hydrodynamic data, the seawater movement in the study area was characterized by tide and tidal current with a semi-diurnal cycle. However, the distortion of tidal current velocity along water depth was observed in the vicinity of abalone aquaculture cage. The minimum and maximum velocity of tidal current were measured at the surface and middle layer respectively. The change of the vertical structure of current velocity seems to be related to the increased abalone aquaculture facilities (cages). Eventually, the increased current velocity at the middle layer would

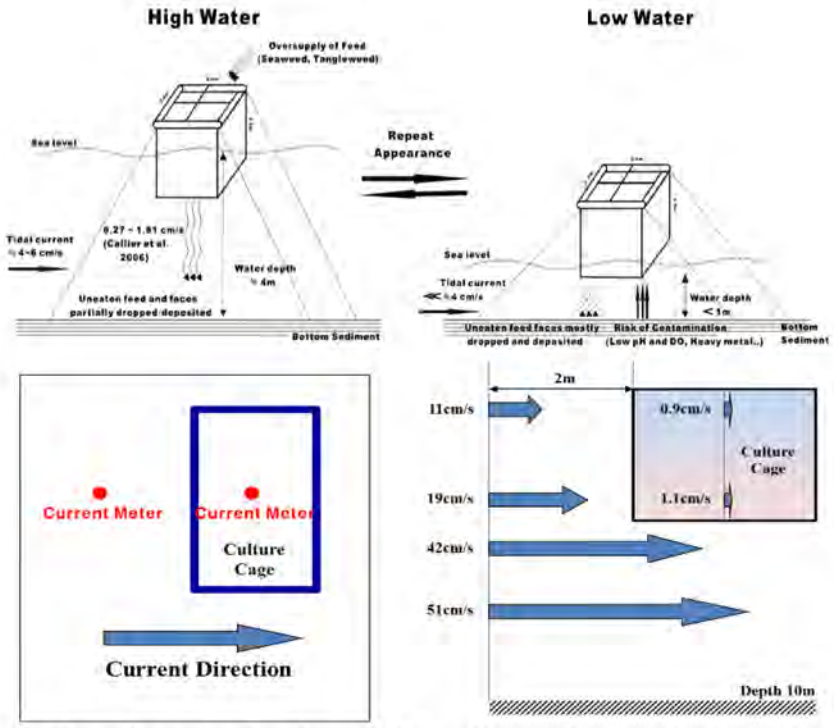

Fig. 1. The schematic drawing of the sedimentation mechanism of organic matters, the deployment of current meter and the vertical structure of tidal current velocity in the vicinity of abalone aquaculture cage.

(Continued on next page)

influence the vertical velocity shear increase at the bottom layer. The periodical variation and high concentration of the suspended particulate matter at the bottom layer and the inside of the abalone aquaculture facilities can be explained by the increased shear velocity at the bottom layer. The decreased current velocity at the surface layer by the dense and massive abalone aquaculture facilities can also be related to the main cause of environmental degradation in the study area due to the restriction of water-mass exchange. The results of the water quality parameters (dissolved oxygen, chemical oxygen demand, nutrients, suspended particulate matter, etc.) analysis indicated that the changes of environmental condition are closely related to the current velocity.

Discussion and conclusion

From the preliminary results, the extent of the environmental impact on the abalone aquaculture area seems to be highly correlated to the change of seawater movement as well as geochemical processes such as the amount of organic matter and the concentration of nutrients. Further research for the interaction of the hydrodynamic and geochemical processes including the variation of the sea surface temperature is essential to understand the environmental effects on the abalone aquaculture area.

NEED OF FEED ENZYMES FOR EFFICIENT RECIRCULTATION AQUACULTURE (RAS) SYSTEMS: A PROTEASE PERSPECTIVE

G.A. Bula, H-L. Brun, and M.A.K. Chowdhury*

Jefo Nutrition Inc., Saint-Hyacinthe, Quebec, Canada J2S 7B6
E-mail: kchowdhury@jefo.ca

Introduction

Frequent disease outbreaks and unpredictable weather conditions are significant threats to intensive farming systems. Farmers are seeking more control over the operations to ensure better return on investment and as well as to reduce the ecological footprint.

Recirculating aquaculture or RAS systems are therefore becoming increasingly popular. They provide better control culture environment and improved waste management.

Efficiency of a RAS system largely depends on its' nutritional wastes removal capacity. Better waste management primarily depends on reducing the waste output and then, efficient removal of the wastes.

In this paper, we summarized the findings from several studies where use of a specific protease improved nutrient utilization thus reducing the waste output to the culture environment.

Methods

We summarized the findings from several commercial studies conducted on farms or in controlled laboratory conditions worldwide. The meta-analyses were mainly focused on protein-efficiency ratio (PER), nitrogen digestibility, and nitrogenous waste-output.

Results

Marked improvement in protein efficiency ratio (PER) was observed when a specific dietary protease complex was supplemented to the diets compared to the same diet without supplementation in studies with tilapia, yellow catfish, snakehead and Chinese mitten crab shown (Fig. 1).

Apparent nitrogen digestibility also showed significant improvement in both fish (rainbow trout and Atlantic salmon) and crustacean (Pacific white shrimp)

Findings of a laboratory trial with yellow catfish have shown a linear decrease in hourly ammonia excretion with graded level of the specific protease (Fig 2

COMPUTER VISION BASED FISH INDIVIDUAL IDENTIFICATION AS AN ALTERNATIVE TO FISH TAGGING

Petr Cisar[1]*, Mohammadmehdi Saberioon[1], Dinara Bekkozhayeva, Rudolf Schraml[2]

Introduction

The optimization of the fish production in intensive aquaculture can lead to the increase of the production with the respect to the fish welfare. The new technologies enable to develop the Precision Fish Farming (PFF) (Fore et al. 2017) concept whose aim is to apply control-engineering principles to fish production, thereby improving the farmer's ability to monitor, control and document biological processes in fish farms. Animals identification is known concept in the precision agriculture used for livestock farming, stock identification or monitoring of endangered species (Bendik, 2013). The same concept can be adopted in precision fish farming.

There are many different ways for individual fish identification. The widespread and popular methods of fish identification are tagging and marking (PIT, RFID or VIE tags). Most of the commonly used methods are invasive and can have adverse effects on fishes, increasing the risk of sequelae or mortality, mainly for small and sensitive fish as most of the stream fish species.

Non-invasive fish identification based on the fish appearance is cheap, less stressful for the fish and accurate. Human based identification of individual fish of the same species using the skin pattern was proved by Hirsch (Hirsch 2015). There are several different patterns which can be observed on the fish body (eye pattern, scale pattern, body texture). The aim of this paper is to demonstrate the usability of visible patterns for individual fish identification from the point of view of identification accuracy and pattern stability for long term identificatio

Materials and methods

The results of three different studies are reported here to demonstrate the ability of computer vision for individual fish identification

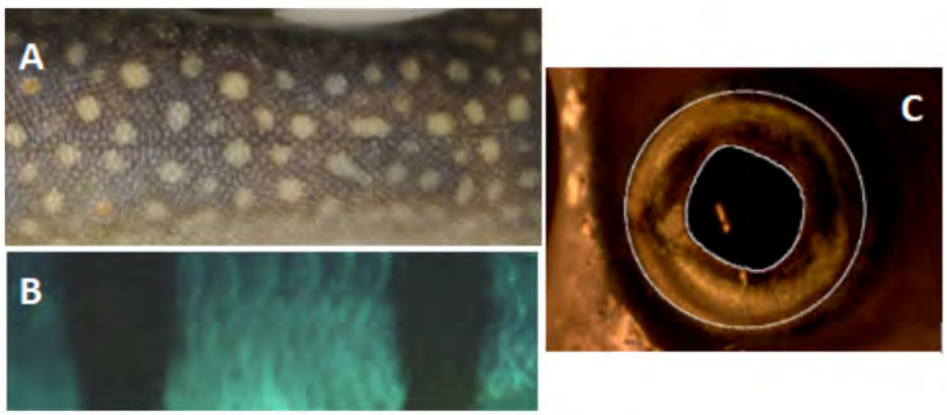

Figure 1. Example of visible pattern used for fish individual identification for different fish species: A – dot pattern of tail part of rainbow trout, B – stripe pattern of middle body part of Sumatra barb, C – iris pattern of salmon

(Continued on next page)

Rainbow trout identification – The aim of the study was to test image based individual identification for the group of 32 rainbow trout. The image database contains 3 datasets representing three data collections of images of the same fish for 3 weeks. One image of each fish out of the water was taken for each session. The fish was automatically detected and the region of interest (ROI), containing unique dot pattern, was determined, Fig1-A. The texture descriptor histogram of oriented gradients (HOG) (Dalal 2005) was used to create the feature vector for identification. The identification was performed for all combinations of the data collection sessions.

Atlantic salmon identification – The image database of 330 fish eyes was collected. From 4-8 images per fish taken for each individual in one session. The iris images were then collected for 30 tagged fish in next 3 sessions (2 months in between the sessions). The inner and outer boundary of iris was automatically detected, Fig 1-C. The image rotation was compensated, and fish iris code based on 1D-Log-Gabor filters was calculated. The power of the iris pattern was tested on the task of identification 330 individuals.

Sumatra barb identification – The 25 fish individuals were used for fish identification within one data collection and between 2 data collections (14 days between data collection). Three images of the lateral view of same fish under water were collected using unified background (green colour). The fish was automatically detected in the image and the central parts containing middle part of the body with two stripes was used as ROI. The identification was tested between data collections and within data collections.

Results

Rainbow trout identification: All 32 fish were correctly identified between all three sessions which corresponds to the 100% recognition accuracy.

Atlantic salmon identification: The equal error rate for the 330 individual fish was 0.84% which correspond to the high accuracy of individual identific tion. The equal error rate for identification between four data collections varies from 10 to 43%.

Sumatra barb identification: The classification accuracy of the fish within the same data collection was 100% (all fish were correctly identified). The classification accuracy between the data collections was 88% (3 individuals were identified incorrectly).

Conclusion

Individual fish identification is one of the keystones of the emerging concept of Precision Fish Farming. This study showed the usability of the visible fish patterns (iris, body pattern) for individual identification using computer vision. The identificati n was tested on three species representing different visible patterns. The identification power and pattern stability for long term identifica ion was studied. High accuracy of the identification was reached for all used patterns with different stability of the patterns for long term identification.

Introduction

In the aquaculture industry, the quality of products is essential to obtain good market price, so maintaining their excellent nutritive value throughout the industrial processing is vital. Carotenoids are compounds responsible for the natural colour of different products which is one of the main criteria to consumers (García-Chavarría and Lara-Flores, 2013). They have great antioxidative activity and astaxanthin is considered as one of the strongest antioxidants and most distributed carotenoid in the aquaculture industry. Among the 750 reported carotenoids found in nature, more than 250 are of marine origin (Maoka, 2011). Until now, carotenoids were mostly analyzed using chromatographic and spectrophotometric methods (Maoka, 2011), which require time-consuming preparation of the sample and high cost of the reagents and analysis. Electrochemical methods could provide a cost-effective and fast-screening alternative. Therefore, in this study, we investigated the electrochemical behaviour of astaxanthin using voltammetry of immobilized microdroplets and its application to determine the carotenoid concentration in shrimp and soft-shell crab samples that are common in the human diet.

Materials and methods

All experiments were performed in the dark by placing aluminium foil around the experimental cell. The electrochemical technique square-wave voltammetry (SWV) was performed in two electrolyte solutions, 0.1mol dm^{-3} $HClO_4$ and 0.1mol dm^{-3} KNO_3 on paraffin-impregnated graphite rod (PIGE) which was mechanically cleaned before each experiment. Voltammetry of immobilized microdroplets (Scholz et al., 2000) was employed using a potential step increment of 2mV and a square-wave amplitude of 50mV. The frequency varied from 10Hz to 1000Hz. Extraction methods according to Michelon et al. (2012) were preceded for analysis of carotenoids in real samples with minor modifications. Spectrophotometric analysis was performed for determination of total carotenoid according to the method by Wellburn (1994).

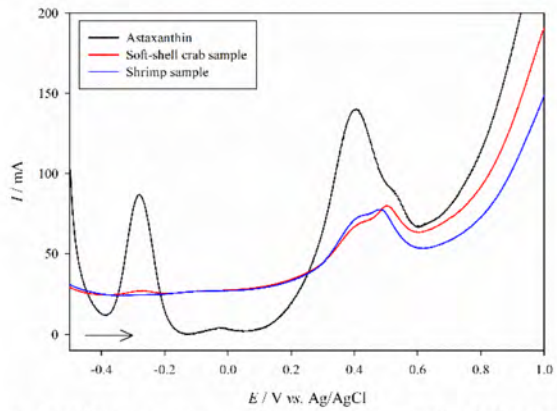

Fig. 1. Square-wave voltammograms of astaxanthin and of the extracts from shrimp and soft-shell crab samples in the form of microdroplets (5µl). The frequency is 100Hz, pulse amplitude is 50mV and the step potential is 2mV.

(Continued on next page)

Results

Voltammetric response of astaxanthin microdroplets consists of four oxidation peaks at potentials E_{P1} = -0.276V, E_{P2} = -0.032V, E_{P3} = 0.529V and E_{P4} = 1.026V when measured in the acidic electrolyte, while increasing pH-value has drastically influenced net peak potentials i.e. responses were shifted toward more negative values. The accuracy of the method is expressed as a recovery for peak P1 and the obtained value was 121.70%. The relative standard deviation for maximum astaxanthin concentration in the form of a droplet expressed for the current of peak P1 was 3.69% and for potential was 0.413%. The limits of detection and quantification were 69.6μmol dm^{-3} and 211.0μmol dm^{-3}. Electrochemically determined concentrations of the astaxanthin in shrimp and soft-shell crab samples were 33.11μg g^{-1} and 52.03μg g^{-1}, while total carotenoid content was determined using spectrophotometry at the λ_{max} = 480nm.

Discussion and conclusion

The optimized voltammetric technique has been developed for the characterization of carotenoids in shrimp and soft-shell crab samples. Electrochemical oxidation mechanism of astaxanthin was further explained using voltammetry of immobilized microdroplets and serves as a "fingerprint" for its determination in real samples. Low standard deviations imply non-contaminated surface of the working electrode and high repeatability in the identification of this oxidation peak. For both shrimp and soft-shell crab samples, 20 times higher values were obtained using the spectrophotometric method when compared to the electrochemical method. This can be explained with non-selectivity of the spectrophotometric method, i.e. carotenoids have similar absorption maxima and they contribute to the total carotenoid content in the samples. In contrast, voltammetric responses for sample extracts are in an agreement with the voltammetric response of astaxanthin (figure 1). Therefore, only astaxanthin is quantified in samples using voltammetry and total carotenoids present in the samples were spectrophotometrically measured. Voltammetric technique has shown to be a more selective method.

The applied electrochemical method allowed quantification of a specific carotenoid in shrimp and soft-shell crab samples and could possibly be applied in industrial processes for measuring carotenoid content in newly developed products.

THE INFLUENCE OF GROWING TANK SIZE ON PADDLEFISH *Polyodon spathula (WALBAUM, 1792*)

M.T. Coada*, V. Cristea

”Dunărea de Jos” University of Galati, 47 Domnească Street, Galați, Romania
Email: marian.coada@ugal.ro

Introduction

The various diversity of shapes and sizes of the current fish species is due to the intercondi- tional reciprocal bonds between them and the biotic and abiotic environment. The different conditions that the aquatic environment offers to fish have led to the appearance of various fish forms (Stancioiu, 2006). The capacity of adaptability of fish to different environmental conditions is taken as a consequence that determines the great diversity of body shapes. Functions of the locomotor system of the fish contribute, as a first fact , to the formation of the shape of the body.

Materials and methods

Research regarding the behavior and growth performance under the influence of the growing tanks size on *Polyodon spathula* were carried out at the pilot research station of the Faculty of Food Science and Engineering, „Dunărea de Jos” University of Galati, România. The experiment took place in a Recirculating Aquaculture system (RAS), provided with four growing tanks, two with the the construction dimensions of 1.40×1.40×0.60m (V1-Basin 1 and Basin 2) and the other two units with the dimensions of 0.50×0.50×0.45m (V2-Basin 3 and Basin 4). Each growing unit was populated with the same stocking density of 1.2 kg m^{-3} (figure 1)

The establishment of the stocking densities was made based on biometrics measuremts, such as: total length (TL-cm)- from the top of the rostrum to the top of the upper lobe of the caudal; the length of the rostrum (LR-cm)- from the top of the rostrum to the eye, and weight (W-g). So, in the presented context, the purpose of this research was to study if the growth performance and behaviour of this species is influenced by the tank size

Results

There are few information in the literature regarding the influence of the growing tank size on behavior and growth performance of fish. Kirschbaum, F., (2006) reported no significant difference regarding the growth performance in a similar study performed on *Acipenser sturio* fish in growth tanks with a volume of 11.6m^3 and 6.8m^3. In this study, the behaviour of *Polyodon spathula* was evaluated, and it was observed that, after two weeks the fish from the V2 variant swim „stuck” by the sidewalks of the tanks over a time interval of 10-15 minutes, or even more. This reaction is a response to the stress caused by the lack of space, and led to the frontal rotation of the rostrum and its damage, but also to the partial or total depigmentation of the fish.

Regarding the mean weight, in the variant V1, fish almost double their weight, while in the variant V2, average weight decreased from 13.79 ± 2.0g/fish to 5.82 ± 0.17g/fish. In the basin B4 there was a slight increase of individual weight from 13.72±1.9 g/fish to 15.56±4.47 g/fish

Regarding the total length of poliodon juvenile it was observed an increase with 31% in variant V1 compared to the basin from the variant V2 where there was an increase of 7.96% in B3 and, 14.02% respectively in B4.

Table I. Average of the biometric measurements at the begining and in the end of the experiment

Growing tank		Mean weight (g)		Total length (cm)		Rostrum length (cm)	
		Initial	Final	Initial	Final	Initial	Final
V1	B1	13.67±3.64	23.39±5.6	16.36±1.78	21.31±1.78	5.56±0.6	7.46±0.53
	B2	13.67±3.8	24±3.95	16.43±1.8	21.83±1.23	5.54±0.7	7.8±0.47
V2	B3	13.79±2	5.82±0.17	16.58±0.9	17.9±2.21	5.56±0.45	6.1±0.8
	B4	13.72±1.9	15.56±4.47	16.4±0.9	18.67±1.85	5.49±0.2	6.48±0.74

(Continued on next page)

The correlation between the TL (cm) and LR (cm) highlights that the fish from the V2 variant registered a short period of growth. At the end of the experiment, the mean of the LR registered in the V1 variant a value of 7.46±0.53cm in B1, and 7.8±0.47cm in B2, while in V2 the growth of the juvenile in the TL and in the LR did not have the same increase as in variant V1 (table 1).

Discussions and conclusion

The results obtained in this experiment highlights the fact that growing tanks of small dimenision have a negative effect on the growth performance of paddlefish. Limiting the swimming space for this fish is a major stressor factor that inhibits the retention capacity of nutrients from the administated feed. The specific characteristics of the polyiodone for feeding by active and passive filtration, as well as those related to the plasticity of the paddlefish feeding mode, to consume the feed deposited on the bottom of the growing tanks, were affected by the limited surface of the basins. In variant V2, due to the small distance between the opposite walls of the tanks (50 cm), the filtration capacity of paddlefish was shortly (2-3 seconds) in comparation with the filtering activity of the fish from th V1 variant, which lasted for 1 to 3 minutes.

In conclusion, *Polyodon spathula* demonstrated a good technological plasticity by subjecting it to different environmental conditions. However, in extreme cases, the growth of the paddlefish in growth tanks with a reduced surface result in a decrease of the growth performance and survival.

PREDICTING LONGTERM EFFECTS OF SMALL CHANGES IN AQUAFEEDS PERFORMANCE USING A DYNAMIC METABOLIC MODEL

Luís E.C. Conceição*, Filipe Soares, Ana Nobre, Tomé S. Silva

Introduction

The aquaculture industry has been pushed towards a significant reduction in the use of fish meal and fish oil, replacing it with alternative protein and oil sources, often of plant origin, driven by economic and environmental pressures. The introduction of plant- based ingredients in feed formulations can affect fish performance through effects of on nutrient digestibility, but these effects are normally considered small as such feed formulations are well well-balanced in nutrients. Still, such small effects, may bring result in considerable impacts when accumulated over time. Moreover, such plant-based feed formulations can also have major impact on nitrogen and phosphorus outputs to the environment. It is therefore of the utmost importance to assess the effect that these changes in feed formulations can may have on fish performance, feed costs, consumer-value, and the environmental impact of aquaculture.

A metabolic, or nutrient-based, model (FEEDNETICS™, Silva and Soares, 2018) was here used to predict the long-term interactive effects of alternative feed formulations, resulting in small changes in nutrient digestibility, on growth performance, feed conversion, and release of nitrogen and phosphorus to the environment.

Materials and methods

The main data (inputs) needed to run the metabolic model are proximal and amino acid composition of the feed and apparent digestibility coefficien s (ADC's) for protein, fat and phosphorus, along with a feeding table and a temperature profile. We have generated two virtual trials using FEEDNETICS™ to generate predictions on the effect of: a) inclusion of the enzyme phytase in feed as to render phosphorus in phytic acid more available (digestible) to Atlantic salmon, against a scenario where the lower phosphorus digestibility was compensated by adding inorganic phosphorus (Mono-Calcium Phosphate, MCP) to the feed, a common practice in the industry; and b) the inclusion of a probiotic that improves protein digestibility in gilthead seabream.

Results

FEEDNETICS™ predicts that salmon fed the Phytase supplemented feed will have a better performance and lead to a considerably lower total phosphorus waste production, compared to the MCP supplemented diet. In fact, the prediction suggests a 6.2% higher fish weight after one year (Fig. 1), and 35% lower total phosphorus waste (Fig. 2). Moreover, FCR is predicted to be 2.5% lower for the Phytase supplemented feed.

Discussion

This study confirms that modelling approaches are useful to study the effect of very small changes in feed formulations on fish performance and environmental impact of aquaculture. A small change (1%) in protein digestibility, along with an improvement in phosphorus bioavailability brought by introduction of an enzyme, lead to small but economically significant changes in growth and FCR in Atlantic salmon, together with a very significant reduction in phosphorus waste production.

Therefore, we trust modelling tools are able to generate realistic predictions of concrete scenarios, including the interactions between feeding level, feed formulation and water temperature, thus being useful tools to optimize the efficiency of feed formulations and feeding regimes, while reducing environmental impacts in fish farming

The effects of different diets on spermatophore production and sperm quality were investigated in the river prawn *Macrobrachium americanum*. Male river prawns were cultured during 244 days fed with three diets: fresh food (50% jumbo squid meat, and 50% Pacific sardine muscle), commercial pellets (Camaronina 35 Purina®), and a 50:50 mix of both diets. Spermatophore production was recorded on average every 24 days as the percentage of spermatophores produced per extraction per diet, their weight and biochemical composition. Sperm quality was measured as the total number of spermatozoa and the proportion of live/dead sperm, and normal/abnormal sperm morphology. Mean biochemical composition of *M. americanum* spermatophores was 36.3% proteins, 25.8% carbohydrates, and 4.6% lipids. Weight of spermatophores and sperm counts were not significantly different among diets, neither as a function of the male initial total length ($p > 0.05$). Male river prawn reproductive exhaustion was observed by the decline of the spermatophore production, weight of the spermatophore, and the number of spermatozoa per spermatophore with an increasing proportion of dead and abnormal sperm throughout the experiment (Figure 1). The recommended period of maintenance in captivity for male broodstock is below 115 days, after which male showed evidence of reproductive exhaustion. It is recommended to feed broodstock males of *M. americanum* with commercial pellets, because they are cheaper and easier to use than fresh food, ensuring a good spermatophore production and sperm quality

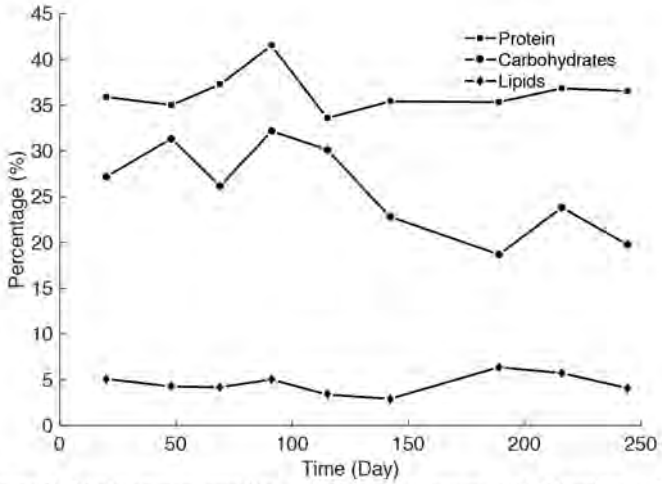

Figure 1. Male sperm quality of *M. americanum*. (A) Number of spermatozoa per spermatophore, (B) Average percentage of abnormal sperm, and (C) Proportion of dead sperm per spermatophore recorded throughout the experiment per diet.

ANCHOVY AND GIANT SQUID HYDROLYSATES CAN ENHANCE GROWTH AND THE IMMUNE RESPONSE OF EUROPEAN SEABASS (*dicentrarchus labrax*) FED VEGETABLE BASED-DIETS

Introduction

Vegetable protein sources are considered sustainable alternatives to fish meal, but they can present anti-nutritional factors, amino acids imbalances and low palatability with concomitant negative effects on fish growth. Marine protein hydrolysates were recently shown to stimulate fish growth and immunity (Gisbert et al., 2018), but different sources and production methods of hydrolysates may cause distinct responses in fish (Martínez-Alvarez et al., 2015). The aim of the present study was to evaluate if the inclusion of marine protein hydrolysates at 3% in a plant-based diet can result in similar growth and immune status of juvenile European sea bass, *Dicentrachus labrax,* compared to a fish meal-based diet

Material and methods

Four hydrolysates developed by Austral S.A.A. obtained from anchovy (ANC) or giant squid (GS), using either a single protease (P1, endopeptidase activity, and P2, endo - and exopeptidase activities) or a protease mix (MIX) were added to a plant protein-based diet at 3%, resulting in four experimental diets: ANC-P1, ANC-P2, GS-P2 and GS-MIX. A plant protein-based diet, without hydrolysates, was used as a negative control, NC, and a fish meal-based diet as a positive control, PC. Diets were fed to triplicate groups of European sea bass juvenile (initial body weight 7.0 ± 2.0 g) allocated to triplicate tanks, and fed the experimental diets for 60 days. At the end of the trial, growth performance, nutrient utilisation, whole body composition and fish immune status were evaluated. The bactericidal and bacteriostatic activities of each hydrolysate were also assessed *in vitro*.

Results

All the hydrolysates showed bactericidal and bacteriostatic activities against some bacterial fish pathogens belonging to the *Vibrionaceae* family, but when the GS was hydrolysed by a single peptide (P2) resulted in a significantly lower killing ability against *Vibrio harveyi* compared to all other hydrolysates. The experimental diets were well accepted by fish that more than tripled their initial body weight (BW). The final BW and specific growth rate of fish fed diets ANC-P1, ANC-P2 and GS-MIX were similar to those fed the PC, and significantly higher than those fed the NC. Growth performance of fish fed GS-P2 did not differ from those fed the NC. The feed conversion ratio (FCR) was low in all dietary treatments (1.0-1.1) and did not differ among diets. Likewise, final whole-body composition, nutrient retention and gain remained similar in all diets.

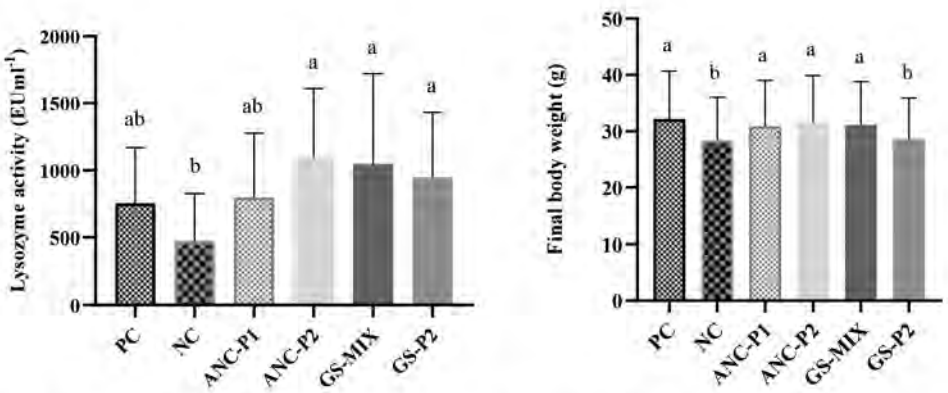

Fig. 1. Final body weight and innate immune status (lysozyme activity) of *D. labrax* after feeding the experimental diets for 60 days.

(Continued on next page)

Total blood cell numbers, haematocrit and haemoglobin concentration were not affected by the experimental diets. Fish fed GS-P2 had a mean corpuscular volume comparable to those fed the NC, but significantly lower than all other diets. Moreover, the ANC-P2, GS-MIX and GS-P2 diets led to a significantly higher plasma lysozyme activity ($P = 0.002$) compared to the NC.

Discussion and conclusions

The present results showed that the inclusion of 3% ANC or GS hydrolysates in a plant protein-based diet was effective in promoting European sea bass growth performance and innate immune status, resulting in values comparable to those obtained by using a fish meal-based diet. However, the hydrolysis process directly affects the benefits of ANC and GS hydrolysates on fish growth and immunity. For instance, the use of a single protease (P2) with both endo- and exopeptidase activities in GS translated in a decreased growth and bactericidal activity against *V. harveyi* compared to the other treatments. These results showed that the application of combined enzymes in the hydrolysis process had an important role in the production of bioactive GS hydrolysates, although that was not observed for ANC hydrolysates. The differential effects of hydrolysates on fish growth and immunity are most likely related to the mechanisms of action of food-borne antimicrobial and growth stimulating peptides (Martinez et al., 2015), suggesting a decreased content of these bioactive compounds in GS-P2 hydrolysate. In fact, the latter presented a lower proportion of high molecular weight peptides (> 6 500 Da) that might act as growth stimulators (Ho et al., 2014).

It can be concluded that hydrolysates obtained from anchovy, mainly those hydrolysed by a single protease with endo-and exopeptidase activity (P2), or from giant squid hydrolysed by a protease mix (MIX) were the most effective in promoting European sea bass growth and innate immunity. Further studies could provide more insight about the influence of distinct hydrolysis methods and hydrolysate sources on the bioactivity of hydrolysates added to fish diets

Introduction

The economic performance and suitability of aquaponics farms has contradicting views (Greenfeld et al., 2018). One point that has been identified as a key factor for the economic success of aquaponics entrepreneurs is the choice of the cultured aquatic and plant species (Bosma et al., 2017; Engle, 2015; Tokunaga et al., 2015). Furthermore, the plant production has been recognized as the main source of income in aquaponics (Adler et al., 2000; Bailey and Ferrarezi, 2017; Love et al., 2015; Quagrainie et al., 2018). To provide the highest return to the farmers, some of the variables to consider when selecting the plant species are the productivity ($kg.m^{-2}$), crop density ($plants.m^{-2}$), production period (weeks) and unit value or sale price (Bailey and Ferrarezi, 2017). Usually leafy vegetables are most cultured in aquaponics systems (Love et al., 2015; Yep and Zheng, 2019), mainly because the combination of the variables $\$.m^{-2}$.week provides a common point for comparison among crops (Bailey and Ferrarezi, 2017). Even when some crops have a higher sale price, a short culture period could be more profitable or attractive. The regional characterization of plant production systems is also a valuable information source for producers as well as for the creation of public policy (Batalha et al., 2010; Hoffman et al., 1987; Mattei, 2014). In Brazil, vegetable production comes mostly from family-owned operations with a little commercialization and small supply chain, supported mainly for a strong relationship between the confidence of the buyer and the availability of production (Celestrino et al., 2017). Given that relationship, the monitoring of vegetable sale prices brings certainty and benefits to the consumers and sellers since this increases the confidence of a fair trade. This work aimed to prospect vegetables of economic interest that have the potential to be produced in the aquaponics system, based on a variety of prices and technical production data collected from local markets and farms in Jaboticabal, Brazil.

Material and Methods

Located in São Paulo State, Brazil, the municipality of Jaboticabal has an estimated population of 76,196 (IBGE 2016). A survey focused on retailers and urban plant producers was carried out in November of 2018. Six retailers were selected (one supermarket chain, two individual supermarkets, two plant retailers and one farmers market) to collect the prices of 42 varieties of herbs, fruits and vegetables for six months, from November 2018 to April 2019. Nominal prices were collected and transformed to real prices using the General Price Index (IGP- DI by its initials in Portuguese) of Getúlio Vargas Foundation (FGV) by using May 2019 as the base year and afterwards they were converted to US dollars (US$1 = R$3.92). Given the real sale price for each plant variety, the real average price was calculated and with the average of the six months, the plants were grouped into five categories. To categorize the plants, the highest and lowest price were identified and five equidistant categories between those values were established. Regarding the urban plant producers, to access the farm production, data were collected with a questionnaire. For each farm were collected: the cultured plant, production area, monthly productivity, average production cost, production cycle duration, number of months of the year in which the production can be done, and frequency of occurrence for the vegetable in the farms. Data were standardized and afterwards a cluster analysis was performed.

Results

The prices of 42 brands of plants (herbs, vegetables and fruits) were collected. A total of 25 plant varieties were identified as feasible to be produced in aquaponics. The plant prices were from US$0.66 $packet^{-1}$ for watercress, to US$2.57 $packet^{-1}$ for "sul"strawberry. However, the majority of the plant prices (66.7%) presented a price lower than US$1.42 $packet^{-1}$ (Table I)

According to the data obtained from urban farms, 15 vegetable species are being produced in the urban zone of Jaboticabal, classified into four groups. Group 1 consisted of four vegetables that have larger productivity (average 2.46 packets. $month^{-1}$) and short growing cycle (46 days). Group 2 comprised of vegetables cultured in a small area in the farms (average 25.25m^2) and produced throughout the year (except for coriander which is produced only for ten months), some of the

(Continued on next page)

vegetables of this group showed high productivity, such as Oakleaf lettuce (average 3.17 packets m^{-2}) and spinach (average 2.83 packets m^{-2}). The iceberg lettuce stands out because it has the largest cultured area in the farms (average 610m^2), it is produced throughout the year and thus, it is separate from all the other vegetables in the group 3. In the group 4, the vegetables have high culture area in the farms (average 401.56 m^2), the production can be done throughout the year, production cost less than US$0.19 per packet and the productivity is low (average 1.39 packet m^{-2}) (Table 2).

Discussion and Conclusion

From the 15 vegetable species that are being produced in the urban area of Jaboticabal, spinach has the highest average sale price (average US$1.45 $packet^{-1}$), while the others show average prices between US$0.66 $packet^{-1}$ and US$1.42 $packet^{-1}$. The production of these vegetables in the region shows that they are adapted to the climate conditions, there are production input suppliers and a market that could be advantageous by showing the potential of these vegetables for use in the aquaponics system. However, the low price of some of the plants is a point to be considered and could be unfeasible in an aquaponic farm. Plants of high value that are commercialized but are not produced in local farms have production potential in aquaponics systems given that the existing demand. These factors are important when considering that the aquaponics system requires high investment for construction and maintenance of the system. The plants with high potential for aquaponics in urban Jaboticabal are those in groups 3 and 4, which have prices over US$1.43 $packet^{-1}$ and over the average, and a good market.

Introduction

The concept of maintaining animal health through the best possible nutrition is well accepted in modern animal farming and functional additives appear to be good candidates to improve health and survival. Amino acids (AA) in particular have known roles in the improvement of the immune response to infection and recent evidence indicates that several immune mechanisms are influenced by their availability in fish (Conceição et al., 2012; Herrera et al., 2019). Still, the potential use of dietary AA supplementation for animal health management is not fully developed. This is particularly important for the aquaculture industry, where few therapeutic possibilities are available against infectious episodes.

Arginine in particular appears to have important roles regarding immune modulation since it is required for macrophage responses and lymphocyte development. For instance, dietary arginine supplementation has been shown to enhance the innate immune system of the Senegalese sole (Solea senegalensis) (Costas et al., 2011). Here, it is intended to give a comparative overview of our recent research using arginine surplus as a tool to improve the health status of farmed fish. Therefore, two independent studies with the same experimental set up aimed to assess whether an increased availability of dietary arginine can improve the immune status of European seabass (Dicentrarchus labrax) and gilthead seabream (Sparus aurata).

Materials & methods

European seabass and gilthead seabream juveniles (8.4 ± 0.4 and 23.1 ± 0.4 g, respectively) were fed 3 experimental diets. A control (CTRL) diet was formulated to meet the indispensable amino acids profile established for both species. Based on this formulation, two other diets were supplemented with DL-Arginine at two different levels (i.e. 0.5 % and 1 % of feed, ARG1 and ARG2, respectively). Fish were fed these diets in triplicates for 2 or 4 weeks until visual satiation under controlled conditions. Blood samples were withdrawn from the caudal vessel at the end of each feeding period for the evaluation of the haematological profile. Blood smears were prepared for differential cell counting. Blood was finally centrifuged and plasma samples were collected and stored at -80 °C until assayed. Head-kidney tissue was also collected for the assessment of immune-related gene expression and kept at -80 °C until processed.

Results

Seabass trial
Fish showed a time-dependent decrease in peripheral lymphocyte numbers regardless of dietary treatment, whereas plasma peroxidase values dropped in time in seabass fed ARG1 and ARG2 and was lower at 4 weeks in fish fed ARG1 than in fish fed CTRL. At the head-kidney level, a slight modulation of the immune status was observed, with some genes pointing to an immune-suppressive state, such as the decrease in matrix metalloproteinase 9 in fish fed ARG2 compared to those fed CTRL.

(Continued on next page)

Seabream trial
The bactericidal activity increased in fish fed the highest supplementation level after 4 weeks. A tendency to increase monocytes relative proportion of peripheral blood leucocytes was observed in fish fed the ARG2 diet after 2 weeks of feeding, compared to their counterparts fed the lower supplementation level. Peripheral monocyte numbers also correlated positively with plasma nitric oxide levels, which showed an increasing trend in a dose-dependent manner. At the head-kidney level, the mRNA expression of the colony stimulating factor 1 receptor tended to be up-regulated at the final sampling point regardless of dietary treatments.

Discussion

As in other vertebrates, a balanced diet is a key factor for an adequate performance including immune response and disease resistance. However, the present study showed opposite effects regarding the fish immune status. Although the observed inhibition of cellular and humoral defences in seabass fed arginine supplemented diets seemed to be somehow faint, data suggested that arginine supplementation could compromise at some extent the seabass immune response. In contrast, results from the seabream trial suggested that dietary supplementation with arginine may have an immunostimulatory effect after 4 weeks of feeding.

Although more health-related biomarkers are being processed for both trials, data point to opposite effects in terms of arginine immune-modulatory effects depending on the species. Having this in mind, further studies should be developed to unravel this double-edge sword effect regarding arginine surplus in diets for these important species for Mediterranean aquaculture.

Introduction

An activated immune system has specific nutrient requirements and increases the competition between nutrients available for maintenance purposes, functioning of the immune system and for body protein deposition in growing animals. In this context, algae have gained a lot of attention as a source of biomass and biomolecules for feed purposes, sine these specialties contain bioactive compounds, or phytochemicals, that may benefit health beyond the role of basic nutrition (Wells et al., 2017). For instance, microalgae exploited at the industrial scale are of increasing interest as a source of valuable compounds such as extracellular polysaccharides, phycobiliproteins and long chain PUFAs (Gaignard et al., 2019). However, microalgae biomass is hardly exploited commercially as aquafeed components, primarily due to their unavailability in large volumes and high price of the marketed products. Therefore, research efforts should be directed to explore the potential of low levels of dietary algae biomass inclusion in animal health.

This study aimed to evaluate the effects of short-term feeding with marine macro and microalgae biomasses on gilthead seabream (*Sparus aurata*) health status.

Materials and methods

Six isonitrogenous (45% protein) and isolipidic (18% fat) diets were formulated. Diet A consisted of a commercial based diet and served as control whereas five other diets consisted of diet A with a 2% inclusion of different algae: Diet B (*Tetrasselmis striata*); Diet C (*Phaeodactylum sp.*); Diet D (*Nannochloropsis sp.*); Diet E (*Gracilaria gracilis*); Diet F (*Ulva rigida*). Diets were randomly assigned to triplicate groups of 110 fish/tank (IBW: 11.7 ± 1.0 g) and fed to satiation twice a day. Fish were maintained in a recirculated seawater system (temperature 22.4 °C; salinity 35.2 ‰; photoperiod: 12 h light: 12 h dark). After 1, 2 and 4 weeks of feeding, 4 fish/tank were sampled for blood, plasma and tissues collection (i.e. head-kidney, liver and gut) for further analyses according to Machado et al. (2015).

Moreover, 15 fish/treatment were also subjected to an inflamm tory insult by intraperitoneally injecting heat inactivated *Photobacterium damselae piscicida* following 1 and 2 weeks of feeding and sampled at 4 and 24 h post-injection. Blood, plasma and liver and gut tissues were collected.

Results and discussion

Total red blood and white blood cells remained unchanged throughout the feeding trial. Plasma bactericidal and anti-protease activities decreased over time while IgM levels followed an opposite trend, increasing from week 1 to the end of the trial. Since fish were not challenged, results showed changes over time, most likely related to fish normal growth and development. At the end of week 1, fish subjected to the inflammatory insult showed a decrease in plasma bactericidal activity at 4 and 24 h when fed diets C and F, respectively. Plasma anti-protease activity also decreased after 4 h post-injection in fish fed diet F. After fish stimulation, preliminary results suggest a possible immune-modulatory effect of dietary treatments after one week of feeding.

Further analyses are currently on-going to obtain a more accurate picture of fish immune response and oxidative status attributable to the different dietary treatments.

Introduction

Despite concerted efforts the cryopreservation of fish embryos has remained a challenge, the development of this technique would significantly contribute to the genetic conservation of endangered species and lineages of interest, facilitating the exchange of genetic material between stocks, as well as enable the year-roundproduction of fish species including those with seasonal reproductive cycles (Digmayer, 2013). The current difficulties in cryopreservation of fish embryos are due tolack of ideal cryoprotectants and necessary advances in related technique to overcome the challenges of relatively large fish embryo size; complex compartmentalization with different properties and permeabilities that hamper the flow of cryoprotectants and water; presence of fat-rich yolk sac and associated susceptibility to intracellular ice formation (Zhang and Rawson, 1995; Lahnsteiner, 2008). Although, recent advances in vitrification techniques are showing promise, the formation of reactive oxygen species (ROS) and apoptotic events triggered during the process are posing considerable hindrance. In this context, the main objective of this study was to determine the use of melatonin hormone, an important inhibitor of ROS formation, in the vitrification of zebra fish embryos *Danio rerio*).

Materials and methods

Four treatments were performed: Control group (non-cryopreserved embryos, without melatonin); Treatment 1 (cryopreserved embryos, without melatonin); Treatment 2 (cryopreserved embryos + 10^{-6}M of melatonin) and Treatment 3 (cryopreserved embryos + 10^{-3}M of melatonin). The vitrification solution as described by Keivanloo and Sudagar (2013) was used as a basis and adapted following toxicity tests. The embryos used were between developmental stage of 22 to 24 somites and had their chorions removed. After cryopreserving embryos for seven days, 30 embryos per treatment were thawed and incubated to evaluate the possible hatching rate. In parallel (immediately post thaw) four embryos per treatment to quantify the relative expression of keygenes involved in apoptotic processes (*Bcl-2* - Anti-apoptotic; *Bax/Caspase-3* - Pro-apoptotic); ten embryos per treatment for quantification of ROS (molecular probe 2′,7′-dichlorofluorescin diacetate); ten embryos per treatment for the study of DNA fragmentation (TUNEL method); and six embryos per treatment for the study of cryo-lesions by scanning microscopy; totaling 240 embryos were analyzed. For the parameters of hatching rate, quantification of ROS and DNA fragmentation, a factorial analysis (Shapiro-Wilk at 5% of significance) was performed, and the significant differences were evaluated by the Tukey test at 5% significance, using the SAS statistical analysis program. For the relative quantification of gene expression, the method $^{-\Delta CT}$ was used.

Results

The control group had an average survival rate of 92.30 ± 4.90%, on the other hand, 100% of the vitrified embryos entered apoptosis after thawing. In these embryos, the most observed cryo-lesions were: vitelynic synchicial layer (VSL) with irregular and/or ruptured forms, invaginations and wrinkling or perforations in the epidermal layer of the embryos. Regarding the relative expression of the genes, *Bax* and *Bcl-2* presented lowerlevels of expression for the control groupof embryos, without cryopreservation. Among the cryopreserved treatments, the inclusion of 10^{-6}M of melatonin improved the results obtained ($p<0.05$) both for the anti-apoptotic (*Bcl-2*) and for the pro-apoptotic (*Bax/Caspase-3*) genes. The analysis of ROS formation showed that the control treatment, that were not cryopreserved, had a lower percentage of affected surface area of the embryo (3.80 ± 0.40%) when compared to Treatments 1 (one) (25.59 ± 8.80%), 2 (34.45 ± 7.90%) and 3 (26.64 ± 12.47%), most of the observed fluorescence was located in the region of the VSL. The cryopreserved embryos with the addition of melatonin, treatments 2 (53.93 ± 18.50%) and 3 (45.41 ± 10.20%) showed a significant reduction in DNA fragmentation($p<0.05$) compared to treatment 1 (one) (cryopreserved/without Melatonin - 79.74 ± 1.00%), and were statistically compare to the control group (47.47 ± 10.82%).

(Continued on next page)

Discussion and conclusion

It was clear that the vitrification solution used was not able to adequately protect all the regions of the embryos, especially the VSL as was also observed by Ninhaus-Silveira (2006), who identified this structure as one of the main obstacles to the successful cryopreservation of fish embryos, because it has extremely sensitive to cryoinjury compared to the rest of the embryonic tissues. Based on favorable expression of the apoptotic genes in embryos cryopreserved with melatonin (10^{-6}M) infused cryoprotectants, it can be inferred that melatonin may be involved in a process of supra regulation that affects negatively the cells. Felici et al. (1999) obtained similar results in fetal primordial germ cells of mice. The increased formation of ROS in the cryopreserved embryos evidences once again the inefficacy of the vitrification solution. As for the analysis of DNA fragmentation, the significant reduction in the presence of fragmented DNA in cryopreserved treatments with melatonin (Treatments 2 and 3), being comparable to the non-cryopreserved embryos of the control group, can be attributed to theuse of this hormone. In general, the inclusion of 10^{-6}M of the melatonin hormone in the vitrification solution of zebrafish embryos significantly improved the response to the post-thaw apoptotic process, especially the expression of the genes involved in apoptotic process and DNA fragmentation. These results will contribute to the future development of an appropriate protocol for the vitrification of fish embryo

TOWARDS A REVISED CLASSIFICTION SCHEME DESCRIBING BENTHIC IMPACTS OF MARINE AQUACULTURE BASED ON SEDIMENT GEOCHEMISTRY

P. Cranford[1]*, L. Brager[1], D. Elvine[2]

[1]Fisheries and Oceans Canada, St. Andrews Biological Station, St. Andrews, New Brunswick (Canada)
[2]Cawthron Institute, Nelson (New Zealand)
E-mail: Peter.Cranford@dfo-mpo.gc.ca

Introduction

The vertical flux of organic matter (waste feed and faeces) at finfis and shellfish aquaculture farms has a known effect on benthic habitat and microbial and faunal communities. Organic matter deposition stimulates benthic aerobic metabolism and anoxic conditions are created in surficial sediments if oxygen consumption exceeds resupply across the sediment-water interface. Under anoxic conditions, sulfate reducing bacteria continue to decompose the organic matter and produce hydrogen sulfide. H_2S and ionization products (HS^- and S^{2-}), collectively referred to as total free sulfides (TFS), are toxic to benthic organisms. Organic enrichment impacts at marine aquaculture farms in Canada, the US, New Zealand and elsewhere are assessed, at least in part, by monitoring TFS concentrations in sediment and comparison of these data against a classification scheme that indicates benthic impacts (Hargrave et al., 2008). However, recent research has shown that the regulatory TFS protocol (ion-selective electrode; ISE), on which the classification scheme was derived, provides biased results owing to the inclusion of nontoxic mineral sulfides and/or oxidation and volatilization of TFS prior to analysis (Brown et al, 2011; Cranford et al. 2017). A new classification scheme will be presented that is based on TFS data obtained with a more reliable protocol that is analytically robust and practical for rapidly measuring TFS concentrations in the field.

Materials and methods

Surficial sediment samples were collected at different distances (0 to 1000 m) from four Atlantic salmon, one trout and one mussel farm in Canada, and five chinook salmon farms in New Zealand. Sampling in Canada employed a core sampler and a grab sampler was used in New Zealand to collect multiple sediment samples at each location. Macrofauna samples (92 cm^2 surface area) were screened through a 0.5 mm mesh and preserved in formalin. Pore-water was extracted for analysis of TFS concentrations using RhizoCera® samplers connected to a syringe. RhizoCera were inserted through the side of core samples at 1 and 2 cm depth below the sediment/water interface and directly into the surface of grab samples to a depth of 2 cm (Fig. 1). Approximately 1 mL of pore-water was extracted under gentle suction to fill and flush the inside of the RhizoCera tubes. 100 µL of water was removed from inside each RhizoCera with a syringe for immediate TFS_{UV} analysis onboard the boat according to the ultraviolet spectro-photometric method (Cranford et al. 2017). In Canada, additional subsampling was conducted for analysis of grain size, dissolved oxygen, total organic content, and TFS based on the standard ISE protocol (TFS_{ISE}). The New Zealand samples were also analysed for TFS_{ISE} and redox potential.

Results and discussion

The elimination of particulates and prevention of pore-water exposure to the atmosphere resolved any possibility for mineral sulfide contamination or loss of TFS through volatilization or oxidation. Comparison of TFS_{UV} and TFS_{ISE} results from New Zealand show the magnitude of errors caused by the known issues with the ISE method (Fig. 2a; also see Cranford et al. 2017). This is supported by comparing redox potential and TFS data (Fig. 2b). Sulfide reduction is associated with negative redox values (Brown et al, 2011) and this is consistent with the TFS_{UV} results. However, the TFS_{ISE} method often gave high TFS values under positive redox conditions; indicating contamination with iron sulfides and pyrite as previously suggested (Brown et al. 2011). The benthic classification scheme based on the ISE approach will exhibit a similar bias. At the time of abstract preparation, the infauna taxonomy was nearing completion. These data will be analysed to determine relationships between organic enrichment indicators (macrofauna diversity, TFS_{UV} concentration, organic content, redox, etc.) for each aquaculture setting and bottom type towards revising the organic enrichment classification scheme.

THE OPPORTUNITIES OF PRODUCING FRUITY VEGETABLES IN AN AQUAPONIC SYSTEM ON COMMERCIAL SCALE

Sara Crappé *, Saskia Buysens

PCG, Vegetable Research Centre, Karreweg 6, 9770 Kruishoutem, Belgium
E-mail: sara@pcgroenteteelt.be

Introduction

Vegetable production in aquaponic systems on a commercial scale is a challenge, but can be achieved whenever optimal growing conditions for both fish and vegetables are realised. This means fish waste water cannot be used as such but water parameters as pH, nutrient content and total EC have to be adjusted to the demand of the plant. These ideal growing conditions can only be obtained in a decoupled recirculating aquaculture system (dRAS). The past years, experience was gained with the culture of tomato, cucumber and sweet pepper in a decoupled aquaponic system. The aim of the research was to determine the sodium tolerance of these vegetable crops and so the potential of growing these vegetables in an aquaponic system. Sodium can be a problem in an aquaponic production system as it is essential for fish but not for plants. In a recirculating hydroponic growing system, used for vegetable production, the accumulation of sodium in the nutrient solution can have a negative effect on yield and quality. Therefor the choice of fish in the system is very important and preference should be given to a vegetarian fed fish as feed and therefor waste water from these fishes have a low sodium content.

Material and methods

A 400 square meter greenhouse for fruity vegetable cultivation is connected to a fish stable, this way forming an aquaponic system. In the greenhouse 11 rows of plants are grown in a hydroponic production system. The two outer rows are buffer rows, the nine inner rows are each individually connected to one of the nine fish tanks in the fish stable, forming 9 individual aquaponic systems. Each fish tank has its own drum filter and biofilte . While rinsing the drum filte , waste water is produced which is used for the preparation of the nutrient solution for the vegetable plants in the decoupled aquaponic system. Before using this water for the cultivation of vegetables, the water parameters are optimized, meaning the pH is adjusted to a correct value for vegetables and the electrical conductivity (EC) is increased by adding the necessary nutrients. After using this nutrient solution for fertigation of the vegetables, the drain water is collected for each row individually and recirculated. There is no backflow from the plant production to the fish. The fish used in this aquaponic system is Omega perch (*Therapon barcoo*), sourced from the neighboring fish farm Aqua4C. Omega perch is a fish that can be produced on a vegetarian diet, meaning the sodium content of the feed can be kept on a low level, avoiding the postulated negative effects of sodium on the cultivation of vegetables.

For each trial, the same three objects were included: one object where the nutrient solution was prepared with rain water (common practice), a second object where waste water from fish production was used to prepare the nutrient solution and a third object where extra sodium was added to the nutrient solution prepared with rain water, to test the sodium tolerance of the crop. During the cultivation period several parameters were intensively monitored. Yield and quality of the fruits were registered every harvest and plant growth, stem diameter and fruit dimension were measured every two weeks. Next to that, every 2 weeks a water analysis was conducted on fish waste wate , drain water and nutrient solution.

Results

Results of the do’s and don’ts in commercially growing tomato, sweet pepper and cucumber in aquaponics will be communicated during the conference as the trials are still in progress.

MICROALGAE DYNAMICS IN A CLOSED FARMING SYSTEM IN THE SEA FOR ATLANTIC SALMON

B.G. Crespo[1], S. Calabrese[1], Å. Åtland[1], T. Rosten[2], JE. Jensen[2] and T. Dale[1]

[1]Norwegian Institute for Water Research, Bergen, Norway
[2] Mowi ASA, Bergen, Norway
Email: Bibiana.Crespo@niva.no

Introduction

The global production of farmed Atlantic salmon exceeds two million tons, Norway being the main contributor (FAO, 2016). Currently, most of this production occurs in net-pens in coastal areas where environmental concerns, such as sea lice, diseases and escapes of farmed fish are hindering increased production. Prolonging the time fish spend in closed-containment systems (CCS) before they are transferred to open sea cages is a potential solution which could help resolve the mentioned sustainability issues. In recent years, besides keeping fish longer in land-based facilities the use of CCS in the sea has become increasingly popular in Norway. These facilities commonly pump in deep water to avoid surface layers where sea lice are the most abundant. In traditional net-pens the exchange rate of water is generally high as water is moved by currents through the farming site, in CCS there are normally only one or a few water/waste outlets hence the water exchange rate is lower. This increases the risk of accumulation of waste and pathogenic microorganisms in CCS, such as harmful microalgae. However, taking in deep water could also reduce the risk of harmful microalgae as they may be more abundant in surface waters. In open net-pen culture it is known that blooms of harmful algae (HABs) can lead to significant fish losses (Berdalet et al. 2016; Landsberg et al. 2005), however very little is known about the microalgae communities in CCS pumping in deep water and the potential risk for HABs in these systems. To understand more about microalgae (MA) dynamics in CCS, data from two monitoring programs at a CCS site in south-western Norway were analysed.

Materials and methods

The CCS prototype involved in the monitoring program is situated in the Hardangerfjord in south-western Norway. The water is taken in from 26m depth, to avoid the sea lice belt, and the total volume of the CCS is 21 000m^3. The data analyzed are from two monitoring programs from the time period 2017- 2019. The programs typically started when smolts were transferred to the CCS from a land-based smolt farm normally in October or November and ended when fish were transferred from the CCS to an open net-pen site in April. Samples for MA analysis were collected every other week in Oct., Nov. and in Feb. to April, in the winter (Dec. and Jan.) samples were collected monthly. Samples were collected with a standard water sampler from 3m depth in the CCS prototype and from 3m depth upstream of the prototype (reference station). 25 ml water samples were fixed with Lugol iodine on site and sent to the lab where they were analysed following the Utermöhl technique. Samples were settled for 24h in composite sedimentation chambers and the organisms were counted to the species level when possible using an inverted microscope.

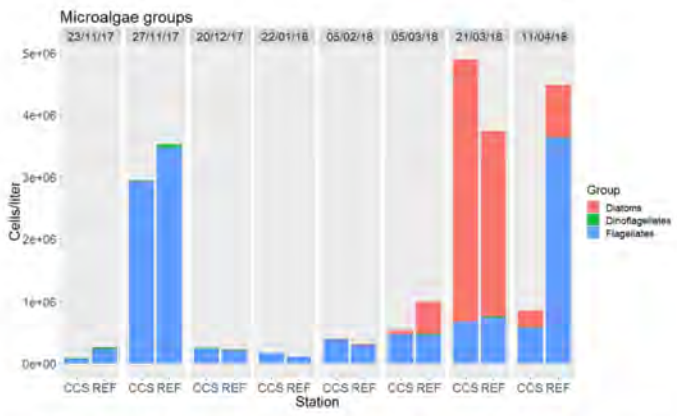

Fig 1. Total number of cells (cells/liter) of the principal microalgae groups (Diatoms- in red, Dinoflagellates- in green, Flagellates- in blue) in the closed containment system (CCS) and at a reference station (REF) during monitoring program 1 (Nov 2017-April 2018).

(Continued on next page)

Results and discussion

Monitoring program 2 (Oct. 2018-May 2019) is currently still running hence these results will be presented at the conference. A comparison between monitoring program 1 and 2 will also be made at the conference. Following are the preliminary results from monitoring program 1 (Nov. 2017 until April 2018). In general, the number of MA cells and the total biomass were low in the period Nov. to Feb. (max 10^6 cells/liter; biomass 30µgC/liter) both in the CCS and at the reference station (REF). The spring bloom of diatoms started slightly earlier at the REF (fig. 1), peaking the 23th of March, when a similar bloom was observed in the CCS. In April 2018 the number of MA cells and the total biomass was lower in the CCS compared to the REF. Overall, the composition of MA by taxonomic group (diatoms, dinoflagellates and flagellates) was similar between the CCS and the REF at most sample points, with flagellates dominating throughout the monitoring period except in March when diatoms were more abundant (fig. 1). *Skeletonema spp*. was the dominating diatom in both the CCS and the reference station sample in the March bloom. *Skeletonema* spp. has long silica spines that protrude outward from the cell, that can irritate and potentially damage the gills of fish. There has been at least one case were species of *Skeletonema* have been associated with fish mortality (Kent et al. 1995). At what concentration certain diatom species become gill irritants is very difficult to conclude from the available scientific literature. This is because most of the studies are not based on experiments, but on field observations where one has little control over other potential factors that may have contributed. However, we believe it is unlikely the concentrations observed in the monitoring program had a negative effect on the fish since Skeletonema spp is a very common species that regularly occurs in high numbers during the spring bloom in Norway.

Heterosigma akashiwo, *Dichtyocha speculum* and *Prymnesiales* spp. were detected at several sampling points in the monitoring program. These species are known to be toxic to fish (Davidson et al. 2011; Henriksen et al. 1993; Johnsen et al. 2010; Moestrup 1994). However, these were mainly observed at the reference station and in very low concentrations.

In conclusion the results from monitoring program 1 indicate that overall the number of MA cells, the total MA biomass and the number of toxic MA may be lower in CCS compared to the surface waters that fish in a traditional net-pen are exposed to. These results will be interesting to compare to the results from the ongoing monitoring program 2.

Introduction

Both in the wild environment and in the aquaculture, fish may be starved when, due to a variety of reasons, such as the occurrence of diseases or changes in the environmental conditions. In aquaculture, compensatory growth can be seen as a management tool to reduce the cost of fish feeding (Guzel et al., 2011) or as a measure to improve water quality (Turano et al., 2008) by controlling the production of residues resulting from overfeeding the fish (Davis et al., 2011). During starvation periods, fish may face various physiological responses to cover their metabolic needs. Rainbow trout is a carnivorous fish, and the necessity of crude protein from diets is between 40 to 50 %, making the cost of feeding very high. In this context, in order to reduce these costs, starvation followed by subsequent feeding of fish, without negatively affecting their growth performance and physiological state can be used as a management tool. In his context, the aim of this experiment was to analyze the effect of applying of cyclical short periods of starvation (2 days and 4 days) on the hematological profile of rainbow trout

Materials and methods

Experimental design. This experiment lasted for 46 days and was carried out in the facility of the University "Dunărea de Jos" from Galați, Faculty of Food Science and Engineering, Department of Food Science, Food Engineering, Biotechnologies and Aquaculture, România. 228 trout (initial weight 111.93±15.76g) were randomly distributed in twelve rearing units (water volume, 132L) of a recirculating aquaculture system. Six treatments with duplicate were assigned, as follows: two control groups, feed daily, ad libitum, with commercial pellets containing 41% crude protein (D41) and 50% crude protein (D50); two groups starved for 2 days (D2) and then fed with commercial pellets with 41% crude protein (D2/41), respectively 50% crude protein (D2/50) and two groups starved for 4 days (D4) and then fed with commercial pellets with 41% crude protein (D4/41), respectively 50% crude protein (D4/50). At the beginning of the experiment the fish from the fasted groups (D2/41; D4/41; D2/50 and D4/50) were deprived of food for two and four days, respectively. After these days, the starvation groups were fed until their food consumption did not differ from the food consumption of the control's groups more than 10% (calculated as the average of three previous consecutive feeding days). This feeding regime was previously demonstrated to elicit super-compensation of growth in the case of *Lepomis cyanellus*×*Lepomis macrochirus* (Hayward et al., 1997).

Blood sampling and biochemical analysis. In order to evaluate the physiological state of the fish, at the end the experiment ten fish were randomly selected and anaesthetized with 2-pnenoxiethanol and 1 ml of blood was collected by caudal vein punction. Red blood cells (RBCx10^6/μL) were determined by dilution with Vulpian diluting solution and counted in a haemocytometer Neubauer. Haemoglobin (Hb, g dL^{-1}) was determined by the cyanometahaemoglobin colorimetric method using Drabkin reagent and then read at spectrophotometer Spectrocord Analytikjena, at a 540-nm wavelength. The hematocrit (PCV, %) was determined in duplicate using heparinized capillary tubes centrifuged 5 minutes at 12000 rotations $minute^{-1}$ at Hettich Hematocrit 210 Centrifuge. The mean corpuscular volume (MCV, μm^3), the mean corpuscular hemoglobin (MCH, pg) and the mean corpuscular hemoglobin concentration (MCHC, g dL^{-1}) were calculated according to Ghergariu et al., 1985.

Table I. The hematological profile of rainbow trout at the end of the experimental period

Exp. Variants	*Hematologixcal parameters (X±SD)*					
	PCV (%)	Hb (g/dl)	RBC x10^6/μl	MCV (μm^3)	MCH (pg)	MCHC (g/dl)

(Continued on next page)

Results

The effect of application of cyclical short periods of starvation (2 days and 4 days) and re-feeding with different protein level for rainbow trout is presented in Table I.

Starvation and re-feeding with different dietary protein level had no significant ($p>0.05$) effect on some hematological parameters including PCV, MCV, MCH, while Hb, RBC and MCHC registered significant differences ($p<0.05$). Significantly higher ($p<0.05$) concentration of hemoglobin was observed in the case of fish fed with higher protein content, while the increasing of the starvation period led to a significant decrease of the hemoglobin concentration. Furthermore, starvation and subsequent feeding led to a significant decrease of the erythrocyte number with the increasing of the starvation period. Generally, the decrease of the number of erythrocytes in the period of starvation is associated with the reduction of oxygen by the control of hematopoiesis, and implicitly the decrease of the metabolic activity.

Discussions and conclusion

From the overall analysis of hematological parameters, it can be concluded that the change of the hematological values occurred as a reaction of adaptation of the fish organism to technological conditions. Thus, the significant reduction in the number of erythrocytes and the amount of hemoglobin associated with starvation has implicitly led to a significant increase in mean red blood cell volume (MCV) and decreases in mean hemoglobin (MCHC), which means the occurrence of hemoconcentration, which may be a consequence of water loss in the body during the period of starvation (Weinberg et al., 1972).

Introduction

Generally, spermatogenesis of teleost varies depending on species and inhabited environments. The burbot *Lota lota* is the only freshwater member of the cod family, Gadidae, living in cold waters (Scott and Crossman, 1973; McPhail, 1997). Almost no report is available on gonad development and ultrastructure of spermatogenesis in burbot. Therefore, aim of the current study was to investigate testis structure and ultrastructure of germ cells during spermatogenesis using transmission electron microscopy.

Materials and methods

The testes were cut into small fragments and fixed for 2 h in 3% glutaraldehyde in 0.1 M phosphate buffer (pH 7.4) and stored at 4° C. Thereafter, the material was post-fixed for 1–2 h in 1% osmium tetroxide in the same buffer, dehydrated in a graded ethanol series and subsequently transferred to ascending concentrations of acetone. Ultrathin sections were cut with ultramicrotome, stained with uranyl acetate and counterstained with lead citrate for later examination using a JEOL Ltd. transmission electron microscope.

Results

The testis of the burbot was tubular and the germ cells were arranged in cysts or clusters within the seminiferous lobules. The differentiation of spermiogenesis stage (spermatids) in this species was characterized by flagellum development, nuclear rotation, nuclear fossa formation, and excess cytoplasm elimination. Spermatozoon ultrastructure revealed that it is anacrosomal teleostean type with round head consisting oval heterogeneously electron dense nucleus. The distal centriole and proximal centriole constituting the centriolar complex were oriented incompletely perpendicular to each other.

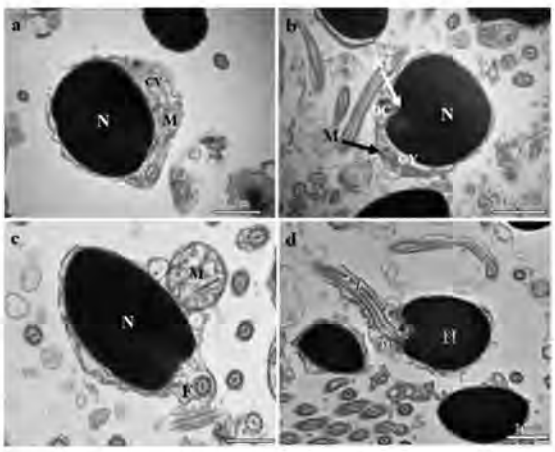

Fig 1. (a) Transmission electron micrograph (TEM) of newly formed spermatids in *Lota lota* showing regular distributed electron-dense nucleus; (b) TEM of spermatid at the second stage of development displaying distal centriole and nuclear fossa (white arrow); (c) The third stage of spermatid development and large mitochondria showing flagellum formation; (d) TEM of mature spermatozoon showing joint centriolar complex (proximal and distal centrioles) in the nuclear fossa (black asterisk) and fully developed flagellum. CY, cytoplasm; DC, distal centriole; F; flagellum; M, mitochondria; N, nucleus; Nf, Nuclear fossa.

(Continued on next page)

Discussion and conclusion

The burbot gonad is tubular anastomosing type with an unrestricted distribution of spermatogonia. This pattern of gonad is in line with identified structure in zebrafish *Danio rerio* (Rupik et al., 2011). The stages of spermiogenesis in burbot are similar to streaked prochilod *Prochilodus lineatus* (De Melo Dias et al., 2017). However, spermiogenesis has shown to proceed to four stages in zebrafish (Rupik et al., 2011).The results of this study provide an opportunity for better understanding of the structure of testis and characterization of the spermatogenesis in burbot.

Introduction

Flesh quality is a complex set of characters involving factors such as texture, chemical composition, color and fat content (Fauconneau et al. 1995). The impact of temperature and light on these mechanisms depends on the affected life stages, as reviewed by Rowlerson and Veggetti (2001). The effect of season may overshadow endogenous rhythms and affect quality (Roth et al., 2005). The aim of this study was to study the combined effect of two photoperiod regimes, continuous light (LL) and simulated natural photoperiod (LDN, Tromsø, North-Norway) at low temperatures (4, 6 and 9°C) on flesh quality and textural properties in Atlantic salmon smolts.

Material and methods

Juvenile (initial mean weight 96.0 g ± 3.1 SEM) Atlantic salmon were reared at six different combinations of temperatures and photoperiods. The experimental groups are abbreviated as: 4LDN, 4LL, 6LDN, 6LL, 9LDN and 9LL. The experiment was carried out in the period from 16 October 2013 to 17 March 2014. At arrival at Bergen High Technology Centre the salmon (95 fish in each tank) were distributed among twelve 1 m^2 (400 l) tanks with each experimental group in replicate. At termination of the trial (17 March 2014) the fish were slaughtered and flesh samples taken to investigate quality and textural properties in the different experimental groups. The chemical analysis included flesh gaping, muscle pH, water content of fillet, water holding capacity (WHC), and texture properties (hardness and breaking force). Possible interactive effects of temperature and photoperiod on flesh quality in Atlantic salmon post-smolts was studied.

Results

Final weight in the six experimental groups varied between 174 and 345 g. The 4LL group was significantly larger compared to the 4LDN group from January onwards (Fig. 1A) and displayed 30% higher overall growth rates, whereas no growth enhancing effect of LL was seen at 6 and 9°C. As a result, an overall interaction effect of photoperiod and temperature on growth rate was found. Softer texture was seen in the fast growing groups. Hardness decreased with increasing temperature, size and growth whereas no effect of photoperiod was found. Accordingly, there was an overall significant linear relationship between fillet hardness and individual growth (Fig. 1B

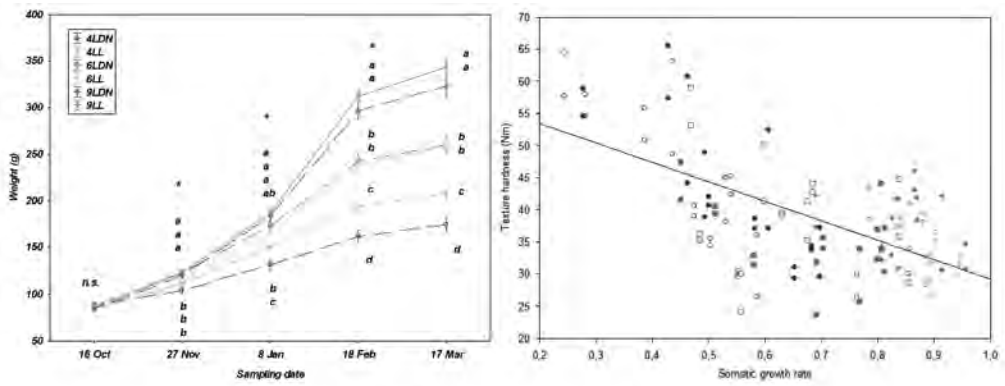

Fig. 1. (A) Mean weight (g) and (B) texture hardness (60% compression) of juvenile Atlantic salmon reared at three temperatures (4, 6 and 9°C) and two light regimes (LL = continuous light, LDN = simulated natural photoperiod for Tromsø, Norway). Letters indicate significant difference between treatments on sampling date. *denotes significant interaction between photoperiod and temperature. Open symbol = LDN. closed symbol = LL. Blue = 4°C and circle symbol, green = 6°C and square symbol and red = 9°C and diamond symbol.

(Continued on next page)

Discussion and conclusion

Results on textural properties in the present study, measured as breaking and hardness, suggest that changes in quality was effected by growth properties and temperature, but photoperiod played only a minor role. Previous studies on other teleost species show the shear forces of the muscles increases in periods with low growth (Hagen et al., 2007). This could help to explain the overall relationship between textural hardness and somatic growth rate seen in the present study (Fig. 1B).

In line with previous studies (Imsland et al., 1995; Jonassen et al., 2000) an interactive effect of photoperiod and temperature on somatic growth was found in this study. Fish exposed to low temperature and continuous light regime (4LL) had a significantly higher growth (30 % gain in overall SGR) than the 4LDN group. These findings demonstrate that the growth promoting effect of continuous light can be stronger at low temperature compared to near optimum temperature.

We conclude that quality in salmon muscle is dependent on growth, where temperature has the major impact, whereas photoperiod only has minor effect on flesh quality and textural properties. The present findings indicate that slaughter of salmon should be avoided in periods of high growth.

MOLECULAR AND PHYLOGENETIC ANALYSIS OF *Dactylogyrus* SPP. PARASITES IN CULTIVATED SILVER CARP (*Hypophthalmichthys molitrix*) AND BIG HEAD CARP (*Hypophthalmichthys nobilis*) IN IRAN

J. Daghigh Roohi*, A. Dalimi, M. Pourkazemi, M. Ghasemi, S. Shamsi

Inland water Aquaculture research center, Iranian fisheries Sciences Research Institute, Agricultural Research Education and Extension Organization (AREEO), Bandar-e-Anzali, Iran
Email: Javad_daghigh@yahoo.com

Introduction: *Dactylogyrus* is one of the most common external parasites on the gills of Cyprind fish. These parasites are highly host specific and many species only have a specific host. Since there are reports of silver carp specific *Dactylogyrus* species isolated from big head carp and vice versa, the molecular investigation of Dactylogyrids have done in these two fish species.

Material and Methods: 81 silver carp and 82 big head carp were caught from 10 fish farms in Guilan province, North of Iran, and after preparing wet mounts of body surface *Dactylogyrus* parasaites divided and fixed by glycerin jelly. In order to morphometric assessments on captured images, Image J soft ware were used for 7 point to point distances. Drawing of parasites was done by drawing tube and then compared by identification keys and parasites identified For molecular investigation the genomic DNA was extracted from one parasite specimen and 28S rDNA region of *Dactylogyrus* specimens were amplified by related primers in PCR (Plaisance *et al*., 2005). Purified fragments of PCR products were sequenced from both forward and reverse sites of each PCR product. Sequences of the parasites were aligned using the clustal W software and then manually adjusted to perform the phylogenetic analysis. The phylogenetic tree was built using Mega 6.0 by the UPGMA method. The pairwise genetic distances also calculated by BioEdit software.

Results: Sequences were deposited in GenBank with accession numbers MG825611 and MG825765 respectively for *Dactylogyrus hypophthalmichthys* and *Dactylogyrus suchengtaii* isolated from *Hypophthalmichthy smolitrix*, and also MH023397 and MH023399 respectively for *Dactylogyrus aristichthys* and *Dactylogyrus nobilis* isolated of *Hypophthalmichthy nobilis.* The phylogenetic tree (Fig 1.) shows the genetic affinity of isolated parasites from these two fish. The pairwise genetic distances (Fig 2.) also shows the isolated *Dactylogyrus* species of these two fish are very closely related.

Discussion and Conclusions: Probably this genetic relationships between *Dactylogyrus* specimens isolated from silver carp and big head carp can be considered as one of the main reasons for the success of transgenic *Dactylogyrus* species between these two fish and the failure of this transfer to common carp and gibel carp, as mentioned in studies by Molnar et al. (1984). Referring to this phylogenetic tree and the results of other studies (Musselius, 1968; Jalali and barzegar, 2004; Molnar et al., 2005), it seems that occasional silver carp parasites may appear in big head carp and vice versa. Most likely the racial impurity of silver carp and big head carp in Iran is the reason for hosting of each other parasites.

Introduction

Genomic selection (GS) can increase the rate of genetic gain in aquaculture breeding. Unfortunately, the cost of GS is high because a large number of individuals need to be genotyped in aquaculture breeding schemes. However, cost can be reduced by genotyping them with a lower-density single nucleotide polymorphism (SNP) panel and impute them to a higher-density panels (Goddard, 2008; Habier et al., 2009). In this study, we quantified the potential of imputation from low marker density for cost effective genomic selection in Atlantic salmon breeding.

Materials and Methods

A dataset from Mowi breeding population was obtained from a sea lice challenge trial. Genotypes and phenotypes from 4564 individuals were available. From each family, parents were genotyped with ~ 53K SNP and the genotypes of the offsprings were strategically reduced from 53K to 0.5K SNP. Three strategies were used to reduce the marker density: 1) proximity to the center of SNP windows (EQ), 2) highest allele frequency in a SNP window (MAF) and 3) based on maximum R-squared of a marker with all markers in the window (R2). In addition, some combinations of the above approaches (i.e. EQMAF, R2MAF and EQR2MAF) were also tested. For the combination strategies, weights were placed on individual strategies. The genotypes of the offsprings were imputed from 0.5K to ~53K SNPs and imputation accuracy was calculated as a correlation between true and imputed genotypes (Calus et al., 2014). Genomic breeding values (GEBV) were predicted using true and imputed genotypes. From each family, the phenotypes of 15% of the sibs were masked (i.e. validation individuals) and accuracies of prediction were calculated as correlations between GEBV and the masked phenotypes. The correlations were weighted by the inverse of the square root of heritability.

Results and Discussion

The imputation accuracies for the different marker selection strategies were between 0.63 - 0.65 when no parents were genotyped and between 0.80 - 0.81 when only one of the parents (either dam or sire) was genotyped (Table 1). When both parents were genotyped, the imputation accuracies were between 0.88 - 0.90 (Table 1). There was no difference in imputation accuracy between genotyping only dams and only sires. It was also observed that there is slight difference in imputation accuracies among marker selection strategies. The results also showed that there no difference in imputation accuracy between male and female offsprings.

Genomic prediction accuracy was 0.78 ± 0.1 when using true genotypes compared up to 0.76 ± 0.11 when using imputed genotypes. Among the marker selection strategies, EQR2MAF gave a slightly higher prediction accuracy (Table 1). Similar trends were also observed for three other disease traits and two weight related traits. The results showed that imputation can be leveraged to minimize genotyping cost without losing too much prediction accuracy. It also noted that both parents needed to be genotyped to get a reasonable imputation accuracy.

Introduction

Rainbow trout is a worldwide cultured salmonid species with numerous breeding programs implemented over the last 50 years in closed populations. Inbreeding is therefore expected to be at moderate to high levels in broodstock populations (D'Ambrosio et al. 2019). Previous works showed significant inbreeding depression effects in female body weight at spawning and spawn weight (Kincaid 1983) as well as in egg number and spawning age of females (Su et al. 1996). Therefore it is important to evaluate the performance for those female reproduction traits and their genetic architecture in current broodstocks.

The aims of the study were to estimate genetic parameters, to identify quantitative trait loci (QTL) and to assess the efficiency of genomic selection (GS) compared to pedigree-based selection (PS) for female reproduction traits in rainbow trout. Six traits were studied: ready-to-spawn female body weight (FW), spawning date (SD), egg numbers in the spawn adjusted for FW (EN), spawn weight adjusted for FW (SW), egg weight (EW) and egg diameter (ED). As far as we know, it is the first report on G AS and efficiency of selection for fish reproduction traits

Materials and methods

1,346 fish were phenotyped (Table I) and 15,265 individuals were recorded in the pedigree (10 generations). The 1,346 fish and their parents (87 dams and 72 sires) were genotyped with the Axiom™ Trout Genotyping array. After quality control, 29,799 SNP were retained for the analysis.

AIREMLf90 program was used for variance component estimation (Misztal et al. 2002) and POSTGSf90 program for GWAS (Aguilar et al. 2014). A 1-Mb portion of the genome was declared as a QTL when this 1 Mb-window explained at least 1% of the genetic variance of the trait.

The (genomic) estimated breeding values (G)EBV were estimated by pedigree-based BLUP and GBLUP linear mixed models using BLUPf90 package (Misztal et al. 2002). To assess the GS and PS efficienc , 40 replicates of Monte-Carlo 'leave-one-group-out' Cross Validation tests were performed considering 1,078 individuals and 269 individuals in the training and validation sets, respectively. Accuracy of selection was derived as the mean over the 40 replicates of the correlation between (G)EBV of individuals in the validation set and their phenotypes corrected for the fixed effects depending on the traits (cohorts, spawning date and over mature egg) divided by the square root of trait heritability.

Results

Genetic architecture. All heritability estimates were medium (Table I). At least 1 QTL was detected for any trait, but no QTL explained over 2.5% of the genetic variance. Therefore the genetic architecture of female reproduction traits appeared to be highly polygenic. For SD, 4 QTLs were detected (on Omy5, Omy9, Omy11 and Omy26), each of them explaining only 1.0 to 1.5% of the genetic variance. For FW, a single QTL was detected on Omy23 and explained 2.4% of the genetic variance. This QTL has not been yet reported in the literature for rainbow trout growth traits. Unique QTLs were also detected for EN and SW, explaining 1.3% on Omy8 and 1.0% on Omy2, respectively. For EW and ED respectively, 2 and 3 QTLs explained between 1.0 to 2.5%; the same 2 QTLs were detected on Omy 1 and Omy8 with the last one showing the largest effect for both EW and ED (Fig1.)

Accuracy of selection. Genomic EBV were more accurate than pedigree EBV for all traits. The gain in accuracy varied from 16% (FW) to 37% (EN) (fig.2)

Conclusion

Female reproduction traits are polygenic with intermediate heritability values. Only 2 QTLs over the 12 identified across the 6 traits studied explained over 2% of the genetic variance. These results suggest that gene-assisted selection will be useless. However, genomic selection based on a reference population of only a thousand individuals related to candidates may improve the efficiency of selection from 16 to 37% depending on female reproduction traits

Introduction

The membrane biological reactor (MBR) is a proven wastewater treatment technology that is used in municipal and industrial applications (Hai and Yamamoto, 2011). MBRs balance denitrification and nitrification within an activated sludge system. Fine-pore (≤ 0.2 µm) membranes within the MBR produce a filtered permeate that excludes solids, fine particles, bacteria, viruses, and other water quality constituents (Hai and Yamamoto, 2011). Onsite research indicates that MBRs can effectively treat concentrated wastewater from aquaculture facilities (Sharrer et al., 2007; 2010). The low-solids filtrate produced by MBRs also appears to be well-suited for return to recirculation aquaculture systems (RAS) which could result in further water savings, reduced discharge volumes, and water treatment advantages.

Materials and methods

A 4-month study was carried out to evaluate the feasibility of incorporating MBRs with the water recycle loop of experimental-scale (9.5 m^3) RAS while culturing rainbow trout. Triplicate RAS with and without MBRs were used for the trial. Control RAS were operated with standard flushing rates known to support acceptable rainbow trout performance and welfare. Three single-vessel MBRs with flat plate membranes (Alfa Laval, Sweden) received, processed, and retained RAS backwash water that otherwise would be removed, and a head-pressure-driven permeate was returned to RAS, creating a nearly closed loop system. Equal numbers of rainbow trout (103 ± 1 g) were stocked into each RAS prior to the study. Water use, water quality, and fish performance were assessed

Results

Integrating MBRs with RAS to reclaim backwash wastewater resulted in significantly reduced water usage, i.e., six and a half times less than RAS operated with traditional flushing rates. Mean daily water exchange rates for RAS with and without MBRs was 1.2 ± 0.4 and 7.8 ± 0.5 % of the RAS volume, respectively. A range of water quality concentrations were significantly greater ($P < 0.05$) in the culture water of RAS with MBRs including: heterotrophic bacteria counts, nitrate-nitrogen (NO_3-N), total ammonia nitrogen, total phosphorous, and true color, as well as dissolved calcium, copper, magnesium, and sulfur. Alkalinity and ultraviolet transmittance levels were significantly lower in RAS with MBRs.

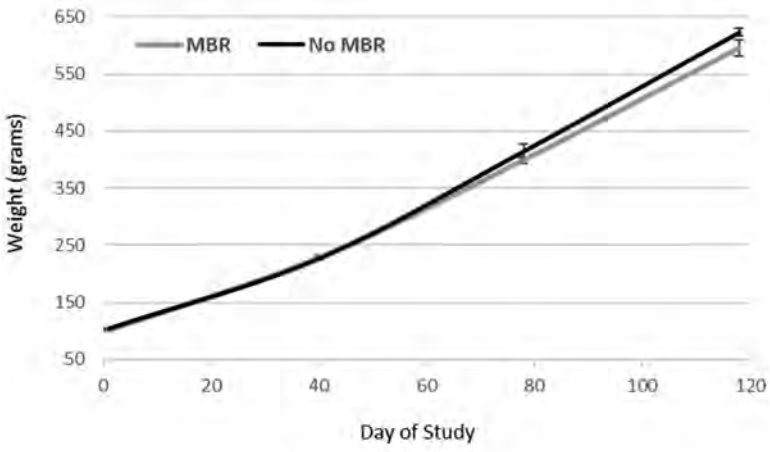

Fig. 1. Rainbow trout growth (mean weight ± standard error) in RAS with and without membrane biological reactors during the 4-month study.

(Continued on next page)

Infrequent addition of sugar enhanced denitrification, resulting in decreased NO_3-N and increased alkalinity in the MBR permeate. Water chemistry differences in MBR-integrated RAS did not affect ($P > 0.05$) rainbow trout growth performance (Fig. 1). At the end of the trial, the mean weight of rainbow trout cultured in RAS with and without MBRs was 595 ± 14 and 623 ± 6 g, respectively. Deficiencies in MBR function were observed including less than optimal MBR permeate production rates.

Discussion and conclusions

Results from this preliminary trial indicate that integrating MBRs within the water treatment loop of RAS is feasible for rainbow trout production. The substantial water savings resulting from MBR integration could have important implications for the developing RAS industry. RAS already reduce the water requirement for fish production; however, large, commercial-scale facilities still have a significant water requirement. We estimate that a 1,000 MT salmonid RAS farm could require ≥ 3,000 m^3 of daily makeup water. However, new RAS farms are being constructed at larger scale (up to ≥ 30 MT) which will demand even greater water volumes. The water savings provided by MBRs could offset this expanded water requirement, which would broaden the scope for facility site selection and potentially allow location of commercial RAS farms near major seafood markets. More research is needed to optimize MBR integration within RAS including faster permeate production rates, enhanced denitrification efficienc , and improved RAS water quality. Use of ozone in MBR-integrated RAS would likely produce significant water quality improvements (Davidson et al., 2011). Future research that seeks to optimize MBR integration with RAS is planned, including the combined use of ozone.

Introduction

Genetically improved farmed tilapia (GIFT), an enhanced strain of Nile tilapia (*Oreochromis niloticus*), exhibit better growth and survival rates than routinely available strains of tilapia. Currently, intensive culture systems are common for tilapia culture and often cause stressful conditions that reduce fish growth and wellbeing. The use of functional feed additives as bio-friendly agents is a sustainable way to improve cultured fish performance, and the use of functional ingredients with immune modulatory properties has become more prominent across the animal feed industry.

Heat-killed *Lactobacillus plantarum* (HK L-137) can positively impact the performance and wellbeing of aquatic animals, as reported in several studies.

Thus, the present study investigated the potential value of HK L-137 as a dietary probiotic for GIFT.

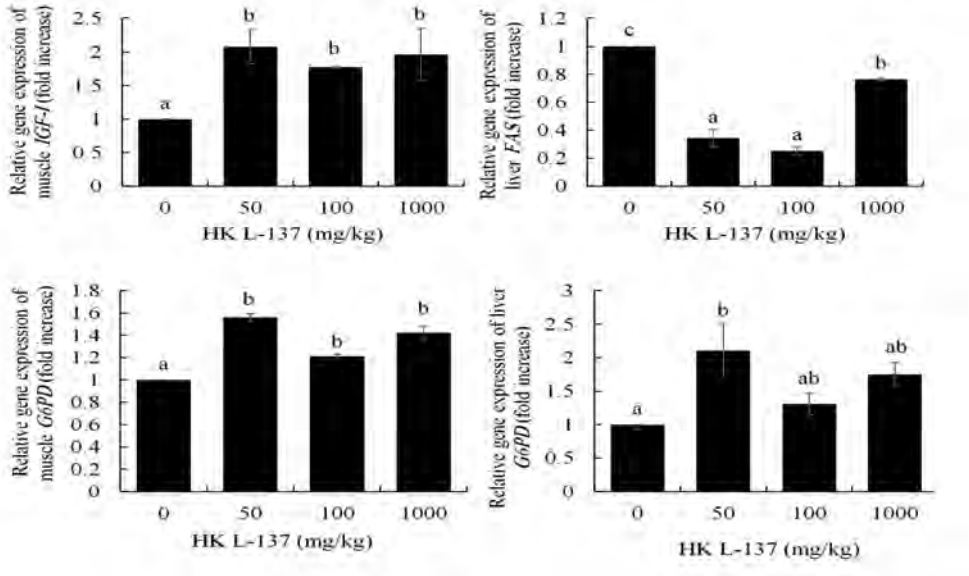
Materials and methods

For 12 weeks, fish were fed a control diet (HKL0) or a diet supplemented with HK L-137 at a concentration of 50 (HKL50), 100 (HKL100) or 1000 (HKL1000) mg kg^{-1} feed.

Table 1. Growth performance and nutrient utilization in GIFT tilapia*

	Test diets			
Item	HKL0	HKL50	HKL100	HKL1000
Initial body weight (g)	16±0.04	16±0.03	16±0.03	15.97±0.04
Final body weight (g)	$36.16±0.9^{a}$	$41.2±1.3^{b}$	$45.2±0.7^{c}$	$42.2±0.93^{b}$
Weight gain (%)	$126.3±5.4^{a}$	$158.3±8.3^{b}$	$183.4±4.3^{c}$	$167.4±5.83^{b}$
Specific growth rate (% BW/ day)	$1.82±0.1^{a}$	$2.1±0.1^{b}$	$2.3±0.04^{c}$	$2.04±0.05^{b}$
Feed efficiency ratio	$0.54±0.02^{a}$	$0.61±0.03^{ab}$	$0.73±0.02^{c}$	$0.66±0.02^{b}$
Survival	$91.1±2.2^{a}$	$97.8±2.2^{b}$	$100±0.00^{b}$	$98.9±1.1^{b}$
Condition factor (%)	1.82±0.1	1.83±0.03	1.84±0.06	1.84±0.04
Hepatosomatic index (%)	2.24±0.2	2.39±0.13	2.09±0.34	2.24±0.17
Viscera somatic index (%)	2.9±0.1	2.87±0.13	2.6±0.03	2.74±0.1

*Values expressed as means ± SE (n = 3). Different superscript letters indicate significant differences for each pairwise comparison between treatments.



(Continued on next page)

Results

At the final sampling, the HKL100 group had significantly ($P < 0.05$) increased performance parameters (FBW, WG, SGR and FER) compared to the control group, while the HKL50 and HKL1000 groups showed weaker improvements. Mucosal thickness and villus length were significantly ($P < 0.05$) increased in the HKL50 and HKL100 groups in the anterior, middle and posterior intestine, but muscle thickness was significantly ($P < 0.05$) improved only in the anterior and middle intestine. Amylase, lipase and protease activity was significantly ($P < 0.05$) increased in fish fed 50 or 100 mg HK L-137 per kg diet compared to control fish. Significant modulation of blood haematocrit, haemoglobin levels, and RBC and WBC counts ($P < 0.05$) occurred in fish fed HK L-137, while total cholesterol and GPT were decreased by HK L-137. Furthermore, antioxidative enzyme (SOD and CAT) activity were significantly ($P < 0.05$) higher in the HKL100 group than in the control group, while MDA levels were lower. Furthermore, fish fed HK L-137 showed enhanced total serum protein and IgM levels. Interestingly, qRT-PCR revealed significant ($P < 0.05$) upregulation of the growth-related gene IGF-I and the glucose regulation gene G6PD but downregulation of the fatty acid synthase (FAS) gene in all HKL groups compared to the control group.

Conclusion

Thus, we conclude that the use of HK L-137 is an efficient strategy to achieve economically feasible and sustainable tilapia production.

COMPARATIVE GONAD HISTOLOGY AND SEMEN QUALITY OF NORMAL (XY) AND NEO-MALES (XX) OF ATLANTIC SALMON (*Salmo salar*)

Pedro Luiz de Castro[2]* and Jawahar G. Patil[1]

Introduction

In Australia the commercial propagation of Atlantic salmon relies heavily on crossing homogametic brood stock i.e. normal females (XX) and neo-males (XX) which results in the production of 100% female offspring. It is necessary because in most salmonids' females have extremely favourable production traits compared to males (Inanan and Yilmaz, 2018). Typically, however, neo-males gametes can only be extracted after sacrifice and dissection, which often results in inconsistencies in quality and quantity of semen used for fertilization, compromising the seed production efficiencies in commercial hatcheries (Parodi et al. 2015; Vikingstad et al. 2016). The objective of the present study was to comparatively evaluate the gonad histology and semen quality of normal (genotype XY) and neo-males (genotype XX) with a long-term view to improve hatchery production of all-female progeny of the Atlantic salmon.

Materials and methods

Four normal (XY) and seven neo-males (XX), distinguished by their ability to- or lack of expressing semen respectively, from the same brood stock, were comparatively evaluated. The sperm collection from both genotypes was made by testis maceration. The Left lobe (from each fish) was fixed in buffered formalin for histological analysis, while the right lobe used for extracting semen by maceration. Prior to sperm extraction, key measurements of fish (body weight and length) and their testis (weight, length, width and depth) were taken and gonadosomatic index computed. Semen qualitative and quantitative analyses (Motility by CASA, duration of motility, viability of spermatozoa, sperm concentration and structural abnormalities) as well as gonad histology (Hematoxylin/Eosin staining and *in situ* cell death detection assay by Tunel) were carried out. All quantitative data followed the normal distribution (Shapiro-Wilk test 5%) and the statistical differences were determined by analysis of variance and mean test (Tukey 5%), using the statistical software R.

Results

Differences were found in body size between the genotypes, with neo-males being on average six times heavier and 42% larger than the normal males. Similarly, their gonads were four times heavier, almost double in length and thickness compared to normal males. Morphometric observations revealed that neo-male gonads are irregularly shaped, have poorly formed seminiferous ducts and lower gonadosomatic index ($P<0.05$).

The CASA analyses showed higher percentage ($P<0.05$) of semen motility for normal (80.69 ± 24.00%) than neo-males (57.2 ± 36.50%). Similarly, the duration of semen motility was also significantly longer for XY (99.31 ± 28.03 sec) compared to the XX (66.84 ± 23.83 sec) males. Significant differences were also found for curvilinear velocity, where the normal males (190.25 ± 56.50 $\mu m/s^{-1}$) had mean values higher ($P<0.05$) than neo-males (155.27 ± 48 $\mu m/s^{-1}$). The average of the remaining semen motility parameters measured i.e. linearity, progression, straight-line velocity, path velocity, wobble and beat cross frequency did not show statistical differences ($P>0.05$). No statistical differences ($P>0.05$) were observed for viability of spermatozoa, sperm concentration and structural abnormalities between normal and neo-males.

Histological analysis performed by H&E staining revealed the existence of consistent differences between the genotypes. A larger area of interstitial tissue, bigger size of Sertoli cells, greater number of Sertoli cell cysts (consisted of more than two cells in a cluster) were found in neo-males ($P<0.05$). Interestingly, the Tunel assay showed that most cells including hypertrophic Sertoli cells of neo-males predominantly remained non-florescent, suggesting that they are live and active.

(Continued on next page)

Discussion and conclusion

The results of this research further highlight the disparity in quality of neo-male semen of Atlantic salmon when compared to the normal males that are routinely encountered by hatchery managers, particularly that these are not just restricted to the harvest method. The key bottleneck is an inability of neo-males to express semen freely, likely contributed by poorly developed seminiferous ducts, irregular shape of the testes and the presence of hypertrophied and cyst forming Sertoli cells. Similar observations have been made in rainbow trout (*O. mykiss*) by Kowalski et al. (2011), suggesting this is a shared bottleneck in salmonid aquaculture, perhaps also applies to other cultured species where reliance on neo-males is a norm. This typically, requires maceration of testis for collection of semen, a relatively complex process that can contaminate the semen samples with impurities (such as blood) and results in lowers parameters of semen quality (Parodi et al. 2015; Vikingstad et al. 2016). Despite the standardization of sperm collection method in this study, neo-males had relatively poor semen quality. Such poor quality of neo-male sperm has been attributed to physiological/genetic obstacles to final maturation for these animals (Kinnberg et al., 2000a). Collectively, these two factors i.e. method of collecting semen and problems related to final maturation, along with the individual maturity variations make it difficult to refine and develop standard and reliable hatchery protocols that consistently yield high fertilization rates for neo-males. Conceivably this has flow on to nursery and grow-out performances and ultimately to economic efficiency of the farming operations. Nonetheless, the study implies that the neo-males may be amenable to physiological priming, which along with improved brood stock management practices may lead to production of semen, without the need for euthanasia. The benefits of such an ability i.e. without compromising the advantage of unambiguously selecting the XX-male brood stock, will improve hatchery efficienc es, including repeat use of neo-male broods. Results and inferences of this study should serve as foundation for future investigation aimed at delineating the causes that preclude expression of semen by neo-males as well as in optimizing general hatchery practices.

Introduction

Pikeperch (*Sander lucioperca*) is a freshwater and brackish fish species natively distributed in Europe and Asia. It is a valuable fish due to its growing consumer demand and its high potential for inland aquaculture. In order to improve the production and profitability of fish in the aquaculture industry, the use of domesticated stocks and breeding programs is inevitable (Gjedrem et al., 2012). Although the impact of several environmental factors has been studied on productive and reproductive pikeperch traits (e.g. Mattila and Koskela, 2018; Olin et al, 2018**)**, to our knowledge, to date no attempt was made to study the influence of genetics. However, for managing genetic diversity and for sustainable breeding, the relationship between genetic and phenotypic variation has to be elucidated. To this end, the study of genomic variation is required. The most common form of genetic variation is the single nucleotide polymorphism (SNP). The identification of SNPs allows its use as markers for the analysis of the genetic structure of populations, for the construction of genetic maps and to help locate genes associated to traits of interest. The objective of this study is to identify SNPs based on a large-scale experiment in a pikeperch breed and to investigate the genomic variation using information of parents and offspring.

Material and methods

Seven full-sib families of pikeperch were generated by a fish production facility (State Research Institute for Agriculture and Fisheries in Hohen Wangelin, Mecklenburg-Western Pomerania, Germany). The progeny obtained from each family were transferred into a common tank and sampled after reaching fingerling stage. Genomic DNA from a total of 394 individuals, including broodstock, was extracted from blood or flash-frozen caudal fin for whole genome sequencing with Illumina (NovaSeq 6000). SNPs were detected using the Haplotypecaller tool of the Genome Analysis Toolkit v4.0 (GATK) pipeline for DNA-Seq. Identifie SNPs are further processed with the genome association analysis toolset PLINK. To study genomic variation, SNPs are filtered by call rate, minor allele frequency and Hardy-Weinberg equilibrium. After filtering, a set of high-quality SNPs are selected for parentage testing (ParentSearch; Boerner, 2017). Then progeny haplotypes are phased from SNP genotypes and blocks of linkage disequilibrium are computed for elucidating regions of particularly high or low recombination activity. Furthermore, runs of homozygosity are investigated to study the extent of inbreeding, which is an important measure of genetic diversity (Curik et al., 2014).

Results

[The computing process is currently taking place.]

Discussion and conclusion

The analysis of the genomic variation is a necessary step for understanding the relationship between genotype and phenotype. This study revealed an extensive panel of high-quality SNPs that can be further employed in genomic selection accelerating the establishment of breeding programs and therefore a more efficient aquaculture industr .

Introduction

Improving feed efficiency in aquaculture is crucial to develop a more sustainable aquaculture. Feeds represent 30 to 70% of the total production costs, and have major environmental and social impacts (de Verdal et al, 2017).

Until now, the contribution of genetic improvement to this goal has been hampered by the lack of efficient phenotyping methods and of accurate genetic parameters of feed conversion rate (FCR) in fish. Different methods have been used to measure individual FCR in fish, but all of them have pros and cons, i.e. the loss of social interactions between fish, the low repeatability of measurements, or the time needed to measure the phenotype.

Indvidual FCR is a difficult trait to measure. Using genomic selection would help to reduce the phenotyping effort by phenotyping fish that are not the candidates to selection (training population). These phenotypes are needed to establish a genomic prediction equation for the selection candidates, thus potentially reducing the phenotyping effort with a higher accuracy. The aim of the present study was to 1/ estimate the genetic parameters of performance and feed efficiency traits and 2/ assess the potential of genomic selection for feed efficie cy. The GIFT strain, selected for growth for more than 15 generations, of Nile tilapia *Oreochromis niloticus*, was used for this purpose.

Material and methods

Video assessment of feed intake (FI) on individual fish reared in groups was used to estimate the genetic parameters of growth traits (body weight gain, BWG), FI, FCR and relative FI ($FI.BW^{-1}$) on 1,000 fish from 40 pedigreed full-sib families of Nile tilapia. Juvenile fish (22.4 g) were evaluated during 13 consecutive meals over 7 days (de Verdal et al., 2018). Each phenotyped individual was genotyped using DarT-seq methodology. A total of 4930 SNPs were used after quality control. Heritability was estimated with a pedigree-based or a genomic approach. Five-fold cross validation was apllied using different methodologies: pedigree-BLUP (pBLUP), genomic BLUP (gBLUP), and single-step gBLUP (ss-gBLUP) and twoBayesian methods (Lasso and BayesC-π) to estimate the reliability of EBVs.

The BLUPF90 family of programs (Misztal et al, 2002) was used for all analyses except for the Bayesian methods where GS3 (Legarra et al, 2010) was used.

Results

As expected, heritability estimates revealed a genetic control for feed efficiency traits in tilapia. Pedigree- and genomic-based heritabilities were rather different for all traits (Table 1). Estimates were lower with genomic data for FI and $FI.BW^{-1}$ but higher for BWG and FCR.

EBVs estimated with different methodologies (pBLUP, gBLUP, ss-gBLUP, Lasso and BayesC-) were compared to observed phenotypes for all traits. Results for FCR and FI corrected for fixed effects are shown in Figure 1. Globally, all correlations were close to the expected accuracy, whatever the trait. The EBVs of FI were the most accurately predicted, with 95 to 100% of the expected accuracy, for pBLUP and Lasso, respectively.

Discussion and conclusions

Using this specific methodology to measure individual FI and estimate FCR, it is clear that genetic improvement of feed efficiency is possible in tilapia. These traits have moderate to high heritabilities. Genetic parameters estimates were not similar using the classical pedigree-based method and the genomic-based method, which can be partly explained by some intra-family effects, not visible using the pedigree-based estimations. The heritability estimates for FCR are relatively close

(Continued on next page)

Trait	Pedigree h^2	Genomic h^2
BWG	0.27 ± 0.08	0.37 ±0.06
FI	0.45 ±0.09	0.17 ±0.05
FI.BW^{-1}	0.31 ±0.001	0.19 ±0.06
FCR	0.32 ±0.11	0.59 ±0.06

Table 1 – Estimation of pedigree and genomic heritabilities ± S.E.

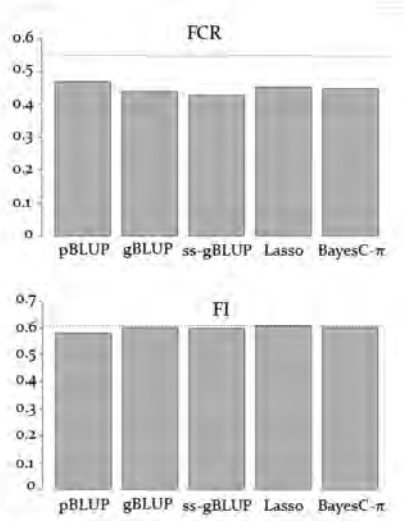

Figure 1 – Correlations between predicted EBVs for fish in the validation data in a given model (predicted from the training data) and the recorded FCR and FI. The dotted line represent the expected accuracy estimated using the equation of Daetwyler et al (2010).

to what was found by Besson et al (2019) in European sea bass, who estimated heritabilities of 0.25 and 0.47 for FCR (log transformed) using pedigree and genomic data, respectively. Regarding FI traits, the heritability drop could be explained by the relatively low number of SNPs used in the analyses, not all the QTLs being tracked by the SNPs.

We showed that accurate predictions of EBVs can be performed using different methodologies. According to the considered trait, the best methodology was not the same but accuracy differences between methodologies were rather small (less than 10%), and all methods were close to the expected accuracy. More genotypes and phenotypes might help increase the reliability of predictions and as a consequence, increase the impact of genomic selection on feed efficiency traits. Finally, although the heritability of FCR using genomic data was much higher than using pedigree data, the accurecy was very similar. As a consequence, using this number of SNPs and this measurement methodology, the clear advantage of using genomic data is reducing the phenotyping efforts, which can be useful knowing the complexity to measure FCR in fish

MicroRNAs (miRNAs) constitute a group of small non-coding RNAs (~22 nucleotides) and act as post-transcriptional regulators of target mRNA. The miRNA can be described as "multivalent" by its ability to target several genes, thereby regulating the expression of several proteins. Apart from miRNAs functions in mammals, teleost miRNAs also have been involved in the development and various physiological processes including growth, development, immune responses, etc. Most miRNAs are highly conserved within the vertebrates but miR-462 has only been described in teleost fishes according to miRBase. In addition, miR-734 is also specific to teleost and has not been reported in higher vertebrates. Therefore, understanding the expression of miR-462 and 734 is important to understand the immune functional role of those specific miRNAs.

We first focused on the constitutive expression of miR-462 and 734 in different tissues (liver, gill, spleen, gut, kidney, brain and muscle) of adult zebrafish (*Danio rerio*). The ubiquitous expression of miR-462 and 734 was detected in all tested tissues, with the highest levels in gills (23.9-fold) and brain (42.1-fold), respectively. Furthermore, we investigated the immune responses of these miRNAs in larvae exposed to pathogenic bacteria *Aeromonas hydrophila* and *Edwardsiella piscicida* at 3, 24 and 48 hours post exposure (hpe). Based on the qRT-PCR results, upregulation patterns of miR-462 and 734 were identified in larvae, upon exposure to *A. hydrophila* (2.4×10^8 CFU/mL) and *E. piscicida* (5.0×10^{10} CFU/mL). The findings of this study imply that miR-462 and 734 could ubiquitously express in a variety of tissues in adult zebrafish and these could be infection inducible miRNAs in zebrafish larvae upon *A. hydrophila* and *E. piscicida* exposure.

QTLs LINKED TO SURVIVAL AND GROWTH OF RAINBOW TROUT FED A 100% PLANT-BASED DIET IN RAINBOW TROUT SINCE THE FIRST MEAL

Introduction

To ensure aquaculture development, composition of aquafeed has changed a lot in the past years. Indeed, classical aquafeed contained high proportion of fish oil and fish meal while these ingredients produced by fisheries are limited by quotas. Use of plant-based diets is a widely adopted option because the availability of plant products allows covering the needs for aquafeeds. For Rainbow trout, substitution rates up to 80 % have no impact on growth and survival. However higher substitution rates, especially total substitution, decrease survival in early stages and growth. Previous works with Rainbow trout showed that selection is highly efficient for survival and growth when trouts are fed a 100 % plant-based diet since the first meal (Callet et al., 2017). The present work aimed to characterize the genetic basis of survival and growth in a commercial population of Rainbow trout fed a 100% plant-based diet from the first meal onwards

Material and methods

20 dams and 10 sires from a selected line of the French breeder, Viviers de Sarrance, were crossed according to a full factorial mating to produce 3000 fish. Fish were fed, since their first meal, a 100% plant-based diet (without any fish oil and any fish meal) manufactured by INRA-NuMeA. Dead fish were collected each day. At 3.5 months, a mink entered and killed or ate a large part of the fish. After 4 months, the 549 surviving fish were weighed, measured and a piece of fin was collected. The 592 fish dead before the 7th week were also considered in this study. The 592 dead fish and the 549 surviving fish were genotyped with the Axiom® Trout Genotyping Array, containing 57k SNPs. After quality control, 28 310 SNPs were retained for the analysis. For the 2 traits, survival at 7th week and weight at 4 months, a GBLUP model was considered to estimate the effects of all SNPs simultaneously. AIREMLf90 program was used for variance component estimation (Misztal et al. 2002) and POSTGSf90 program for GWAS (Aguilar et al. 2014). A 1-Mb portion of the genome was declared as a QTL when this 1 Mb-window explained at least 1% of the genetic variance of the trait.

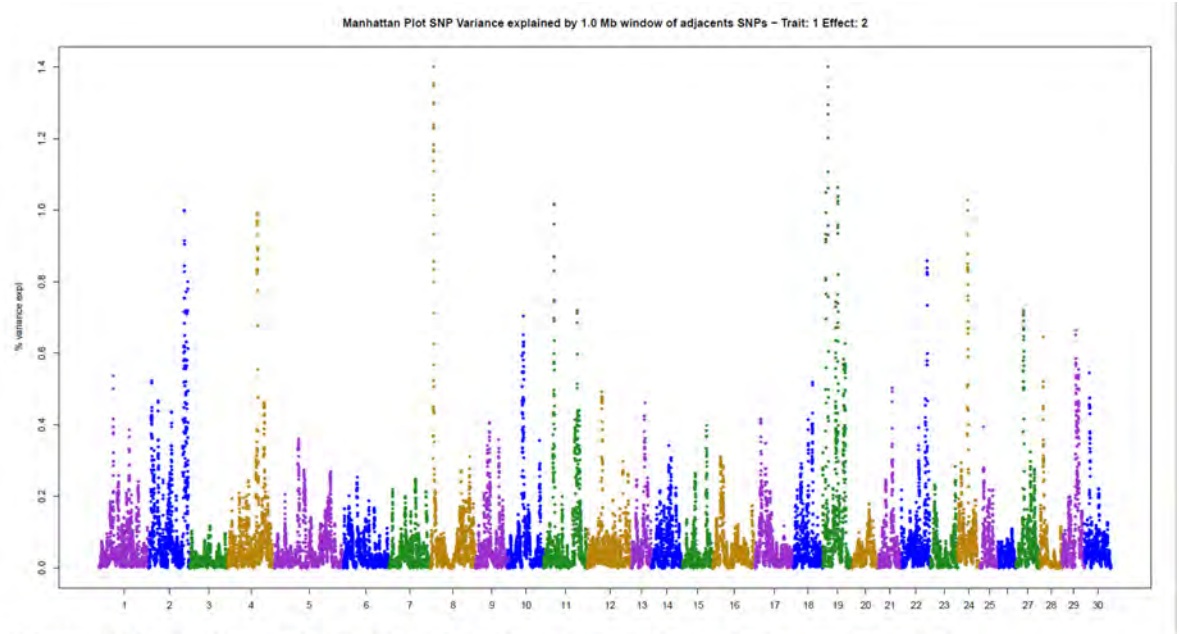

Figure 1-Manhattan plot of the proportion of genetic variance explained by 1Mb-window of adjacent SNPs for survival.

(Continued on next page)

Results and discussion

Mean weight of the 549 surviving fish was 16.73 ± 6.88 g and their mean length was 111.9 ± 18.37 mm at the end of the experiment. Four fish were discarded because of inconsistency between their weight and length

Genomic heritability was estimated at 0.38 ± 0.07 for body weight and 0.31 ± 0.05 for survival. Genetic correlation between body weight and body length was 0.96 ± 0.01 so that only body weight was further considered.

As shown in Figure 1, five QTLs were detected for survival on Omy2, Omy8, Omy11, Omy 19 and Omy24. All of them explained only between 1 and 1.4% of the genetic variance.

For body weight, four QTLs were detected on Omy3, Omy5, Omy16 and Omy18. The last QTL explained over 2% of the genetic variance.

Globally, these results confirmed the polygenic inheritance of survival and growth traits with a 100% plant-based diet. A more precise design (considering more animals and a higher-density chip) should be considered in the future to fine map the QTLs as well as to accurately estimate the QTL effects. A signature of selection on the 5th generation of the INRA selected line (Callet et al., 2017) is under analysis.

Introduction

Innovation of aquaculture feeds is progressing fast. Reducing feed costs and improving feed efficiency represents a major challenge for economic and environmental sustainability of aquaculture. Plant ingredients have been extensively investigated for their stable production and cost-effectiveness, however their use involves some nutritional and environmental drawbacks (Baruah et al., 2017). In this scenario, insects and animal by-products are regarded as attractive ingredients to replace fish meal in alternative or in combination to plant ingredients (Belghit et al., 2019; Lu et al. 2015), however their effects on fish physiology and welfare have still been little investigated (Elia et al., 2018).

The aim of this study was to evaluate stress response and nutritional status of rainbow trout fed new formulated diet containing insect meal from *Hermetia illucens* larvae and poultry by-product meal as partial substitutes of plant meal, by analyzing blood chemistry parameters.

Materials and Methods

Diets and feeding trial - Six extruded isoproteic (42% DM) and isolipidic (24% DM) diets were formulated: **CF -** a fish based diet with 90:10 and 80:20 ratios between fish and a vegetable mixture derived proteins and lipid, respectively; **CV -** a vegetable mixture based diet with inverted ratios respect to CF diet (10:90 and 20:80 respectively); two insect meal based diets (**IM30**-**IM60**) and two poultry by-product meal based diets (**PBM30**-**PBM60)** formulated by replacing 30% and 60% of vegetable mixture derived proteins with the alternative ingredients and by maintaining constant the 20:80 ratio of crude lipid from fish sources and vegetable/alternative animal sources.

The feeding trial was carried out at Experimental Aquaculture Centre of the Foundation Edmund Mach (Italy). Juveniles rainbow trout (54.2±1.45g) were reared in 1600 l triplicate flow-through tanks at 13°C for 13 weeks

Sampling and analysis - 15 fish for each tested diet were sampled at the end of the trial after 24 h of fasting. Blood was withdrawn from the caudal vein of anaesthetized fish (100mg/l MS 222; Pharmaq, Italy). After centrifugation, serum was collected and stored at -80°C for analysis of cortisol, metabolites and enzymes according to Di Marco et al. (2017). Biometric measurements and autoptical analyses were also performed. Kruskall wallis test and post-hoc multiple comparisons were performed to evaluate the effect of dietary treatment on blood chemistry parameters.

Results

Dietary treatment did not significantly affect fish growth (One way ANOVA ns). The hepatosomatic index were significantly higher in CF compared to the other groups ($p<0.001$). Diet composition significantly influenced the levels of glucose, total proteins, albumin, cholesterol, creatinine and transaminase (Kruskall wallis test $p<0.01$). Glucose level was significantly lower ($p<0.001$) in CV compared to CF group and similar to IM60 and PBM60 groups (Fig.1). Total protein content was significantly lower in all groups except CV ($p<0.05$), compared to CF group. Conversely, albumin concentration was significantly higher in all groups, except PBM30 group, respect to CF ($p<0.05$). Cholesterol and creatinine concentration were significan ly lower in all groups than in CF group ($p<0.001$). AST and ALT values were significant lower in IM60 group compared to PBM60 and PBM30 groups respectively ($p<0.05$).

(Continued on next page)

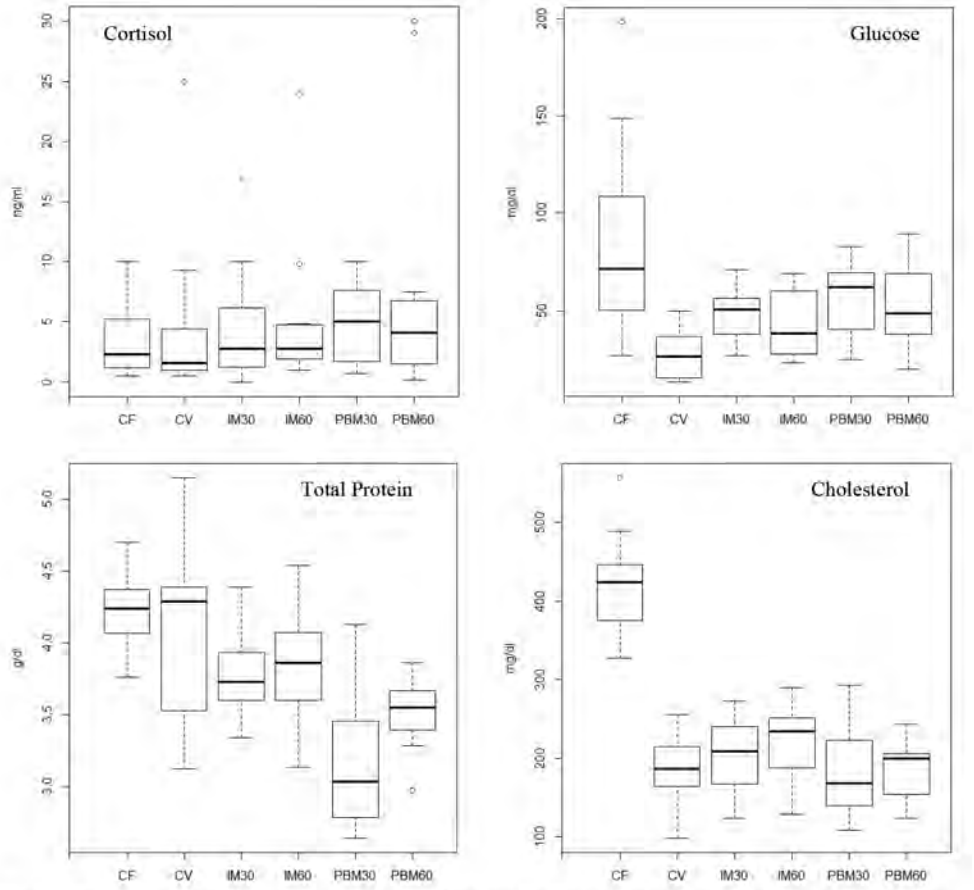

Fig.1. Cortisol, glucose, total protein and cholesterol levels in rainbow trout fed experimental diets.

Discussion and conclusion

All formulated diets sustain the fish growth without differences in relation to type of ingredients and levels of inclusion. Cortisol and metabolites levels measured in all groups are within the normal range reported for the species, suggesting no fish stress and a good nutritional status (Manera and Britti, 2006; Pinedo-Gil. et al. 2019). A comprehensive evaluation of blood lipid and protein content indicates that fish fed IM diets have a slightly higher metabolic profile compared to fish fed PBM diets and also a minor liver lipid accumulation as results from hepatosomatic index and liver histological analysis.

This study suggests that IM and PBM meals are promising alternative sources of protein for rainbow trout diet. Long-term feeding trials at commercial farms are needed for further investigations on fish physiology and welfare over the production cycle.

Introduction

The change in eating habits causes consumers to seek products with greater quality and convenience to their taste, so the demand for new processed foods from fish has increased. According to Gonçaves (2011) the importance of processing and elaborating products based on fish, be in what concerns: food safety; quality; insertion of species that are not consumed in the market; adding value to unattractive fish; and encouraging the consumption of these fish. Therefore, as a way of adding commercial value to streaks, allowing an increase in its consumption, and also to verify the use of regional spices capable of increasing the shelf life of elaborated products based on fish, it was a concern to direct efforts for the development of this research. Therefore, the present work had as objective to elaborate small cake from stingray (*Potamotrygon sp*.) And to evaluate the anti-rancid potential of the spice *Eryngium foetidum L*., used as additive in the elaborated product.

Materials and methods

The stingray (*Potamotrygon sp.)* and spices (*Eryngium foetidum* L.) were purchased in the state of Amapá, Eastern Amazonia, Brazil. For the preparation of the small cakes, the stingrays were processed, cooked for about 40 minutes and then the protein material (MP) was separated from the skin and cartilage. The small cakes were made according to Sary et al. (2017), with adaptations, where they were divided into four groups: negative control (GCN), positive control (GCP), with spice powder (GPE) and another with spice extract (GEE). The prepared product was stored and frozen in a freezer at -20ºC. For the oxidative rancidity analysis (TBARS) in the small cakes, the methodologies described by Yagi (1976) were used. Moisture, lipid and ash determinations were also performed according to the methodologies proposed by Official Methods Of Analysis (AOAC, 1990), carbohydrate and caloric value as described in the literature. The analyzes of centesimal composition were made by groups of triplicate.

Results

The small cakes made from MP from *Potamotrygon sp*, were shown to be easy to prepare, the results obtained for the centesimal characterization are described in table 01, for fish in nature and for the elaborated product, with averages and standard deviations, for each parameter, through the quantitative analyzes of the samples.

The results for the evaluation of oxidative rancidity are shown in figure 1, for analyzes performed after 01 day and 07 days, divided into groups, in which they are expressed in mmol of products produced (malonaldehyde) from lipoperoxidation, per liter (mmol / L).

Discussion and conclusion

The elaborated product presented with smaller amounts for the nutritional constituents and calorific value when compared to the fish in nature, this can be explained due to the previous cooking process. According to Pedrosa and Cozzolino (2001) in the cooking process, there is an expressive loss in the nutritional composition present in the fish, thus evidencing what was found in these analyzes.

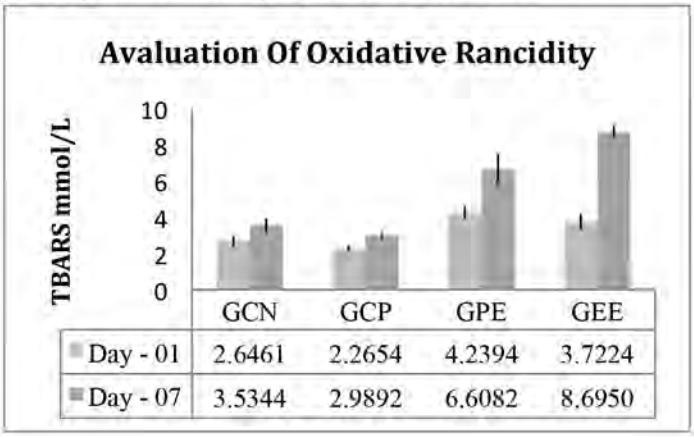
On the evaluation of oxidative rancidity (Figure 01), comparing the others with the control groups, it can be inferred that the spice used as an increment to increase the shelf life of the processed product is possibly inducing and accelerating the process of oxidative rancidity instead of rezudi it, thus causing the rapid damage of the product elaborated, even this being stored in place and the appropriate temperature. The result for the evaluation of oxidative rancidity is worrisome because according to Cluton (1997) and Ferrari (1998) the ingestion of substances produced from the lipoperoxidation process promotes irritation of the intestinal mucosa and tends to cause diarrhea, hepatic degeneration and even death of cells.

(Continued on next page)

Table 1 - Centesimal characterization of stingray of the genus *Potamotrygon*, in nature and the product elaborated from this raw material, both acquired through donations, in the state of Amapá, Eastern Amazon.

Parameter	Product	
	In nature	Elaborate
Humidity (g/100g)	61,80±3,26	79,38±0,60
Mineral waste (g/100g)	02,30±0,29	01,10±0,01
Total lipids (g/100g)	04,11±0,04	1,16±0,11
Total proteins (g/100g)	19,42±1,30	16,52±1,71
Carbohydrates (g/100g)	11,75±1,19	01,55±1,50
Calorific value (Kcal/100g)	164,84±1,87	95,62±9,59

Figure 1 - Results of oxidative rancidity evaluation, for analyzes after 01 day and 7 days, in which the Thiobarbituric Acid Reacted Substances (TBARS), expressed in mmol/L, were quantified in small cakes made from stingrays (*Potamotrygon sp.*), divided into four groups: GCN; GCP; CPE; e GEE.



Thus, it was possible to conclude that the product is easy to prepare and prepare, and can be replicated without many costs, since products have been used that can be easily found in markets and fairs. Results of centesimal composition for *Potamotrygon sp.* where, therefore, these data may serve as a subsidy in nutritional diets for humans, thus allowing an adequate dietary use of the said species.

Regarding oxidative rancidity analyzes, the use of *Eryngium foetidum L.* as a spice in the process of elaboration of fish products should be avoided, in which they will be stored for a long period of time, since this spice may possibly accelerate the oxidation process in the food. There is a warning about the use of spices in the preparation and production of fish-based foods, without previous study of their oxidizing activity. More studies will be carried out, aiming to certify and elucidate the oxidant activity processes of the spice used in this work.

COMBINATIONS OF BROWN SEAWEEDS AS FEED ADDITIVES IMPROVED THERMAL SHOCK RESISTANCE OF *Litopenaeus vannamei* POST-LARVAE

D.D. Schleder*, P.C. Rezende and F.N. Vieira

Instituto Federal Catarinense - Campus Araquari, 280 road, Colégio Agrícola, 89245-000, Araquari, Santa Catarina, Brazil
E-mail: delano.schleder@ifc.edu.br

Introduction

Brown seaweeds have important nutritional and functional properties. These seaweeds show higher antioxidant activity than red and green seaweeds, and have a diverse content of bioactive compounds, such as polysaccharides, terpenes, phenols and polyphenols, minerals, polyunsaturated fatty acids, vitamins, and carotenoids (Balboa et al., 2013; Gómez-Gil et al., 2000). The present work aimed to assess the effect of different combinations of the brown seaweeds *Sargassum filipendula* and *Undaria pinnatifida* as feed additives on growth parameters and thermal shock resistance of Pacific white shrimp post-larvae reared in biofloc system, during nursery phase.

Materials and methods

The experiment was performed at the Marine Shrimp Laboratory (LCM, *Laboratório de Camarões Marinhos*), of the Federal University of Santa Catarina (UFSC, *Universidade Federal de Santa Catarina*, Brazil), using *Litopenaeus vannamei* post-larvae at the stage of 20 days post-hatchery (PL20, ± 0.006 g). PLs20 were stocked in 400 L tanks at 1500 PLs m^{-3}, and the rearing was managed as a superintensive biofloc system for seven weeks (until they reach 1 g), under four treatments: PLs fed diets containing different ratios 0.5%:2%, 0.5%:4%, 1%:2% and 1%:4% of the dry biomass of *S. filipendula* (S):*U. pinnatifida* (U), respectively, and control diet (without addition), all in triplicate. During the experiment, animals were fed six times day^{-1} and the water quality parameters were monitored (temperature, pH and dissolved daily, and total ammonia, nitrite and nitrate once a week). Following the feeding trial, we determined the growth parameters, and subjected the PLs to thermal shock (28.6 °C to 13.5 °C for 1h, and then back to 28 °C).

Results

The water quality parameters remained at acceptable levels for shrimp nursery, as suggested by Van Wyk and Scarpa (1999), and did not differ among the treatments. Growth parameters also did not show any significant differences among the treatments.

On the other hand, PLs fed diets containing the 1S:2U ratio showed higher survival after thermal shock (Table 1.).

Table 1. Survival rate (%) of *Litopenaeus vannamei* post-larvae fed diets containing 0.5%:2%, 0.5%:4%, 1%:2% and 1%:4% of the dry biomass of *S. filipendula* (S):*U. pinnatifida* (U), and the control diet with no supplementation, after 24 hours post-thermal shock .

Treatments	Survival rate (%)
Control	50.0^{a*}
0.5S:2U	44.5^{a}
0.5S:4U	46.7^{a}
1S:2U	73.3^{b}
1S:4U	55.6^{a}

*ANOVA one-way, followed by Tukey test (p=0.0001)

(Continued on next page)

Discussion and conclusion

Many studies have shown that brown seaweeds can affect the resistance of different organisms to thermal stress (Kandasamy et al., 2011, 2014; Schleder et al., 2016). In previous reports, shrimp fed *S. filipendula* did show higher survival after thermal shock (around 97% compared to 43% in the control group), while increasing levels of *U. pinnatifida* had negative effects on thermal shock resistance, with the higher level (4%) causing 100% mortality. The combination of both brown seaweeds in the diets (0.5S:1U, 0.5S:2U and 0.5S:4U) avoided the negative effect of *U. pinnatifida* on the resistance of shrimp juveniles to thermal shock, but the survival remained similar to the control group (around 30%) (Schleder et al., 2016, 2017). Interestingly, in the present work, the combination 1S:2U improved significantly the resistance of shrimp post-larvae to thermal shock.

In conclusion, the combination of *S. filipendula* and *U. pinnatifida* in the diet can improve PLs resistance to acute thermal stress without affecting their growth performance. These results are particularly important for shrimp industry, since after nursery phase shrimp are transferred to grow-out tanks in the shrimp farms, where they face several environmental stresses, such as thermal stress.

BACTERIAL FISH DISEASE MONITORING OF RAINBOW TROUT IN TURKEY: 3 YEARS OBSERVATION OF AEGEAN REGION

E. Dinçtürk*, T. T. Tanrıkul

Izmir Katip Celebi University, Faculty of Fisheries, Department of Fish Disease, 35620 İzmir (Turkey)

Introduction

The fish farming industry in Aegean Region is mainly based on rainbow trout (*Oncorhynchus mykiss*) in Turkey and the production rates have steadily grown every year (TUIK, 2019). It is important to determine new and emerging bacterial fish diseases due to their substantial economic and environmental impacts. Some of the most known diseases were reported over the years such as Lactococcosis (Çağırgan and Tanrıkul, 1995), Vibriosis (Tanrıkul, 2007) and Yersiniosis (Çağırgan ve Yüreklitürk, 1991) in rainbow trout from this region. However, it is substantial to track disease threats and their effects to the area along with containment and eradication of fish disease. For these purposes, 3 years of observation was conducted in the most productive area for rainbow trout farming in Turkey.

Materials and methods

Bacterial fish pathogens were isolated from 10 different rainbow trout farms in Aegean Region of Turkey during 3-year research. The commercial size diseased fish (250-350g) were detected in ponds and moribund fish were transferred to Izmir Katip Celebi University Faculty of Fisheries Fish Disease and Biotechnology Laboratory. Clinical and pathological symptoms were detected after full necropsy. The primer isolation of pathogens was conducted on both TSA (Tryptic Soy Agar, Merck) and proper selective medium based on presumptive identification. The initial identification of pathogens was conducted with using API identification products (BioMérieux, France) then further characterization and identification were performed with amplifying the 16S rRNA gene of the strains. The antibiotic susceptibility of the strains was determined by Kirby-Bauer disk diffusion susceptibility test (Hudzicki, 2009) and considered due to The Standards of Clinical and Laboratory Standarts Institute (CLSI) agains 20 different antimicrobial agents (Oxoid, UK). The Minimum Inhibitory Concentration (MIC) values of the pathogens were also determined with E-test strip (BioMérieux, France) according to EUCAST and Austin and Austin (2007).

Results

The current status of the bacterial fish pathogens was determined during 3-year field research from 10 different rainbow trout farms and the profile of the bacterial fish pathogens are shown in Table I. *Lactococcus garvieae* is the most abundant pathogen with 37.8% ratio among others which is followed by *Yersinia ruckeri* with 32.4%. *Pseudomonas fluorescens* and *Hafnia alvei* are the least common cause of disease and determined only 3 and 2 times during 3 years, respectively. *L.garvieae* strains were not susceptible to 20 different antibacterial disks which were used in the study and many of them were resistant to antibiotics. Also, all pathogens have different MIC parameters to different antibiotics according to the E-test results.

Table I. Isolated bacterial fish pathogens during this research

Pathogen	Number of identified strains	Isolation percentage (%)
A.hydrophila	5	6.8
L.garvieae	28	37.8
P.fluorescens	3	4.1
V.anguillarum	12	16.2
Y.ruckeri	24	32.4
H.alvei	2	2.7
TOTAL	74	100,0

(Continued on next page)

Discussion and conclusion

In the present study, the main cause of bacterial disease of rainbow trout is determined as *L.garvieae*. It was recorded from all the rainbow trout farms during spring and summer months and observed chronic effects of Lactococcosis during the winter period. Generally, the pathogen does not exist in hatcheries, but if the sanitary conditions were not provided properly, it was isolated from even 3g fry with clinical symptoms. Furthermore, the implication being that the vaccines are not effective if fish become infected in the hatchery. The antibiogram and E-test results show that, the pathogen develop resistance to different antibiotics which is well supported by several research (Kubilay et al., 2005; Raissy and Ansari, 2011; Raissy and Moumeni, 2016). Vibriosis usually observed in fish farms which are located in high altitude, besides it was determined only in the winter season from other farms. Yersiniosis was not seen in temperatures below 12 °C and observed above 13 °C from almost every rainbow trout farm. On the other hand, *Hafnia alvei* were mostly confused with *Yersinia ruckeri* based on API 20E identificatio results (Popovic et al., 2007). In this study, *H.alvei* was isolated from 2 different rainbow trout farms which had high stocking density and low water conditions and confirmed with molecular identification. *Vagococcus salmoninarum* was reported in rainbow trout broodstocks from the same region before (Tanrıkul et al., 2014), but it was not observed during 3 years of field research from commercial size fish in this study. It is important to determine the disease profile of a region to detect a proper treatment strategy and prevent antibiotic resistance over time. This study highlights the profile of bacterial diseases in the most productive area for rainbow trout in Turkey.

ESCAPED FARM SALMON AFFECT THE GENETICS OF WILD SALMON (*Salmo salar*) POPULATIONS ALL ALONG THE NORWEGIAN COAST

O.H. Diserud[1]*, K. Hindar[1], S. Karlsson[1], K.A. Glover[2] and Ø. Skaala[2]

[1]Norwegian Institute for Nature Research, Høgskoleringen 9, 7034 Trondheim, Norway
[2]Institute of Marine Research, Nordnesgaten 50, 5218, Bergen, Norway
E-mail: ola.diserud@nina.no

Introduction

The Norwegian Institute for Nature Research and Institute of Marine Research have classified 225 wild Atlantic salmon populations according to the level of genetic introgression from escaped farmed salmon (Diserud et al. 2019). The assignment given by the Norwegian Ministry of Climate and Environment is to classify wild Atlantic salmon populations in terms of "Genetic Integrity" according to the "National Quality Norm for Wild Salmon (*Salmo salar*)".

Material and methods

Genetic introgression from escaped farm salmon has been quantified for more than 40 000 salmon (Diserud et al. 2019). These analyses include only salmon that hatched in the wild, so escaped farm salmon were excluded from the data set, identified by differing growth patterns in their scales. Only populations with a sample of at least 20 individuals from no earlier than year 2000 were included among the final 225 populations.

The genetic introgression is quantified using molecular genetic markers (Karlsson et al. 2011, 2014, 2016; Glover et al. 2013). The genetic integrity of the wild salmon populations is distributed among the four quality classes defined by the Quality Norm:

Green Status very good or good: No genetic introgression observed
Yellow Status moderate: Weak genetic introgression indicated
Orange Status poor: Evidence of moderate genetic changes
Red Status very poor: Evidence of large genetic changes

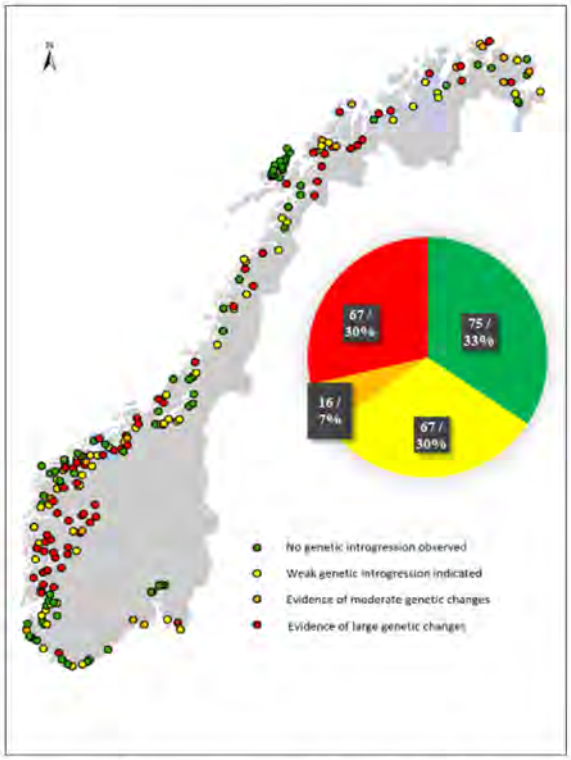

Fig. 1. Genetic introgression of escaped farm salmon into 225 Norwegian wild Atlantic salmon populations.

(Continued on next page)

Results

No genetic introgression was observed in 75 wild salmon populations (33%), weak genetic introgression was indicated in 67 populations (30%), evidence of moderate genetic changes was found in 16 populations (7%), while evidence of large genetic changes was found in 67 populations (30%) (Diserud et al. 2019). The genetic status was classified as very good or good in a third of the populations, as moderate in another third, and as poor or very poor in the last third of the populations (figure 1). The populations with poor or very poor genetic status are more common in western Norway and in Troms county in northern Norway, while the south-eastern parts of Norway have more populations with very good or good genetic status.

Discussion and conclusion

Genetic introgression has been analysed for half of the Norwegian salmon populations, representing more than 94% of the total spawning stock in Norway. The level of introgression in a wild population is significantly associated with the average proportion of escaped farm salmon in the river over the last 25 years (Diserud et al. 2019; Glover et al. 2019). Our approach allows quantification of genetic introgression from the individual level to populations, regions and the national level, and in rivers with and without a historical baseline. The highest average levels of genetic introgression were found in the regions of Norway with the highest aquaculture activity. A large proportion of the variance in the level of introgression could not be explained by proportions of escaped farm salmon though, river properties like water discharge and wild population characteristics like population size or density will also affect the genetic introgression.

To protect the genetic integrity of wild Atlantic salmon populations, only low levels of introgression from escaped farm salmon can be allowed into wild populations. Further introgression is likely, unless substantial reduction of escaped farm salmon in the wild, or sterilization of farm salmon, can be achieved. This is a unique work; no other country has a similar documentation of genetic introgression from escaped farm salmon into wild salmon populations.

STRATEGIES FOR WATER PREPARATION IN A BIOFLOC SYSTEM: EVALUATION OF A CHEMOAUTOTROPHIC, HETEROTROPHIC AND MATURE SYSTEM FOR PACIFIC WHITE SHRIMP REARING

Felipe do N. Vieira[1]*, Frederike Schmachtl[2], Mirko Boegner[2], Ana Clara C. da Silva[1], Vitor F. Silva[1], Walter Q. Seiffert[1], Cláudia Machado, Daniele dos Santos[1], Gabriela S. Ferreira[1]

Introduction

Biofloc technology (BFT) has advantages over traditional shrimp farming systems, such as improved space utilization, reduced water uses and reduced effluent discharge (Bossier and Ekasari, 2017). However, one of the main questions about BFT, is how to achieve a stable system faster, aiming to prevent spikes of nitrogen compounds such as ammonia and nitrite. In BFT the nitrogen compounds can be recycled basically by two pathways: heterotrophic bacteria and chemoautotrophic bacteria (Ebeling et al., 2006). Heterotrophic bacteria require organic carbon sources such as sugar, dextrose, molasses, or other sources as energy, in addition to requiring a (C/N) ratio higher than 10:1. Chemoautotrophic bacteria have slower growth rates and use inorganic carbon instead (Ebeling et al., 2006). When comparing the performance of chemoautotrophic and heterotrophic bacteria to fix 1 g of ammonia in the BFT system, produce a very low bacterial biomass (0.2 g) compared to heterotrophic (8.07 g) (Ebeling et al., 2006). However, the chemoautotrophic bacteria are slow growing, taking about 20 days to appear on the system. The use of chemoautotrophic bacteria in the beginning of BFT systems could then be an interesting strategy in order to avoid the formation of excess sludge and peaks of nitrogen compounds as seen at the beginning of an organic fertilization period. Thus, the objective of this work was to assess different water preparation strategies (heterotrophic, chemoautotrophic and mature) on BFT system for the Pacific white shrimp (*Litopenaeus vannamei*) rearing.

Material and Methods

Pacific white shrimp (*Litopenaeus vannamei*) from the lignage HB16 (Aquatec, Rio Grande do Norte), free of pathogens that require notification of the International Organization of Epizootics, with 3,45g were used on the trial. The experiment evaluated shrimp rearing in different biofloc systems: heterotrophic, chemoautotrophic and mature biofloc. The experiment was randomized with three treatments of four replicates each. It consisted of twelve fibe glass tanks with a volume of 300L of water (0.58 m^2 bottom area), with fou artificial substrates and stocked with 350 shrimp m^{-3}. Shrimp feed (Guabi Potimar 1.6mm – 35% crude protein) was added to the tanks four times a day. For the heterotrophic system, three days before stocking of shrimp, water was fertilized with feed and molasses at carbon/nitrogen ratio (C:N) of 15:1 in order to reach 200 mg L^{-1} of total suspended solids (TSS) at the beginning of the rearing period. During the experiment, the same C:N ratio was maintained. When TAN surpassed 1 mg·L^{-1}, additional carbohydrate (molasses) was added to the system at a ratio of 20g of carbohydrate per each gram of TAN. For the chemoautotrophic system, 30 days before stocking shrimp, water was fertilized with 1 mg L^{-1} of sodium nitrite $NaNO_2$ and 1 mg L^{-1} of ammonium chloride NH_4Cl per day in a bioreactor tank with 400L. The bioreactor tank was equipped with 16 artificial substrates (needlona®), heaters, aeration system and no light. After thirty days, the water of the four experimental tanks was prepared to receive shrimp by adding 100L of water from the bioreactor tank and 200L of seawater. For the mature biofloc system, the experimental units were prepared to receive shrimp by adding 90L (30%) of water from shrimp in the biofloc system (matrix tank) and 210L of seawater. Dissolved oxygen and temperature were monitored twice a day. TAN, nitrite, alkalinity, salinity and pH were monitored three times per week. Nitrate, orthophosphate, TSS, volatile and fixed solids were analyzed once a week. TAN concentration of nitrite, nitrate and orthophosphate was analyzed using the colorimetric method according to the procedure described by Strickland and Parsons (1972). After 35 days, shrimp performance (final weight, weekly growth rate, survival, feed conversion ratio and yield) was evaluated .

(Continued on next page)

Table 1. Shrimp performance of the Pacific white shrimp *L. vannamei* using biofloc with heterotrophic, chemoautotrophic and mature biofloc systems for 35 days stocked at a density of 350 shrimp m^{-3}.

Parameters	Heterotrophic	Mature	Chemoautotrophic
Mean final weight (g)	9.85±0.87[a]	9.81±0.47[a]	9.42±0.83[a]
Growth rate (g $week^{-1}$)	1.28±0.70[a]	1.27±0.44[a]	1.19±0.41[a]
Final biomass (Kg)	942.87±120.21[a]	961.70±51.98[a]	938.87±54.08[a]
Survival (%)	90.9±6.24[a]	93.3±2.57[a]	91.6±3.59[a]
Feed conversion ratio	1.48±0.34[a]	1.64±0.24[a]	1.29±0.04[a]
Yield (Kg m^{-3})	3.14±0.40[a]	3.20±0.17[a]	3.12±0.18[a]

Means ± SD. The different letters indicate significant difference ($p<0.05$) between treatments in the same line by Tukey test.

Results and Discussion

The pH, alkalinity, nitrite and SS were different among treatments in that variables were higher in heterotrophic treatment tanks compared to mature and chemoautotrophic treatment tanks. No significant differences were observed in salinity, nitrate, VSS and FSS concentration among the treatments. Total ammonia and nitrite were higher in heterotrophic treatments tanks. Orthophosphate was lower in chemoautotrophic treatment tanks compared to heterotrophic and mature treatment tanks. This study demonstrated that the stimulation of the nitrification on the water can maintain the nitrogen compounds on the water (ammonia and nitrite) in low levels, avoiding peaks, without the addition of organic carbon sources. No significant differences were observed in the average weight, growth rate, final biomass, survival, feed conversion ratio and yield among treatments (Table 4). Therefore, the growth performance of shrimp was not affected by the different water preparation evaluated.

Conclusion

Mature and chemoautotrophic system controls better the nitrogen compounds on the water, without the use of extra carbon source. Shrimp performance in all systems (mature, chemoautotrophic and heterotrophic) is not affected.

Introduction

The current drive for aquaculture sustainability has pushed feed formulators for the design of novel aquafeeds, where alternative ingredients (e.g. insect products, by-products of fisheries and animal production, and algae-based products) have been prefered in relation to those commonly used up to date (e.g. fish meal, fish oil, soybean meal) due sustainability issues (Oswald et al., 2019). A challenge associated with this transition is ensuring that novel feeds provide all required nutrients, without affecting, and when possible improving, fish farming performance (feed conversion, fish composition, and environmental impacts).

Thus, a nutrient-based model (FEEDNETICS, Silva and Soares, 2018) was applied *a priori* of a nutrition trial with Gilthead seabream (*Sparus aurata*) performed in the framework of the H2020 GAIN project, in order to have a preliminary assessment of the performance of three novel aquafeeds formulations against a traditional diet. The objective of this study was to compare these results with the ones that will be obtained by the nutrition trial with the same feed formulations, in order to evaluate to what extent this model can be used as a decision-support tool in the formulation of novel aquafeeds.

Methods

Four different diets where tested in both the nutritional trial and the virtual trials performed using FEEDNETICS model (calibrated for Gilthead seabream): 1) a control diet containing traditional soy products (CONTROL); 2) a diet rich in processed animal proteins (PAP); 3) a diet with alternative ingredients without the inclusion of PAP (NPAP); and 4) a diet containing a mixture of alternative ingredients (MIXED).This nutritional trial was performed with four replicates, each one with 55 fish with an initial weight of 30g. Each treatment followed a single-dietary regime (i.e. diets abovementioned), under a temperature of 23º±C, during 9 weeks. The results of virtual and nutritional trials were compared, in terms of growth, FCR, fish DHA+E A contents, and total nitrogen excretion (g N/kg biomass gain).

Results

Results after running the model revels that the average body weight tends to be greater in fish fed with MIXED diet and the lower body weight was predicted as being in fish fed with PAP diet (Figure 1). This is consistent with outcomes observed in other parameters such as the lower FCR and N waste predicted for fish fed with MIXED diet (Table 1). On the other hand, percentage of DHA seems to be greater in all formulated diets when compared to CONTROL. However, EPA percentage was higher in CONTROL diets (Table 1).

Discussion and Conclusions

The model suggests that some of the formulated diets for this experiment bring different results in fish performance, nitrogen waste and lipids composition. The model has also shown adaptability in running predictions for diets with different formulations for specific temperatures in gilthead seabream. The results of the virtual vs. actual nutritional trial will be compared, and divergencies will be discussed taken into account differences in digestibility and feed intake of the diets. Results suggest that the use of a modelling tool such as FEEDNETICS can help on the screening of formulated diets before *in vivo* experiments and decrease the number of fish used in aquaculture trials, reducing costs and increasing speed of development of novel aquafeed formulations.

Introduction

Substitution of fish based ingredients may alter the nutritional profile of the feeds, including the vitamins contents, ultimately leading to unbalanced vitamin supply (Hansen et al., 2015). Requirements for several vitamins have been established for species such as carps and salmonids (NRC, 2011), but adequate levels for gilthead sea bream are yet unknown for most vitamins.

Vitamin A is directly involved in preserving the epithelium, cell differentiation and reproduction, and is also required for regeneration of rhodopsin, essential for vision (Halver and Hardy, 2002; NRC, 2011). It also intervenes in chondrocytes development, hence playing a role in skeletogenesis (Lall and Lewis-McCrea, 2007). Therefore, low levels of vitamin A supplementation may cause poor growth and abnormal bone development amongst other symptoms (Halver and Hardy, 2002; NRC, 2011). Besides, in gilthead sea bream excess vitamin A led to changes in bone homeostasis and structure (Fernández et al., 2012).

Vitamin D is mainly involved in Ca homeostasis by regulating Ca uptake and liberation from bone intervening in bone remodelling (Halver and Hardy, 2002; NRC, 2011; Boglione et al., 2013). Fish are unable to synthesise vitamin D and so require absorbing it directly from the diet (Lock et al., 2010). Once it is absorbed deposition takes place mainly in liver, intestine, kidney, spleen, gills, skin and muscle (Lock et al., 2010). Bone mineralization has been used as a biomarker for vitamin D optimum levels (Fleming et al., 2005).

Vitamin K is involved in blood clotting, and inhibiting bone resorption (Halver and Hardy, 2002; Lall and Lewis-McCrea, 2007; NRC, 2011). Deficiency curses with increased blood clotting times, anaemia, haemorrhages and skeletal anomalies (Halver and Hardy, 2002; Roy and Lall, 2007). Skeletal anomalies and bone mineralization have been described as biomarkers for vitamin K requirements (Roy and Lall, 2007).

The essentiality of these vitamins for gilthead sea bream nutrition is evident, thus the aim of these three studies was to evaluate the effect of dietary vitamin A, D and K supplementation in gilthead sea bream growth, productive parameters and health status when fed diets low in FM-FO.

Material and Methods

Three parallel trials were conducted based on a similar plant-based diet (FM 10% and FO 6%) containing five increasing supplementation levels for the different vitamins. Feeds from the vitamin A trial were supplemented with 0.38, 0.75, 1.50, 3.00 and 6.00 mg kg^{-1} retinyl acetate; those from the vitamin D trial contained 0.054, 0.057, 0.060, 0.066 and 0.078 mg kg^{-1} cholecalciferol; while the vitamin K trial included 0.0, 4.9, 9.8, 19.6 and 39.2 mg kg^{-1} menadione. Gilthead sea bream fingerlings, weighing 20.4 ± 1.3 g were distributed into 45 tanks (15 per trial) in triplicate groups per diet and fed until apparent satiation thrice daily for 70 days. Water temperature, oxygen and feed intake were monitored daily. Growth and productive parameters were monitored along the trial and samples for X-ray analyses, bone molecular markers, histology and proximal composition were taken.

Results

At the end of the feeding trials, fish had doubled their weight independent of the diet, and no mortalities were registered. Fish fed vitamin A presented an increase in growth when fed up to 1.50 mg kg^{-1} retinyl acetate. At the end of the trial skeletal anomalies were predominantly found in the anterior region including cranium and pre-haemal vertebrae, especially due to the high prevalence of pre-haemal lordosis. However, the prevalence of pre-haemal lordosis was not directly related to the dietary inclusion of retinyl acetate. Only maxillary anomalies seemed to follow a quadratic regression which appeared to be reduced with increasing levels of dietary retinyl acetate.

(Continued on next page)

Vitamin D supplementation did not produce a significant effect on growth regardless of the different levels. The prevalence of total severe skeletal anomalies, anomalous maxillary and caudal vertebrae seemed to decrease until 0.06mg kg $^{-1}$ cholecalciferol supplementation, while higher supplementation translated in an increase in the prevalence of anomalies.

Only fish fed 19.6 mg kg^{-1} menadione presented an increased growth. The prevalence of severe skeletal anomalies and abnormal caudal vertebrae decreased with increasing dietary menadione up to 19.6 mg kg $^{-1}$ supplementation.

Discussion and conclusions

Overall, the results on growth, analysis of skeleton anomalies and molecular markers denoted the importance of these vitamins on bone development of gilthead sea bream fed diets containing low levels of fish ingredients

Introduction

The current trend in aquaculture production is to shift from the traditional fish to plant based ingredients due to the rising prices and to the competence with other industries. However, the profile of vitamins in the plant based diets tend to be different to traditional fish based feeds, thus requiring vitamin supplementation in order to cover fish requirements. Vitamins are essential micronutrients which cannot be synthetized by the fish, and must be supplied through the diet in order to improve growth and health status. Amongst these B-vitamins are a group of water-soluble vitamins, that include thiamine (vitamin B1), folic acid (vitamin B9) and cobalamin (vitamin B12). These are involved in several metabolic processes, where they act as coenzymes or cofactors.

Thiamin is essential for enzymes involved in energy production, being its cofactor thiamin pyrophosphate. B1 must be constantly supplied in the diet to avoid deficiency signs such as neurological disorders, haemorrhages and congested fins (NRC, 2011).

Folic acid intervenes in blood synthesis and carbon transfer making it essential in the synthesis of amino acids, purines and nucleotides (Halver, 2002; NRC, 2011). Macrocytic normochromic megaloblastic anaemia is, probably, the most characteristic symptom of vitamin B9 deficienc , however other deficiency signs include poor growth, anorexia and dark skin coloration (NRC, 2011).

Cobalamin is an essential vitamin for animals, however certain microorganisms present in the intestinal tract can synthesise trace amounts of this vitamin. It intervenes in hematopoietic processes and is a growth factor. (Halver, 2002; NRC, 2011). Deficiency of this vitamin can lead to abnormal development of erythrocytes, thus leading to megaloblastic anaemia, but also to reduced growth. Other signs are rare, possibly due to the synthesis which takes place by the intestinal microflora (NRC, 2011).

Despite their importance, requirements for these vitamins have not been stablished for gilthead sea bream, and in fact, information regarding their effects on commercial marine species is scarce. Thus, the aim of this study was to evaluate the effects of dietary vitamin B1, 9 and 12 supplementation in gilthead sea bream growth, productive parameters and health status when fed diets low in FM-FO.

Material and Methods

A practical plant-based diet (FM 10% and FO 6%) containing five increasing supplementation levels for vitamin B1, B9 and B12 was formulated (Table 1).

525 gilthead sea bream fingerlings, weighing 12.5 ± 0.27 g (mean ± S.D.) were randomly stocked into 15 tanks, in triplicate groups per diet, and manually fed until apparent satiation four times per day for 9 weeks. Water quality parameters, including temperature and oxygen, and feed intake was recorded daily. Fish performance, in terms of growth and productive parameters (including hepatosomatic HSI, and viscerosomatic VSI indexes) was monitored several times during the experiment. At the end of the trial all the fish were anesthetised, fish were individually weighed and measured, and samples were collected for proximate composition, vitamin content in different tissues, histology, molecular markers and haematology.

Results

Feed acceptance was good in all the treatments, and by the end of the experimental period fish almost tripled their weight. Sporadic mortalities were recorded, although they were limited to one individual in some tanks, thus not being significant. External signs of vitamin deficiency (including changes in behaviour, haemorrhages, loss of equilibrium, anorexia or dark skin coloration) were not observed in the fish.

(Continued on next page)

Table 1. Vitamin B supplementation levels of the experimental diets

	Diet number				
mg kg^{-1}	**1**	**2**	**3**	**4**	**5**
Vitamin B1	0.04	3.10	3.80	5.10	7.80
Vitamin B9	0.06	1.71	3.12	6.00	11.60
Vitamin B12	0.042	0.070	0.140	0.280	0.560

Table 2. Weight, HSI and VSI of gilthead sea bream and liver proximal composition (% dry weight) of gilthead sea bream liver fed increasing contents of vitamin B1, B9 and B12.

Diet	1	2	3	4	5
Weight (g)	42.3±6.2	42.4±5.7	41.1±5.5	42.4±6.0	41.7±5.5
HSI (%)	1.70±0.33	1.56±0.37	1.68±0.32	1.68±0.40	1.43±0.23
VSI (%)	11.0±1.7	9.9±1.3	10.0±1.2	10.0±1.1	10.4±1.6
Lipids (%)	45.0±3.6	44.6±2.9	41.9±2.9	43.5±3.5	48.6±0.6
Protein (%)	32.4±0.4	32.0±2.3	34.0±3.6	32.5±1.5	33.2±0.6

At the end of the experiment there was no significant effect of vitamin supplementation on weight, HSI or VSI or on liver proximal composition (Table 2).

Discussion and conclusions

These preliminary results show that vitamin B1, B9 and B12 supplementation on gilthead sea bream fingerlings is not required to maintain growth during a 9 week period, if fed a practical diet based on plant ingredients. In fact, B vitamin requirements are usually based on growth, survival, absence of deficiency signs, tissue accumulation and metabolic biomarkers (Hansen et al., 2015). According to the first three criteria, it may seem as though sea bream fingerlings do not require additional vitamin B supplementation when fed practical plan-based diets for 9 weeks, nevertheless, vitamin B deficiencies can be more subtle and produce an effect at another analytical level. Further analyses are being conducted to understand these effects.This project has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No 727610 PerformFISH project. Introduction

The environmental impacts of aquaculture wastes should be predicted for sustainable aquaculture when the site and production density are determined. Sustainable Aquaculture Production Assurance Act was established in 1999 to preserve the environment of the aquaculture area. However, the problems of algal blooming and hypoxic waters occur frequently especially in semi-closed bays, resulting in decreasing the production of cultured fish (Zhang and Kitazawa, 2016). The proper density of aquaculture has not been estimated because the reason for water pollution is complex. The pollution is caused by the wastes of cultured fish as well as by the external loading of nutrients. The tool for estimating the carrying capacity of the cultured area is required for sustainable aquaculture. The estimating tool must combine preliminary monitoring and numerical simulation. In the present study, however, a simple index is presented by dimension analysis to discuss the carrying capacity of the aquaculture site.

Materials and methods

An index considers the balance between the rates of waste excretion and water exchange. The local pollution of the seabed and hypoxic water tend to appear in case of shallow waters because the wastes fall directly to the sea bottom. Current velocity is one of the key parameters in a view of horizontal diffusion of wastes. The index can be proposed

$$I = \frac{\rho \cdot d \cdot S \cdot u}{E \cdot d_s} \quad (1)$$

where r (=1,025kg m^{-3}) is the density of seawater, d (m) the mean depth of the aquaculture site, S (m^2) the area of the aquaculture site, u (m s^{-1}) the mean current velocity, E (kg s^{-1}) the rate of waste excretion, and d_s (m) the vertical position at which the waste is produced. The mean depth of the aquaculture site, the area of the aquaculture site, the rate of waste excretion, and the vertical position of waste production are the parameters determined by the aquaculture planning. The mean current velocity is obtained from more than 2-week measurement. Otherwise, the current velocity can be estimated approximately by the equation of small amplitude wave theory for shallow waters.

$$u = \frac{gak}{\sigma}\cos(kx - \sigma t) \quad (2)$$

where g (=9.8m s^{-2}) is the acceleration due to gravity, a (m) the amplitude of tidal waves, k (m^{-1}) the wave number, s (s^{-1}) the angular frequency of tidal waves, x (m) the coordinate in the direction of wave propagation, and t (s) the time. The mean current velocity can be calculated by the integration of the equation (2).

Three aquaculture sites are selected for estimating the index. The information on the aquaculture site, approximate current velocity, and the estimated waste excretion rate are summarized for each site as represented in Table 1.

Results and Discussion

The numerical values of the indices are 78.9, 24.2, and 6.0 x 10^7 for Site A, B, and C, respectively. The indices versus waste excretion rate per square meters, i.e. the density of aquaculture, current velocity, and water depth are represented in Fig. 1. The d and d_s are set as 15m and 5m, respectively, in the left graph, and u and d_s are set as 0.1m s^{-1} and 5m, respectively, in the right graph. Naturally, the index increases with decreasing waste excretion rate, increasing current velocity and

(Continued on next page)

Table 1 Information on aquaculture at three sites.

Parameter	Site A	Site B	Site C
Production	4,500t year^{-1}	2,500t year^{-1}	1,000t year^{-1}
S	1.3 x 10^{6}m^{2}	2.5 x 10^{5}m^{2}	1.3 x 10^{5}m^{2}
u	0.2m s^{-1}	0.1m s^{-1}	0.1m s^{-1}
ρ	1,025kg m^{-3}	1,025kg m^{-3}	1,025kg m^{-3}
E	35,500t year^{-1}	10,000t year^{-1}	14,000t year^{-1}
d	50	15	30
d_s	15	5	15

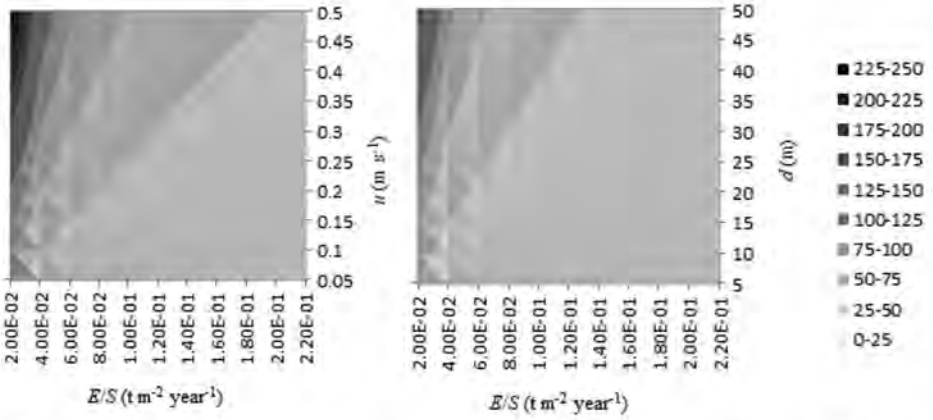

Fig.1 The index versus waste excretion rate per square meters and current velocity (left) and the index versus waste excretion rate per square meters and water depth (right).

water depth, so the aquaculture becomes sustainable if the value of the index is higher. The combination of the different parameters can represent the same value of the index. However, the threshold of the index for sustainable aquaculture cannot be still determined. Before determining the threshold, the accuracy of the index should be improved. For example, the definition of the area of the aquaculture site should be reviewed, whereas the licensed area is given in the present study. The relative importance of the parameters, i.e. the density of production, approximate current velocity, and water depth, should be considered, so each parameter will be weighed by factors. Also, the loadings of nutrients from neighboring aquaculture sites and land are not taken into account. Initial water quality before the installation of the aquaculture site may provide the information on the existing loadings of nutrients in the target area. The observations and the numerical simulation using a hydrodynamic and ecosystem coupled model can increase the accuracy of the index. Finally, the index should be applied to the aquaculture sites as much as possible in order to compare the index and the current environmental situation with each other.

EVALUATION OF BIOACCUMULATION FACTOR (BAF) OF SOME METALLIC ELEMENTS IN ARAS RIVER FISH - EAST AZERBAIJAN PROVINCE

*Mastooreh Doustdar[1], Mahmoud Ramin[2], Arezoo Vahabnejad[3]

1,2,3- Iranian Fisheries Science and Research Institute, Agricultural Research Education and Extension Organization, Tehran, Iran

The Aras River is one of the Border Rivers of Iran which flows 470 km from the border of Azerbaijan, Iran and Armenia to the Caspian Sea. Aras River water is used for domestic, agricultural, industrial and mining purposes. The entry of some environmental pollutants including metallic elements due to the activity of some mines at the margin of the river has contaminated the Aras River and because heavy metals are one of the most important environmental pollutants that cause harmful effects such as growth retardation, behavioral changes, genetic variations and fish mortality. In the present study, the amount of some heavy metals in the Aras River fish was investigated. The survey was conducted from 2015 to 2016 in four seasons at four stations in the Aras River from Jolfa County up to 25 km after the Nurduz border. Fish were captured using the electric fish shocker and cast net. The table below shows the changes in the average amount of bioaccumulation factor of copper, molybdenum, arsenic and mercury in the Aras River fish, and the total length and weight of fish. The bioaccumulation factor of molybdenum had the highest amount as compared to others, whereas the bioaccumulation factor of arsenic had the lowest amount as compared to others.

Among fish species, *Alburnoides bipunctatus* with the lowest total length and weight had the highest amount of bioaccumulation factor of molybdenum as compared to others, whereas *Barbus lacerta* had the highest amount of bioaccumulation factor of copper as compared to others.

FEEDING REQUIREMENTS OF THE TRITONS *Charonia seguenzae* (ARADAS & BENOIT, 1870)

C.K. Doxa[a,b*], A. Sterioti[a,c], and M. Kentouri[b]

Introduction

Aquaculture is commonly considered an alternative for sustaining populations of endangered and intensively exploited aquatic species. In the case of te marine gastropod *Charonia seguenzae* (Aradas & Benoit, 1870), the population declined due to over-fishing for shell trade (Katsanevakis et al., 2008)but still exploited by Man, the present study attempts to gather and review the available scientific information on molluscs of minor commercial importance in order to assist in the adequate management and protection of their populations. Forty one species (18 gastropods, 13 bivalves, and 10 cephalopods and is protected in the Mediterranean Sea (Bern convention, Barcelona convention). Re-establishment of *C. seguenzae* populations in the depleted habitats requires knowledge of its biology and successful maintenance and breeding in captivity.

The diet of *Charonia seguenzae* is highly versatile with a wide range of alternative feeds (Doxa et al., 2012) supplementing natural preys. The knowledge of the feeding requirements of an organism is a prerequisite for the development of diet protocols for successful adaptation and husbandry in captivity with respect to welfare. Information about the optimal diet of an organism can derive from the study of its feeding preferences.

Materials and Methods

Fifteen wild individuals (641.9 ± 83.1g weight, 22.4 ± 1.4cm shell length) were submitted to three trials. For each trial one animal was placed at the center of a cylindrical tank (500L). Tritons were offered four different food types (sea cucumber, *Holothuria polii;* fish, *Boops boops*; squid, *Loligo opalescens;* shrimp, *Penaeus kerathurus*), placed at the circumference of the tank and allowed to consume *ad libidum* the preferred feed/s for 23h. The chemical composition of each food type was analyzed with the methods specified by the A.O.A.C, 1984 A.O.A.C., Official Methods of Analysis. In: S. Williams, Editor, Association of Official Analytical Chemists, Washington (1984), p. 1018.A.O.A.C. (1984). The energy contained in the food was calculated according to Garling and Wilson (1976). Preferred feed/s and food consumption (g) per type was measured and the content of consumed food in organics and energy was calculated.

Results

Sea cucumber was the most consumed feed reaching 80% of the trials (Fig. 1A), followed by fish (73.33%), squid (46.66%) and shrimp (44.44%). Tritons chose to consume more than one feed during 84.44% of the trials, consuming two types at 37.78%, three types at 33.33% and all of the 4 available options at 13.33% of the trials. Sea cucumber was also the feed that was consumed in higher quantity reaching 35.94±6.7g per trial (Fig. 1B) followed by squid (9.68±3.52g), fish (8.71±2.57g) and shrimp (0.96±.17g) with observed differences being statistically significant (Kruskal-Wallis, $p<0.001$). The consumed food content in terms of organics (Fig.1C) and energy content (Fig.1D) was higher when consuming more than one types, however the observed differences were not statistically significant.

(Continued on next page)

Discussion

Tritons showed a clear preference for sea cucumbers. It was the feed that was consumed during most of trials, in higher quantities. This is probably associated with the natural diet of the species that consists at echinoderms (Russo et al., 1990). Despite the high preference for sea cucumbers, tritons chose to consume more than one food types, indicating that sea cucumbers do not entirely cover their feeding requirements. Furthermore, the organics and the energy they acquired when consuming more than one species were higher. Summing up, an appropriate feeding protocol should integrate a variety of food sources including fish and squid to supplement sea cucumbe .

Introduction

The bighead catfish, *C. macrocephalus* is one of the important fresh water culture species in the Mekong Delta of Vietnam because of its high market value and demand due to delicious meat and attractive yellow saffron meat color. For enhancing quality of the juvenile bighead catfish, this study was conducted to determine effects of HK L-137 on growth performance and immune response of the juvenile bighead catfish

Materials and methods

The feeding experiment was included four treatments with iso-nitrogenous (45 % crude protein) and iso-lipid (8 % lipid). The diets were formulated to contain different HK L-137 (It was made by House Wellness Foods Corporation in Itami, Japan) levels of 0 (as control diet), 10, 20, and 50 mg kg^{-1} diet. The feeding experiment was conducted in the 200-L composite tank (filled with 150 L of fresh water) in the recirculating aquaculture system. The juvenile bighead catfish (9.69±0.24 g/ind) were randomly stocked in previously prepared twelve tanks at a stocking density of 150 fish per tank with triplicates per dietary treatment, and were fed the respective diets for 60 days. The bacteria challenge with *Areomonas hydrophila* was conducted continuously at the end of the feeding experiment.

Results

At the end of the feeding experiment, the results showed that the fish was fed the diet at 10, 20, and 50 mg/kg HK L-137 significantly grew faster than control treatment. Similarly, significantly improved protein efficiency ratio, feed conversion ratio, survival rates, and serum lysozyme activity than those in without HK L-137 treatment. Total leukocytes count were significantly improved in fish fed 20 and 50 mg/kg HK L-137 compared to this in without HK L-137 treatment. Apparent digestibility coefficients (ADC) of crude protein and lipid were not significantly different among all treatments; however, ADC of dry matter and ash were higher significant in diet at 10 and 20 mg/kg HK L-137 compared to this in without HK L-137 treatment.

A bacterial challenge test with *A. hydrophila* revealed that the fish was fed the diet at 10, 20, and 50 mg/kg HK L-137 (~50, 100, 250 ppm of LP20) significantly had the lower cumulative mortality than those in control treatment

Discussion and conclusion

From previous studies, it has been suggested that enhanced growth performance of fish fed dietary HK L-137 might be attributed to elevate health status, digestibility, stimulation of gastric development and/or enzymatic secretion (Tovar-Ramirez et al., 2002; Nguyen et al., 2019). In additional, Dawooda (2015) suggested that HK L-137 helped farmed tilapia utilize the test diets efficientl , resulting in improved FER, which would be one reason for the faster growth of fish fed HK L-137. The improved feed utilization may increase the availability of protein and energy from food to be used for fish growth (Zaineldin et al., 2018). This study demonstrated that HK L-137 enhanced non-specific immune defense system of bighead catfish, providing them with higher resistance to with *A. hydrophila,* and better growth performance.

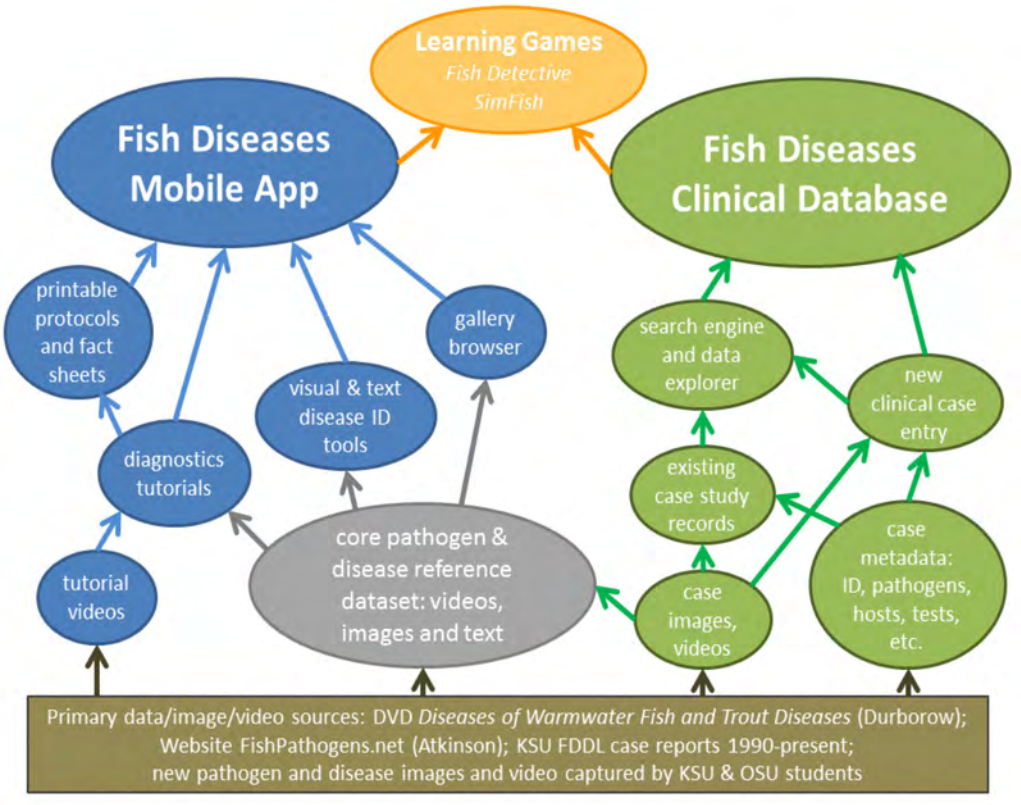
DEVELOPING A CLINICAL DATABASE, MOBILE APPLICATION (APP), AND LEARNING GAMES FOR FISH DISEASE DIAGNOSTICS

R. M. Durborow*and S. D. Atkinson

Aquaculture Research Center
Kentucky State University
Frankfort, KY 40601
E-mail: Robert.Durborow@kysu.edu

Kentucky State University and Oregon State University are developing a mobile application (App) with associated clinical Database and learning games to facilitate identification and treatment of fish disease cases encountered in the field. The clinical Database will enable fish disease diagnostic laboratories to organize disease records to allow for searches and epidemiology work; standardization of the Database among laboratories will facilitate capabilities for regionally coordinated epidemiological work. The App and learning games can be used as teaching tools to aid in fish disease education. The Database will complement the App by using learning machine technology (an artificial intelligence agent) to inform the App on patterns of disease occurrence and treatment efficac . This will aid App users to identify problems they find in the field and decide on treatment recommendations that have the highest likelihood of succeeding. The following flow diagram illustrates the objectives of this US Department of Agriculture funded Extension and teaching project.



DESIGN AND DEVELOPMENT OF RECIRCULATING LIFE-SUPPORT SYSTEM AS AN AMENDED LIVE FISH ROAD TRANSPORTATION FACILITY

S. Dutta* and V. K. Tewari

Department of Agricultural and Food Engineering, Indian Institute of Technology Kharagpur, Kharagpur-721302, India
Email: sdutta@iitkgp.ac.in

Introduction

Live fresh fish is often the most preferred and highly priced form of fish trading and has the largest amount of share for direct human consumption, 45% in 2016, followed by frozen (31%), prepared and preserved (12%) and cured (dried, salted, in brine, fermented smoked) (12%) (FAO, 2018). The main attraction in selling fish live and fresh is the increased return obtained because of their greater market value. Technological developments, improved logistics and increased demand improved the commercialization of live fish. Nevertheless, marketing and transportation of live fish is a challenging task. It involves complicated interaction between fish carrying activities, the environment and human factors as well as they are often subjected to stringent health regulations, quality standards and animal welfare requirements.

Orthodox systems for transporting live fish range from simple artisanal systems of plastic bags with an atmosphere supersaturated with oxygen, to specially designed or modified tanks and containers. All these conventional practices have technical issues and pragmatic research is lacking which identify the need of improvement for the levels of acceptability in all aspects of fish welfare (Ashley, 2007). In many developed countries, live fish transportation has been evolving from traditional methods to more advanced and sophisticated life support systems that regulate temperature, filter and recycle water, and add oxygen (King, 2009).

Design overview of the life support system

Designed life-support systems are typically composed of special purpose built insulated tank fitted with provisions for filtration of tank water to control the critical water quality parameters like temperature, dissolved oxygen (DO) levels, pH, carbon dioxide (CO_2) and ammonia (NH_3) concentrations. Recirculation of water is planned to be achieved by means of a hydraulic ram pump which uses kinetic energy of falling water. The potential energy of tank height holding water will govern the ram pump to recirculate the water through the filtrati n unit. Two water wheel is adequately designed in the path of flowing water in the system to add oxygen in the water. This system is continuous self-functioning and does not require any external energy to filter and recirculate the water during transportation

Conclusion

On-trip functioning life-support device can be a very effective and economic option to provide a continuous quality maintenance system to withstand all the suboptimal condition and shock loading during transportation. This amended transportation facility will also explore the distribution possibilities of fresh live fish to a distant market

Introduction

A measure of the efficiency of converting feed into growth is the feed conversion ratio (FCR), which is the amount of feed consumed per unit of growth. Improved feed efficienc , by improved growth or other means, will reduce production costs and reduce the environmental footprint per unit of product (Besson et al., 2016). Direct genetic selection for improved feed efficiency assumes that both individual growth and individual feed intake can be routinely recorded for a large number of individuals. However, since salmonids are kept in large units and fed communally by dispersing feed into the water, recording of individual feed intake is difficult at current. Individual feed efficiency in fish is, therefore, improved through indirect selection for a larger growth rate (Thodesen et al., 2001). Although growth and feed efficiency are correlated traits, the growth rate does not explain all variation in feed efficienc . Hence, it is time to address new indicator traits potentially more related to feed efficiency than growth in order to improve selective breeding for feed efficienc . The aim of the study was to identify novel indicator traits for the individual metabolic efficiency using stable isotopes to define the phenotypes.

Materials and methods

A 12-day experiment was conducted with 2281 Atlantic salmon parr, from 23 full-sib families that were allocated to 46 family tanks and fed an experimental diet enriched with the stable isotopes ^{15}N and ^{13}C. The fish were pit-tagged with a 2x12mm unique glass tag (RFID Solutions, Hafrsfjord, Norway), and a fin-clip was collected for genotyping. All fish were genotyped using AquaGen's custom Axiom®SNP genotyping array from Thermo Fisher Scientific (San Diego, CA, USA), which contains 56,177 single-nucleotide polymorphisms (SNPs). Muscle tissue samples were analyzed for the stable isotopes ^{15}N (AMN_i) and ^{13}C (AMC_i), and these were used to obtain individual indicator phenotypes for the metabolic efficiency (IFCR); and , defined as follows (takin ^{15}N as an example):

$$IFCR\_AMN_i = \frac{FW_i * APE_{Ni}}{FW_i - IW_i},$$

where FW_i and IW_i are final and initial weights of individual i, and is the excess atom percentage ^{15}N in muscle for individual i adjusted for the initial atom percentage (IA%) in the muscle tissue. The IFCR is a ratio of the "metabolic costs" (synthesis allocated to growth and replacement of nutrients) to total body growth, within the same time period. In addition, feed conversion ratio was recorded on a tank level (). Bivariate genetic analyses were conducted between and tank averages of $\overline{IFCR\_AMN}$ and $\overline{IFCR\_AMC}$.

Results and discussion

The metabolic efficiency is a major determinant in the conversion of feed into growth. Consequently, minimizing the energetic cost of maintenance is a strategic goal to obtain fish with enhanced growth and improved feed efficienc . Using feed enriched with certain isotopes (i.e., with altered ratios of ^{14}N/^{15}N and/or ^{13}C/^{12}C) and monitoring the subsequent rate of change in isotope profile in various tissues, the relative contribution of the nutrients to protein growth can be assessed (Le Vay & Gamboa-Delgado, 2011). After a dietary switch, the IFCR variables for nitrogen and carbon in the muscle are expected to be proportional to the mass of newly deposited nutrients in muscle and, as such, relate directly to the efficiency complex. Because the ratio is expected to be proportional to the amount of newly deposited body nutrients per g increase in body weight, fish that exchange a larger fraction of the body mass per unit of growth will be less feed-efficient. Efficient fish should be characterized by a low ratio between total synthesis (to replace degraded nutrients and synthesis of new tissue) and growth, i.e., as much as possible of the synthesis should be allocated to growth and as little as possible to replace

(Continued on next page)

degraded nutrients. The estimated genetic correlation between and was very high, to the extent that the estimate was fixed at the border of the parameter space (~ 1.0) for both nitrogen and carbon metabolism in muscle. The corresponding phenotypic (tank-level) correlations were 0.72 and 0.58, respectively. These results indicate that the mass of new nutrients in the muscle is closely genetically associated with FCR at the tank level. Since IFCR can be measured in individual fish, it is a promising indicator trait for individual feed efficienc . However, the heritability estimates of IFCR for both carbon and nitrogen were low (0.06 to 0.09). The indicator ratio traits, IFCR, are intuitively appealing and can easily be interpreted biologically. The IFCR variable allows for direct measurement of carbon and nitrogen fluxes by using stable-isotope profiling to trace the contribution and allocation of nutrients from feed to growth in animal tissue (Barreto-Curiel et al., 2018), and it is expected to have a universal relationship with FCR and could be of use independent of life-stage and species.

For complete results see Dvergedal et al. (2019).

Conclusion

Our findings show that the use of indicator ratio traits to assess individual feed efficiency in Atlantic salmon have great prospects in selection programs. Given that large quantities of feeds with contrasting isotope profiles of carbon and/or nitrogen can be produced cost-effectively, the use of stable isotopes to monitor nitrogen and carbon metabolism in various tissues have potential for large-scale recording of individual feed efficiency traits, without the requirement of recording individual feed intake.

Introduction

Today the majority of aquaculture production is done in land-based flow-through or pond systems, marine cages or recirculating aquaculture systems (RAS), with a range of production costs and environmental impacts. The increasing demand for fish has resulted in more costly, intensive aquaculture solutions with increasing sizes in rearing environments on land (RAS), coastal (semi-closed containment systems) and off-shore systems. This leads to new challenges to contain stress and maintain fish health and welfare in these production systems. Reducing stress will reduce its deleterious effects on fish behaviour, development and growth, feeding yield, reproduction, and immune function, improving overall health and welfare (Ebbesson and Braithwaite 2012). Some of the key preventative measures to maintain healthy populations is 1) to monitor the environmental and biological dynamics and limits in the systems through real-time monitoring, 2) the use of quality feeds with proper nutritional value, including functional additives to boost the immune system, reduce stress and aggression, and welfare, if needed (Sutili et al 2017).

Summary

The EU-funded iFishIENCi innovation action is bringing together 16 partners in a trans-disciplinary effort towards making genuine improvements to fish farming worldwide. Fish aquaculture is essential for providing healthy food to a growing world population, but its success depends upon our ability to find more sustainable farming practices. This means more effective ways of monitoring fish-health and welfare, as well as more efficient ways of feeding fish that reduce pressure upon the present sources of fish-feed ingredients, such as agricultural crops and wild-caught fish for fishmeal and oil. The ambition of iFishIENCi is developing and demonstrating disruptive IoT/AI based innovations, considering the feeding value chain as a whole, and addressing four commercially-important species (salmon, rainbow trout, sea bass and African catfish), with consumers demand as focus.

iFishIENCi aims to deliver breakthrough innovations supporting sustainable aquaculture, based on enabling technologies and circular principles, thereby providing the European aquaculture industry with the competitive advantage and growth stimulation needed to be a mover in revolutionizing global efficiency in fish production and meet society's needs for food from the ocean. This ambitious task will be achieved by providing to the market a flexible iFishIENCi Biology Online Steering System (iBOSS) that significantly improves production control and management for all fish aquaculture systems. iBOSS will maximise feed utilisation through smart feeding, provide continuous monitoring of fish behaviour, health and welfare and reduce response times to aberrations. iFishIENCi will target circular principles and zero waste by qualifying new and sustainable organic value chains for feeds, and valorisation of by-products. iFishIENCi´s innovations will provide important new assets to the consortiums SMEs, fish-farmers, feed producers and technology providers in the aquaculture sector, leading to market growth and job creation. Assets will be maximized through comprehensive sustainability assessments and engagements with the sector, regulators and consumers.

The overall strategy of iFishIENCi is to set a world standard on digital aquaculture: (1) by setting "the fish" at the heart of the decision-making in fish production, through joining forces between experts in fish and fish-farming and experts in digitization, IoT and AI; (2) by selecting the most promising emerging technologies on smart monitoring and control system, and pushing them forward through targeted development and integration; (3) by demonstrating the value of new and sustainable feed sources, contributing to the consolidation of a circular and blue bioeconomy; and (4) by proposing optimal value-chain for valorisation of waste from fish farming. To reach its ambition of improved competitiveness of the European aquaculture and greener society, iFishIENCi is built around five innovation pillars leading to four main products (Figure 1).

The iFishIENCi project is funded by European Union's Horizon 2020 Research and Innovation Program under grant agreement No. 818036.

STUDY OF THE EVOLUTION OF MICROORGANISMS COMMUNITIES IN AN AQUAPONIC SYSTEM OVER THE COURSE OF A FULL LETTUCE GROWTH CYCLE

M. Eck*, I. Szekely, S. Massart and M. H. Jijakli

Integrated and Urban Plant Pathology Laboratory, University of Liège, Passage des Déportés 2, B-5030 Gembloux (Belgium)
E-mail: mathilde.eck@uliege.be

Introduction

Aquaponics is a combination of recirculating aquaculture and hydroponics techniques that enables the recycling of the nutrient-enriched aquaculture effluents whilst at the same time avoiding the use of mineral fertilisers for the growth of plants. Aquaponics is also a system based on a fragile equilibrium between 3 groups of living organisms i.e. fish, plants and microorganisms. Except for the nitrification process, little is currently known on the roles and properties of these microorganisms and even less when it comes to the bacteria and fungi which may be involved in plant beneficial interactions. The nitrification process is crucial in aquaculture and has therefore been studied in depth. The principal bacteria involved in the transformation of ammonia to nitrite are *Nitrosococcus*, *Nitrosospira* and *Nitrosomonas* while the bacteria responsible for the conversion of nitrite to nitrate are *Nitrobacter*, *Nitrospira* (Rurangwa and Verdegem, 2015), *Nitrococcus* and *Nitrospina* (Itoi et al., 2007). The aim of this work is thus to thoroughly study the microorganisms communities harboured by the closed-loop aquaponic system of Gembloux Agro-Bio Tech throughout a full lettuce cycle, in real conditions. To this end, high throughput sequencing is used to sequence microorganisms' DNA and bioinformatics tools are then used to assign taxonomic identification. Gaining a better understanding of the role of microorganisms in aquaponics could help foster the development of more viable and productive systems.

Material and methods

A first experiment was conducted between the 5th and 19th of May 2017 in the PAFF Box aquaponic system (Delaide et al., 2017) in Gembloux Agro-Bio Tech, which was at the moment hosting a variety of plants in the greenhouse compartment and Nile tilapias (*Oreochromis niloticus*) in the tank compartment. One sump sample and one biofilter sample per week were collected in the system. Bacterial DNA was then extracted from the samples and the 16S rRNA gene was sent for Illumina sequencing. The aim of this first trial was to gain a first insight of the evolution of the bacterial communities in our aquaponic system. To obtain a more in depth view, a second experiment was launched in 2019. 90 lettuces (*Lactuca sativa* var. Lucrecia) were sown on the 27.02.19 in rockwool plugs and were then transferred in the floating raft compartment of the PAFF Box (Delaide et al., 2017) aquaponic system on the 11.03.19. The system was at the moment hosting 34 Nile Tilapias (*Oreochromis niloticus*). Microbiota samples were collected twice per week during the first three weeks and then once per week during the last three weeks. Samples were harvested from the sump, the biofilte , the roots' rhizoplane and the roots' endosphere. DNA was then extracted with the FAST DNA Spin Kit (Mp, Biomedicals) and is currently being sequenced on an Illumina MiSeq machine. Data will be analyzed with the QIIME 1.9.1 program (Caporaso et al., 2010).

Results and discussion

The results of the first experiment showed that there seemed to be different communities harboured in the sump and in the biofilter with the biofilter community being significantly more diverse. No significant difference was observed in any community over the course of the three weeks.

Results from the second experiment are now awaited to answer our new hypotheses:

- Can we observe changes in the composition of the microbial communities when the aquaponic system is relaunched after the winter break?
- Do the bacterial AND fungal communities evolve over the course of a complete lettuce cycle of 6 weeks?
- What is the composition and the evolution of the microbial community present on the lettuces' roots?

USE OF COPPER ALLOY MESH IN MEDITERRANEAN MARINE AQUACULTURE

P.A. Efstathiou*, E. Kouskouni, P. Karlovasiti, Z. Manolidou, A.P. Efstathiou

Biopathology Laboratory, Aretaieion Hospital of the Medical School of the National and Kapodistrian University of Athens
E-mail: panosefstathiou@usa.net

Introduction

Biofouling is a major problem in marine aquaculture with significant production impacts (Braithwaite & McEvoy 2005; Fitridge et al. 2012; Floerl et al. 2016). Nets made from nylon are susceptible to biofouling and require frequent maintenance with high costs. The use of copper alloy nets in aquaculture brings a promising solution to this problem (Chambers et al. 2012). In the present study, that was conducted for the first time in Greece, we demonstrate the comparative results between fish s microbial flora, length, weight and mortality being cultured in conventional net cage and those being raised in brass UR30® net cage. The wire UR30® is environmentally friendly, antifouling, has anti-microbiological properties, durability, is corrosion resistant and 100% recyclable.

Materials and methods

As part of the research process, two fish cages were used in Kefalonia Fisheries where the species *Sparus aurata* (Linnaeus, 1758) (sea bream) was cultured. The cage A-249 was made of copper UR30® mesh whereas the cage B-228 was constructed of nylon mesh. Video recordings of fish and algae growth were conducted with a camera GHOST-S, HD DRIFT at various stages in both cages. Seven samplings of 10 random fish from each cage took place between December 2014 and November 2015. The somatometric characteristics of fish (weight, length) were measured. For the microbiological research of fish, samples of the oral cavities, the gills and blood were examined. The evaluation of the microbial flora of fish tissue samples took place at the Biopathology Laboratory of the Medical School of the National and Kapodistrian University of Athens by using 5 different culture media (Blood Agar, Mac Konkey Agar, Chapman Agar, Sabouraud Agar, and SS Agar). The identification of the strains was made by the automated system VITEK2 of Biomérieux Company.

Results

No biofouling was recorded in the copper net cage A-249 in contrast to nylon cage B-228 during the study period (Photo 1). The fish in the copper alloy mesh cage demonstrated increased mobility. The weight and length measurements of the tested fish are shown on Figure 1. The fish from the copper alloy cage were of greater length and weight compared to those raised in the nylon cage.

The microbiological examination showed that the microbiological flora (*Aeromonas* spp, *Vibrio* spp, *Pantoea* spp., *Brevudimonas* spp., *Sphingomonas* spp., etc.) of fish from both cages (A-249 and B-228) ranged in normal levels (Figure 2). However it was clear that the samples from the gills and the mouth of fish coming from the copper cage showed lower microbe values compared to those of the nylon cage. No microbial growth was recorded in the blood of fish from either cages.

Discussion and conclusion

The increased mobility of the fish in the copper alloy mesh cage is an indicator of good health in fish, which was also confirmed by the reduced mortality in copper alloy net cage, in relation to that of the nylon cage. The greater length and weight of the fish from the copper alloy cage can potentially reduce the harvest time, leading to multiple economic benefits for aquaculture. The absence of biofouling from the copper cage can increase the oxygen levels in the cage and reduce the microbial load of the fish. Thus, the fish health is promoted and the operational costs associated with net cleaning are decreasing. Therefore the use of copper alloy nets can contribute to a sustainable aquaculture. Further long-term studies will reveal the impacts of copper netting in aquaculture.

Fishmeal, once a major component in aquafeeds, especially for carnivorous species, is now becoming an unsustainable ingredient. Efforts to replace fishmeal with alternative nutrient sources, such as plant proteins, are on-going but research has found that fish growth and health are often negatively affected. Fish protein hydrolysates (FPH) are supplemental ingredients that have been shown to have some positive effects on the health and growth in aquaculture species previously. This study investigated the effects of feeding an 80% plant protein diet, with and without FPH supplementation, on the growth and gut health of Atlantic salmon parr. A feeding trial was conducted with four different diets over a 12 week period. At the end of the trial it was found that fish on the plant protein diet grew significantly less than fish on the other diets. However, supplementing this diet with a partly hydrolysed fish protein allowed fish to grow as well as fish fed a traditional 35% fishmeal control diet. Blood amino acid results suggest that the fish hydrolysate supplements provided more bioavailable amino acids that were easily absorbed. In particular, fis on the PHP diet had significantly higher levels of blood essential amino acids. Furthermore, dietary protein source was found to have a significant effect on fish gut microbiota in terms of α– and β-diversity. This study has shown that Atlantic salmon parr can grow successfully on a very high (> 80%) plant protein diet when it is supplemented with a small quantity of high quality FPH.

EFFECT OF MAGNETIZED WATER ON THE GROWTH PERFORMANCE AND OXIDATIVE STATUS OF NILE TILAPIA (*Orechromis niloticus*)

Gehad Eisa*[1], Mohamed F. Farouk[1], Elbanna Ramadan[1], Ahmed Elashram[2]

*Presenting author
[1] Faculty of Veterinary Medicine, Cairo University, Department of Nutrition and Clinical Nutrition, Giza Square, Giza, Egypt
[2] Suez Canal University, Fish disease and hygiene department, Suez governorate, Egypt

Introduction

Improving the efficiency of aquaculture could be achieved not only through the proper nutritional program but also through improving the ecological system, one method for improving the aquaculture system is Magnetism. Magnetic water is produced when water is exposed to magnetic field, which could affect fish growth performance parameters Cho and Lee (2005).

Therefore, we hypothesis that use of magnetized water could improve the growth performance of Nile tilapia.

Materials and methods

A total of 180 Nile Tilapia (*Oreochromis niloticus*) fingerlings weighing (11.7± 8.25) g were randomly allotted into two groups each has 6 replicates (15 fingerlings/ replicate). Fingerlings were reared in glass aquaria, the first group was supplied with clean de-chlorinated water (**CON**). The fish in the second group were reared in magnetized water (**MAG**). Magnetizing the water was achieved by water magnetizer that fixed at the main water source, the aquaria in the two groups were supplied with air pumping and filtration system applied. Fish in the two groups were fed the same commercial pelleted isocaloric, isonitrogenous basal diets that were prepared to cover the nutrient requirements of Nile Tilapia fingerlings according to NRC feeding standards (2011). The experiment lasted for 3 months after 2 weeks which served as acclimatization period during which the suitable feeding regime were suggested to be (4% of fish biomass). Body weight was recorded biweekly and at the end of experiment blood samples were collected for serum separation. Serum samples were used to analyze the MDA (malondialdehyde), glutathione, and glutathione peroxidase calorimetrically, data were statistically analyzed using Minitap software (REF)

Results and Discussion

Fish reared in magnetized water show enhancement in growth performance parameters. Body weight gain was significantly increased ($P < 0.05$), where it was 26.63 (±0.42) g in MAG and 23.76 (±0.42) g in CON group, our findings are similar to REF. The oxidative stress biomarkers were affected by magnetizing the water. The oxidative stress biomarkers are presented in Table I. MDA was significantly decreased, while, Glutathione and Glutathione reductase were significantly increased in MAG group compared to CON group.

Conclusion

It could be concluded that the use of magnetized water under intensive fish farming condition was advantageous as it has the ability to improve fish growth performance and minimize the oxidative stress

Introduction

In European aquaculture, Eurasian perch, Perca fluviatilis L., is perceived as one of the most highly valuable freshwater fish species and a strong candidate for the development of freshwater aquaculture. In the pursuit of improving the quality of reproduction in this domesticated species, investigating the hormones mediating the follicle oocyte maturation (FOM) is therefore indispensable. Up to date, 17α,20β-dihydroxy-4-pregnen-3-one (DHP) was postulated to be a possible MIS in Eurasian perch according to previous studies investigating the seasonal variations of this steroid in the blood. Using in vitro follicle incubations, this hypothesis was suggested to be true in a very close species to Eurasian perch, namely the Yellow perch. In other perciforms, THP or 20β-S (17,20β,21-trihydroxy-4-pregnen-3-one), was also recorded to be the possible MIS. However, some corticosteroids have shown a peak in their concentrations which synchronised with the peri-ovulatory period in some percids. This latter finding could signify the existence of a crucial role for these corticosteroids in the final stages of percid oogenesis.

Material and Methods and Results

Therefore, to further validate the existence in Eurasian perch of a maturation inducing activity behind the mentioned steroids, we tested in vitro a group of eight steroids namely, estradiol-17β (E2), testosterone, and the four main corticosteroids: cortisol, 11-deoxycortisol, corticosterone, and 11-deoxycorticosterone (DOC), in addition to the previously mentioned progestagens DHP and THP. The experiment was divided into two parts; in the first one, we tested all the mentioned steroids except for THP at three different doses on oocytes at the start of the FOM from sexually mature female perch. The cells were in-vitro incubated during 52 hours in Cortland media with and without the incorporation of human chorionic gonadotrophin (hCG) as an additional attempt to investigate the importance of hCG incorporation in such in vitro biological assays. This part of the experiment revealed that DHP was the only hormone showing to be a prominent MIS (with and without hCG) with highest proportion of GVBD and ovulation at the end of the hormonal exposures. On the other hand, hCG incorporation with the hormones showed to be of no significant importance. DHP was thereafter tested in the second part of this experiment in parallel with THP. Both progestagens were tested at five different doses on the oocytes of six other sexually mature female perch at the initial stage of FOM.

Conclusion

The results suggest that both DHP and THP trigger progress in FOM even at low doses in vitro and that progestagens are more credible candidates than the corticosteroids to be considered as the MIS in the Eurasian perch. Hence, the results of this experiment strongly show that both THP and DHP inductions should be taken into account when investigating the hormonal mediation of FOM and ovulation in Eurasian perch.

SITING GUIDELINES, MONITORING STANDARDS, AND ENVIRONMENTAL MODELS FOR COASTAL FINFISH AQUACULTURE

Najat El Moutchou[1]*, Lisa Wickliffe[1], Barry King[1], Jennica Hawkins[1], Trevor Carpenter[2], and James A. Morris, Jr[1]

*najatelmoutchou@gmail.com

The growth of strong coastal aquaculture industry in Morocco is expected in the near future given the national strategy, available suitable marine space, investor interests, and proximity to high demand seafood markets. Governments have made decisive efforts to increase their management capacities by implementing science-based strategies to monitor and control aquaculture's effects on the environment.

An aquaculture alliance was created between the National Oceanic and Atmospheric Administration (NOAA), Morocco's Department of Marine Fisheries (DPM), and National Aquaculture Development Agency (ANDA) with support from the U.S. Department of State to develop comprehensive guidelines for sustainable marine aquaculture.

Three written guidelines were developed, focused on siting, modeling, and environmental monitoring of marine finfis aquaculture along the Mediterranean and Atlantic coasts of Morocco, applying the most current management frameworks and tools available.

This scientific guidance is intended to assist the government agencies, coastal managers, industry, and scientists to make appropriate management decisions for the current industry as well as future development. Accomplishing the goals set forth in this guidance will encourage investment in the Moroccan green economy, promising international competitiveness and completion of the national strategy and challenging the aquaculture industry toward sustainability.

HIGH RESOLUTION COPERNICUS-BASED INFORMATION SERVICES AT SEA FOR AQUACULTURE**

The increasing availability of data and technological advancements, such as the combination of Earth Observation and numerical model outputs, have been contributing to today's capability of better understanding the coastal environment and providing improved forecasts of future conditions.

Improved management of marine resources, with the assistance of forecast tools, is likely to enhance industry resilience and adaptive capacity under climate change. Among others, fishery and aquaculture activities are strongly influenced by environmental conditions and therefore can benefit from short-term forecasts of water quality. Short-term environmental fluctuations, including sea water temperature, chlorophyll concentration and turbidity, wind velocity and persistence, and current velocity, combined with long-term climate-related trends, can indeed impact growth rates of cultured animals and wild stock habitat distributions.

To this end, Earth Observation and models have proved to be complementary and effective to develop forecast tools. However, the accuracy and spatial resolution of the data play a crucial role in representing physical, chemical and biological processes. The EU funded HiSea project aims at tackling these issues by delivering accurate and reliable information, readily available, easily understandable and with a high resolution to fit seamlessly users' operation, planning and management requirements. The HiSea services will integrate high resolution Copernicus Services Products, such as Copernicus Marine Environment Monitoring Service (CMEMS) products, local monitoring data and advanced numerical modelling. The services offered as the end product will be based on the harmonization of different types of data and the added value is in their fusion and merging including estimates of the uncertainties and including data provided by the users/citiziens.

This allows improving operation, planning and management of different marine activities in aquaculture sectors. Such information services include among others early warning services, real-time crisis management, key performance indicators, information for planning operations, and a knowledge data base.

**This project has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No 720815.

QUANTIFYING METHIONINE REQUIREMENT OF AFRICAN CATFISH (*Clarias gariepinus*) USING A PLANT-BASED DIET

F. E. Elesho[1*], J.A.J. Verreth[1], D.A.H. Sutter [2], S. Kröckel[2], J.W. Schrama[1]

Introduction

The increasingly use of plant ingredients to replace high cost fishmeal has motivated fish nutritionist to investigate the amino acid (AA) profile and their individual requirements in commonly cultured species (Rotili et al., 2018). Problems associated with the use of plant ingredients include the presence of anti-nutritional factors (NRC, 1993) and AA deficiencies (Cai & Burtle, 1996). Methionine is the first limiting AA in most leguminous plants (Ovie & Eze, 2010). It is a sulphur-containing essential amino acid that is required for the synthesis of cysteine in animal and humans (Niu et al., 2013). Methionine is an initiation codon required during protein synthesis for protein formation (Rotili et al., 2018). Inclusion levels of methionine below the requirements may cause growth reduction and decrease feed efficiency in fish (Harding et al., 1977). Therefore, adequate supply of methionine is essential in fish diets. Methionine requirements have been determined for several fish species, however, no reliable information is currently available for African catfish (*Clarias gariepinus*). Few studies (Fagbenro, Balogun, & Fasakin, 1999) conducted on methionine requirement of African catfish used purified ingredients as intact protein. Therefore, the goal of this study was to determine the methionine requirements of African catfish. It was hypothesized that AA utilization and protein retention can be improved by supplementing diets with appropriate levels of crystalline AA. This experiment was aimed at establishing the minimum level at which the supply of methionine results in maximum growth.

Materials & methods

A 7-week experiment was conducted to estimate the dietary methionine requirement of juvenile African catfish (initial weight 78 g), reared in a recirculation aquaculture system. A low-methionine (plant-based) diet was formulated using soy protein concentrate and faba beans as intact protein. Based on the methionine requirements for other species, which was obtained from literature (NRC, 2011), 7 diets were formulated, which all had the same basal composition but supplemented with different amount of crystalline DL-methionine: 0, 0.12, 0.24, 0.36, 0.48, 0.60, and 0.84%. At the start of the experiment, fish were weighed for initial body weight and randomly distributed among 21 aquaria (40 fish aquarium^{-1}). Experimental tanks were randomly assigned to each of seven diets with three replicates per diet. Fish were fed restrictively twice a day at 90% satiation. Apparent digestibility coefficient (ADC) of nutrients were measured by using settling tanks connected to the outlet of the aquaria in which African catfish are housed. The body composition of the fish were analysed both at the start and end of the experiment to determine the amino acid deposition, energy and nitrogen balance. At the end of the experiment, fish were weighed to determine the final body weight. Broken-line regression analysis (Robbins et al., 1979) was used to determine the quantitative methionine requirement by estimating the break-point for retained nitrogen and growth.

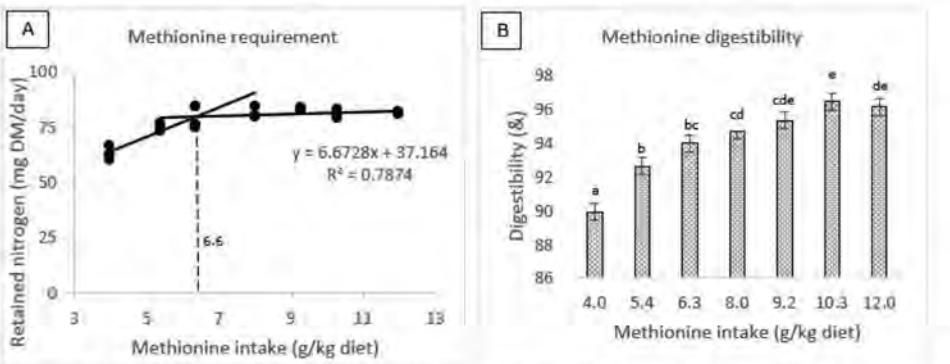

Figure 1: (A) Relationship between retained nitrogen and methionine intake and (b) apparent digestibility coefficient of methionine in African catfish fed diets containing different levels of crystalline methionine. Treatments sharing a common letter are not significantly different ($p<0.05$).

(Continued on next page)

Results

There were no significant difference in the ADC of protein among dietary treatments. Whereas, methionine digestibility increased with increase inclusion levels. Dietary methionine supplementation had a significant effect on branchial and urinary losses, retained nitrogen and protein efficiency (p-value<0.001). Increasing crystalline methionine significantly increased nitrogen retention up to 0.24% inclusion level, after which it remained before it declined at 0.84% methionine level. The mean weight gain values showed a slight increase in weight of fish as dietary methionine supplied (12-36g/kg protein) increases, which eventually levels up at the inflection point (requirement) then declined at higher inclusion level. The breakpoint of the growth response curve occurred at 6.55 g methionine /kg diet. The reported methionine requirement value in this study can be used to formulate least cost- diets using plants ingredients for production of African catfish

Introduction

Fish welfare is an important issue within aquaculture, not only for the health and well-being of stock but also for the sustainability and profitability of farms. To monitor the effect of husbandry procedures or the outcome of research designed to improve welfare, methods to assess fish welfare are required. These methods should be reliable, rapid, economical, easy to apply and preferably not require extensive training or expensive equipment. Experienced fish farmers can look at their stock and just know whether there are welfare issues evident within that tank or pond. They do this intuitively by observing the way fish interact with each other, how they move, how they feed, how they use the environment. It is not necessarily *what* the animal is doing but *how* it is doing it, which is often referred to as 'body language' or more scientifically as 'behavioural expression' (Wemelsfelder et al. 2012). Body language can therefore be used to infer an animal's physical or physiological state but potentially also its psychological (emotional or affective) state. In doing so this can give us insight into both negative and positive indicators of the welfare status of the animal.Qualitative Behavioural Assessment (QBA) is a scientific method for assessing the subjective experience of animals through the expressive qualities of behaviour. QBA is used extensively in the social sciences and is increasingly being applied in animal welfare science, where it bridges the gap between subjective judgements and scientific measurement approaches (Wemelsfelder, 2007). QBA uses a selective list of terms to describe qualitative behavioural expressions (e.g. tense, relaxed, calm, agitated). Observers use this list while viewing live animals or retrospectively using videos and assign a score based on how intensively they felt a particular expressive quality was evident. The scores are then used for statistical analysis. QBA has been validated as a welfare assessment tool for terrestrial animals and has been incorporated into EU Animal Welfare Assessment schemes for pigs, poultry and cattle. However, QBA has not yet been applied to fish, therefore this study seeks to evaluate whether QBA has potential for use as a welfare monitoring tool in fish

Material and Methods

Video footage, 17mins in duration, was recorded in 20 tanks at a commercial Atlantic salmon (*Salmo salar*) fish farm located in North-West Scotland. Ten tanks had environmental enrichment in the form of plastic strips to represent artificial kelp, while the remaining tanks had the standard production environment.

Fixed List Term generation
From the video footage, twelve short videos (45secs to 1min) were generated that showed a range of overt and contrasting behaviour such as darting, drifting, interacting with conspecifics or artificial kelp. The aim was to generate video clips that represented a number of expressive states, ranging from high to low valence and arousal. Experienced fish farmers viewed the clips and generated a number of terms to describe the behaviour. During a group discussion the preferred terms, considered most relevant in describing fish body language, were agreed and behaviours not evident in the videos added. The literature on fish emotion was also scrutinised to determine if any significant expressive terms were overlooked. This resulted in a list of twenty qualitative descriptors arranged in a fixed list to be used in subsequent QB sessions.

Qualitative Behaviour Assessment Sessions
A group of observers viewed 25 video clips, 1min in duration, created from the original footage. The video clips displayed contrasting expressive qualities and although the enrichment was visible in some clips it was not expressly selected for in this session. The observers were provided with a scoring sheet for each video clip. Each scoring sheet had the fixed list of twenty descriptor terms and each term had a 125mm horizontal line to be used as a visual analogue scale (VAS). For each video clip observers were instructed to make a single vertical line along the VAS, corresponding with how intensively they felt a particular expressive quality was evident in that clip and that all elements in the fixed list should be scored. Scoring was measured by the length of the vertical mark along the horizontal line. For intra-observer reliability a second session was held with the same observers and same video clips (in a different order) ten days later.

(Continued on next page)

A separate QBA session was held with different observers to determine whether there was a detectable difference in behaviours between tanks with and without enrichment. Twenty video clips (45 secs duration) were created from the original footage. Clips were selected for enrichment type although observers were unaware of the different enrichment. Expressive qualities were not selected for in this session. The same fixed list of descriptors was used and instructions for scoring was the same as previous session.

Quantitative Analysis
An ethogram was developed to quantitatively analyse the video clips used in the QBA sessions. Behaviours were either recorded as frequencies or as a duration.

Results

Principal component analysis, of the first QBA session identified four main principal components (PC), explaining 79% of the variation in the data. Many of the terms load strongly on the first PC, accounting for 56% of the total variation and range from anxious/tense to calm/relaxed. Only PC1 had a strong to moderate inter- and intra-observer reliability based on Kendall's coefficient of concordance (W= 0.68, chi-square= 335.31, p = <0.001) and partial correlation (r = 0.65, p = <0.001), respectively. Quantitative validation of QBA identifie strong correlations (r >= 0.68) between duration of calm movement and QBA scores within the first three Principal Components. PC1 (tense/calm) scoring was highly correlated with duration of calm (r = -0.68, p = <0.001) and of chaotic movement (r=0.62, p=<0.001).
Data analysis from the enrichment QBA session is still ongoing but will be available at conference

Discussion

Results here show that even observers with limited experience of fish show good agreement when scoring fish using QBA and are able to consistently observe differences between tense and calm fish. In addition, there was very good correlation between quantitative measures of behaviour and QBA which provides further validation of this methodology. More work is required to validate this method however initial results are encouraging.

EFFICIENCY OF WITHIN-GROUP MASS SELECTION ON THRESHOLD TRAIT AND SUCCESSIVE MASS OR INDEX SELECTION ON CONTINUOUS TRAIT

F. Enez*, P. Haffray

SYSAAF, Station INRA/LPGP, Campus de Beaulieu, 35042 Rennes
Contact: florian.enez@inra.f

Introduction

Within-group mass selection consists in combining the efficiency of independent mass selection within groups and the simplicity of inbreeding management by rotational crossing of those groups. Previous simulations have shown that a first within-group mass selection on a threshold trait, such as disease resistance, is efficient to create genetic progress and that rotational crossing between groups could limit efficiently inbreeding (Enez & Haffray, 2018). The aims of this present *in silico* study were to simulate a successive 1st within-group mass selection on a threshold traits and a 2nd mass or BLUP (or index selection) on a continuous trait to evaluate the expected gains on the two traits depending on trait heritabilities, their genetic correlations and different selection pressures. The opportunity to get access to the pedigree by DNA parentage assignment was also investigated to optimize breeding program.

Materials and methods

Stochastic computations were used to simulate a breeding program for 10 generations. Factorial mating were generated with 160 parents distributed in 4 groups. Simulated progenies were reared in mixed family groups. True breeding value (TBV) was defined as the mean of additive value of sire and dam, modulo meiosis uncertainty. Individual phenotypic value for threshold (T-trait) and quantitative (Q-trait) traits was considered as the sum of genetic effect (weighted by heritability h^2), micro-environment effect (weighted by 0.1 for T-trait only), and residual effect. Each effect was sampled in Gaussian distribution. Threshold phenotypic value was determined by comparing underlying phenotypic value with a sensitive threshold dependent on eliminated phenotype prevalence. Individuals were available for selection only if their phenotypic value was larger than the threshold. Then selected individuals could be randomly sampled without Q-trait consideration, or selected by mass or BLUP selection on Q-trait with or without inbreeding management based on parentage assignment. Threshold on the T-trait was fixed at 50% in the reference situation and cumulated selection pressure on the two traits at 4% from 4000 individuals. HAN-rotational system was applied to cross groups and to produce the next generation. The effect of some heritabilities (0.1; .25; 0.50), genetic correlations r_g (-0.5; 0; 0.5) and selection pressure (0.50 and 0.25 on T-trait, and 0.32 and 0.10 on Q-trait) on inbreeding, phenotypic and genetic gains were estimated.

Results

Selection on T-trait only had no significant impact on TBV of Q-trait (Fig. 1). Adding mass selection on Q-trait, after mass selection on T-trait when genetic r_g in null, had no impact on genetic gain for T-trait.

Index selection with 32% selection pressure from estimated breeding values (EBV) on Q-trait didn't impact gain on T-trait but increased gain on Q-trait in the same order than mass selection with higher inbreeding. When Q-trait h^2 was limited (0.10), expected genetic gain on Q-trait was lower (1-2% vs 19%) than when h^2 was higher (0.5). Inbreeding also increased faster.

Introduction of inbreeding constrains limited up to 50% genetic gain on Q-trait compared to mass or index selection, whereas genetic gain on T-trait was quite similar. Inbreeding management seemed to be particularly useful when Q-trait heritability was more limited.

When index selection was considered with inbreeding management and the initial selection pressure on T-trait was the highest (0.25), genetic progress on T-trait was 50% higher than when initial selection pressure on T-trait was more limited (0.50), without effect on genetic gain on Q-Trait. (Fig. 2). Increase of selection pressure on Q-trait moderately impacted T-trait, but genetic gain on Q-trait rose by 50%. When r_g was closed to 0, then combined selection on T and Q-trait allowed similar genetic gain by trait than if each trait would have been selected independently.

(Continued on next page)

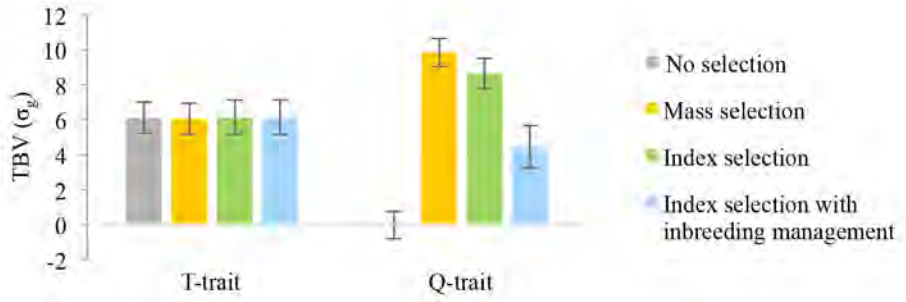

Fig. 1: TBV (in σ_g) of simulated individuals after 5 generations according to method of selection of Q-Trait. Heritability of T-trait and Q-trait is fixed at 0.25 and genetic correlation at 0.

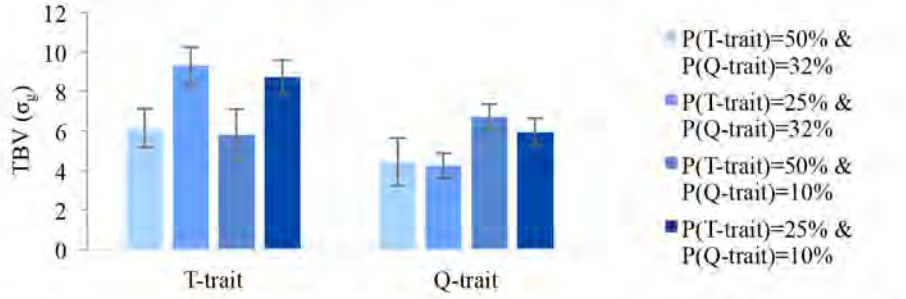

Fig. 2: TBV (in σ_g) of simulated individuals after 5 generations with index selection with inbreeding management according to selection pressure on T-trait and Q-trait. Heritability of T-trait and Q-trait is fixed at 0.25 and genetic correlation at 0.

Discussion

This work demonstrated that within-group multi-traits selection is an efficient strategy to improve simultaneously a threshold trait, such as survival, and then a second quantitative trait with low-cost inbreeding management when genetic correlation is limited. Results not reported in the abstract also shown possible simultaneous genetic gains when genetic correlation is -0.5, but more limited as also reported by Sonesson et al. (2005) with only one group.

The use of DNA parentage assignment in within-group multi-traits selection program may improve inbreeding management while guaranteeing the genetic variability of the selected individuals. The effectiveness of such selection program depends directly on the heritability of the traits, their genetic correlation, and selection pressure and/or number of assigned individuals used to estimate EBV.

Given its simplicity of implementation and effectiveness, both in terms of genetic improvement and inbreeding management, successive within-group multi-trait selection could be easily applied in breeding programs in aquaculture species.

Introduction

High quality gametes are those that have a high ability to fertilize or be fertilized and result in high survival rate during incubation as well as after hatching until the first feeding (Bobe and Labbé 2010; Valdebenito, C Gallegos, and Roldán 2013). Broodstock nutrition, genetics, and environmental conditions such as stress, temperature, handling and photoperiod are among the main parameters susceptible to modulate gamete quality (Bobe and Labbé 2010; Migaud *et al.* 2013; Valdebenito, C Gallegos, and Roldán 2013). Since nutrient content of the eggs is key to the good development of larvae, and directly linked to the broodstock diet, several authors have stressed the importance of this factor to ensure high quality offspring (Fernández-Palacios *et al.* 2011; Izquierdo, Fernández-Palacios, and Tacon 2001). To our knowledge, very little work has been published on the effect of antioxidants in rainbow trout broodstock nutrition. Indeed, whilst it is known that vitamin C and E are essential to obtain good quality gametes (Sandnes *et al.* 1984; Izquierdo, Fernández-Palacios, and Tacon 2001; Fernández-Palacios *et al.* 2011; Valdebenito, C Gallegos, and Roldán 2013; Bilguven 2014), study on other compounds, known for being involved in the antioxidant mechanisms are scarce.

The aim of this study was to evaluate the effect of a supplementation of rainbow trout (*O. mykiss*) broodstock with a small dose of dry grape extract on their reproductive performances, the impact on the eggs metabolome and on the offspring's growth performances.

Materials and Methods

Fish were divided in two groups of 80 females and 50 males each. The supplemented group's diet (NG, males and females) contained 80ppm of a commercial grape extract (Nor-Grape®), while the control group had none (CTL, males and females). Fish were fed the experimental diets for 5 months prior to spawning. Ova were collected and either analyzed for their metabolomic profile, or fertilized with the semen from males from the same group and incubated until hatch. Egg weight, embryonic survival rate and live fry after resorption were recorded. Fry from both groups was then raised for 8 weeks with the same diet.

Ova for metabolomic analysis were freeze-dried, then submitted to pressurized liquid extraction using sequential polar (dichloromethane) and polar (methanol) extractions. Liquid extract were then dried under nitrogen, before being re-solubilized in their respective solvent for LC-MS analysis. Mass spectra were then compared using MZMine2 software.

Results

Results did not show statistically significant differences between groups in egg weight (50.1mg vs.51.4mg. for CTL and NG respectively, ns.), embryonic survival (81.8% vs. 84.4% for CTL and NG respectively, ns.) or live fry at resorption (79.5% vs. 81.7% for CTL and NG respectively, ns.). However, fry from the NG parents had significantly higher growth at 6 weeks (1.78g vs. 1.80g, for the CTL and NG fry respectively, $p<0,01$, t-test) and at 8 weeks (3.25g vs. 3.42g for the CTL and NG fry respectively, $p<0,01$, t-test). Moreover, a general shift in the metabolomic profile of eggs was observed in the NG group, in both polar and non-polar fractions of the ova.

Discussion and conclusions

Whilst other research have shown a beneficial effect of supplementing broodstock with dietary antioxidants on the offspring's antioxidant status (Wischhusen *et al.* 2019), they did not study its impact on growth performances. Our findings show a benefic al effect of the supplementation with a standardized dry grape extract on the next generation's growth performances. They are thus in accordance with other research showing the beneficial effect of a supplementation with dietary antioxidants, thus demonstrating the interest of natural antioxidants such as grape polyphenols.

(Continued on next page)

The study of the impact of such a supplementation on the metabolomic profile of ova has, to our knowledge, not been studied before. Recent research has shown that a supplementation with certain dietary polyphenols could impact the metabolism of fish, more particularly the lipid metabolism (Torno *et al.* 2017; Welker *et al.* 2017). Whilst these studies showed modulation only at high doses of polyphenols, the present work evidenced a positive impact on the modulation of the egg metabolome at a low level of supplementation (80ppm) of a standardized dry grape extract.

Thus, the addition of the standardized dry grape extract in the diet of rainbow trout broodstock had a beneficial impact on their offspring performances, potentially due to a favorable change in the metabolomic profile of their eggs. More research is required to better understand the mode of action behind this phenomenon.

Introduction

The Aquaculture industry is a key animal production sector to provide food and nutrition for direct human consumption, and by 2030 with the increasing population more 40 million metric tons of aquatic products will be necessary to maintain the actual seafood consumption *per capita*. Hence, it is important to study strategies to increase the production in aquaculture in a sustainable way. In winter, when water temperature drops below 13°C, gilthead seabream reduces activity, feed intake, metabolism, and growth. Therefore, it is essential to determine how nutrition may help the fish to cope with adverse conditions in order to establish predictability and ensure optimal feed utilization during the whole production cycle. The objective of the present study was to mitigate the impact of adverse water temperature during gilthead seabream juveniles' production through diet formulation.

Materials and methods

Gilthead seabream juveniles with an average body weight of 155g were distributed by nine 500L-tanks, at an initial density of 8.6 kg/m^3, in a flow-through system. Fish were fed once a day, *ad libitum*, with one of the three experimental diets: Control (43%Protein:17%Lipids); Low (41%P:17%L); Low$^+$ (41%P:17%L). A mixture of feed additives was included in the Low$^+$ diet. Each diet was assigned to triplicate tanks. The impact of experimental dietary formulations on several juvenile key performance indicators (growth, FCR, K, proximal composition, nutrient retention, diet digestibility, HSI and VSI) were determined at the end of the experimental period (84 days).

Results and Discussion

In order to ensure a sustainable growth, the Aquaculture industry needs to improve aquafeeds sustainability through a reduction in dietary fishmeal inclusion and/or an increase in feed efficiency by adding additives to the fish diets. At the end of the experimental period key performance indicators, like growth and FCR were similar between the fish fed Control and the Low$^+$ diet. In addition, energy digestibility was higher for fish fed Low$^+$ diet when compared to the other diets. This absence of significant differences in growth performance indicators implies a significant reduction of protein and fishmeal in juveniles' seabream diets. The results indicate that is possible to mitigate adverse conditions through a nutritional approach.

Introduction

The ornamental trade has been growing in the last decade. Traditionally, fish are collected from the wild, causing the destruction of reef habitats and wild populations. Consequently, ornamental aquaculture is the viable strategy to a healthy and sustainable ecosystem. One of the most popular ornamental fish is the clown anemonefish (*Amphiprion ocellaris*). This species presents a bright orange body colour with three white bars, where the middle one has forward projecting bulge and bars with a very narrow to almost non-visible black margins. Fish value is mainly based on two quality parameters, colour and fish size. However, one of the main problems in reared fish is the loss of colour due to carotenoid deficiency in the diets. Therefore, nutrition appears as a valuable tool to improve the quality of the reared ornamental fish. One strategy could be the dietary inclusion of marine biomasses (microalgae, macroalgae, and zooplankton) and alternative new ingredients to overcome this situation. The main objective of the present study was to assess how innovative diet formulations could improve performance of *Amphiprion ocellaris* juveniles, as well as to standardize a feeding protocol that promotes fish quality, based on growth and colour.

Materials and methods

A stock of 180 juveniles with a mean initial body weight of 0.36g were divided in 9 rectangular tanks (10.5l) in a closed recirculation system (temperature: 26 ±2˚C; salinity: 30-31g.L^{-1}; dissolved oxygen: 97± 4%). Each diet was assigned to triplicate tanks. Fish were fed by hand to apparent satiety, several times a day with one of the three experimental diets. Diet A was used as control and was formulated with high levels of traditional marine protein sources (fishmeal, krill meal, squid meal, marine hydrolysates) and was supplemented with synthetic astaxanthin; diets B and C comprised a marked increase of various emergent raw materials such as natural Artemia biomass, microalgae (Nannochloropsis sp., Tetraselmis

Table 1- *Amphiprion ocellaris* juvenile's performance indicators and colour at 90 days after hatching (DAH).

	Diet A	Diet B	Diet C

(Continued on next page)

sp., Spirulina, Chlorella sp.) and insect meal, at the expenses of traditional marine protein sources and without the addition of synthetic astaxanthin. All diets were isonitrogenous and isoenergetic. The impact of experimental dietary formulations on several juvenile key performance indicators (growth, FCR, K, proximal composition, digestive capacity, colour) were determined at the end of the experimental period (90 days). Skin colour was measured through photo analysis and the L*, a* and b* coordinates from CIELab system were recorded. To estimate perceptible colour differences (ΔE*) among dietary treatments the CIE76 formula was applied. Hence, dorsal area of each fish was evaluated and average values of colour coordinates were used for ΔE* calculation (Diet A vs Diet B; Diet A vs Diet C and Diet B vs Diet C). Distance between colours were considered as being indicative of either an "irrelevant perceptual difference" (ΔE* < 1), a "slightly perceptual difference" (1< ΔE* < 2.3) or a "clean perceptual difference" (ΔE* > 2.3).

Results and Discussion

Regarding fish performance indicators, all the fish presented similar body weight (FBW), daily growth index (DGI), final length (ST), condition index (K), specific growth rate (SGR), viscerosomatic index (VSI) and hepatosomatic index (HSI) at the end of the experiment independently of the experimental diet. Weight gain was similar between Diets A and B. Experimental diets had impact on Feed conversion rate (FCR), with diet A having the lower FCR ($p<0.05$). Voluntary feed intake (VFI), was significantly higher in fish fed with diets B and C when compared to die A ($p<0.05$).

Fish skin colour was positively influenced by the inclusion of novel and emergent ingredients (Diets B and C) ($p<0.05$). The skin colour in the dorsal area showed that fish fed lower level of novel and emergent ingredients (Diet B) had higher redness (a*), followed by a higher incorporation in Diet C. The lower redness (a*) was observed in the fish fed traditional marine protein sources and supplemented with synthetic astaxanthin (Diet A). There was a clear perceptible colour difference between Diet A and Diet B (ΔE* Diet A vs Diet B = 5.23), while between Diet A and C, and Diet B and C (ΔE*=2.82 and ΔE* = 2.42, respectively) values were similar.

During this study it was observed that the innovative diets formulations positively improved the colour of *Amphiprion ocellaris* juveniles. Novel and emergent ingredients, such as microalgae, Artemia biomass and insect meal, supported an overall growth performance similar to that of a commercial ornamental feed with high levels of traditional marine derived proteins. In addition, natural carotenoids from microalgae and Artemia successfully pigmented clownfish attaining a higher redness (a*) pigmentation efficacy than synthetic astaxanthin

SOURCES AND SINKS OF BACTERIA IN RECIRCULATING AQUACULTURE SYSTEMS (RAS)

A. Ernst, P. Maurer and U. Waller

Hochschule für Technik und Wirtschaft des Saarlandes (htw saar), Goebenstraße 40
66117 Saarbrücken (Germany)
E-Mail: anneliese.ernst@htwsaar.de

Introduction

Recirculating aquaculture systems (RAS) provide numerous niches for suspended and attached bacteria, collectively addressed as the microbiome of a RAS. Bacteria perform important functions in water purification of a RAS but they also compete with fish for oxygen and some may even challenge the immune system of the animals. Biofilters for nitrification and denitrificati n are indispensable for sustainable RAS technology (Martins et al., 2010). The bacteria in these filters convert nitrogenous fish excretions into gas, which can leave the system, and in bacterial biomass. However, the terminal denitrification process is complicated and not easy to control (Stavrakidis et al. 2019). Bacteria are a significant part of the solid waste produced in RAS. While fish, feces, not-consumed feed and biofilters are sources of bacteria, water exchange and physical filters, which reduce or remove solid waste, are sinks of bacteria. Modern RAS, which abstain from periodic water exchange but rather replenish losses by evaporation and flushing out of solid waste (Orellana et al., 2014), operate with very high hydraulic retention times of the process water. Hence, also bacteria may stay in a RAS for very long time. Little is known about the (taxonomic) composition and temporal changes and development of the microbiome of RAS (Llewllyn et al., 2014, Rud et al., 2017). In this study we analyzed the microbiome and studied effects of sources and sinks on the microbiome in a RAS, stocked with *Sparus aurata*, in the first commercial, marine fish farm operated without connection to the sea.

Materials and methods

The marine fish farm in Völklingen, Germany, operates four marine RAS (4 x 2500m³). Water quality (pH, temperature, salinity, nitrate-N, total ammonia-N,nitrite-N, phosphate) is monitored three times per week in the fish production tank using standard methods. For microbiome analyses, process water was sampled at nine positions in the RAS. Sampling positions started with water from the fish production basin entering the water treatment unit, comprised seven positions inside the water treatment and a sample of process water leaving the treatment towards the production basin. Samples were frozen at -20° and transferred to -80°C. A commercial service provider (SeqIT GmbH, Kaiserslautern, Germany) analyzed the microbiome using Illumina sequencing of the V3-V4 region of the microbial 16S rRNA gene. Sequences were aligned with sequences in the SILVA database (https://www.arb-silva.de) using the Burrows-Wheeler Aligner (Li, 2009). To facilitate recognitionof pattern, we combined operational taxonomic units (OTUs) of the same phylum. Sources and sinks of bacteria were inferred from changes of fractions of phyla rather than from bacterial counts.

Results and conclusions

During the first year of operation, the RAS was successively stocked with 4 cohorts of seabream (*Sparus aurata*), each cohort adding about 100 000 fingerlings to the RAS. Fish harvest started 12 months after first stocking

The microbiome was analyzed 16 times during a period of 2 years, starting 1.4 years after first stocking. At 12 of 16 sampling dates, the relative contribution of γ-proteobacteria was smaller in samples taken at the exit of the water treatment (clean water) than in water leaving the production basin (soiled water). This indicated that the production basin, likely the fishes, were sources of γ-proteobacteria.

Samples of particles removed from RAS by first drum filtration, were greatly enriched in flavobacteria and α-proteobacteria compared to process water passing the filte . Only on 3 of 16 dates, the fraction of γ-proteobacteria removed from RAS was higher than in the passing water. After 3.4 years of continuous RAS operation, planctomycetes, clostridia and fusobacteria, which showed low abundance in the second year of operation had increased their shares on expense of flavobacteria, α-and γ-proteobacteria.

ϒ-proteobacteria were more efficiently removed by the flotati n apparatus (foam fractionation) than by drum filtration. This is a significant observation because this taxon not only increased in the fish basin but also comprises several important fish pathogens. The result shows that the two filter systems complemented each othe .

(Continued on next page)

Eye-catching was the contribution of a number of uncultivated/unknown OTUs assigned to ε-proteobacteria. At 11 of 16 sampling dates they dominated the microbiome of water entering the fish tank. Although their relative abundance decreased in the fish tank, dominance was restored during passage of the water treatment by preferential removal of other phyla. We were unable to identify a source of these bacteria, but high abundances of members of this phylum were reported in cod larvae (Vestrum et al., 2018). From our observation, we can infer that these bacteria proliferate slower than other proteobacteria in the fish tank. These bacteria have hydrophilic surface structures that prevent enrichment in the liquid-vapor interface of the flotation apparatus and the formation of larger aggregates that could be removed by the drum filte . Apparently, they were not harmful to fish

- It is obvious that a better sustainability of RAS requires a prolonged hydraulic retention of process water.
- A longer retention time requires a denitrification biofilter in RAS that could be an additional source of bacteria if the effluent is not treated by flotatio
- This study proofed that drum filtration and ozone enhanced flotation are complementary filter process
- Nevertheless, an inefficient removal of solitary bacteria may necessitate additional sinks to comply with animal welfare.

VITAMIN AND MINERAL COMPOSITIONS OF THE ROTIFER *Brachionus plicatilis, müller* 1786 CULTURED WITH DIFFERENT FEEDS

K.M. Eryalçın[1] and M. Izquierdo[2]

[1] Istanbul University Faculty of Aquatic Sciences, Ordu Cad. No:8, Laleli, 34470, Istanbul, Turkey
E-mail: eryalcin@istanbul.edu.tr
[2] Grupo de Investigación en Acuicultura (GIA), Instituto EcoAqua, Universidad de Las Palmas de Gran Canaria, Crta. Taliarte s/n, 35214 Telde, Spain.

Introduction

The rotifer Brachionus plicatilis is the first live prey feed to marine fish larvae (Hamre et al., 2013). It is commonly fed commercial diets or freshly cultured microalgae species (Ferreira et al., 2008), which may differ in their biochemical composition and physical properties (Hamre, 2016). Despite their importance for larval performance, there is scarce information on micronutrients contents in live feeds from commercial hatcheries (Hamre et al. 2013; Izquierdo et al., 2017). The objective of the present study was to determine the effects of two different forms of *Nannochloropsis oculata* and common commercial rotifer diets on the vitamin and mineral compositions of rotifer.

Materials and methods

Rotifers (Brachionus plicatilis, L-type, lorica size 250 μm) were cultured in 1000 L circular tanks with baker's yeast (Saccharomyces cerevisiae; Pakmaya, Turkey) at Akvatek Aquaculture Company, İzmir, Turkey. The rotifer stocking density was 600 rot/mL in all experimental tanks. Rotifers were fed one of five different types of food: Algome® (dried Schizochytrium sp.), ProteinPlus® (PP), Inactive Beaker's Yeast® (INBY), spray-dried Nannochloropsis oculata (SDN) and freshly cultured N. oculata (FN). The experimental diets were given 4 times a day during 16 days of semi-continuous culture.

Results and Discussion

At the end of the experiment, eight essential vitamins (Vit A, Vit E, Vit C, Vit B1, Vit B6, Vit B2, Niacine and Folic acid), nine minerals (Ca, Mg, P, I, Co, Se, Mn, Cu and Zn) and three antioxidant (Lutein, Likopen and β-carotene) compositions of rotifers were determined. Ca, Zn and I levels were found higher in INBY fed rotifers (P<0.05). P and Mn levels were significantly higher in SDN fed rotifer groups (P<0.05). Se and Cu levels of rotifers were increased by utilization of fresh *N.oculata* biomass (P<0.05). Co and Mg levels were found higher in rotifer fed Algome diet (P<0.05). In terms of vitamin composition of rotifer, PP supported Niacine, B2 and folic acid levels (P<0.05). B6 level of rotifer was increased by utilization of fresh *N.oculata* (P<0.05). Vitamin E and A were found higher in rotifer fed SDN diet (P<0.05). Vitamin B1 level was found higher in INBY group. Vitamin C was not detected among groups. Lutein and β-carotene were found higher in rotifer fed SDN diet (P<0.05) (Table 1). Overall, the results indicated that vitamin and mineral compositions of rotifers could largely vary depending on the diet selection.

Rotifer nutritional quality and production success are main concerns for commercial hatcheries. The present study showed that vitamin compositions of rotifers differ innrelation to the diets used. The results could suggest a benefit from the combination of SDN and PP diets according to rotifers vitamins and carotenoids contents. However, according to our results, rotifers should be enriched vitamin C and vitamin A after rotifer cultivation. Regarding mineral compositions results are more similar among rotifers fed the different diets, excluding Mn.

Content

Norwegian government aim for a 5-fold increase in Atlantic salmon aquaculture production within 2050. At the same time aquaculture industry has to be sustainable and has a responsibility towards many of the UN Sustainable Development Goals. The goals regarding growth have to be achieved at the same time as salmon industry is still facing challenges with e.g. sea lice infestation and escapes. These challenges have resulted in zero growth in salmon farming in Norway the last years. A sustainable growth therefore enforces alternative and innovative production methods, with collaborative forces.

Already, there are several alternative production methods, besides the traditional open cages, and some of these methods originate in the belief that in order to avoid sea lice and escapes, you should keep the fish longer on land. Salmon start their life on land, either in flow through systems, or in systems using recirculation technology (RAS). After smoltification, there are several alternative ways of post-smolt and grow out production. After Norwegian regulations from 2016 allowed land-based production all the way to slaughter, this is a growing production method in Norway, and world-wide. Additionally, some farmers move their post-smolt to semi-closed containments (Fig 1), before transferring them to open cages in the last production phase. In addition, several different prototypes for on-growing production off-shore are developed.

CtrlAQUA is an SFI (centre for research driven innovation) that has been given eight years to contribute to the development of closed (RAS) and semi-closed containment (S-CCS) aquaculture. CtrlAQUA shall develop technological and biological innovations to make closed containments a reliable and economic sustainable technology, and contribute with knowledge transfer and innovations within the research fields Technology and Environment, Production and Welfare, and Preventive Fish Health. In focus is the post-smolt, since this is a sensitive life stage for the salmon in which their health and welfare are highly dependent on optimal environment and treatment. The centre goals are achieved with joint forces between seven R&D institutions, and thirteen industry partners representing fish farmers, suppliers and biotechnology companies, in addition to an impressive amount of master - and doctoral students.

Among research questions that CtrlAQUA is working with are to facilitate innovation of CCS technology, hydrodynamics, water treatment processes, and sensors, to achieve a high level of production control. Further, we are working to identify physiological and environmental requirements for post-smolts in CCS, optimize environmental parameters, innovate new welfare and robustness indicators and maximize output from each CCS platform without compromising welfare and robustness. Finally, we are working towards innovations to prevent, detect and control disease in closed production systems, strengthen the fish s robustness and disease resistance with focus on barrier functions and cardiovascular capacity, strengthen pathogen control and management of disease outbreaks in CCS, and developing new or improved vaccines and protocols for pathogens that represent a particular threat in CCS.

During the presentation, highlights of research results will be shown.

FutureEUAqua – FUTURE GROWTH IN SUSTAINABLE, RESILIENT AND CLIMATE FRIENDLY ORGANIC AND CONVENTIONAL EUROPEAN AQUACULTURE

Åsa Maria Espmark

[1]Nofima AS, 6600 Sunndalsøra, Norway
*e-mail: asa.espmark@nofima.n

Content

European aquaculture production has reached 1.25 million tonnes of seafood annually, with a value of over 4 billion euro. Of this amount, 4% is certified as organic, amounting in 2015 to a total of approximately 50,000 tonnes (EUMOFA, 2017). In 2015, EU consumers spent 54 billion euro for buying fisheries and aquaculture products, reaching the highest amount ever recorded (EUMOFA, 2017). Nevertheless, Europe is still heavily dependent on external markets to cover this demand. The increased demand for aquaculture products has to be covered at the same time as food production need to be more sustainable, climate friendly and supporting the UN Sustainable goals.

The newly started EU project FutureEUAqua aims to effectively promote sustainable growth in aquaculture that is resilient to climate changes, and environmental friendly organic and conventional aquaculture of major fish species in Europe. It is a well-documented assumption that aquaculture that will meet future challenges with respect to the growing consumer demand for high quality, nutritious and responsibly produced food. FutureEUAqua will promote innovations in the whole value chain, including genetic selection, ingredients and feeds, non-invasive monitoring technologies, innovative fish products and packaging methods, optimal production systems such as IMTA and RAS, taking into account socioeconomic considerations by the participation of a wide spectrum of stakeholders, training and dissemination activities.

To achieve these ambiguous goals, 32 partners from R&D, industry and associations, originating from nine countries will collaborate in research, training, dissemination and contact with stakeholders through e.g. stakeholder events.

FutureEUAqua will contribute with innovations that will arrive Technology readiness level (TRL) ranging from five to nine. Innovations will result from all research topics, including sustainable genotypes, feeds and farming management solutions; smart tools to monitor the farming environment that guarantee aquatic animal health and welfare, tailor-made aquaculture fresh/processed foods and packaging, IT tools and information packages to improve consumer's awareness about aquaculture products and related markets.

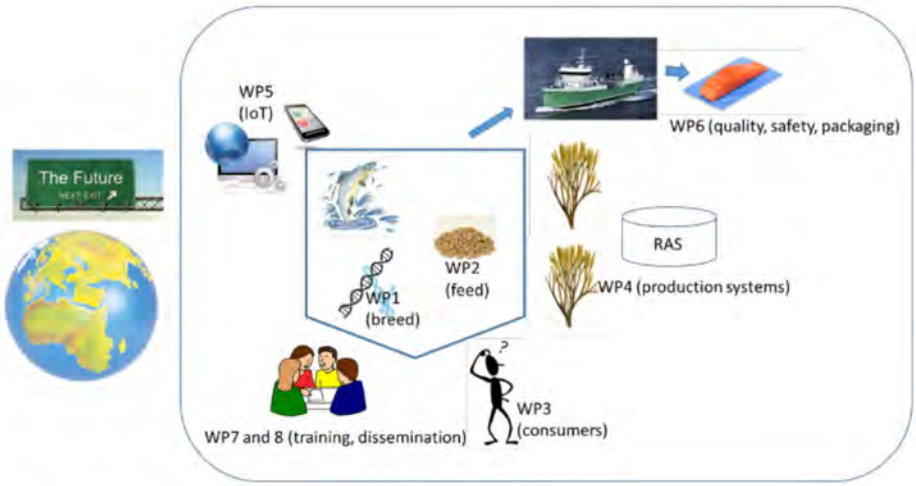

Figure 1. Structure of FutureEUAqua

(Continued on next page)

The results and innovations will have impacts by improving resilience and sustainability of aquaculture farming systems and practices. The results will have impact on a diversity of end users representing the whole value chain from breeding companies to processing plants and intelligent packaging, including e.g. digital farming solutions for improved animal health and welfare, retailers and customer care providers. We intend to gather stakeholders to contribute to the professional skills and competences of those working and being trained to work within the blue economy and support the implementation of the EU Common Fisheries Policy (CFP) and contribute to policymaking in research, innovation and technology.

The outcomes and recommendations will be presented at the two planned stakeholder events, and discussed at the dedicated conference at the end of the project's timeline. These meetings will address all stakeholders and interest groups affected by the scope of FutureEUAqua. A final roadmap for the exploitation of results, including efforts for technology transfer will be presented at the final conference.

Introduction
Organic acids (OA) and botanicals are widely used in terrestrial animals as zootechnical feed additives and they gained an increasing interest as alternative to reduce antibiotic usage. Usually they have been used as feed additives with the aim of improving performance, intestinal health, immune status and as antimicrobials. To the best of our knowledge, the available studies in aquaculture are very limited and little is known about their impact on the fish immune system. The aim of this study was to determine the effect of AviPlus®Aqua (Vetagro SpA), a blend of OA (sorbic and citric acid) and nature-identical compounds (NIC, thymol and vanillin) on gilthead seabream (*Sparus aurata*) growth performance and immune status. Gilthead seabream was selected as a fish model due to their interest in marine aquaculture

Materials and Methods
One hundred and sixty gilthead seabream specimens of an average weight of 50g were obtained from a local farm (Spain), distributed randomly into eight aquaria (20 fish per aquarium) and acclimatized for 15d. Fish in each aquarium were fed one of the following experimental diets (control, CTR, or AviPlus®Aqua 250ppm, 500ppm and 1 000ppm). Fish were fed twice daily *ad libitum* during 4 weeks and after 2 and 4 weeks of the feeding trial, 5 fish of each aquarium were sampled to determine growth performance and immune status. Two humoral immune parameters (alternative complement activity and IgM values) and two cellular immune parameters (phagocytosis and respiratory burst activities) were determined for each sampled fish. Data were analyzed with one-way ANOVA.

Results
Growth performance. Fish fed diet supplemented with AviPlus®Aqua 500ppm for 4 weeks showed higher body weight ($P<0.05$). Regarding the specific growth rate (SGR) and weight gain (WG) of the fish, no significant differences were detected among the different groups after 2 weeks of the experimental trial whereas after 4 weeks, fish fed AviPlus®Aqua 500 and 1 000ppm had higher SGR ($P<0.05$).

Immune status. The complement activity found in sera from fish fed the different diets for 2 weeks was always lower than the values recorded for fish fed the same experimental diets for 4 weeks. Regarding IgM, fish fed AviPlus®Aqua 250, 500 and 1 000ppm for 2 weeks showed higher values compared to CTR, although the observed differences were only statistically significant with AviPlus®Aqua inclusion at 1 000ppm ($P<0.05$).

Regarding phagocytosis of head-kidney (HK) leucocytes, fish fed diet with AviPlus®Aqua 500ppm showed higher significant phagocytic capacity after 2 weeks ($P<0.05$), but not after 4 weeks. No significant differences were observed about phagocytic ability. Finally, respiratory burst activity of HK leucocytes of fish fed AviPlus®Aqua 500ppm and 1 000ppm was significantly increased after 2 weeks, but not after 4 weeks $P<0.05$).

Conclusions
In conclusion, the present data showed that AviPlus®Aqua was able to improve growth performance in seabreams starting from 500ppm of inclusion, after 30d of feeding. Moreover, the same inclusions showed an increase in immune parameters, such as respiratory burst and serum IgM levels, after 15d. These data highlight a potential immuno-boosting effect at d15, that seems to prime the immune response of the fish. This primary boosting seems to have a positive effect on the general health status of seabreams, that leads to improved performance after 30d of feeding. Further immune-parameters needs to be studied to better understand the mechanism of action.

Introduction

Norway is the world's leading producer of Atlantic salmon (*Salmo salar*) (FAO 2018). Further strategic development and research is needed to realize the Norwegian government's long-term aim to increase fourfold the current production volume by 2050 (Olafsen et al., 2012, Parliament message nr. 16 (2014-2015) p.15). Through the growing concern about the environmental impact of increasing waste load from salmon production a stronger focus on environmental sustainability of the production, including improved resource and energy utilization is required.

Approximately 39% of the total nitrogen content from feed given to salmon, is released as dissolved inorganic nitrogen (DIN), and Ammonium (NH_4^{+}) (Wang et al 2013). The sugar kelp *S. latissima* has been presumed to have a DIN removal rate of 5-40% from salmon farm emission (Broch and Slagstad, 2012 Forbord et al., 2012; Sanderson et al., 2012; Sjøtun 1993; Subandar et al., 1993). The major objective of this study was to investigate uptake of Ammonium and Nitrate in *S. Latissima* from an IMTA perspective and if the pulses of waste released from fish farms are accessible for S. Latissima in during growth phase.

Material and Methods

Nitrate depleted and saturated *S. latissima* (~10cm) were exposed to a gradient of Ammonium (0.25-16 µmol), for 5 hours. By following the depletion of substrate concentration at 8 different point of time, uptake rates (µmol L^{-1} gDW^{-1} h^{-1}) were determined.

Results

Interestingly, S. latissima was observed to rapidly adapt to different concentrations of Ammonium (NH_4^{+}), with a swift increase in uptake rates. Maximal uptake rates were observed within 50 minutes as shown in figure 1. Furthermore, uptake of NH_4^{+} increased linearly with augmenting concentration, regardless of nutritional history. The nutritional history of *S. latissima* appeared to affect the uptake, as nitrogen depleted specimens had a significant faster uptake of NH_4^{+} than nitrogen saturated specimens as shown in figure 2

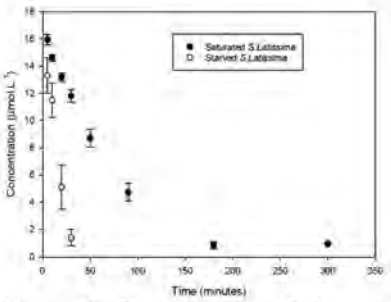

Figure 1: Time course of decrease in ammonium concentration (initially16µmol L^{-1}) in culture medium with juvenile plants of *Saccharina Latissima* for nitrate saturated and depleted plants (n=5±SD)

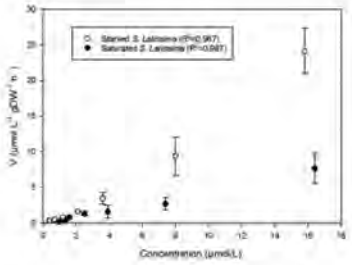

Figure 2: Ammonium uptake rates for *Saccharina Latissima* from 5 to 50 minutes related to available concentration for both nitrate saturated and depleted plants (n=5±SE, linear regression with R^2=0,987 for depleted and saturated).

(Continued on next page)

D**iscussion**

With an increase in initial substrate concentration, the uptake rates were also increasing. Furthermore, the uptake rates were consistently higher for the nitrate depleted *S. Latissima* than in the experiment with the saturated sugar kelp. The rates for nitrate depleted *S. Latissima* were also increasing to a higher degree with an increase in initial concentration. This shows that the depleted *S. latissima* had a higher capacity to take up NH_4^+ than saturated *S. latissima*. The difference increased with increased available concentration. This confirms that the nutritional history influences the NH_4^+ uptake for *S. latissima*, as is generally believed to be the case for seaweed (Hurd et al., 2014). The results from this experiment indicate that juvenile *S. Latissima* have the ability to utilize pulses of Ammonium released from the fish farms for growth, independent of nutritional state.

EFFECT OF *Plukenetia voluvilis* AS ALTERNATIVE TO FISHMEAL ON GROWTH AND DIGESTIVE ENZYMES AND BODY COMPOSITION IN WHITE LEG SHRIMP (*Litopenaeus vanameii*)

Dmitri Fabrikov, Patricio Renteria, Antonio Vizcaino Torres, Fernando R. García-Barroso, Carmen Fernández-Mañas, Mª José Sánchez-Muros

E-mail: dimitri.fabrikov@gmail.com

Introduction

Shrimps need high percentage of protein in diet ranged to 25% to 33% (%, dry matter) of which minimum 12% is fishmeal (Suarez et al., 2009). Fishmeal is an essential ingredient in fish feed, although it is not a sustainable source so that, it is foreseen a decrease of fishmeal inclusion in shrimp feed and an increase of alternative protein used, in fact, aquaculture depends less and less on fishmeal. The FIFO for crustacean 0.91 in 2000 and 0.46 in 2015 (IFFO 2018). *Plunkenetia volubilis* belongs to Euphorbiaceous family native to the Peruvian jungles. The flour and oil from the seeds contain approximately, 48% oil and 27% proteins which are rich in cysteine, tyrosine, threonine and tryptophan. The fatty acids of sacha are mostly unsaturated, about 85% polyunsaturation, comprised of approximately 34% linoleic acid (18:2*n*6) and 51% linolenic acid (18:3*n*3). Given the above considerations, the objective of this work was to evaluate the effect of different dietary levels of *P. volubilis* as an alternative protein source on growth performance, body composition and digestive enzyme activities of *L. vanamei* juveniles.

Material and methods

A feeding trial was carried out at a shrimp farm located at Santa Rosa provincia de El Oro – Ecuador (79° 57' 21'' 3° 23' 45'') in cages of $1m^3$ arranged in 1 hectare ponds. Fifteen *L. vanameii* juveniles with an average initial weight of 3.41 ± 0.31 g were randomly distributed and stocked into 8 cubical cages of $1m^3$ capacity at a density of 15 individuals per cage. Shrimps were fed during 10 weeks three times daily (08:00, 12:00, 16:00) at 15 % of their body weight with four iso-nutritional (35% and 9% DM, respectively) experimental diets designed with increasing levels of *P. voluvilis* biomass: 0% (D-0), 15% (D-15), 25% (D-25) and 50% (D-50) substitution. Every week, the total weight of shrimp in each tank was recorded to adjust the daily amount of feed. At the end of the feeding trail, 8 morphometrics traits and daily gain, Specific Growth Rate (SGR) and Feed Convertion Ratio (FCR) were determined. Crude protein and total lipid contents of abdomen samples were determined by standard methods. Finally, for enzymatic activity analysis, hepatopancreas from 10 shrimps per treatment were pooled to obtain enzymatic extracts in order to determine trypsin (Erlanger et al., 1961) chymotrypsin (Del Mar *et al*., 1979) and total alkaline protease (Alarcón *et al*., 1998) activities.

Table 1. Growth performance, morphometric traits and nutrient utilization of juvenile *L. vanamei* at the end of the feeding trial.

	D-0%	D-15%	D-25%	D-50%
Total weight	14.34 ± 2,36	14.48 ± 1,64	16.01 ± 1,33	16.75 ± 2,70
Cephalothorax weight	3.99 ± $0,59^{ab}$	3.65 ± 0.36^{a}	4.48 ± $0,41^{b}$	4.40 ± $0,82^{b}$
Abdomen weight	8.74 ± $1,17^{a}$	8.86 ± $1,04^{ab}$	9.75 ± $0,99^{ab}$	10.32 ± $1,71^{b}$

DAILY GAIN (g/dia)	0.17 ± 0,01	0.13 ± 0,06	0.16 ± 0,01	0.15 ± 0,01
FCR	0.94 ± 0,08	0.95 ± 0,03	0.96 ± 0,08	1.04 ± 0,04

Values are expressed as mean ± SD (n = 10). Values in the same row with different lowercase letters indicate significant differences ($p< 0.05$).

Table 2. Digestive enzyme activities (U mg soluble $protein^{-1}$) measured in hepatopancreas extracts of juvenile *L. vanamei* at the end of the feeding trial.

	Trypsin (U/mg prot)	Quimotrypsin (U/mg prot)	Basic protease (U/mg prot)
Control	0,09 ± 0,02	0,195 ± $0,025^{b}$	295,2 ± $65,5^{b}$
15% replac.	0,07 ± 0,02	0,167 ± $0,010^{ab}$	203,7 ± $22,9^{ab}$
25% replac.	0,07 ± 0,005	0,130 ± $0,004^{a}$	156,1 ± $4,03^{a}$
50% replac.	0,07 ± 0,005	0,139 ± $0,031^{ab}$	139,0 ± $16,1^{a}$

Values are expressed as mean ± SD (n = 10). Values in the same row with different lowercase letters indicate significant differences ($p< 0.05$).

(Continued on next page)

Results and discussion

The results obtained indicate that the inclusion of *P. volubilis* up to 39% in practical diets did not cause noticeable negative effects on growth performance of *L. vanamei* juveniles. Total weight and abdomen weight in shrimps fed with 25 and 50% sacha inchi were elevated, although significant differences from those fed the D-0% diet were only observed in abdomen weight (**Table 1**). This increase in the abdomen weight have a positive effect on shrimp quality. None of the treatments produced any clear adverse effects on tail composition (data not shown). Regarding digestive enzyme activities, fish fed *P. volubilis* supplemented diets showed lower chymotrypsin and alkaline protease activities compared to shrimp fed D-0% diet, although significant differences were only observed in D-25% and D-50% groups. Trypsin activity remained unaffected by *P. volubilis* inclusion. This fact could be related with the presence of diverse antinutritional factors including trypsin inhibitor in Sacha inchi seeds and in the cake (46.19 UTI/mg urinary trypsin inhibitor) (Lázaro Aguilar, 2015).

Conclusion

The results of this experiment indicates that *Plukenetia voluvilis* is very interest as alternative source to fishmeal in shrimp feeding that could be studied more deeply.

Introduction

In the last years, the interest for the insect as protein source has been increased. The insects are being studied as food as humans and as protein source for animals. In this sense, its use as alternative protein source to fishmeal is one of the main applications of insects.

The inclusion of *Tenebrio molitor* and *Hermetia illucens* meal has been studied in several fish species mostly focused in growth and nutritive parameters, digestive efficiency and effect on the quality of the product, but the effect on amino acid metabolism has not been studied. This experiment study the changes in the intermediary metabolism of amino acids of three commercial fish species Trout (*Oncorhynchus mykiss*), Gilthead (*Sparus aurata*) and Tench (*Tinca tinca*).

Material and methods

Five diets isonegetic, isolipidic and isoproteic; one control and four experiments were designed for this experiment: H30 (30% of fish meal was replaced by *Hermetia* meal), H15 (15% of fish meal was replaced by *Hermetia* meal), T 30 (30% of fish meal was replaced by *Tenebrio* meal) and T15 (15% of fish meal was replaced by *Tenebrio* meal).

Values are expressed as mean ± SD (n = 10). Values in the same row with different lowercase letters indicate significant differences (p< 0.05).

(Continued on next page)

The fish were feed with experimental diets until triplicate the weight. After experimental period, the fish were sacrificed and the liver were quickly removed and frozen in N_2 liquid and kept at -80ºC until enzymes determination. The method used for the determination of enzyme activity is based on the spectrophotometric measurement of the decrease in optical density caused by the oxidation of nicotinamide adenine dinucleotide (NADH). All enzymes were measured using methods described by Bisswanger (2011). Alanine aminotrasferase (EC 2.6.1.2, ALT) was measured at different concentrations of L-alanine (0.01, 0.1, 1, 10, 25 and 50 mM) as substrate. Aspartate aminotransferase (EC 2.6.1.1, AST) was measured at different concentrations of L-aspartate (0.01, 0.1, 1, 10, 25 and 50 mM) as substrate. Glutamate dehydrogenase (EC: 1.4.1.3, GDH) was measured at different concentrations of α-ketoglutarate (0.01, 0.05, 0.1, 0.5, 1 and 10 mM) as substrate.

Results

In the table 1, 2 and 3 show the data obtained for kinetic parameters (Km, Vmax and EC) obtained in the three fish species studied. The data show that the enzyme activity change depending on fish and insect species

Discussion:

Rainbow trout and seabream are considered as carnivore species, with a crude protein requirement of 43% (FAO 2019a) and 45-50% (FAO 2019b) for juveniles respectively. The tench feeding habit are not completely known, although it is considered omnivore (Benzer et al. 2009, 2010). The data obtained for kinetic parameters are in agreement with the feeding habit of these species, tench displays a high amino acids degradation probably due to an excess of dietary amino acids. Regarding insect inclusion, in tench any diets seem to have a great effect except for H-30. However, in trout the insect inclusion increased Vmax in the three enzymes assayed, which could be consequence of amino acids utilization for gluconeogenesis o energy purposes. In Gilthead seabream GPT and GOT show different mechanisms of adaptation to the insect inclusion, while GOT modified the Km, GPT modified Vmax. The changes of GDH it is considered a good indicator of amino acids utilization (Sánchez-Muros et al., 1998) because all the glutamate produced in the transamination is deaminated by GDH, with the formation of NH_4^+. In this sense, the catalytic efficiency of GDH, the inclusion of insect don´t affect except for H-30 while in seabream decreased and in trout increased.

In conclusion, the results show that the inclusion of insect lead changes in amino acids catabolism through the modification of kinetic parameters. In general term, inclusion of insect increased the efficiency of oxidative deamination in trout and decrease it in seabream, without changes in tench, except for H-30 diet.

Introduction

White Feces Syndrome (WFS) is a disease problem in shrimp farming along with increasing production through intensification. Early indications appear in feed trays and water surface, where abundant floating white fecal strings were observed. In severely affected shrimp, hepatopancreas and gut become white and pale yellow in color (Mastan, 2015). WFS was caused by interaction between gregarine (protozoa) and *Vibrio* sp. (Limsuwan, 2010).

WFS caused decreasing of immunity respond which related to immune gene *CypA* (Muhammad *et al*., 2017). One ingredient of Squid (*Loligo* sp.) ink extract is oleic acids which has an antibacterial function (Fadjar *et al*., 2016).

The objective of this research was to know the effect of squid ink extract to *CypA* gene polymorphism in white shrimp (*L. vannamei*) under WFS condition.

Material and Methods

Squid ink was taken from squid (*Loligo* sp.). Maseration was carried out with 96% methanol solvent with a ratio of 1: 3 and then stored for 7 days. Evaporation was carried out using 200 ml of maceration results with a rotary evaporator. The shrimp in WSF condition and pond water was taken from the shrimp pond with an average weight of 2.18 grams and fed with shrimp feed mix with : 6 ppm (treatment B), 8 ppm (treatment C), and 10 ppm (treatment D) squid ink extract , while WFS shrimp as positive control (treatment E) and healthy shrimp as negative control (treatment A). Shrimp was reared for 2 weeks in laboratory. After 2 weeks, shrimp samples were taken from every treatment aquarium and counted for survival rate.. Shrimp meat were taken as much as 0.05 grams and chopped until smooth then added with pH 7 TE-buffer for quantitative testing with NanoDrop Spectrophotometry (Fatchiyah *et al*., 2011). DNA amplification was done using thermal cycler and PCR mix with F primer (5'-CTGTAAAGTTTCAGAACATTCCCCC-3') and R primer (5'-GGACACCTATCTTGTTTCACCACCT-3'). Electrophoresis was done using gel agarose electrophoresis methods. Result of DNA extraction was sent for DNA sequencing and the result was confirmed using BLAST program. Survival rate was analyzed using ANOVA.

Result

Nucleotide composition was dominated by T (36.3%), A (24.8 %), C (21.9%), and G (17.0 %). WFS shrimp (E) have very different nucleotide bases compared to *CypA* of healthy shrimp (A) and WFS shrimp which had treated with squid ink extract (treatment B, ,C, D) but there were still mutation at base pair number 30 and 33.

125 number of sites was investigated resulting 15 polymorphic sites number and 17 mutation sites. Percentage of polymorphism can be seen as treatment B= 8 %, C= 9.6 %, D= 9.6% and WFS shrimp (E) = 10.4 %.
Maximum Likelihood Estimation resulted treatment B (8.5 %), C and D (10.3 %), and control positive/WFS shrimp (E) (11.3 %).

No significantly different between healthy shrimp (A) and treatment shrimp (B,C, and D), but highly significantly different with WFS shrimp (E).

Discussion and conclusion

Domination of nucleotide T and A make the gene mutate due to weak bonds. CypA gene in vannamei shrimp is categorized as rich in A-T which has a weak bond because it has 2 hydrogen bonds compared to C-G (Lee and Luo, 1977).

Polymorphism occurs because the percentage of polymorphism is more than 1% as mentioned by Lusiastuti *et al*. (2015) that polymorphisms (changes in one changing nucleotide in the genome) can occur at any genetic location and can be found at least in two different sequences. At least 1% cut off is classified as polymorphism and if the frequency is smaller than 1%, the allele is considered to have a mutation.

(Continued on next page)

The smallest polymorphism is obtained in treatment B (6 ppm squid ink extract) which means that only a few genetic changes in the *CypA* gene.

Based on survival rate analysis, using squid ink extract can increase SR of white shrimp and can be related to *CypA* gene in immune system.

The conclusion of this study was polymorphism was happen in WFS on white shrimp and the use of 6 ppm squid ink extract is the best because it causes the least change in the *CypA* gene.

Introduction

Viral nervous necrosis (VNN) is a serious pathology and one of the major threats for European sea bass (*Dicentrarchus labrax* L.) hatcheries and farms, having severe impacts, both in terms of animal and economical losses (Munday et al., 2002). Recently, interest has been directed towards selective breeding for improved genetic resistance, supported by the estimated magnitude of additive genetic variation (Doan et al., 2017; Palaiokostas et al., 2018). The aim of this study was to estimate the heritability for mortality after a VNN challenge test in a sea bass experimental population derived from a commercial stock, as well as for cortisol concentration after stress exposure and body weight at a fixed age. Genetic and phenotypic correlations among traits were also estimated, with the aim of identifying possible indicator traits to be used in indirect selection approaches to improve VNN resistance.

Materials and methods

A sea bass experimental population (N = 650) derived from a commercial breeding stock (Valle Cà Zuliani Società Agricola s.r.l.) and reared in external facilities (open sea-cages, Valle Cà Zuliani client) was subjected to a confinement stress firs and to a VNN challenge test later. All the fish were individually weighed (body weight, BW, at 548 days post-hatching) and tagged. The mortality (MORT) was recorded daily throughout the 29 days of the challenge test. Post-stress cortisol concentration (HC as ng ml-1, later normalized through the square root transformation of the original data, SRHC) were measured through radioimmunoassay technique from a blood sample collected from each fish before infection. A genome-wide SNP dataset for sea bass was generated through a high-throughput sequencing approach (2b-RAD), obtaining 16 075 SNPs. All the experimental fish and their parents were genotyped; the parentage and a high-likelihood pedigree were reconstructed for each tested individual. We estimated the genetic parameters of the traits using Bayesian procedures: univariate (to estimate heritability) sire-dam model for MORT (binary trait) or animal models for BW and SRHC; bivariate (to assess the genetic and phenotypic correlations between traits) sire-dam models when MORT was one of the trait, animal models for the other traits. To estimate the genomic heritability, five different regression models were implemented: Bayes A, Bayes B, Bayes C, Bayesian LASSO and Bayesian Ridge Regression.

Results

The survival rate at the end of the VNN challenge test was 52.2%. Genetic heritability and correlations are presented in Table I and II. Genomic heritability estimates for each of the five Bayesian models are presented in Table III.

Discussion and conclusion

Our results evidenced the presence of a genetic basis for the traits under investigation. The heritability of MORT estimated through a univariate model was low, but when it was estimated through bivariate models, the estimates were higher and comparable to estimates on larger datasets (Doan et al., 2017; Palaiokostas et al. 2018). Non-trivial genetic correlations among the traits (except for MORT and SRHC) suggest the possibility to develop indirect selective strategies to enhance VNN disease resistance. The genomic heritabilities were in general lower than the genetic estimates obtained using sire-dam or animal models (except for SRHC), probably due to the "missing heritability" phenomenon and the inability of the SNP effects to pick up all the variation due to additive genetic effects (De Los Campos et al., 2015). Despite the high number of iterations (2 000 000), the Bayesian LASSO was the only model that failed to reach convergence, and such estimates were not consistent with those obtained with the other genomic models. In conclusion, our results suggest the feasibility of selective breeding approaches to improve resistance to VNN, resistance to stress and body weight in European sea bass, also directing the interest to genomic prediction tools in the view of developing strategies to implement such selection.

SPATIAL FRAMEWORK FOR SITE SELECTION AND REGULATION OF FRESHWATER CAGE AQUACULTURE IN EUROPE

L. Falconer*, A. Ekpeki, R. Ozretich, T.C. Telfer

Institute of Aquaculture, University of Stirling, FK9 4LA
Email: lynne.falconer1@stir.ac.uk

Introduction

The use of cages for fish production in freshwater lake systems has declined in recent decades as production has moved to land-based systems in many locations. In the past, lake systems in northern European countries were important for intensive aquaculture as cages were used for production of Atlantic salmon (*Salmo salar*) smolts, rainbow trout (*Oncorhynchus mykiss*) and brown trout (*Salmo trutta)*. There are a number of reasons for this migration including the desire to have more control over production, technological advances, environmental concerns, and regulation and policy. For salmon aquaculture in particular, Scotland is now the only country where there are high numbers of smolts produced in freshwater cages. However, there are many freshwater lake systems throughout Europe and, if planned and managed appropriately, cages in freshwater systems can be an efficient and cost-effective production method. Site selection is of vital importance, as this will underpin the success and sustainability of a farm. Geographic Information Systems (GIS) can be used to identify the most suitable locations based on selected criteria. However, to date, the use of GIS to investigate spatial aspects of freshwater cage culture has been limited, particularly in comparison to the marine sector. There is a need for a spatial framework that can be used to identify suitable locations for culture, supporting sustainable growth of aquaculture in Europe in line with Blue Growth strategies.

Methods

A spatial framework was developed to assess the physical suitability and carrying capacity of freshwater lake systems and tested on a freshwater lake (loch system) in the north of Scotland. Environmental and socio-economic data layers were developed from fieldwork, earth observation data and secondary datasets. The modelling approach uses a number of GIS-based sub-models which are then combined to produce the final result.

Results and discussion

The model identified a number of sites that could potentially be suitable for aquaculture. Physical parameters were a key constraint, but socio-economic factors also affected overall suitability. The results also highlight the importance of the wider catchment and land-based activities, which must also be considered when selecting a site and managing farm operations as these influence carrying capacity. The framework can be applied to freshwater lake systems throughout Europe to assess suitability for cage production.

SURVEY OF WATER QUALITY AROUND RAINBOW TROUT (*Oncorhynchus mykiss*) CAGES IN THE SOUTHERN CASPIAN SEA

S.M.Vahid Farabi*[1], S.Reza, Sayed Mortezaei[2]

1- Caspian Sea Ecology Research Center (CSERC)
2- Iranian Fisheries Science Research Institute (IFSRI)
3- Agricultural Research, Education and Extension Organization (AREEO), P.O. Box: 961, Sari (Iran)
E-mail: Smv_Farabi@hotmail.com

Introduction

Water status is determined using the water quality index (WQI), which is presented to simplify the reporting and interpretation of water resources information (Rubio-Arias *et al*., 2012). Water quality index is one of the important tools for summarizing information on water parameters as well as transferring water quality information to authorities (Sanchez, 2007). This index is used to understand water quality issues by aggregating complex data and creating a single body to describe water quality (Bhargava, 1983).

Materials and methods

This study was carried out in two rainbow trout aquaculture farms in 5 floating cages in two regions of Mazandaran province (klarabad and Abbas Abad) on the southern coast of the Caspian Sea in the January to August 2015. The Iranian surface water quality index (IRWQIsc) for was determined around the floating cages using water parameters including turbidity, temperature, pH, electrical conductivity, dissolved oxygen, nitrate, ammonium and phosphate during *Oncorhynchus mykiss* aquaculture and the factors above plus biochemical oxygen demand of water, three months after aquaculture (APHA, 2005). The water quality index around the cage was determined by separating the different sampling periods in two modes: 1. Close the cage (cage shadow and distances of 50 and 100m); and 2.Distance of 1000m away from the cage (Karakassis *et al*., 2000). In order to calculate the water quality index of Iran, I-value was determined using standard tables for each parameter and then the IRWQI value was determined by the following formula.

$$IRWQI_{sc} = [\prod_{i=1}^{n} I_i^{w_i}]^{\frac{1}{\gamma}}$$

$$\gamma = \sum_{i=1}^{n} W_i$$

Wi: Weight of parameter i, Ii: Quality index value for parameter i of rating curve
n: number of water quality parameters

Results

The results showed that there was no significant difference between the two fish breeding centers and the distances to and from the cage ($P < 0.05$). However, the calculated values of water quality index in the study period in August (outside the fish farming period) were higher and significantly different than other periods ($P < 0.05$), but the water quality status of the sampling area during the period. According to the Iranian Surface Water Quality Index (IRWQIsc), it was in moderate condition.

Discussion and conclusion

The results seem to be influenc d by the natural conditions of the region. These results indicate that the quality and status of water around fish farms in cage culture are more dependent on the natural environment. Because, far from the cage and outside the fish farming period, the impacts of rainbow trout cage culture on water quality are not observed

(Continued on next page)

Table1. Iranian Surface Water Quality Index (IRWQIsc) and Water Quality Status (WQS) around rainbow trout breeding cages in two regions of Clarabad and Abbas Abad in the southern Caspian Sea (2015)

Marine Farm (fish cage culture)	Months of sampling	IRWQIsc Close to cage (up to 100m)	IRWQIsc Away from the cage (1000m)	WQS
Kelar Abad	January	46.39b	46.39b	moderate
	March	46.93b	46.93b	moderate
	May	46.96b	46.80b	moderate
	August	51.03a	50.82a	moderate
Abas Abad	January	46.69b	46.27b	moderate
	March	46.75b	45.91b	moderate
	May	46.71b	46.08b	moderate
	August	50.32a	49.51a	moderate

* The Latin letters represent a significant difference in each column between the 5% sampling periods under the F test.

THE IMPACT OF A PISCINE ORTHOREOVIRUS (PRV) INFECTION ON THE RESPIRATORY PERFORMANCE AND CAPACITY OF ATLANTIC SALMON AND SOCKEYE SALMON IN BRITISH COLUMBIA, CANADA

Yangfan Zhang[1], Mark P. Polinski[2], Phillip R. Morrison[3], Colin J. Brauner[3], Anthony P. Farrell*[1,3] and Kyle A. Garver[2]

tony.farrell@ubc.ca

Concern exists over the high prevalence of piscine orthoreovirus (PRV) in farmed Atlantic salmon (*Salmo salar*), which is now approaching 100% in British Columbia, Canada because PRV is known to be associated with heart and skeletal muscle inflam ation (HSMI). Even though the HSMI-associated mortality of farmed Atlantic salmon in British Columbia is reported to be negligible, the risk of the virus spreading to and harming wild salmon is considered to be very real given the suggestions that adult sockeye salmon (*Oncorhynchus nerka*) infected with PRV are failing to successfully swim up the Fraser River to reach their natal spawning areas. Given that PRV replicates in red blood cells of salmonids and can be associated with cardiac inflam ation, we reasoned that the respiratory capacity of an infected salmon should be impaired if they had been deliberately infected with a strain of PRV from British Columbia and viremia had become established. Therefore, we monitored the respiratory capabilities in sockeye salmon smolts for 9 weeks after they were injected with purified virus and in Atlantic salmon smolts for 21 weeks after they were injected with PRV-infected red blood cells. Comparisons were made with time-matched measurements on control fish that had received sham saline or non-infected red blood cell injections. Well-established performance indices (maximum, routine and standard oxygen uptake; recovery from exhaustion; performance in a hypoxic exposure) were measured over 4-days during a whole-animal respirometry trial, along with *in vitro* measurements of red blood cell oxygen affinity and hemoglobin concentration. None of the Atlantic salmon injected with a strain of PRV from British Columbia died during the respirometry experiment despite being chased to exhaustion and were made severely hypoxic, even though had developed severe viremia, a transient cellular antiviral response and minor heart pathology. Furthermore, when compared with sham-injected controls, none of the respiratory indices that were measured, including red blood cell oxygen affinity and hemoglobin concentration, changed appreciably or consistently at weeks 3, 9, 18 and 21 post-infection. Similar results were found for sockeye salmon smolts that were tested at weeks 3 and 9 post-infection. In contrast, an IHNV injection, which caused 34% mortality, initially suppressed energetic demanding cell proliferation and protein synthesis pathways while the IHNV load was being cleared in the surviving smolts (up to day 28). Also, the IHNV load in the survivors was associated with reduced standard (19%; p=0.015) and routine (19%; p=0.019) oxygen uptake, as well as a reduced ability to tolerate hypoxic water (15%; p=0.0007). Thus, while standard respirometry practices detected sub-lethal consequences of an IHNV infection, the viremia produced by a PRV infection did not impair respiratory functions of sockeye and Atlantic salmon smolts.

THE OPTIMAL DIETARY γ-Aminobutyric ACID (GABA) LEVEL IN JUVENILE OLIVE FLOUNDER, *Paralichthys olivaceus*

Nathaniel W. Farris, Ali Hamidoghli, Jinho Bae, Seonghun Won, Wonsuk Choi & Sungchul C. Bai*

Department of Marine Bio-materials and Aquaculture/Feeds and Foods Nutrition Research Center, Pukyong National University, Busan 608-737, Republic of Korea
E-mail: scbai@pknu.ac.kr

Due to the potential benefits of γ-Aminobutyric acid (GABA) in marine finfis culture, an 8-week feeding trial was conducted to determine the optimal dietary level of GABA and its effects in Juvenile olive flounde , (*Paralichthys olivaceus*). Eight groups of fish were randomly distributed into 24 rectangular 40 L tanks. Triplicates of 30 fish averaging 4.90 ± 0.1 g (mean ± SD) were fed one of the eight experimental diets; a basal diet without GABA as a negative control (CON), a positive control composed of CON + 4g/kg oxytetracycline (CON_{OTC}), and six other diets prepared by adding 50,100, 150, 200, 250, and 600 mg/kg GABA. Parameters including growth performance, non-specific immune response, disease resistance, enzyme activity, histology, and genetic expression will be measured after the trial is concluded. Results from this experiment will be reported in conference.

EFFECT OF LIGHT POLLUTION ON DIURNAL RHYTHM OF MELATONIN IN *Catla Catla* AND *Labeo Rohita*; COMPARATIVE STUDY IN FARM AND INDOOR FACILITY ILLUMINATION CONDITIONS

S. Fatima, *[1]

[1]Department of Zoology, Lahore College For Women University, Lahore, Pakistan
*Corresponding Author Email: shafaq.fatima@y7mail.com

Introduction

Use of artificial light at night (ALAN) for outdoor illumination has been exceeded in metropolitan, semi urban areas and animal farms including aquaculture research facilities. worldwide. ALAN has caused disruption in natural light and dark periods. These modified day lengths have profound effects on internal body clocks regulated by melatonin. ALAN at indoor research facilities might interfere with the results of scientific trials which have not be fully realized yet.

Materials and Methods

Present study investigated the effects of ALAN on diurnal profile of melatonin at indoor facility/laboratory (artificial light group: AL) compared with that at outdoor farm (natural light group: NL) in *Catla Catla* and *Labeo rohita*. Light intensity was measured to be 5 and 156 lux at farm and indoor facility, respectively. Blood samples were collected over the period of 24 hours.

Results

Levels of melatonin in NL group of both species started increasing at sunset (107.44 ± 0.10 pg/ml in labeo; 103.05 ± 1.23 pg/ml in catla). Highest levels were observed at midnight (180.90 ± 0.21 pg/ml in labeo; 175.06 ± 1.30 pg/ml in catla). Hormone profile started decreasing after sunrise and the minimum values were observed at mid-day. Diurnal profile of melatonin did not show any significant variability ($P > 0.5$) in AL group in both species and remained low over the period of 24 hours. This study concluded that ALAN in laboratories and indoor aquaculture facilities disrupts the hypothalamus-pituitary-pineal (HPP axis) and might affect the physiological activities regulated by melatonin in fish.

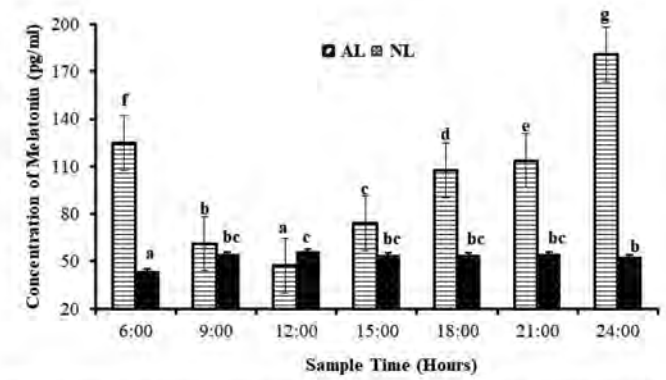

Fig. 1 Profile of melatonin (mean ± SE) in *Labeo rohita* exposed to natural (NL) and artificial photoperiod (AL) under farm and indoor facility conditions. Study was conducted on 27.03.2018 and 30.03.2018, respectively. Timings of sunrise and sunset were 6:00 and 18:00, respectively. Data Labels represents the homogenous subsets by Tukey's post hoc test.

Content
A growth trial with European seabass was performed to assess the effect of the dietary inclusion of *Ulva rigida* as is or with technological pre-treatment with ultrasounds (US) or solid-state fermentation (SSF) with *Aspergillus ibericus*. Promising results of the pre-treatment of *U. rigida* prior to dietary inclusion on growth performance and feed utilization efficiency of seabass were obtained, however, the effect of these treatments on fillet nutritional and sensory quality was not yet evaluated.

Introduction
Macroalgae show high productivity and do not compete for arable land to be cultivated as terrestrial alternatives (Bikker *et al*., 2016)a biorefinery approach aimed at cascading valorisation of both protein and non-protein seaweed constituents is required to realise an economically feasible value chain. In this study, such a biorefinery approach is presented for the green seaweed Ulva lactuca containing 225 g protein (N\\thinspace{\\texttimes}\\thinspace4.6. *U. rigida* is a green macroalgae with promising applications in food and feed industries (Biancarosa *et* al., 2018). However, its high fiber content may impair its inclusion in aquafeeds as fish lack the digestive enzymes able to hydrolyze it. Therefore, pre-treatment can be

(Continued on next page)

a helpful strategy to disrupt the complex macroalgae cell-wall and promote the release of fermentable sugars and other valuable compounds and facilitating the access of digestive enzymes to the cell content (Fernandes *et al*., 2019a)and new applications for macroalgae should be considered. In this work, sequential biological treatments as solid-state fermentation (SSF. In a previous growth trial, it was observed that dietary replacement of fish meal by 5% untreated *U. rigida* reduced growth performance and feed efficiency of on-growing European seabass, while the dietary inclusion of *U. rigida* pre-treated with ultrasounds or solid-state fermentation with *Aspergillus ibericus* did not affect growth performance nor feed efficiency (Fernandes *et al*., 2019b). However, the influenc of these biological and physical pre-treatments of *U. rigida* on the nutritional and sensory quality of commercial-size European seabass was not yet evaluated.

Materials & Methods

For the biological pre-treatment, dry micronized *U. rigida* was fermented with *A. ibericus* (MUM 03.49) for 7 days at 25°C, in tray-type bioreactors; for the physical pre-treatment, *U. rigida* was submitted to ultra-sounds (US) during 1 hour in protective containers, using a high-intensity ultrasonic processor at 50-60 Hz. A control diet containing 25% fishmeal (FM) (D1); untreated and pre-treated *U. rigida* were incorporated in test diets replacing 5% (w/w) FM, as follows: D2: untreated *U. rigida*; D3: US-treated *U. rigida*; and D4: SSF-treated *U. rigida*. All diets were isoproteic (45%) and isolipidic (18%). Triplicate groups of European seabass with 108 g IBW were fed to apparent visual satiation for 64 days. At the end of the experimental period (FBW averaging 240 g), plasma metabolites and fillet fatty acids profile and sensory properties were assessed.

Results & Discussion

Plasma glucose levels were lower in fish fed ultra-sound treated *U. rigida* diet relatively to fish fed the untreated *U. rigida* diet. Dietary inclusion of *U. rigida* increased plasma cholesterol levels, which were restored to the control levels in fish fed the SSF *U. rigida* diet (Table I).

Even though fillet polyunsaturated fatty acids (PUFA) content was similar among groups, fish fed *U. rigida* diets presented 8 to 13% more α-linolenic than fish fed the FM-based diet. The ω3/ω6 ratio was 8% lower in fish fed ultra-sound *U. rigida* diet but 7% higher in fish fed solid state fermented *U. rigida* diet than with the untreated *U. rigida* diet.

Concerning the organoleptic properties of European seabass, no significant differences in typical odor, color, and taste between groups were found (Fig.1).

Conclusions

U. rigida pre-treatment by solid-state fermentation or ultra-sounds did not compromise fillet FA profile and the sensory quality of European seabass. Such results support the potential for inclusion of pre-treated *U. rigida* in sustainable diets for European sea bass.

VITAMIN K IN FISH NUTRITION: AN INTEGRATIVE UPDATE OF FUNCTIONS AND REQUIREMENTS

Ignacio Fernández*, Cristina Tomás-Almenar, Ana Larrán

Center for Aquaculture Research, Agricultural Technological Institute of Castilla and León, Ctra. Arévalo, s/n. 40196 Zamarramala, *Segovia,* Spain
fermonig@itacyl.es

Introduction

Vitamin K (VK) is a fat-soluble molecule known to be essential for blood coagulation and bone metabolism by two different pathways: (i) the gamma-carboxylation of different VK dependent proteins (VKDPs) and (ii) the transcriptional control of several genes through the pregnane X receptor (PXR) signaling. Recently, new biological functions of VK have been suggested in mammals. In this regard, dietary VK levels regulates testosterone synthesis in testis, promoting male fertility (Karsenty and Ferron 2012). Furthermore, nutritional status of VK has been also associated with neural development and cognitive capacities (Ferland 2012).

In fish species, a relative limited impact of VK on fish physiology, with low nutritional requirements, were reported for blood coagulation and bone development/homeostasis (reviewed in Krossoy et al., 2011). This could be related with an extensive use of menadione (VK3; either as menadione sodium bisulphite or menadione nicotinamide bisulphite) as the nutritional source of VK in commercial diets. Interestingly, several reports evidenced that fish growth and development might depend on the source of VK-used.

Here, we will review the molecular basis of VK metabolism and the recent literature on this issue, showing how VK has a higher impact on fish hemostasis and skeletal system than previously considered. Furthermore, new reports suggest a broader role in another biological functions such as brain and visual organs development, as well as reproductive status.

Results and discussion

A specific nutritional requirement of VK during fish larval development for a better skeletal development, reducing the incidences of skeletal deformities when supplementing live prey enriching emulsions with phylloquinone (VK1), was first shown in 2014 by Richard and co-workers. In the same study, the initial evidence of VK having new roles was provided through a comparative proteomic approach, where proteins involved in muscular contraction, energy metabolism and/or osmorregulation were found differentially expressed in fish fed with VK1 supplemented diets. Afterwards, we characterized the effects of VK deficiency and expanded the biological roles where it might be involved through the localization and quantification of the genes involved in the VK recycling and the PXR signaling. Chemically induced VK deficiency ¡during fish larval development caused hemorrhages in brain, skeletal deformities and triggered ectopic calcifications (Fernández et al., 2014). The genes encoding the enzymes responsible for VK recycling during VKDPs carboxylation, the VK epoxide reductases (VKORS: VKORC1 and VKORC1L1), were found differentially expressed along larval development and in adult tissues through qPCR, suggesting a high requirement of VK during fish early development (embryonic and endotrophic larval period), but also at visual organs, brain and ovary in adult fish (Fernández et al., 2015). Through *in situ* hybridization procedures, PXR was found to be specificaly expressed in cells from the granular layer, which has been related with cognitive capacities; and at inner nuclear and nerve fiber layers, regions related with night blindness and other retinal disorders (Marques et al., 2017).

More recently, and following previous results, we explored how a dietary VK supplementation affected the reproductive status and the early development in fish species through high throughput transcriptomic analysis (RNASeq). VK1 supplemented diets increased testosterone levels and sperm quality (reducing sperm DNA fragmentation) in fish (Fernández et al., 2019). In addition, using an innovative approach, we were able to identify some small non-coding RNAs (sncRNAs) within blood plasma directly associated with nutritional and reproductive status, highlighting the potential use of these sncRNAs as an integrative and less invasive biomarkers in aquaculture (Fernández et al., 2019). In addition, through a chemically induced VK deficien y we have revealed its high impact on early fish development (embryonic and endotrophic period), inducing mortality, hemorrhages and retinal atrophy, and reducing skeletal development (Granadeiro et al., 2019). To gain insights into the underlying mechanisms a RNASeq analysis identified 766 differentially expressed (564 up- and

(Continued on next page)

202 down-regulated) genes related with particular cellular components (cytoplasm, extracellular matrix, lysosome and vacuole), biological processes (mainly amino acid and lipid metabolism and response to stimulus) and pathways (oxidative stress response and apoptosis signaling pathways). Last, but not the least, dietary VK level might have an additional effect on the intestinal microbiome (Fernández et al., unpublished).

Altogether, these research studies highlighted the need for a reformulation of the nutritional requirements of VK in commercial diets used in farmed fish species along the whole production cycle (from gametes to broodstock)

SKELETOGENESIS OF TENCH (*Tinca tinca*) REARED IN EXTENSIVE AQUACULTURE: TOWARDS A HIGH QUALITY PRODUCTION STANDARDS

Ignacio Fernández[1*], Ana Larrán[1], Luis M. Laguna[1], Pedro Cárdaba[1], Jose A. Mateos[2], Cristina Tomás-Almenar[1]

[1]Center for Aquaculture Research, Agricultural Technological Institute of Castilla and León, Ctra. Arévalo s/n. 40196 Zamarramala, Segovia, Spain
fermonig@itacyl.es
[2]Tencas Mateo S.L., C. Campo, 17, 40297 Sanchonuño, Segovia, Spain

Introduction

Tench (*Tinca tinca*) is a freshwater fish that belongs to the Cyprinidae family inhabiting stagnant waters with abundant vegetation of central and southern Europe. Although it has been cultured for centuries, there is a limited production in quantity (around 1400 t) and value (4.5 M USD) per year, mainly located at France, Check Republic, Germany and Poland (http://www.fao.org/fishery/e). In Southern countries, Spain (Extremadura and Castilla y León) and Italy (Piedmont), it has been traditionally reared with a preferred commercial size of 80-120 g with a high value (16-18 € kg^{-1}; Parisi et al., 2014).

Tench is considered a promising new species for aquaculture diversification since it can tolerate low levels of oxygen, a wide range of temperatures (10-34 ºC), vegetable sources on their diets and the regular manipulation during rearing procedures. The main bottlenecks are: (i) the use of Artemia nauplii during the early development in indoor systems; (ii) the climatic variability on extensive rearing systems with the slow growth and feeding stop under 10 ºC, requiring 2-4 years to reach the commercial size (120-500 g, respectively); (iii) the lack of specifically formulated commercial feeds; and (iv) the high rate of skeletal deformities (Parisi et al., 2014).

It is long known that skeletal deformities hinders production efficienc , decrease animal welfare and product value if deformed specimens reach the market (Boglione et al., 2013).

Although some research effort has been placed to determine the optimal nutritional composition of diets for tench (one of the main factors determining skeletal development in fish species), there is a knowledge gap on the sequential development of its skeleton and the required nutrients for its successful development. In this sense, describing the ontogeny of skeletal development (when and how skeletal structures are formed) will pave the future studies to optimize rearing conditions during early development in order to mitigate and/or avoid the appearance of bone deformities.

The aim of the present study was to implement an acid-free double staining protocol, providing a detailed description of the skeletogenic process during tench larval development as well as assessing the skeletal quality (types and incidence of skeletal deformities) of juveniles reared in traditional extensive systems.

Materials and methods

At a local producer facilities (Tencas Mateo), fish gametes were obtained by manual abdominal striping of tench females and males and an *in vitro* fertilization was performed. Embryos were maintained at 22 ºC for two days, and newly hatched larvae were released in a small natural pond. Sampling of tench larvae/juveniles was performed at 2, 5, 7, 30, 42, 65 and 85 dpf using a 60, 100, 200 or 1000 µm sieve according with fish size (10-15 fish per sampling point). Fish were euthanized with a lethal dose of tricaine methanesulfonate (MS-222, Sigma-Aldrich), its standard length (SL) measured, rinsed in distilled water, fixe in 4% buffered (pH 7.4) formaldehyde and stored at 4 ºC until the skeletal analysis. To evaluate the degree of mineralization of the skeleton, and to identify and quantify the incidence of skeletal deformities, animals were stained for bone and cartilage in whole mount preparations using an optimized acid-free staining protocol (Fernández et al., 2018). Skeletal structures were identified and named according to Cubagge and Mabee, 1996; Bird and Mabee, 2003). The development of skeletal structures was categorized as cartilaginous, on its onset of ossification and with and advanced ossification in order to mathematically represent the ossification process along larval developmen

(Continued on next page)

Results

Tench larvae in extensive systems shows an exponential growth in standard length although showing a large variability. The skeletal system started to be represented by a low developed cartilage structures at the fish skull, only being identified structures for breathing and preys capture at 4-9 mm SL. First structures to be ossified at 9-16 mm SL were cleithrum, maxilla, dentary and operculum. Posteriorly, while cranial structures underwent extensive ossification, caudal fin complex start to be formed through chondral ossification (from 14 mm SL onwards). Finally, axial skeleton was progressively formed through intramembranous ossification, being fully mineralized at 25 mm SL. Early juveniles (20-48 mm SL; 85 dpf) have a considerable incidence of skeletal deformities, mainly located at the end of the vertebral column (around 50%), although the first type of deformity clearly identified along the development was the absence of pectoral fins (at 14 mm SL).

Discussion and conclusions

The implementation of an acid-free staining protocol allowed us to perform an accurate description at which size each skeletal structure appeared and ossified since such procedure avoid the loss of calcium in incipient ossified structures, typical of acid cartilage staining procedures. Furthermore, the present detailed description of how the skeleton is formed will represent a basic knowledge to apply in regular monitoring procedures to compare how nutritional regimes, rearing conditions and systems might improve skeletal quality of produced tench.

Introduction

The sustainable use of natural resources is a key issue to ensure food safety, nutrition and the sustainable development of aquaculture (FAO, 2018). Among other factors, fish nutrition is one of the most critical in fish farming, representing 40–70% of the production costs and determining survival, growth potential and quality of farmed fish. Nowadays, the future of aquaculture relies on the identification of suitable and alternative raw materials to substitute fishmeal (FM). Different sources and percentage of inclusion have been evaluated in order to develop Fish-Free Feeds (F3) and/or alternative diets (with important but not total FO and FM substitution). Although meal from insects and other invertebrates, algae, microorganisms, feather and/or byproducts from other agrifood industries are also currently considered, FM replacement is currently done with protein vegetable sources, considered as the best candidates. Soybean meal (mainly produced in USA, Argentina and Brazil) is still the most used alternative raw material to substitute FM, although it hampers fish physiology by unknown. In order to reduce the import of soybean meal, European aquaculture needs to explore, identify and promote local vegetable proteins sources in order to reduce its dependence of third countries.

Narbonne vetch *(Vicia narbonensis)* is a legume crop widely available and abundant in several regions of Southern European countries (France, Turkey and/or Spain), with seeds containing 20-30% protein and a partially balanced amino acid profile. Although a low inclusion level has been already implemented in diets for pork and broilers, little is known about their effects on aquatic animals. Thus, the present study aimed at evaluating the effects on growth, digestive system and nutritional value of increasing levels of inclusion of Narbonne vetch in diets for rainbow trout (*Oncorhynchus mykis*).

Materials and methods

After acclimatation, 25 fish (26.8 ± 0.7 g and 13.4 ± 0.1 cm) were randomly allocated into 9 cylindrical fibe glass tanks (500 L) connected to a recirculating aquaculture system. Water conditions were 15 ± 1 °C, > 7 ± 1 mg/L of dissolved oxygen, and 12:12 h light:dark cycle photoperiod.

Fish were hand-fed to apparent satiation once a day (until a maximum of 3% daily feed intake) for 63 days with experimental diets containing graded levels of Narbonne vetch (*Vicia narbonnensis*). The presence of anti-nutritional factors (ANFs) in Narbonne vetch was previously determined *in vitro* through the assessment of rainbow trout alkaline proteases inhibition (Alarcón et al., 1999). An analysis of essential amino acids was also performed to identify potential deficiencies was also done. Finally, three isoproteic (44%) and isolipidic (18%) diets with increasing levels of inclusion of Narbonne vetch (*Vicia narbonnensis*; 0 (Control), 10 (A10) and 30% (A30)) were formulated.

Growth performance (weight and length) was evaluated at 21, 42 and 63 days, being fish previously fasted during 24 h. Fish were anesthetized with MS-222 (180 mg/mL), SL was assessed using a graduated ictiometer (± 0.1 mm) and wet weight with a GRAM S3R-6KD balance (± 0.1 g). Apparent digestibility analysis was carried out during the last two weeks of the growth trial. At the end of the experiment 3 fish from each tank were randomly sampled and sacrificed with an overdose of MS222 in order to: i) biochemically assess the blood plasma composition (glucose, cholesterol and triglycerides) as well as the aspartate aminotransferase and alanine aminotransferase activities (Bio-Science Medical S.L.) using a microplate reader (ELx800TM; BioTek Instruments); ii) histological characterization of key tissues (liver, proximal and distal intestine) by HE and alcian blue staining as described by Bancroft and Stevens (1990); and iii) determine the fatty acid composition of fillet samples through HPLC analysis

(Continued on next page)

Results

Narbonne vetch has a low content of methionine, isoleucine, leucine, phenylalanine, histidine and lysine as alternative raw material to substitute FM. Furthermore, the presence of ANFs has been evidenced by a progressive inhibition of alkaline proteases with the increase of inclusion levels (with a 28% and 46% inhibition in A10 and A30 diets, respectively). In agreement with these results, a 30% inclusion of Narbonne vetch in rainbow trout diets reduced the final fish growth, SGR and FCR; while a 10% inclusion only reduced the FCR. Fish from A30 group had a higher hepatosomatic index, reflecting a histological disorder on their hepatocytes. Among the parameters evaluated regarding the histological organization of the intestine (villi folds height, density of goblet cells, height and nucleus position of enterocytes, etc.), some slight effects were also observed when increasing the levels of Narbonne vetch in fish diets. Fatty acids composition of the muscle was also affected, particularly the content on Docosahexaenoic acid (DHA), but only in fish fed A30 diet.

Conclusions

Present results showed as 30% Narbonne vetch inclusion in fish diets affected rainbow trout growth and physiology. Similar results were previously reported in another freshwater fish species, the tilapia (*Oreochromis niloticus*), were inclusion of > 20% provided lower growth (Buyukcapar et al., 2010). The present poor growth in fish fed high inclusions of Narbonne vetch seemed to be due to the presence of ANFs that had an impact on the digestive system. Future studies will explore the inclusion of another locally produced legumes and/or different varieties of Narbonne vetch as potential alternatives to soybean meal in fish feeds

Introduction

Atlantic cod (*Gadus morhua*) is a key fish in the marine trophism of the Northern Hemisphere and an emerging species in aquaculture. Cod is characterized for being iteroparous with synchronous oocyte development and spawning up to 19 batches over several weeks (February-May) (Kleppe et al., 2014). Viability of eggs and embryos is unpredictable and mortality as well as malformations in early-life stages are high. Currently, egg quality and survival is determined by fertilization rates and cleavage patterns. Although those measures provide reasonable indication of egg quality, knowledge of the molecular basis of embryonic development would improve current practices of egg quality determination. Gametic transcripts are essential during early developmental stages (Lawrence et al., 2006) since zygotic gene transcription is not activated until several cell divisions had been completed (Skjærven et al. 2011). Even though the Atlantic cod genome is now sequenced and more transcripts are available (Dale et al., 2019) a limited number of studies have analysed its early transcriptome. This study opens up the possibility of finding links between six stage specific genes and egg quali .

Materials and methods

In order to develop molecular criteria to assess egg quality in Atlantic cod we stripped gametes from 12 parental pairs and obtained 4-7 egg batches from them during the 2018 spawning season. Eggs and sperm were stripped every 48-72h, fertilized and incubated until full batch hatching. Samples were taken at six embryonic developmental stages during the incubation period (unfertilized egg, zygote, blastula, gastrula, early somatogenesis and late somatogenesis) as well as newly hatched larvae for further molecular analyses. Conventional egg quality determinants such as fertilization rate, normal cleavage pattern and egg mortality were also recorded.

Seven out of thirty-three genes were selected upon their effici ncy values for gene expression analysis to delve into the temporal transcriptome activity during cod embryogenesis and twelve housekeeping genes were included to normalise mRNA levels between samples.

Results and discussion

Standard egg quality indicators have revealed significant egg quality variation throughout the spawning season within female, being significantly higher in the middle of the period. Besides, egg quality seems to differ among females, what is an additional source of variation to be explained in this study using gene expression analyses. According to the efficiency values of the tested genes they seem to be adequate to explore early gene expression in cod.

Gene expression comparison among females and among spawns could allow the development of egg quality-associated markers for cod aquaculture improvement.

Introduction

European sea bass (*dicentrarchus labrax*) and gilthead sea bream (*sparus aurata*) are both an economically important cultured fish species along the Mediterranean coast. Both species represent respectively 10.9% and 13.5% of the total value of the European aquaculture sector. The EU is one of the largest producers of sea bass and sea bream in the world, being Greece the largest producer within the EU followed by Spain. However, the Turkish sea bass and sea bream industry has been steadily increasing production volumes for the last decade to the point where Turkey is now the world's major producer of seabass, competing with European producers with lower prices (Globefish, 2015). As consequence, during this period of time, European firms have been struggling to maintain profitability of their farm

The main aim of this work, which is part of the MedAID project funded by the European Commission (H2020, GA727315), is to carry out a sensitivity analysis to assess the impact of changes in output quantities and prices on firms profitability and operating risk of European producers of cultured sea bass and sea bream in the Mediterranean Sea using the classical cost-volume-profit (CVP) model. This model is an important and well-known managerial tool that attempts to specify a firm s cost and revenue functions, allowing to business owners and managers to perform break-even analyses as well as to predict profit behavior in different conditions in order to evaluate business viability (Ingram, Albright, & Hill, 2003; Weygandt, Kieso, & Kimmel, 1999).

Methodology

To perform the sensitivity analysis, the CVP model employed in our study is as follows:

$$TR = pq$$

$$TC = c_0 + c_1 q$$

where TR = Total operating revenues; TC = Total operating costs; p = Sales price per unit; q = Number (quantity) of units to be manufactured and sold during the period; c_0 = Constant parameter of the total cost function (total fixed expenses for the period), being $c_0 >= 0$; and c_1 = Slope parameter of the total cost function (unit variable cost), i.e. variable expenses to manufacture and sell a single unit of product, being $c_1 >= 0$.

The *margin of safety* (MOS)**,** which is the difference between the actual sales and the break-even sales of a firm, is an important figure for any business because it tells management how much reduction in revenue will result in break-even serving as a measure of operating risk (Ingram, Albright, & Hill, 2003; Weygandt, Kieso, & Kimmel, 1999). The margin of safety can be also expressed in the form of ratio, which is calculated by using the following formula:

$$\text{MOS ratio} = 100 \times (\textit{Actual sales} - \textit{Break-even sales}) / \textit{Actual sales}$$

Thus, the larger is the ratio the lesser is the risk in reaching the breakeven point and the risk of business to have losses.

Table I. Representativeness of the sample used in this research

Country	Number of firms			Number of employees

	–10	50.0	269.5	0.71	–5.96

A representative sample of the 30 main firms producing cultured sea bass and sea bream in the Mediterranean Sea from 7 European countries was employed in our analysis (see Table I). The period of time analyzed ranges from 2005 to 2014 (10 years). The *TR* curve was estimated with a linear function by ordinary least squares (OLS). The *TC* curve was estimated through nonlinear regression with parameter constraints using linear, quadratic, and cubic functions although, finall , we have employed in the results section a simple linear function because the fit obtained with it was the best. The variables used to estimate the two curves for each firm were *TR* = yearly total operating revenues of the firm (in thousands of euros) obtained from the AMADEUS database, *TC* = yearly total operating costs of the firm (in thousands of euros) obtained from the former database, and *q* = yearly sales of the firm (in tons), which was estimated using the yearly total operating revenues of every firm divided by the yearly average of sea bass and sea bream ex-farm prices in the firm s country. In this case we hypothesized that the firm is producing and selling in the same proportion both species since we cannot observe the firms actual level of production and sales. The yearly sea bass and sea bream prices in each country were obtained from the EUMOFA database.

Results

In Table II we present the results of the sensitive analysis where we have simulated how different changes in economic conditions (variation of market prices) or decisions (variations in production levels) have affected on the profitability (operating profit) and risk of the sampled firms. We have increased and decreased those factors in different proportions (1%, 5%, and 10%) to estimate the effects. The largest positive and negative effect on firms operating profits has been obtained with the price variable (*p*) although this variable is not over firms control (competitive market). On the other hand, changes in the level of production (*q*) had the lowest effect on firms profits. Likewise, similar results have been obtained with the firms operating risk (average variation in the MOS ratio) although the negative effect of a reduction in price is stronger than the effect obtained with the opposite variation.

Conclusion

Regarding the sensitive analysis that we have performed to analyse the effect of price and production changes on firms profitability and operating risk with European producers of cultured sea bass and sea bream, we can conclude that the changes in market prices have had the largest effect (positive or negative) on firms operating profits and risk, whereas changes in production levels have had the lowest effect on those variables.

Introduction

Garra rufa (Heckel, 1843) is the only recommended fish species to be used in ichthyotherapy, an activity in which the fish are used to clean the skin, wounds or treat other skin conditions. Notwithstanding, this activity raises several questions regarding fish welfare. One of the main constraints regards the fact that some fish keepers are accused of starving the animals, as to motivate them to interact with humans and feed on their dead skin cells. In order for the fish to be interested in removing cells from the corneal layer of the epidermis, it will be necessary to provide them with good quality feed, in adequate quantities, as to avoid a decline in the animals' health and physical condition.

An experimental trial was conducted to determine the quantity of food that could be adequate to establish a commitment between fostering the interest of *G. rufa* in interacting with humans and avoid compromising the fish welfare. Accordingly, fish submitted to a daily chthyotherapy session were given four different food doses. At the end of 3 weeks, *G. rufa* were evaluated in what regards: survival; growth in terms of total length and individual weight, specific growth rate (SGR), absolute growth rate (AGR), feed conversion rate (FCR) and body condition index (K), plus the fish nibbling interest throughout the experimental trial.

Materials and Methods

During 3 weeks, *G. rufa* were subjected to a single ichthyotherapy session of 30min.day^{-1} with a different human subject. The fish were maintained in 2 recirculating aquatic systems (RAS), from which were used 15 aquaria of 22L, with 9 individuals each. Five sets of 3 aquaria, randomly distributed in the RAS, were assigned with a different quantity of a commercial granulated feed (energy content of 4230Kcal.Kg^{-1}), given at 05:00PM of each day. The food supplied to each treatment corresponded to 25% (dose 1), 50% (dose 2), 75% (dose3) and 100% (dose 4) of the daily dose, corresponding to an *ad libitum* circumstance (≈0.065g.fis $^{-1}$). The fifth set of aquaria portrayed a reference situation (RS), in which *G. rufa* received 100% of the daily dose and were not subjected to ichthyotherapy procedures. On weekends, all the fish were given 100% of the daily dose of food and were left quiet in the RAS to simulate the conditions of a commercial establishment practicing ichthyotherapy.

The fish were transferred to 12L aquaria 30min before the ichthyotherapy sessions. The aquaria contained only tap water, left to warm by means of water heaters with the thermostat set for 28ºC and strong aeration to eliminate chlorine disinfectant residues, since the previous day. People's hands were inspected for the absence of active lesions, carefully washed, disinfected with alcohol and passed thoroughly through clean water, for the health safety of both humans and fish. During these sessions, the number of times that the fish came in contact with humans, nibbling the hands of each volunteer.

At the beginning and at the end of the experimental trial, all *G. rufa* were measured for total length with an ichthyometer and weighed on an analytical balance.

Results

By the end of the trial, only 2 fish died because they tried to escape the RAS and not in consequence of the ichthyotherapy procedures. All *G. rufa* grew in terms of total length, without significant differences between treatments (Kruskal-Wallis test H_4=6.18, p>0.05), but those who were given dose 1 gain more weight than those from dose 4 (One-way ANOVA $F_{4,126}$=3.35, p<0.05, Bonferroni test p<0.05). *G. rufa*'s behaviour evolved with time. The number of times that fish invested in exploring hands increased from 8.15±6.66 to 21.85±11.15incursions.fis $^{-1}$ from the 1st to the 3rd week of ichthyotherapy. Although, the most active fish were always those who were given less food. Accordingly, fish fed with dose 3 invested less time in nibbling hands (12.01±2.31incursions.fis $^{-1}$) and those from dose 1 were the most interactive (32.60±2.40incursions. fis $^{-1}$) in the last week of the trial.

(Continued on next page)

The performance parameters SGR and AGR showed that *G. rufa* fed with dose 1 showed values almost as good as to those from the reference situation (RS), while those from dose 4 showed the worst results. Regarding DGI, the values obtained did not differ between the fish treatments (H_4=8.85, p>0.05), while *G. rufa* from dose 4 presented a significantly lower K than those from RS ($F_{4,126}$ =2.87, p<0.05, Bonferroni test p<0.05).

Discussion

The present work was able to perform daily sessions of ichthyotherapy without registering mortality of *G. rufa* fish. For reasons of hygiene, fish were transferred daily between their RAS and the treatment aquaria, disinfected and with new water. Although this procedure induced stress for the animals, *G. rufa* shown to be a resilient fish. Their behaviour evolved during the experimental trial, evidencing a learning capacity related to daily routine procedures. This was manifested by the increased frequency of contact between fish and humans over the course of three weeks, regardless of the amount of feed given to them. However, the most interactive fish were always those to whom less food was given. All fish grew under the experimental conditions, in terms of total length, but not in terms of individual weight. Fish submitted to daily ichthyotherapy sessions and fed with the whole daily dose showed more reluctance to nibble human skin and decreased in body weight. This result reflected as a decrease in the body condition index, probably as a consequence of the daily stress to which they were subjected. Although the skin of vertebrates in aquatic habitats (including humans and other fish) reveals itself as an alternative food source, easier to obtain (Sayili et al., 2007), epidermal cells appear not to be part of the typical diet of *G. rufa* (Yalçin-Özdilek and Ekmekçi, 2006). Therefore, the welfare of the fish is put into question when adopting this type of procedure. Without an adequate diet, fish growth can be delayed and may even cause the animals' death (Wildgoose, 2012). For this reason, it is recommended that a good quality commercial feed be supplied to satisfy the fish nutritional requirements. The amount of feed recommended as a daily dose will be between the 50% and 75% of the dose *ad libitum*, which corresponded to an energy content among 0.14 and 0.21Kcal.fis $^{-1}$. In this way, a compromise can be found between the interest of *G. rufa* to interact with humans and ensure the fish welfare

Introduction

Sea anemones *Actinia equina* (Linnaeus, 1758) and *Actinia fragacea* Tugwell, 1856 have relevant characteristics to be exploited as ornamental species or as potential organisms for the extraction of bioactive compounds. There are currently some successful records of asexual propagation of anemones in captivity. Generally, this propagation is done by longitudinal cutting healthy specimens in several portions (Olivotto et al., 2011; Scott et al., 2014). However, there is a limited number of studies with sufficient details on the optimization of the process and it has been reported only for a few species

The main objective of this work was to evaluate the viability of propagating sea anemones *A. equina* and *A. fragacea*, by longitudinal fission of the animals in two halves. It was evaluated the survival rate of these anemones, the time it took them to regenerate and evaluate the growth of the new sectioned anemones.

Materials and Methods

The anemones were collected manually at Praia do Portinho da Areia Norte (in the middle Atlantic coast of Portugal), transported to laboratory and acclimated in a recirculation aquatic system (RAS) for 1.5 months. Sixty anemones of each species were selected, based on their similar size. The animals were left to fix on a small identified pebble, with a known weight, and kept at 10ind.aquarium^{-1}. The *A. equina* anemones were distributed by 6 random 18L aquaria in the RAS, while *A. fragacea* anemones were inserted in other 6 aquaria of the same RAS. For the trial, all anemones were forced to contract at their maximum capacity, in order to minimize variations of water content within the gastrovascular cavity and body shape. Then, each individual was gently dried with absorbent paper, to remove excessive water, weighed on an analytical balance and measured for height and diameter. In 3 aquaria of each species, the animals were kept intact (control), while in the other 3 aquaria, the individuals were cut longitudinally in half (treatment). Afterwards, all the anemones were monitored for 20 weeks, regarding their survival, size (height of the body column and diameter of the pedal disc), biomass and regeneration of the sectioned individuals (how long it took them to join the ends of the cut, protecting the gastrovascular cavity; the number of individuals who did fully regenerated; and the time it took them to achieve it, with the disappearance of the scar).

Results

None of the anemones died during the acclimation or the experimental periods. Although anemones *A. fragacea* were initially larger than *A. equina* (in terms of biomass, diameter and height), both species showed similar behaviour throughout the experimental trial. At the end of 20 weeks, all the anemones lost biomass and became smaller in height and diameter, independently of the species and of being cut in half or not.

In what concerns the severed anemones, *A. equina* were faster to curl and seal the cut zone than the anemones *A. fragacea* (41.75±2.45 versus 54.5±2.23days; Mann-Whitney test U_{118}=4385.00, $p<0.001$), re-establishing their shape and the gastrovascular cavity. Almost all *A. equina* were able to fully regenerate (90%), whereas only 71% of *A. fragacea* were able to eliminate their scar during the experimental period (Pearson's chi-square test χ^2_1=5.79, $p<0.05$). Moreover, *A. equina* also took lesser time to achieve this accomplishment than *A. fragacea* (Mann-Whitney test U_{95}=2580.00, $p<0.001$; 98.89±1.01 days *versus* 105.00±0.00 days). Indeed, the first *A. equina* to fully regenerate was observed at day 75, whereas the first individual *A. fragacea* without a scar was detected at day 90.

Discussion and conclusion

The methodology of dividing anemones longitudinally in half has proven to be effective as an asexual propagation method, both for *A. equina* and *A. fragaceae*. It employs procedures of low technological exigency and, consequently, implies low economic costs. The anemones *A. equina* and *A. fragacea* were able to regenerate without any mortality. Despite the damage inflicte on the anemones, they must not have suffered pain due to the lack of a developed nervous system. They

(Continued on next page)

have only clusters of sensory neurons, as essential structures of a diffuse network, without a central information processing organ (Hickman et al., 2014; Castro & Huber, 2016). However, the fact that all specimens decreased in size, during the experimental procedure, evidenced the need to investigate in the future: 1) the best environmental conditions to be supplied to these organisms in captivity; and 2) what is the best diet, which will allow them to regenerate and grow as fast as possible.

As the sea anemones *A. equina* and *A. fragacea* gather potential as ornamental species and scientific research subjects, the asexual propagation process will help to reduce the impact on their native populations and ecosystems. The process of obtaining two organisms from a single one is feasible. Thus, the need to capture natural specimens of anemones, for ornamental, scientific research or biotechnological application purposes, would be reduced. This process can be carried out in captivity, at a desirable frequency, to obtain an intended number of individuals with similar genotypes, all year long, without the need of collecting wild specimens.

Introduction and Modelling Approach

Carrying capacity for aquaculture has been defined in different ways, and can be considered to be the lowest common denominator of physical space, production capacity, ecological sustainability, and social aspects (McKindsey et al, 2006; Ferreira et al., 2013). The latter includes factors such as social license and governance, which are not amenable to mathematical modelling.

The ABC (Aquaculture, Biosecurity, and Carrying Capacity) model focuses on four key pillars of sustainability: physics, husbandry, environment, and pathogens.

Previous work on ABC has described innovations with respect to combining production and pathogen modelling, through a combination of Individual-Based Models (IBM) that simulate physiological processes in a quasi-deterministic manner, and a state-of-the-art stochastic approach to host-pathogen interactions. One of the key features of this model is the ability to simulate disease events triggered by accumulation of pathogen in the host through uptake from the environment (i.e. from the surrounding water), rather than through contact between animals.

The disease component can only be used stochastically to simulate scenarios and does not provide predictive modelling on the timing of disease outbreaks. Nevertheless, risk assessment, which is key for licensing, insurance, and investment decisions can benefit significantly from the application of such combined models. The model has been used to examine the effects of climate change on the onset of disease, production, and mortality, but also to look at the effect of stocking density on water quality, by means of indicators such as oxygen depletion and build-up of ammonia in farm areas.

Results and Discussion

Fig. 2 shows the results of an ABC model run for gilthead bream (*Sparus aurata*), considering two different mixing conditions for a farm with five culture areas 100 m apart. The upper pane shows results for dissolved oxygen and ammonia with high lateral dispersion, whereas the lower pane considers a situation where the effect of turbulence is minimal.

The troughs (oxygen) and peaks (ammonia) are shown in Fig. 2, and illustrate how site selection can significantly affect water quality. At present, the onset of disease events in ABC is determined only by water temperature, and not by e.g. low oxygen, but as better data become available on the triggers for pathogen outbreaks, ABC can be used to analyse interactions between environmental degradation and disease.

The effect of pathogens on aquaculture production is shown in Fig. 3, using as a host-pathogen pair Atlantic salmon (*Salmo salar*) and Infectious Hematopoietic Necrosis virus (IHNv). Under the appropriate temperature conditions, and provided the virus concentration in the water is above a certain threshold, fish become infected and can subsequently either recover or die. The biological FCR (Fig. 3) is acceptable for an early stage pathogen outbreak (top panel), but untenable for a late-stage outbreak (bottom panel) because of the amount of money already spent by the farmer on feed.

The IBM component of the ABC model means that every individual animal (finfis or shellfish) in a simulated population can be traced. This is used in ABC to simulate traceability of a fish crop, using the principles of blockchain analysis (and other DLTs) to illustrate how the trajectory of an individual animal can be described in terms of growth rate, welfare with respect to environmental conditions, and exposure to pathogens during its culture cycle.

Introduction

The increasing demand for sea urchin roe and consequent rising prices have resulted in a worldwide escalation of sea urchin fisheries, which are causing a depletion of the wild stocks. Therefore, a change is needed to preserve this resource, which may be achieved through the development of sustainable echinoculture. Moreover, this activity can also contribute to improve the roe nutritional content and quality, supplying this product all year long. For these reasons, the European attention has focused on the edible sea urchin *Paracentrotus lividus* (Lamarck, 1816).

The present study intended to evaluate the growth, gametogenic and offspring development of *P. lividus* fed with three artificial diets, formulated with vegetables. The determination of sea urchins' daily feed intake was made for each diet and their performance was estimated through the individuals' somatic growth (daily growth rate, weight gain and linear growth rate), gonadosomatic index (GI) and gametogenic development stage (GDS) of their gonads. Moreover, the effect of broodstock feeding was evaluated in their offspring (concretely, in what concerned the time of occurrence and duration of the embryonic and larval development stages).

Materials and Methods

Paracentrotus lividus (N = 234) were harvested in the intertidal zone of Praia de São Marcos (Portugal; 39º19'08.9"N, 009º21'18.9"W), with a test diameter of 3.72±0.03cm and a total weight of 22.23±0.31g.

The sea urchins were randomly distributed by three recirculating aquaculture systems (RAS) and fasted for 44 days at 16°C, with a photoperiod of 12h, being measured and weighed afterwards. Then, 18 individuals were sacrificed, had their gonads weighed for determining the GI (Carboni et al., 2015) and further analysed histologically for their GDS, according to Byrne (1990).

Afterwards, the remaining sea urchins were individually hand fed *ad libitum* for 120 days, at 20°C, with a known amount of the formulated diets, using agar as a biding agent: diet A with maize (*Zea mays*) and spinach *(Spinacia oleracea)*; diet B with maize, spinach and acorn (*Quercus ilex*) and diet C with maize, spinach and pumpkin (*Cucurbita maxima*). At the beginning of each day, the feed remaining on the tanks was weighted to measure ingestion rates. At each 30 days, 9 random individuals of each diet were measured, weighted and then dissected for assessing the GI and the GDS. At the end of the trial, all the remaining specimens underwent the same procedures. Furthermore, 12 random individuals per diet were induce to release gametes at the end of the 3rd and 4th months of the trial, by injecting 40µL.g^{-1} of potassium chloride 0.5M through the peristomial membrane. Each batch of resulting embryos were distributed by 3 cylindroconical tanks of 50L, with an initial density of 2larvae.mL^{-1} and fed using a mix of frozen microalgae *Tetraselmis suecica* and *Phaeodactylum tricornutum*. Samples of 15mL were collected in triplicate, in order to assess the embryos density and development, at 12, 24, 36, 60 and 84 hours after fertilisation.

Results

Diet B was the least consumed diet (0.75±0.70g.ind^{-1}.day^{-1}), followed by diet A (2.44±1.21g.ind^{-1}.day^{-1}) and then diet C (3.40±1.28g.ind^{-1}.day^{-1}).

In what concerns test diameter, sea urchins grew on average 0.88mm.month^{-1} with diet A and 0.52mm.month^{-1} with diet C, while for diet B the individuals decreased 0.28mm.month^{-1}. The same pattern was observed for individual wet weight, in which sea urchins gained 41.60mg.ind^{-1}.day^{-1} with diet A, 11.90mg.ind^{-1}.day^{-1} with diet C and those from diet B lost 45.56 mg.ind^{-1}.day^{-1}.

(Continued on next page)

At the end of the starvation period, the GI was 2.48±1.12%, plus 72% of *P. lividus* were at the spent stage and 28% were in the recovery stage. In the end of the trial, the highest GI was attained by individuals fed with diet A (8.71±2.18%), followed by diet C (4.44±2.20%), whereas those fed with diet B showed a GI below the value obtained from the starvation period. Diet A led to a relative frequency of 14% of sea urchins in the mature stage, 36% in premature stage, 11% in growing stage, 25% in recovery stage and 14% in spent stage. Meanwhile, diet C resulted in a relative frequency of 28% of the specimens in mature stage, 17% in premature stage, 14% in growing stage, 25% in recovery stage and 17% in spent stage.

Individuals fed with diet B did not made any progress in the gametogenic cycle, with 100% individuals in the spent stage reason for which it was not possible to induced them to reproduce and obtain gametes. In general, larvae from broodstock fed with diet A reached advanced stages faster than those from broodstock fed with diet C and showed a better survival response, as well.

Discussion and conclusion

Maize, spinach and agar (diet A) was the most successful feed, leading to higher values of test diameter, individual wet weight and GI, followed by diet C (maize, spinach, pumpkin and agar). Both diets A and C promoted more advanced gametogenic stages of the gonads. Diet A also allowed obtaining better survival and faster embryonic/larval development of the sea urchins offspring than diet C.

Although, *Q. ilex* acorn seemed a promising ingredient, due to its nutritional composition (namely, its fatty acid profile), the presence of tannic acid eliminated the possibility of success of diet B. In the future, this substance should be eliminated, before considering using acorn as an ingredient in formulated feeds for aquatic organisms.

The results obtained in this study showed that the use of land vegetables and their by-products can improve gonadal growth of *P. lividus*, proving to be efficient food resources to obtain sea urchin roe. Accordingly, jellified diets may improve adult sea urchins rearing, as well as aiding in the development of sea urchin larvae, due to the improvement of necessary energy reserves present in the oocytes.

Introduction

The seafood industry seeks healthy and sustainable solutions to meet consumer trends that are increasingly moving towards healthy and natural eating habits. The replacement of the traditional fish meal and fish oil in aquafeeds with environmentally sustainable ingredients like algae has instigated interest due to their high nutritional value and richness in bioactive compounds. In this context, natural feed ingredients (macroalgae, microalgae and yeast biomass) were exploited as alternative to fish meal (FM) and fish oil (FO) sources, as well as vehicles for bio-fortification of fish in iodine, selenium and n-3 PUFAs.

Material and methods

Gilthead seabream (370g) were fed for 10 weeks at EPPO-IPMA facility (Olhão, Portugal) with four diets in triplicate tanks: a commercial-based diet (FMFO) and three experimental diets with a 33% replacement of fish meal by a microalgae biomass (*Chlorella, Tetraselmis* and *Schizochytrium*) (AB diets). A further replacement of 20% FO was tested in ABVO diet. All AB rich diets were supplemented with both *Laminaria* and Se-yeast: diets $ABVO_{\mathbf{I8+Se1}}$ and $ABFO_{\mathbf{I8+Se1}}$ provided equivalent levels of iodine (8mg.kg^{-1}) and selenium (1mg.kg^{-1}), whereas an extreme diet $ABFO_{\mathbf{I13+Se}1.3}$ was further enriched with I (13mg.kg^{-1}) and Se (1.3mg.kg^{-1}). All diets had similar EPA+DHA contents.

At the end of the trial, growth performance, whole body and muscle composition, nutrient retention and gain were evaluated. The expression of genes related to fatty acids, iodine and selenium metabolism were also evaluated in liver and muscle.

Results

Final body weight of fish fed the bio-fortified diets was similar to those fed the FMFO (622-625g) diet, with the exception of the $ABFO_{\mathbf{I13+Se}1.3}$ that resulted in a significantly lower weight (589.46g). This diet also showed a significantly lower protein efficien y ratio (PER) than all other diets. The specific growth rate (SGR) and feed conversion ratio (FCR) remained similar among dietary treatments. Lipid intake was significantly affected by the dietary treatments: $ABVO_{I8+Se1}$ = FMFO < $ABFO_{I8+Se1}$ < $ABFO_{I13+Se1.3}$ but did not affect whole-body lipid (including EPA+DHA), protein or I content. Whole-body content and gain of Se increased significantly with the inclusion of Se-yeast, reaching the highest values in fish fed $ABFO_{I13+Se1.3}$ diet. The DHA content in the fillet increased significantly in fish fed diets $ABFO_{I8+Se1}$ and $ABFO_{I13+Se1.3}$ compared to the FMFO diet, whilst the I content was highest in the $ABFO_{I13+Se1.3}$ diet. The Se fillet content increased with the inclusion of selenised yeast: $ABFO_{I13+Se1.3}$ > $ABFO_{I8+Se1}$ > $ABVO_{I8+Se1}$ > FMFO (figure 1)

Discussion and conclusion

The present results indicate that the concomitant replacement of 33% FM and 20% of FO by a blend of microalgae biomass (*Chlorella, Tetraselmis* and *Schizochytrium)* can be achieved without any significant impact on growth performance or whole-body composition in large-sized *S. aurata*. The Se content increased concomitantly with increasing dietary inclusion of Se-yeast. Fish were able to selectively retain DHA and I in muscle resulting in its fillet fortification in DHA, I and Se. However, the highest dietary levels of both Se and I resulted in growth impairment.

(Continued on next page)

In conclusion, the bio-fortificati n of gilthead seabream fillets in Se, I and DHA through dietary supplementation with Se-yeast and algae is possible but requires a cautious selection of ingredients at adequate level to avoid growth impairment.

E-mail: guilherme.wolff@unesp.br

Introduction

The theme about environmental sustainability is increasingly gaining the attention of the population, becoming a global concern. Environmental sustainability indicators can be used in the management of environmental externalities. Indicators provide values that simplify more complex phenomenon and summarize characteristics of a system in a simplified way. These indicators are combined into an index that can be used in the comparison of different systems or the same system over time (Valenti, 2008; Valenti et al., 2018). In this context, the present study aimed to provide information on the environmental sustainability of two tilapia net-cage production system in the state of São Paulo, Brazil, by using a set of environmental indicators.

Materials and methods

Samples of water, sediment, fish, feed provided and greenhouse gases were necessary to measure the environmental sustainability from each farm. These samples were collected three times throughout the production cycle of each property (189 days on farm A; 263 days on farm B), representing the beginning, middle, and end of cultivation. Environmental sustainability was measured using the indicators defined by Valenti et al. (2018). The environmental indicators were divided into five criteria: the use of natural resources; efficienc in the use of resources; release of pollutants and unused by-products to the environment; pollutants accumulated on the bottom of the water body; and conservation of genetic diversity and biodiversity.

Each indicator was converted into a performance scale, with scores ranging from 0 to 100. The treatment with the best indicator value (more sustainable when compared to the others) was arbitrary scored as 100, and the others were determined by proportion.

Results

Table I Environmental sustainability indicators

Indicator	Farm A	Farm B
1. Use of Space (ha.t-1)	0,0017	0,0014
2. Dependence on Water (m^3.t-1)	199	248
3. Use of Energy (MJ.t-1)	30 378	30 376
4.Proportion of Renewable Energy (MJ.t-1)	0	0
5. Use of Nitrogen (kg.t-1)	90	87
6. Use of Phosphorus (kg.t-1)	20	20
7. Efficiency in the Use of Energy (%)	22,8	22,0
8. Efficiency in the Use of Nitrogen (%)	20,7	21,4
9. Efficiency in the Use of Phosphorus (%)	16,5	16,4
10. Production Actually Used (%)	100	100
11. Potential of Eutrophication (kg P.t-1)	11	6
12. Potential of Eutrophication (kg N.t-1)	71	70
13. Potential of Organic Pollution (kg.t-1)	983	371
14. Potential of Global Warming (kg.t-1)	-334.50	97.81
15. Pollution by Hormones (kg.t-1)	0	0
16. Pollution by Heavy Metals (kg.t-1)	0	0
17. Accumulation of Phosphorus (kg.t-1)	5	11
18. Accumulation of Organic Matter (kg.t-1)	157	759
19. Risk of Farmed Species	4.0	4.0

(Continued on next page)

Discussion and conclusion

The environmental sustainability index for fish farms A and B were 93 and 81, respectively and influenced by the higher accumulation of pollutants in fish farm B. This farm had almost 5 times more accumulation of organic matter and 2 times more accumulation of phosphorus. When comparing the values of this indicators with the one published by Moura et al. (2016), farm B showed 11 times more amount of organic matter accumulated per ton than the farm evaluated by these authors (759 kg.t-1 and 67.20 kg.t-1, respectively). In this scenario, using the environmental sustainability index was possible to identify which criteria is the main concern on the farm. The use of these index and indicators allows to, in an easier way, plan and apply changes to the management, minimizing more effectively the impacts of aquaculture on the aquatic ecosystem, becoming a more sustainable production.

EFFECTS OF COMPLEXED TRACE MINERALS AT DIFFERENT INCLUSION RATES IN COMMERCIAL SEA BASS (*Dicentrarchus labrax*) DIETS

A.C. Figueiredo-Silva[1]*, C. Boggino[1], M. Sun[1], Maria Mastoraki[2], I. Papadakis[2], A. Theodoridou[3], M. Pavlidis[3], S. Chatzifotis[2]

Introduction

Trace minerals are key elements for activation and function of hormones and hundreds of enzymes. They are essential for proper development and function of bone, nervous and reproductive systems, being critical to epithelial tissue production and maintenance and thus affect health through enhanced skin, gill, fin, scale and gastrointestinal integrity. By playing essential roles in activation and modulation of several processes involved in fish immune response, optimal trace mineral nutrition is very important in helping fight stress and disease. Among these, zinc is known to exert beneficial effects beyond growth, namely through modulating immune response and resistance to disease development of muscle and bone, reduction of cataract incidence and oxidative stress (Gammoh and Rink, 2017). In addition, zinc plays an essential role in wound healing, and speeds re-epithelialization processes in both humans (Lin et al., 2018) and fish (Ogino and Yang 1979; Hughes 1985; Jensen et al., 2015; Gerd et al., 2018). Interestingly, metal-amino acid complexes have proven to be more efficient than inorganic minerals in reducing skin lesions of Atlantic salmon after infestation with *Caligus* (Figueiredo-Silva et al., 2019), indicating enhanced barrier defense mechanisms against pathogens. Major objectives of this study were to evaluate effects of metal-amino acid complexes (Availa®Zn, Availa®Fe, Availa®Mn, Availa®Cu, Availa®Se), supplemented at half the level of inorganic or in combination with inorganic minerals (sulfates of Zn, Fe, Mn and Cu, and Se in the form of selenite), on growth performance, gut and skin morphology, hepatic enzyme activity and zinc content in skin of European sea bass.

Material and methods

Quadruplicate groups of European sea bass, with an initial body weight of 15 g, were daily fed one of 3 diets, formulated to vary in trace mineral source and/or level to apparent satiety, for 4 months. A Control diet was formulated to include an inorganic trace mineral premix of 100 ppm Zn (ZnSO4), 80 ppm Fe (FeSO4), 24 ppm (MnSO4), 6 ppm Cu (CuSO4) and 0.24 ppm Se from (Na2SeO3). A second and third diet were formulated to include metal-amino acid complexes as a 50:50 combination with inorganic minerals or at one-half the dose of inorganic minerals in the Control diet, respectively. In order to magnify response to trace mineral source and level, fish were submitted to a temperature challenge in the second- half of the feeding period (last 2 months), with feed restricted by 50%, from the pre-stress period intake, in the last month of the feeding period.

Results and discussion

Metal-amino acid complexes supplemented at one-half the level of inorganic sources maintained growth performance of European sea bass (Fig.1). Performance results indicate metal-amino acid complexes are a more effective or bioavailable source of trace minerals than inorganic sources in European sea bass, as demonstrated previously in Atlantic salmon (Figueiredo-Silva et al., 2019) and catfish (Paripatananont and Lovell, 1995a,b). In work by Paripatananont and Lovell (1995a), zinc methionine complex (Zn-Met) was shown to be 3 to 5 times more bioavailable than inorganic Zn ($ZnSO_4$), in meeting growth requirements in purified and practical diets containing phytic acid, respectively. In addition, benefits of supplementing channel catfish diets with metal amino acid complexes vs. inorganic minerals were observed to go beyond growth performance, with Zn-Met being 3 to 6 times more effective than $ZnSO_4$ in protecting channel catfish against *Edwardsiella ictalurid* (Paripatananont and Lovell 1995b).

Increased hepatic activity of glutathione peroxidase (GPx) found in European sea bass supplemented with metal-amino acid complexes at one-half the level of inorganic trace minerals (Fig.1), indicate metal-amino acid complexes are more effective in promoting the antioxidant capacity of fish. Partial or complete replacement of inorganic trace minerals with metal-amino acid complexes had a clear impact on the number of goblet cells, in both intestine and skin of European seabass. As part of the mucosal immune system, goblet cells play an important role in protecting fish against pathogens, especially in aquatic animals that are in close contact with their environment. Enhanced antioxidant capacity (i.e. GPx) and barrier defense lines (i.e. goblet cells) are expected to translate to better response of fish to disease, and thus result in healthier fish, especially when grown under commercial farmed conditions. Outcomes of this project are expected to contribute to the development of more efficient diets for European seabass, through the supply of trace minerals that are highly available and efficiently meet seabass performance targets, contributing toward their welfare status.

Introduction

Fish vaccination is considered an optimal strategy for the prevention of infectious diseases in the global farmed salmon industry. Failure in the protection of vaccines against the intracellular bacteria *Piscirickettsia salmonis*has been proposed as the cause of the increased use of antibiotics in the Chilean farmed salmon industry.The salmon farming industry in Chile during the year 2017 produced 791103 tonnes of fish, which generated exportation of $ 4800 million USD, corresponding to 6% of the country's total exports. *P. salmonis* is the main bacterial pathogen that infects to salmon during its culture in the sea; it affects more frequently the Atlantic salmon being the cause of the mortality of 69.4% of fish grown in seawater (Salmon Farming Health Report, 2017). *P. salmonis* generates large economic losses in the salmon industry, estimating annual losses of $ 700 million USD Maisey et al. (2016).There are several vaccines used in Chile for prevention of *P. salmonis* in atlantic salmon, however does not exist studies for analyse of their efficac .The main of this work is to evaluate the efficacy of an injectable pentavalent commercial vaccine against *P. salmonis* in fish exposed to cohabitation challenge and to evaluate the efficacy of pentavalent plus live attenuated injectables vaccines against *P. salmonis* in fis intraperitoneally inoculated.

Materials and Methods

5,586 Atlantic salmon fish were separated between three main groups called Controls (Mean weight = was 331.7g): group without infection, Cohabitants (Mean weight = 331.4g): to evaluate *P. salmonis* dissemination by water and Trojans (Mean weight = 152.4g): to evaluate the intraperitoneal inoculation of *P. salmonis*. Controls and cohabitants were distributed between unvaccinated and vaccinated with a pentavalent inactivated commercial vaccine. Whereas Trojans were distributed in four treatments: Unvaccinated, Pentavalent vaccinated, Live attenuated commercial vaccine, Pentavalent plus Live attenuated vaccine. We evaluated the survival probability by Kaplan-Meier analysis and Relative percentage survival (RPS). Further, Total IgM and Specific IgM against *P. salmonis* was evaluated by ELISA immunoassay.

Results

The survival probability of vaccinated and unvaccinated Controls were 100%, Unvaccinated Cohabitant was 60.3% and Vaccinated Cohabitant was 56.7%.Whereas survival probability of Trojans were Unvaccinated 0%, Penta-Vaccinated 1.3%, Live-Vaccinated 0.1%, Penta-Live-Vaccinated 0.5% (Figure 1).Thus, in Vaccinated fish exposed to the cohabitation

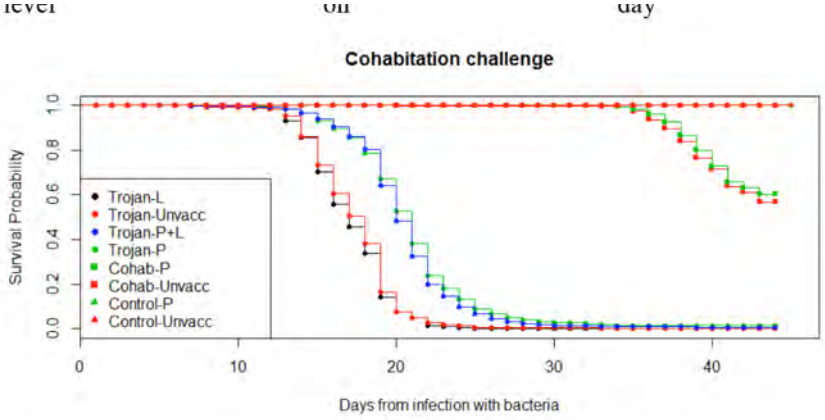

Figure 1. Cohabitation challenge. Survival analysis by Kaplan Meier.

(Continued on next page)

challenge 45 days after trojans inoculation, the relative percent survival (RPS) was -13.9%. In trojans fish exposed to intraperitoneal inoculation of *P. salmonis*, the RPS_{60} was -0.91% in the group that received Live attenuated vaccine, 75.5% in the group that received Pentavalent vaccine and 71.8% in the group that used both Pentavalent plus Live attenuated vaccines (P+L).The RPS decreased in all groups of Trojans after 45 days post inoculation, the final RPS was 0.10% in the group treated with Live attenuated vaccine, 1.3% in the group treated with Pentavalent vaccine and 0.5% in the grouptreated with both Pentavalent plus Live attenuated vaccines (P+L). Levels of Total IgM in vaccinated cohabitants and vaccinated controls were lower than unvaccinated controls on day 21. At day 41 at the end of challenge, vaccinated cohabitants and vaccinated controls showed higher levels of Total IgM than unvaccinated controls. Levels of specific IgM were similar for all groups of cohabitants and controls on day 21, whereas vaccinated cohabitant fish decreased the specific IgM level on day 41.

Discussion and conclusion

Our results conclude that the use of pentavalent vaccine in Atlantic salmon does not prevent the mortality of fish on a cohabitation challenge. Respect to the cohabitation challenge, we conclude that the injection of Pentavalent vaccine against *P. salmonis* reduces the IgM antibody level at 21 days of challenge, but increases this on day 41. Also we observed that fish exposed to cohabitation infection increases the level of total IgM antibody in comparison with fish without infection. Our results indicate that in the case of the natural infection of PS, fish does not need vaccination against PS, because we observed the same mortality between both groups vaccinated and unvaccinated, despite we found increased level of IgM antibody at the end of challenge. These results suggest the implementation of vaccination trials evaluating the efficacy of vaccines, with the purpose of to prevent high mortality and to reduce the use of antibiotics in salmon industry.

Introduction

The growing demand for aquaculture products can only be maintained by increasing the production of lower trophic species such as bivalves and tunicates. Low trophic species avoid the energy losses during trophic transfers to build animal protein, making them ideal candidates to exploit available resources in coastal waters. In the particular case of fjords, forced upwelling of deep nutrient-rich waters can promote phytoplankton growth, or in other words, the growth of bivalve and tunicate food. However, the density at which bivalves and tunicates are cultured can compromise phytoplankton populations and consequently, marine food chains. A highly configurable environmental model was constructed to study the ecosystem effects and potential biomass production of hypothetical bivalve and tunicate aquaculture scenarios in a Norwegian fjord under forced upwelling conditions.

Materials and methods

A multi-box spatial model which included utrients, phytoplankton and zooplankton, with the addition of a suspension-feeder and detritus sub-models was created for Lysfjord following Filgueira et al. (2010). A new Dynamic Energy Budget model was parameterized for the tunicate *Ciona intestinalis*. All farming scenarios were initialized based on the size and length of natural populations of *Mytilus edulis* and *C. intestinalis* and densities were adjusted according to current and expected aquaculture practices for mussels and tunicates, respectively. A series of 7 farming scenarios were defined for each species (Table I), which resulted from the combination of a different degree of aquaculture development, characterized in terms of area occupied with farms (2.5, 10, 20, 30 and 50%), and the possibility of activating/deactivating the forced upwelling (only in 2.5 and 30% scenarios).The effects of farming scenarios on phytoplankton populations has been evaluated in terms of chlorophyll depletion (*Chl depletion*) using the following calculation:

$$Chl\ depletion\ (\%) = \frac{Chl_{background} - Chl_{farming}}{Chl_{background}} \times 100$$

where $Chl_{background}$ and $Chl_{farming}$ are the chlorophyll concentrations in background and farming scenarios, respectively. This approach assumes that chlorophyll concentration is a good proxy for phytoplankton abundance. Positive values of this index suggest a reduction or depletion of phytoplankton in the farming scenario compared to the background. Similarly, negative values indicate an enrichment in phytoplankton.

Result and discussion

The simulations objectively determined the level of aquaculture development that maximizes the sustainable utilization of resources towards bivalves and tunicates biomass production (Table I). The model also highlighted the positive effect of the forced upwelling on both cultured production and phytoplankton abundance under aquaculture scenarios. Finally, the model predicted that tunicates would be more efficient than mussels at extracting resources (Table I) due to their lower metabolic cost and higher filtration capacity. Although a full economic analysis would be required to decide on the preferred species to be cultured, these results encourage current pilot studies in which tunicates are explored as a sustainable way to efficiently exploit marine resources for aquafeed production

Introduction

Biofloc technology (BFT) has shown to be a beneficial technique implemented in the production activity in many countries, this production system is increased in the last years, given that it represents a low cost in equipment and a versatile way to transform aquaculture waste into valuable products that can be used in horticulture (Gallardo-Collí et al., 2019). The benefits of BFT were noted by Pinho et al. (2017) who used this water for lettuce in aquaponics units. Despite the favourable attributes of BFT, its use has not been assessed at different trophic modes and its application in hydroponics has not been evaluated yet. Diversifying the production system is clearly a necessity in developing countries, which is why this investigation was focuses on the characterisation of macro- and micronutrient residuals from *O. niloticus* BFT in three different trophic modes and their relationship with the NFT hydroponic horticulture with five green leaf plant species: lettuce (*Lactuca sativa*), pak-choi (*Brassica rapa* subsp. *chinensis*), rocket (*Eruca sativa*), spinach (*Spinacia oleracea*), and basil (*Ocium basilicum*) during the complete nursery and grow-out tilapia culture.

Materials and methods

This study was conducted in Centro de Investigaciones Biológicas del Noroeste (CIBNOR) located in La Paz, Baja California Sur, México. A greenhouse (35.3 m x 13 m) was designed. It included two areas as follows: (a) Aquaculture: 15 culture tanks of 1 m^3 (1.4 m x 0.7 m); (b) Hydroponics NFT: 12 hydroponic beds (204 holes per bed). The experiment was divided into two phases (nursery and grow-out) used Nile tilapia (*Oreochromis niloticus*) (40 weeks). The cultivation method was BFT and the effluents were used in Hydroponic experiment with six treatments with two replicates: Control HO= Hoagland, H = Heterotrophic, Q = Chemoautotrophic, CS = *C. sorokiniana* 2805, CV = *C. sorokiniana* 2714 and M = *C.* spp., with the following plant species: lettuce (*Lactuca sativa*), pak-choi (*Brassica rapa* subps. *chinensis*), rocket (*Eruca sativa*), spinach (*Spinacia oleracea*), and basil (*Ocium basilicum*). The effluent from every fish tank (200 L) was transferred to an anaerobic tank (1 m^3) (only one per treatment) without light or aeration. The content of each tank was mixed and left to stand for settlement process for 24 h. After this period, the residual water for every treatment was transferred to each hydroponic 200-L tank, each one corresponding to one hydroponic bed. This experiment was performed for five weeks; plants were harvested after this period. Every day the parameters were analysed also a set of 50-ml samples (liquid fraction) were obtained from each tank once a week for evaluated the nitrogen residuals and every 10 weeks to evaluate 16 elements (B, Ca, Co, Fe, K, Mg, Mn, Mo, N, Na, Ni, P, S, Se, Si, and Zn) by optic spectrophotometry (ICP–AES VARIAN® model Liberty II; Mulgrave, AUST). At the end of the experiment the growth parameters were evaluated in the plants. One-way ANOVA was performed followed by Tukey's tests to detect significant differences between treatments (significance level of 0.05) (Minitab 17 Statistical Software, 2010).

Results

Conductivity in Q and H showed the lowest level during the first weeks, and after week 11 they increased to the highest level (> 6 dS m^{-1} maximum level) until week 21. In the liquid fraction, the dominant macro elements were Na and Ca at all treatments. Potassium, N, P and Si accumulated during all the experiment in all treatments ($p < 0.05$). Regarding micronutrients, Fe and Mn were detected after week 20 ($p < 0.05$). During the experimental period, the photoautotrophic treatments showed the highest levels of micro and macronutrients among all treatments. Rocket (*E. sativa*), and spinach (*S. oleracea*) showed the highest wet growth with treatment Q ($p < 0.05$), and lettuce (*L. sativa*) reached the highest growth with Hoagland solution. According to growth percentage, lettuce (*L. sativa*) and pak-choi (*B. rapa*) did not show significant differences ($p > 0.05$) while for basil (*O. basilicum*) and spinach (*S. oleracea*), the best results were obtained with treatment CS ($p < 0.05$), and rocket (*E. sativa*) with treatment Q ($p < 0.05$).

Discussion and conclusion

The physicochemical parameters obtained in *O. niloticus* rearing were ideal for hydroponics cultivation. The nitrogen level that could be retained in the biofloc system was optimal for plant cultivation when compared with the hydroponics. The ideal conductivity for hydroponics was 1.5 to 2.5 dS m^{-1} (Trejo-Téllez and Gómez-Merino, 2012). In this case Q and H had the best conductivy profile for sensitive plants, so photoautotrophic treatments were ideal for moderate tolerance. The

(Continued on next page)

effluents from aquaculture are rich in N and P (Lazzari and Baldisserotto, 2008)the amount of residue deposited into the rearing tanks has increased significantl . Nitrogen (N. Rakocy et al. (1997) reported that aquaculture effluents supplied at least 10 nutrients required by plants. In this research, only five (P, Mg, Mo, B and Mn) essential macro and micronutrients were detected in optimal quantities. Pinho et al. (2017) implemented heterotrophic biofloc and obtained favourable results for butter lettuce (17.7 SGR); in this study, the SGR value obtained for lettuce (*L. sativa*) was 8.9-17.4 SGR ($p > 0.05$). In addition, Castillo-Castellanos et al. (2016) detected a wet weight of 18.8 g plant^{-1} for lettuce (*L. sativa*) with a yield of 47.9 g m^2, using effluents from aquaponics with *O. niloticus*; in this study, lettuce (*L. sativa*) wet weigh was 320 g plant^{-1} with Hoagland, and values from 35.1-112.9 g plant^{-1} were obtained with the rest of the treatments ($p > 0.05$); thus, lettuce (*L. sativa*) growth was irregular and highly variable. The best combination was with spinach (*S. oleracea*) and/or pak-choi (*B. rapa*) and/or lettuce (*L. sativa*). Therefore, *O. niloticus* BFT rearing in the photoautotrophic mode and its integration with NFT hydroponics horticulture in a non-recirculating system is beneficial in coastal arid zones where water is scarce and there is a need to improve aquaculture performance, reuse water, BFT nutrients and increase profit.

For many years, fish farmers have struggled in the battle against ectoparasitic infestations, which are generally due to the intensification of the production process. The traditional use of chemotherapeutic agents to prevent and control fish diseases in aquaculture, such as antibiotics and disinfectants, have been heavily criticized due to the emerging resistant pathogenic strains, the environmental impact of its application and the accumulation of residues in fish, leading to an increased interest towards the developments of alternative sustainable treatments. In the last years, nutritional strategies focused on the use of feed additives as modulators of the immunological and physiological responses, as well as anti-stress and antioxidant therapies, have aroused great interest in the aquaculture industry. Thus, the use of functional feeds in aquaculture is a reality due to their numerous productive, welfare and environmental advantages.

In gilthead seabream farming the use of chemical solutions on-site sea cage treatments to fight against *Sparicotyle chrysophrii* (a monogenean gill parasite specific for the gilthead seabream (*Sparus aurata*)) is common. These treatments include formalin baths and other chemicals used in routine disinfections, in addition to net removal and cleaning (Sitjà-Bobadilla et al. 2006). However, the environmental impact of chemical treatments and the apprehension about human health risks have to be taken into consideration. This raised the importance of developing alternative treatments which are necessary (Wooster et al., 2005).

Essential oils as feed additives

Essential oils (EOs) have been evaluated in the past two decades in several farmed and domestic animal species due to their antimicrobial, antiparasitic, anti-inflammatory and antioxidant properties. Regarding aquatic species, abundant evidences of their benefici l properties and efficacy on fish performance and health have been demonstrated (Encarnação, 2016). The inclusion of EOs in aquafeeds, reported positive results as dietary additives, such as appetite stimulants, feed utilization and growth, boost of the innate immune system with enhancement of the resistance against bacterial and parasitic diseases (Sutili et al. 2017). Besides, the microencapsulation of EOs in fish diets is a suggested strategy to ensure their stability, to prevent ingredients interactions with the host and with the environment. So, it allows a sustained release throughout all the gastrointestinal tract where their effects can be predicted more effectively. The use of garlic thymol and/or carvacrol essential oils in functional feeds for aquaculture have been tested and demonstrated for its effectiveness in the fight against bacterial and parasitic challenges, both in in vitro and in vivo trials.

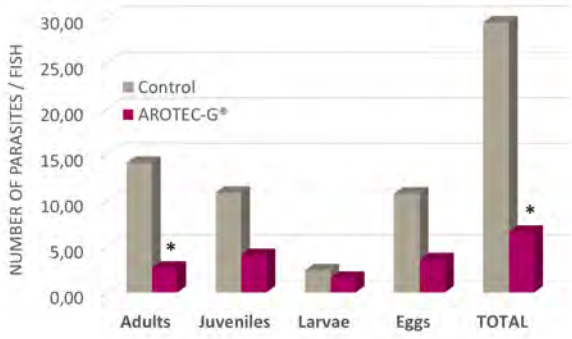

Figure 1: Number of S. chrysophrii parasites per fish fed with the AROTEC-G® and control experimental diets (mean ± standard deviation). Three parasite categories according to morphological characteristics (adults, juveniles and larvae) are represented, as well as the total prevalence of the ectoparasite. Different letters indicate significant differences between dietary groups (P < 0.05).

(Continued on next page)

Evaluation of AROTEC-G® inclusion in feed

Under this context, recently a study was conducted to evaluate the response of juvenile gilthead seabream (40.26±0.14 g) to the dietary administration of AROTEC-G from TECNOVIT-FARMFAES (a microencapsulated combination of garlic, thymol and carvacrol (EOs). The aim of this trial targeted immune response and effect over ectoparasites. Tissues such as gills and skin were analyzed so asses the effect that *Sparicotyle chrysophrii* had in the immune system, target for most ectoparasites. For this purpose, a 65-day nutritional assay was performed to evaluate the biological processes activated in the skin and gills of fish fed with additive

Skin mucosal response to AROTEC-G®

After the nutritional assay, the effect of the dietary additive in skin was analyzed. Results obtained from epidermal mucus as health status indicator revealed a significative decrease in the classical stress biomarkers, such as cortisol, lactate and glucose, when animals were fed with AROTEC-G®, suggesting an improvement in the overall fish health condition and welfare. Moreover, the mucus from fish fed with AROTEC-G® also significantly inhibited the growth of other fish pathogenic bacteria. Those results were supported by the transcriptomic analysis of the skin-associated lymphoid tissue (SALT).

AROTEC-G® antiparasitc efficiency

Further effect of AROTEC-G® in the control of the parasitization by *S. chrysophrii* was also assessed through an in vivo co-habitation trial for 39 days. The outcomes of in vivo parasitization support the results obtained from the nutritional trial, where a significant decrease in the *S. chrysophrii* total number per fish fed AROTEC-G® (*Figure 1*).

Conclusions

Throughout this study, the microencapsulated additive AROTEC-G® demonstrated to be an effective natural compound with immunostimulant properties designed to be included in functional fish diets to protect gilthead seabream against infestations by ectoparasites such as *S. chrysophrii*. In seabream, the effect of the additive is still being evaluated in other mucosal tissues, such as the intestine, in order to access its global immune effect and consider further applicability. The positive results obtained showed a promising potential for several marine cultured species in the treatment against other ectoparasites as well.

QUANTIFICATION OF SULFOLIPIDS FROM DIFFERENT MARINE ORGANISMS

J. Fischer*, T. Sitz, M. Treblin, S. Rohn

University of Hamburg, Institute of Food Chemistry, Grindelallee 117, 20146 Hamburg, Germany
E-Mail: sascha.rohn@chemie.uni-hamburg.de

Introduction

For many years, algae and cyanobacteria play an important part in the human nutrition in many cultures. *Spirulina* sp., for example, serves as aliment in Mexico and African countries. In Asian countries, filamentous cyanobacteria (e.g. *Nostoc* sp.) are wildly used as food. Besides the use of cyanobacteria, there are numerous records of historical usage of algae (Gantar and Svincev, 2007). *Pyropia* sp. and *Undaria* sp., for example, are commonly used in Asian cuisine (Wells et al., 2017).

Nowadays the use of macro- and microalgae as well as cyanobacteria becomes increasingly important for human nutrition even in Western diets. Mostly they are being consumed for their functional benefits beyond the traditional considerations of nutrition and health (Wells et al., 2017). In Europe, many algal and cyanobacterial species are legally on the market as food or ingredient. Furthermore, even some products have been already legalized according to Regulation (EU) 2015/2283 as novel foods such as algal oil from the microalgae *Ulkenia* sp. or *Odontella aurita*. The positive effects on human health, hypothesized to result from certain macro and especially minor nutrients are widely discussed in the literature. On the other hand, there is little known about the negative aspects or about minor components with bipolar properties. Sulfolipids (SQDGs) represent one of these minor components.

SQDGs consist of sulfoquinovose and a diacylglycerol, whereas sulfoquinovose is a sulfonated hexose analogous to D-glucose, but features a stable carbon-sulfur bond. The meaning of sulfolipids within the human diet is controversially discussed. On the one hand, they are attributed to some health promoting effects and are known to have antiviral properties. On the other hand, sulfur compounds can have a negative impact, because some microorganisms of the lower gastrointestinal tract are able to produce H_2S as a (toxic) metabolite during the biodegradation in the gut (Burrichter et al., 2018). Therefore, knowledge about the impact of SQDG on human health is a crucial factor. To investigate such effects and due to the fact that SQDGs are not commercially available, it is essential to obtain these standards in very high and pure amounts. Therefore, within this study it was aimed at the extraction and isolation of the sulfolipid fraction and the characterization as well as quantification of the chemical structures in di ferent marine organisms.

Materials & methods

Fresh plant material was dried in liquid nitrogen prior to lyophilization, followed by homogenization using mortar and pestle. The extraction of the crude lipid extract was achieved with four steps. First, the powder was grinded in a ball mill, then extracted on a vortex and ultra-sonication. Then the extract was centrifuged and the supernatant was removed and collected. The extraction steps were repeated three times. The supernatants were combined and evaporated to dryness under nitrogen stream.

The residue was re-dissolved in chloroform/methanol (3/2, v/v). The crude lipid extract was cleaned using a solid phase extraction.

SQDGs were analyzed on an Agilent 1260 Infinity Quarternary LC System (Agilent Technologies Germany GmbH, Waldbronn, Germany) coupled to a triple quadrupole API 4000 QTrap mass spectrometer (SCIEX, Darmstadt, Germany) equipped with a turbo spray source, operating in negative ion mode. MRM was performed by using mass transition between specific parent ions into corresponding fragment ions for each analyte.

Results

The sulfolipid extraction, clean up, and quantification, using a targeted-HPLC-ESI-QqQ-MS/MS multimethod, were developed and validated based on a cyanobacteria *Spirulina* sp powder model matrix. This method allowed the simultaneous determination and quantification of 30 SQDGs. The analysis of SQDGs was validated in terms of linearity, precision, lower limit of quantification. The results indicate that the method is accurate and precise for the quantification of SQDGs in dried plant material. Using this method, different marine organisms were screened on their SQDG content. The marine organisms varies in their SQDG content and in the fatty acid distribution.

(Continued on next page)

Discussion & conclusion

As a result, up to 17 different sulfolipids were detected and quantified in the different species. The results showed similarities in the sulfolipid composition of the different species. The SGDG with the molar mass of 816 g/mol was identified as the predominant sulfolipid. In addition, the comparison between the samples showed that the lower plants had a higher sulfolipid diversity than tested cormophytes.

With this new developed method, SQDGs can be characterized and quantified. Subsequently the effect of cultivation parameter such as composition of the culture medium, light or temperature on the content of SQDGs shall be investigated. Furthermore, it should be enquired if negative metabolites in human digestion occur there.

Introduction

Foods based on aquaculture production are still on the rise in human diets and nutrition. In order to minimize the need for fishmeal and oil in fish feed in the sense of sustainable aquaculture and to counteract the disturbed ecological balance, the joint project "FENA – fishmeal and oil substitute for sustainable aquaculture" was created and supported by the BMEL/BLE. On of the aims of that project was to develop a high-quality fish food based on yeast, cyanobacteria, and microalgae to reduce the need for fishmeal and oil, which are currently the main ingredients of many fish feed

This study aimed at characterizing the changes in antioxidant activity from the fish feed production to the accumulation of (potential health-beneficial) antioxidants in the fish fillets of *rainbow trout (Oncorhynchus mykiss)* and pike-perch *(Sander lucioperca*), when being fed with an innovative microorganism-based fish feed. On the one hand, this study looks at the change in the antioxidant profile from the raw materials via the extrusion process to the final product the fish feed. On the other hand, the accumulation in the fish fillet over the timeframe of 16 weeks was considere

Material & methods

In this study, 70 fishes per species were studied over a 16 week feeding period. Besides the new sustainable fish feed, a commercially available control diet with fish meal and oil were tested. A further common industrial diet was purchased from Aller Aqua GmbH (Golßen, Germany) as gold standard for the health parameters. The antioxidant activity was analyzed at hand of the total phenolic content, the well-known TEAC assay, and electron paramagnetic resonance spectroscopy.

Results

Schafberg et al (2018) already showed that this kind of feed formulations, consisting of a mix of the cyanobacterium *Arthrospira* sp., the microalgae *Crypthecodinium cohnii*, and the yeast *Rhodotorula glutinis*, led to good feed performances, but the present study showed a more efficient and balanced growing behavior of the fish. Antioxidant activity in the fish filets was improved

Discussion & conclusion

At first, the present study showed that the enrichment with bioactive compounds, stabilizing primarily the feed, was successful. Furthermore, there was a significantly enhanced bioactivity in the rainbow trout filets at the end of this study, while the pike perch filets did not show any significant enrichment

This recipe can serve as a basis for a sustainable fish feed that can also compete with conventional fish feeds for rainbow trout mast. The enhancement of antioxidant activity of the fish filets might consequently also improve product's shelf-life.

gfischer@uwsp.ed

Introduction and Discussion

Walleye is a prized sport fish and food fish and is often on the menu of white tablecloth restaurants throughout the Great Lakes region of the U.S. Walleye has been recognized as a species with substantial aquaculture potential because of its high market value and limited supply from traditional commercial sources (National Aquaculture Development Plan; Summerfelt (1996). Researchers at the University of Wisconsin -Stevens Point Northern Aquaculture Demonstration Facility (UWSP NADF) has experienced substantial success rearing walleye and hybrids to a food market size in a recirculation aquaculture system over the past 10 years and have built upon a wealth of existing knowledge with this species, Summerfelt and Johnson (2014); Bristow et al. (1996); Barrows et al. (1993); Bulkowski et al. (1983); Johnson and Summerfelt (2014). Despite the existence of a strong market demand and the existence of aquaculture methods for raising walleye, commercial production is still constrained by several factors. Making production methods commercially efficient which include understanding tank stocking density, swimming speed, flow rates and fish performance are critical to move walleye forward in the aquaculture food fish movement. Researchers at the UWSP NADF have recently made strides in understanding these critical components to rear walleye and hybrids successfully in RAS and will provide an overview.

The Guaraíra Lagoon, Rio Grande do Norte State, Brazil, is surrounded by a large number of marine shrimp farms under the semi-intensive and intensive management. Some of these farms started developing as marine fish farms after in 1924 an artificial connection between the former freshwater lake and the nearby sea had been made while others were established only recently. Despite of the concerns in the public about the ecological sustainability of the shrimp industry in Brazil and decreasing prices on the international market the marine shrimp industry around Guaraíra Lagoon is growing steadily.

In 2001, one conventional shrimp farm located on Guaraíra Lagoon started to develop an organic management, using the natural pond biota as the main food source in contrast to the conventional system where the feed is the main food source. In 2004, this farm was certified as the first ganic shrimp farm in Brazil. Due to the lower stocking density and the dispense with feeding, organic farming is claimed to be more environmentally friendly, the organic shrimp farming has significantly lower variable cost, can produce larger shrimp and catches higher prices on national and international markets.

In order to compare the pond ecology and environmental impact of different shrimp farming systems, the organic farm, and shrimp farms using semi-intensive and intensive management around Guaraíra Lagoon where investigated during a rearing cycle at the first semester of 2005. Macro-benthos organisms, aquatic animals living on the bottom of the body of water, are considered as good indicators of environmental changes inside and outside the marine aquaculture ponds and were therefore chosen as one parameter to be analysed.

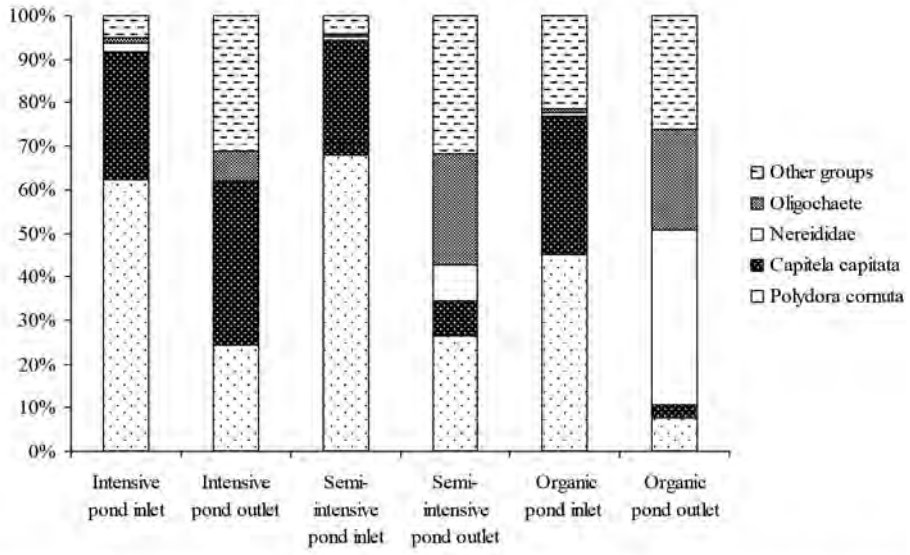

Figure 1. Occurrence (%) of dominant macrobenthos groups inside and at the outlet of the intensive, semi-intensive and organic marine shrimp ponds.

(Continued on next page)

Benthos samples were collected with a corer of 100 mm diameter, sieved with 1.0 mm mesh size and the organisms fixed in 5% buffered formalin for later analysis. Samples were analysed for the occurrence of different taxa and their abundance.

The results showed an increase of the macro-benthos density during the rearing cycle mainly in the intensive and semi-intensive system where artificial feed was provided. The initial abundance of the macro-benthos inside the ponds was higher at the organic system. The polychaetes dominated in all the systems as the main macro-benthos group but crustaceans, oligochaetes and nemertines were also found. In the semi-intensive and intensive system, the polychaetes of the family Spionidae were predominant (Fig. 1). Only in the organic system the biodiversity was higher inside the ponds than outside. Results of macro-benthos analyses will be related to the organic matter in the soil, water nutrients, redox potential and pH in the soil.

HEMATOLOGICAL AND BIOCHEMICAL BLOOD PROFILE OF ADULT GYNOGENETIC SIBERIAN STURGEON *Acipenser baerii* BRANDT

Fopp-Bayat D.*, Gomułka P., Własow T., Szczepkowski M., Ziomek E.

University of Warmia and Mazury in Olsztyn, Oczapowskiego 5, 10-719 Olsztyn, Poland
E-mail: foppik@uwm.edu.pl

Introduction

The aim of the present study was to investigate the hematological indices, morphological characteristics of peripheral blood cells and biochemical indices of mature gynogenetic diploid Siberian sturgeon *Acipenser baerii*.

Although some data about the blood cells or hematological analyses in gynogenetic offspring and juvenile forms of Siberian sturgeon was published, there is no information regarding mature fish. Moreover, there is no information about biochemical indices of blood of gynogenetic of Siberian sturgeon.

Materials and methods

The gynogenetic diploids of Siberian sturgeon (average body weight - 5,78 kg) and control diploids (average body weight - 7,76 kg) were used in the present study. The meiotic gynogenesis was conducted based on methods described by Fopp-Bayat (2007).

Hematological indices were determined according to Svobodova et al. (1991) and covered haematocrit, red blood cell count, white blood cell count, hemoglobin concentration, mean cell volume, mean cell hemoglobin concentration, mean cell hemoglobin and differential white blood cell count.

Biochemical indices were determined with Catalyst Dx chemistry analyzer (Idexx Lab., USA) and covered blood concentration of albumin, globulin, total protein, ammonia, glucose, triacylglycerols, calcium, phosphates and activity of alanine aminotransferase, aspartate aminotransferase, alkaline phosphatase and creatinine kinase.

Results and discussion

Gynogenetic fish were significantly ($p<0.05$) shorter and lighter when compared to control diploids. Mean erythrocyte volume in this group was slightly bigger. No other differences (based on studied indices) between studied groups of fish were recorded.

In our study, differences between gynogenetic and control diploids were limited to significantly weaker growth of gynogenetic fish only. Although differences in erythrocyte indices were noticed in gynogenetic fish of several species, the results of our study suggest that morphological erythrocyte changes in gynogenetic Siberian sturgeon are noticeable only in larval / juvenile fish

Introduction

Monitoring the fish during production is an essential element in realising Precision Fish Farming (PFF) methods in commercial aquaculture, as the ability to apply control engineering principles to a process always depends on the ability to observe the dynamics of that process.

There exist several different methods for collecting data on fish kept in production facilities, ranging from those targeting the fish at group/population level (e.g. sonars, echo sounders) to purely individual-based techniques such as biotelemetry. Although group/population level data may be useful to assess large scale dynamics in the system, the ability to harvest data on the individual level may be crucial in determining the status of the fish during production. This is particularly important during critical operations such as crowding, as the fish are subjected to external stressors that may affect different individuals in several ways. To assess various aspects of the fish responses during such operations, it is therefore beneficial to look at individual based data rather than focusing on the population as a whole.

Biotelemetry has previously been used to monitor both behavioural (activity) and physiological (heart rate) aspects in full-scale crowding operations on farmed salmonids. Although these studies demonstrated that there were relationships between heart rate and activity, and the crowding pressure, it is still unknown how this relates to the actual stress levels of the fish. We therefore conducted a controlled small-scale experiment to investigate the links between activity and heart rate, and the stress levels/physiological states of the fish

Materials and methods

The experiment was conducted in six outdoor tanks of ca. 4 m^3. Twelve fish carrying data storage tags measuring heart rate (Star Oddi Inc.), four of which also carried transmitter tags measuring activity (Thelma Biotel AS), were distributed equally between four of the tanks, meaning that each of these contained three tagged and four untagged fish. The two remaining tanks contained only untagged reference fish. After tag deployment, the fish were allowed to recover for two weeks before they were subjected to an intensive stress regime. Although it is not possible to recreate the stressors experienced during industrial crowding procedures, the regime was designed to approximate such processes as much as possible in both duration and method by sequentially reducing the water level in the tanks four times over four hours. After the stress test, the fish were allowed to recover for 1.5 weeks before the experiment was finally terminated. Data was collected throughout the experimental period, while blood samples were collected to assess the physiological status and stress of the fish before tagging, before and after the stress trials, and after the final recovery period.

Results and discussion

Data processing is still ongoing, but some initial results from the study are ready. In the first period after tagging, the fish carrying heart sensors reported a gradual decrease in heart rate until it eventually stabilised into a circadian rhythm (higher heart rate during daytime) after a few days. This may indicate that the tagging procedure induced a stress response in the fish, but that this response declined as the fish were allowed to recover. The heart rates of the fish changed during the stress tests, with the circadian rhythm breaking down and generally higher heart rates than in the preceding period. After the stress tests, the heart rate subsided again and stabilised at a circadian rhythm after a few days. This suggests that induced stress affected the heart rate of the fish, which in turn may indicate that heart rate can be a useful stress indicator for farmed fish.

(Continued on next page)

There was also a response in the activity data, but it was less clear than that seen in heart rate. As for heart rate, there was a circadian rhythm in swimming activity in the period preceding the stress testing (higher activity during daytime). This was expected as salmon are known to be more active during daytime than at night, which also probably explains why the heart rate had a similar diurnal variation. During stressing, measured activity levels dropped to lower values than in the preceding period. This was probably because the primary stressor in the experiments (lowering the water level in the tanks) also led to the fish having less volume available for movement. Less movement in turn leads to lower accelerations which again leads to the tags computing lower activity scores. After the stress period had concluded, activity levels increased to higher values than before the stress testing, implying a similar response as that seen in commercial crowding. This may suggest that increased swimming activity also may be a potential stress indicator for salmon in sea-cages, although measured activity was lower during stressing due to the reduced volume for movement.

Although both these sensor principles are possible to apply at a full-scale farm level, further analyses correlating the sensor values with physiological values from the blood samples will be carried out in the SalmonInsight project to establish the validity of data provided by the use of such sensors as operational welfare indicators.

HYDRODYNAMIC LOADS ON EXPOSED FISH FARMS

Introduction

Fish farming at exposed locations requires robust and reliable structures that facilitate sustainable, safe and efficient production. Performance under increased exposure must be evaluated for structural components and the complete fish farm. During the previous years, there has been a focus on increasing the quality of input for structural analysis, including design values for environmental loads and dimensions of netting (solidity). More precise design input values will also require more precise load models: Input parameters and analysis methods are closely linked and will combine yield loads on and response of the structures. It is thus insufficient to change the input parameters without changing the analysis methods accordingly.

The net is the main barrier preventing escape of fish, and the design and dimensioning of nets is therefore of crucial importance in the development of safe and robust fish farms. Analysis of fish farms shows that for a traditional fish farm, drag loads on nets are the major contribution to hydrodynamic loads on exposed fish farms. For new types of fish farms, established and validated load models exist for rigid parts of the structure, while loads on the nets will be a major source of uncertainty.

Methods and results

Methods for establishment of design values for water currents with 10- and 50-year return period were developed based on measurements of current velocity at 22 different locations over periods between 7.5 months and 2.5 years.

It was found that estimating design values for current velocities based on physical measurements for one month, which is the current standard, is not sufficient. It is recommended that design values are found using extreme value analysis based on at least one year of measurement data. If this is not possible in practice, the highest value found during at least three months of measurements can be used with a given multiplication factor.

A new method for measuring solidity of netting was developed. This includes a rig to apply a constant pretension in the netting, backlight illumination, a machine vision camera and custom photogrammetry software.

Moreover, a method for model testing of netting materials was developed. This involved towing of net panels. Loads and relative velocity between fluid and the net panels were measured. The results will be applied to establish drag coefficients and drag loads on traditional nets. Initial tests on traditional netting materials were performed.

THE EFFECT OF DENSITY ON GROWTH IN RED CUSK EEL (*Genypterus chilensis*) – A NEW SPECIES FOR CHILEAN LAND-BASED AQUACULTURE

A. Foss*[1], F. Briceno[2], A. Imsland[1] and X. Gutierrez[2]

[1]Akvaplan-niva AS, Fram Centre, 9296 Tromsø, Norway
E-mail: af@akvaplan.niva.no
[2]Norwegian Institute for Water Research (NIVA) Chile S.A. 5550547. San Pedro 465, Of 306. Puerto Varas, Chile

Introduction

The red cusk eel (also known as Congrio colorado) is a promising new species for the Chilean aquaculture industry. The fish is in high demand in the Chilean market, but landings have declined rapidly due to overfishing. During the last ten years, a pilot-scale commercial company (Colorado Chile SA) has closed the lifecycle for culture of this species and is now producing offspring and juveniles from cultured broodstock fish. With a stable and predictable production of juveniles, the next step is to optimize juvenile on-growing, and to select a rearing system that fulfils the requirements of the species. As the fish are bottom-dwelling and negatively phototactic, a low-light shallow-raceway system was tested, and the present study investigated growth in such a system at three different densities of fish

Material and methods

Six raceways (2.5 x 0.6 m) were used in the experiment. In each raceway, a restricted area was assigned for the fish, and juvenile red cusk eels (100-110 g) were placed in these chambers at three different densities (replicate treatments); Low (~30 kg/m^3), Medium (~45 kg/m^3) and High (~60 kg/m^3). In each raceway, 20 fish were individually tagged using Trovan® Passive Transponder tags. At the start of the trial (24 January 2018), each fish (tagged and untagged) was weighed (g) and measured (cm). The study lasted for 266 days, and fish were measured on approximately monthly intervals throughout the experiment. Water (RAS) was supplied at a constant temperature of 17 °C and oxygen levels were kept above 80% in the water outlet. The fish were kept in the dark apart from during the period of daily feeding and cleaning routines

Results

At the end of the experiment, mean weight was not statistically different between fish from the three treatment groups. However, due to an initial (non-significant) lower mean weight in the high density group, overall SGR in the high density group was significantly higher (13% and 10%, respectively) than the low and medium group. (SGR high density=0.47, medium density=0.43 and low density=0.42). Mean density in each group increased from the initial densities of 30, 45 and 60 kg/m^3 to 77, 132 and 193 kg/m^3, respectively.

Discussion and conclusion

The experiments demonstrated that red cusk eel can be reared at very high densities without compromising growth. In fact, high densities seem to be an important prerequisite for the species to thrive. These fish are negatively phototactic and hides in burrows and between rocks in nature. In culture, a high density may function as a potential shelter, where fish are hiding underneath each other, only leaving their hiding place to feed. Shallow raceways were evaluated as promising rearing units for juvenile on-growing of this new aquaculture species.

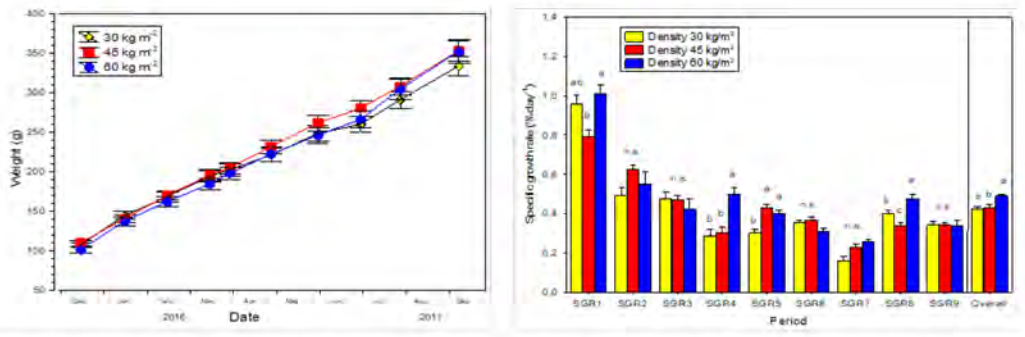

Fig. 1. Mean weight and periodic and overall SGR of juvenile red cusk eel reared at three densities for 266 days. Different letters denote significant differences (two-way nested ANOVA, $P < 0.05$) between treatments in each growth period.

MICROBIAL COMMUNITY DYNAMICS IN RECIRCULATING AQUACULTURE SYSTEMS REARING ATLANTIC SALMON PARR *(Salmo salar)* WITH REDUCED ORGANIC LOADING THROUGH MEMBRANE FILTRATION

Ragnhild Fossmark*[1], Kari Attramadal[2], Trond Rosten[2], Deni Koseto[2], Jenny Nesje[1], Ingrid Bakke[1], Niels Jørgensen[3], Gema Raspati[2], Stein Østerhus[1] and Olav Vadstein[1]

Introduction

A key challenge in recirculating aquaculture systems (RAS) is the accumulation of particulate organic matter. This can stimulate growth of bacteria, influence nitrification kinetics, general water quality, and fish health (Chen et al., 1993). Integration of a membrane for ultrafiltration in the water treatment loop has been proposed to reduce the amount of organic matter build-up, thereby lowering bacterial substrate and other negative effects of turbid water (Wold et al., 2014). An environment with rapid escalation of bacterial numbers, and frequent fluctuations in the microbial community dynamics could reflect an environment rich in opportunistic unfavorable bacteria (Skjermo et al., 1997). The supply of organic matter is typically the limiting resource determining the carrying capacity of heterotrophic bacteria in the system. Thus, a low and stable carrying capacity is suggested to be a strategy for securing an optimal microbial environment with less bacterial blooms and stable community dynamics (Attramadal et al., 2014). This experiment was conducted in order to study the effects of membrane filtration and varying levels of organic matter on the microbial community dynamics in RAS water and biofilm.

Materials & methods

The work was funded by the ERA-NET COFASP (Europe 2020 strategy) and the Norwegian Research Council project "Water treatment technology for recirculating aquaculture systems to increase efficiency by reducing the negative effects of organic matter (RAS-ORGMAT)" (260872/E40). The experiment was set up at NTNU/Sintef Sealab with two replicate small-scaled (4.2m^3) RAS rearing Atlantic salmon parr (*Salmo salar)*. One control system (cRAS) and one system with membrane filtration (mRAS) were run for 72 days. The experiment was separated into three different periods (P) where the water exchange rate was manipulated (40 – 90% recirculation d^{-1}) in order to ensure variations in organic load. P1 had increasing organic load↑, P2 decreasing organic load↑ and P3 increasing organic load↑. The ultrafiltration membrane (Compact 4.0G X-flow/Pentair) had an average pore size of 30nm and filtrated 10% of the total water flow (120 l min^{-1}) prior to the biofilte . Water samples and moving bed biofilm reactor (MBBR) carriers were collected for microbial analysis at two samplings each period. The V4 region of the bacterial 16S rRNA gene was targeted for taxonomic classification through Illumina sequencing. Bacterial concentrations and bacterial growth rates in the water were measured with flow cytometry and thymidine incorporation, respectively.

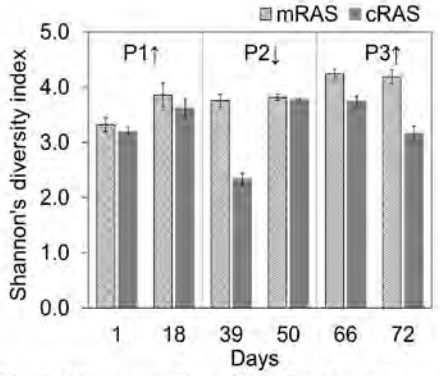

Fig. 1, Shannon's diversity index for water samples

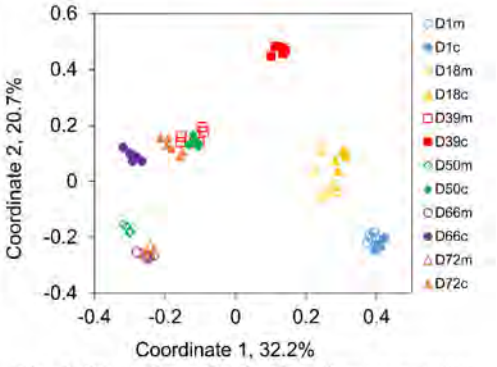

Fig. 2, PCoA Bray-Curtis plot of water samples D=day of sampling, m=mRAS, c=cRAS

(Continued on next page)

Results & discussion

Flow cytometry and thymidine incorporation revealed that both systems had higher bacterial densities and growth rates in the water after the periods of increasing organic load (P1 & P3). However, cRAS had throughout the study significantly higher numbers for both variables except after P2. Thus, the membrane filtration had a clear effect on densities and growth rate of the bacteria with increasing organic load, whereas the effect was not that evident with decreasing organic load. Illumina sequencing showed different microbial community compositions in the two systems. The Shannon's diversity index (Fig. 1) shows more diverse and even communities in mRAS in P2 and P3. The difference is especially evident at Day 39, which was about two weeks after the systems had gone from high to lower organic loading. Principal Coordinates Analysis (PCoA) based on Bray-Curtis similarities (Fig. 2) shows development of the microbial communities over time through the periods. The plot indicates that after the systems experienced the first change in the environment (by Day 39), the communities evolved in separate directions. At the end of the study, the microbial communities of mRAS overlapped more than cRAS. A change in the environment can be a window for bacterial blooms (De Schryver and Vadstein, 2014), which could be seen in the flow cytometry data for cRAS in the beginning of P2 and a genus of *Gemmobacter* dominating the microbial communities at Day 39. The results could indicate that the membrane filtration stabilized the environment by keeping the organic load more constant. At times with increased organic pressure on the system, mRAS was less affected than cRAS. In the MBBR biofilm, the diversity was similar between the systems, and little variation in microbial community dynamics was observed. The growth and mortality rates of the fish were not significantly different between the two systems.

Conclusion

Different organic loading on the systems affected the microbial community dynamics of the RAS water. The applied membrane filtration kept the organic load more constant in the periods of increasing organic loading, and this resulted in a higher diversity and more stable microbial communities with fewer bacterial blooms. Variations in organic loading did not affect the microbiota of the biofilm in the MBBR

Introduction

Micronutrient requirements such as Fe, Cu, Mn, Zn, and Se are essential to fish (Kaushik S. 2002). A lower or higher than optimum supply of dietary minerals can affect the biochemical and physiological responses in fish. Fish meal (FM) is a rich source of micro minerals and has been the major protein source in aqua feeds for fish over the years. However due to the limited supply, its use in fish feeds has been significantly reduced and replaced to a large extent by plant ingredients (Tacon et al., 2008). The later has a direct effect on the availability of minerals in fish. The knowledge of the requirements for these micronutrients in European sea bass, *Dicentrarchus labrax.* were restricted to limited data from the NRC, 2011 while promising data have been arisen from the European research project "ARRAINA" concerning the inclusion of inorganic minerals in low FM based diets. The availability of the minerals depends on various factors among which the chemical form of the minerals. The aim of this study was to examine the effect of different forms of minerals (inorganic vs organic) on the growth, immune system and antioxidant capacity of European sea bass, *Dicentrarchus labrax*, when fed on a low FM diet. Lower levels of mineral premix than optimum were also investigated in order to assess if lower levels would be sufficient to cover the needs of this fish species. This was accomplished through a feeding trial at the end of which both growth, humoral and mucosal immunological parameters, antioxidant capacity and tissue mineral concentration were assessed. In the present abstract preliminary results will be presented, concerning growth, protein efficiency and some immunological parameters.

Materials and methods

European sea bass juveniles (~20g) were fed the 6 experimental diets. The selection of mineral level addition was based on the optimal levels of selected minerals reported by the ARRAINA project. Feeds were formulated as described on the table below. Low fish meal diets contained as main ingredients, wheat and corn gluten, soya protein concentrate, fish oil and rape seed oil. All diets were isonitrogenous and isoenergetic.

Results

After 94 days feeding, juveniles sea bass showed significantly improved growth performance (SGR) and protein efficiency (PER) in fish fed the ORG diet (Fig 1). This difference was significant when compared to diet INORG. Immunological parameters were assessed in blood, serum and in skin and gut mucus. Hemoglobin was improved in ORG diet fed fish. Ceruloplasmin, an indicator of inflammation, was elevated in the blood of fish fed the deficient (CTRL-) and INORG plant-based diets. Blood respiratory burst activity was significantly reduced in the blood of fish fed the INORG diet compared to all the other tested diets. In contrast with the growth parameters, serum and gut lysozyme activities were significantly reduced in ORG-fed fish

Discussion & Conclusions

The growth parameter and protein efficiency results showed a significant improvement of the fish performance when fed the organic minerals enriched plant based diets even when compared to the FM based diet (CTRL+). This improvement was not apparent with levels below optimum or with excess of organic minerals, the latter suggesting a potential toxicity of the high concentrations of dietary minerals. The use of organic mineral premix was also more potent than the inorganic premix at the same dietary dose. The same improvement of some hematological/immunological parameters in fish fed with the optimum organic mineral premix was evident concerning the hemoglobin level and respiratory burst activity and reduction of the inflammatory response but the effect was not so clear concerning many other immunological parameters assessed in the present study. The results on the antioxidant capacity of the fish may give more information about the beneficial e fects of the organic mineral addition to sea bass diets based on plant protein sources.

On the whole, the use of organic mineral premix at the optimal level seem to improve fish performance and some immunological parameters when these fish were fed plant meal based diets up to or above levels obtained in FM fed fis

APPLICATION OF RESPONSE SURFACE METHODOLOGY TO OPTIMIZE THE GROWTH AND FEED EFFICIENCY RESPONSE IN EUROPEAN SEABASS FED GRADED LEVEL OF FISH MEAL AND SHRIMP HYDROLYSATE

V. Fournier, M. Herault, M. Hervy

DIANA AQUA – ZA du Gohélis – 56250 ELVEN
vfournier@diana-aqua.com

Introduction

Marine protein hydrolysates are promising ingredients that can bring critical functionalities to fish feeds, formulated to meet fish nutrient requirements. Palatability and digestibility are known to be driven by the peptide profile of the dietary hydrolysate. However, interactions with fish meal are expected to be dose and quality dependant making any model, or prediction, about final dietary palatability and digestibility a bit uncertain. This is where statistical tools, such as full factorial design, may help us quantifying ingredient individual effects, along with their interactions, at graded inclusion levels, with optimization of zootechnical performance as the final ta get.

Materials and methods

Two full factorial experimental trials were designed in juvenile European seabass (5-10g initial body weight) reared in 100l tank and fed 24 different diets with graded levels of fish meal (0, 5, 10 and 20%) and shrimp hydrolysate (0, 2.5, 5, 7.5 and 10%), including 4 repetitions. Fish (40 per tank) were fed either *ad libitum* or at 80% satiety for 7 weeks using an automatic feeding system. At the end of the trial, specific growth rate (SGR) and feed conversion ratio (FCR) were calculated and estimated response surfaces were then calculated for both parameters using Statgraphic 2.0 software.

Results and discussion

Results showed that at low level of inclusion, shrimp hydrolysate performed better than fish meal for growth and for FCR. From 8% dietary inclusion, a quadratic effect was observed mostly due to the too high level of peptides supplied by hydrolysate. The statistical model gave us a optimal combination of 20% fish meal and 6.6% shrimp hydrolysate then 20% fish meal and 3.9%% shrimp hydrolysate for maximizing growth rate and feed utilization respectively. Higher dietary level of fish meal would have to be studied to check the benefit of dietary hydrolysate at higher level of fish meal. Other variables such as the quality of fish meal as well as the origin and the peptide profile of hydrolysate would deserve to be evaluated too.

ESTABLISHING METHODS FOR DETERMINATION OF FISH QUALITY IN DOMESTIC FISH SPECIES IN THE AQUACULTURE OF MECKLENBURG-WESTERN POMERANIA

K. Komolka*, G. Franz, Y. Kaya, B. Grunow

e-mail: Komolka@fbn-dummerstorf.de
Institute of Muscle Biology and Growth, Leibniz Institute for Farm Animal Biology (FBN), Dummerstorf, Germany

Introduction

Aquaculture is the fastest growing area of food production with a steady expansion of more than 8% per year since the 70s (Burbridge et al. 2001; Knaus 2012). Besides this, the fish flesh quality has gained importance among the consumers because it is directly related to human health and nutrition. But so far, fish flesh quality of only few species (e.g. *Oncorhynchus ssp., Oncorhynchus mykiss, Salmon salar)* has been examined and this mostly in regard of the chemical composition. These results exhibited that lipid and protein composition in fish muscle vary greatly between species and are depending on age, sex, environment and season (Johnston 2001). Presently, there are no established methods and regulation to measure the physical properties of fish flesh. Therefore, the aim of this study was to transfer the protocols used for beef, pork and chicken to fish for analyzing the physical parameters of fish flesh. For a first description and to ensure improvement of fish flesh quality in future due to adaptation of fish cultivation in aquaculture, two economically important fish species, the European perch (*Perca fluviatilis*) and marena whitefish *Coregonus* maraena), were analyzed.

Methods

Fishes were cultured in a recirculation system in the Institute for Fisheries in Born, Germany. Adults of both sexes from *Perca fluviatilis* (PFL, n = 15) and *Coregonus maraena* (CMA, n = 15) were slaughtered by standard procedure in accordance to the German Animal Welfare Act (§ 4(3) TierSchG). Morphometric measurements of animals and filets as well as the physical measurements were taken immediately after death. Quality parameters of muscle like pH, isoelectrical conductivity and impulse-impedance were measured at 5min and 1h post-mortem using pH-Star (Matthäus), LF-Star (Matthäus), and Meat Check 150 (Matthäus), respectively. The filet firmness was measured 0h post-mortem by Texture Analyser TA.XTplus (Winopal) with Warner Bratzler blade in caudal central to the lateral line of the filet, in triplicate. Color of muscle divided by dorsal and ventral filet was measured three times with CR-300 Chroma Meter (Minolta). The water holding capacity (WHC) was determined by filte -press-method via Hypress (Grau and Hamm, 1953), in triplicate. Morphometric and quality parameters were statistical analyzed using SAS (v.9.2).

Table I: Physical parameters of fish quality in European perch (*Perca fluviatilis*, PFL) and marena whitefish (*Coregonus maraena*, CMA) in aquaculture of Mecklenburg-Western Pomerania

	PFL (n = 15)		CMA (n = 15)	
Physical parameter	mean	SEM	mean	SEM
lightness	42.70	0.70	43.64	0.91
pH (5min)	6.68	0.04	6.87	0.04
isolectrical conductivity (5min)	4.79	0.26	4.05	0.17
impulse-impedance (5min)	70.93	1.54	60.33	1.30
water holding capacity [%]	16.45	0.60	20.90	1.26
shear force max. [N]	53.89	1.76	24.74	0.65

(Continued on next page)

Results

The morphometric data of PFL, member of Percidae and CMA as member of Salmonidae differs significantly ($p \leq 0.001$) in species-specific manner. At slaughter PFL has a total length of 37.58 ± 0.37 cm and a weight of 777.07 ± 0.30g. CMA exhibited a total length of 32.58 ± 0.27cm and a total weight of 327.07 ± 7.59g. Carcass weight (exclusion of head and internal organs) of PFL and CMA has been 469.07 ± 14.41g and 237.27 ± 11.21g. For the consumers, especially the amount of free water in the fish filet, defined as WHC and texture, represented by the maximal shear force (SF), is of interest. Under the present fish cultivation condition, the results show a firmer texture (53.89 ± 7.76N) with lower WHC (16.45 ± 7.76%) in the PFL filets. Compared to this, the CMA filets exhibit a softer texture with 24.74 ± 0.65N and a higher WHC (20.90 ± 1.29%). Furthermore, also the impulse impedance showed higher values in PFL filets (able I).

Discussion

In the meat production, firm regulations for pork, beef, and poultry meat quality have been existing. Due to the high diversity of fish species, regulations for fish muscle quality has not been defined thus far. With the present study, we could show that an adaptation of the used physical methods can be transferred to fishes as well. Therefore, the obtained results are a first step in order to develop consistent regulation and statements regarding the physical values of fish filet to define the quality of fish fles

Introduction

Rainbow trout (*Oncorhynchus mykiss*) is a male heterogametic (XY) sex-determined species and the master sex-determining gene, sdY, has been identified (Yano et al., 2012). Surprisingly, a small proportion of phenotypically male individuals is regularly observed in all-female trout livestock (produced by crossing sex-reversed XX-males with standard XX-females). Maleness has also been described in gynogenetic families (expected to be all-XX females) (Quillet et al., 2002). In further studies we showed that the maleness ratio could depend on both genetic background and rearing temperature (Valdivia et al, 2014) and found several QTL associated with spontaneous masculinization (Guyomard et al., 2014). Those results indicate the existence of a complex genetic and environmental control of gonad differentiation underlying the major sdY determinism. In this study, we aimed at further describing the genetic architecture of spontaneous maleness in a French all-female trout population using a GWAS approach based on a medium-throughput SNP chip.

Materiel and methods

Fish were produced at the trout farm "Les Fils de Charles Murgat" in June 2017 from 5 factorial mating designs (50 dams and 50 sires in total). Eggs were separated into two batches and were kept at 12°C until the end of yolk resorption. At that time, temperature was increased to 18°C for one of the batches for a period of 1100 degree-days, covering the expected window of gonad differentiation. The two groups were then reared at the same temperature (between 12 °C and 14.5°C) until they were sexed. Sex was determined by visual observation of both gonads for 10 000 fish per temperature. In each group, about 6 500 fish were examined at 10 months post-fertilization and the 3 500 remaining 5 months later. Fish were distributed in 3 sex classes: female (2 ovaries with no visible sign of testis area), male (two testis, with no visible female area/ovocyte) and intersex (presence of both male and female areas in at least one gonad) and encoded as 1, 2 and 3, respectively. A fin clip was sampled from all males (n=163), intersex (n=132) and from 858 females randomly chosen for genotyping using the 57K SNP Axiom™ Trout Genotyping Array. Sex was analyzed as a linear trait modelled by GBLUP accounting for the fixed effect of the rearing temperature and the random effects of all retained SNPs. Using BLUPF90 software, genomic variance, phenotypic variance and heritability were estimated using AIREMLF90 program and GWAS were based on the POSTGSF90 program (Aguilar et al., 2014). Different options of POSTGSF90 were used to derive QTL significan e, QTL effect and proportion of genomic variance explained by QTL, considering 1Mb-sliding windows of adjacent SNP and weighted GBLUP (wGBLUP).

Results and discussion

The overall maleness rate (males + intersex) was 1.99% at 12°C and 0.87% at 18°C. After quality controls, 30 811 SNP and 1 139 fish were retained.

Genomic heritability was estimated at 0.51 (± 0.05) with genomic and phenotypic variances estimated at 0.22 (± 0.03) and 0.43 (± 0.02), respectively. With the GBLUP model, we detected 5 sex- QTL on 4 chromosomes (see Figure 1). One QTL on Omy1 was highly significant and explained 1.92% of genetic variance; the suggestive QTL on Omy7 explained 2.98% of genetic variance. The other QTL explained between 0.83 and 0.91% of genetic variance, whether they were significant at the chromosome level or not (Figure 1, B). Using the wGBLUP model with two iterations to better quantify the QTL effect, we confirmed the role of the two QTL on Omy1. Interestingly, none of the QTL was located on the male-specific Y-chromosome.

This study paves the way for the identification of the causal mutation(s) and the gene(s) responsible for this spontaneous maleness of XX female rainbow trout.

Introduction

The socio-economic role of mussel aquaculture in the Galician rías (NW Spain) and its dependence on environmental conditions have generated an increasing concern about the impact of future climate scenarios on this production system.

ClimeFish is an on-going H2020 project committed to the study of the impacts of climate change on freshwater and marine fisheries and aquaculture across Europe. Within this framework, the aim of this work is to forecast the effects of future climate scenarios on mussel growth in the Galician rías,

Methods

We have simulated mussel shell and soft tissue growth using the dynamic model proposed by Fuentes-Santos et al. (2019) under observed (2006-2015) and projected (2016-2055 at decadal intervals) climate conditions under the RCP4.5 and RCP8.5 emission scenarios.

Our growth model is driven by sea surface temperature, solar irradiance and food availability, which in turn is driven by the coastal wind regime and river discharges (Aguiar et al., 2015). We have used three climate models (POLCOMS-ESM, CSIRO-Mk3.6.0, and the NorESM1-ME) to account for model uncertainty in SST projections. RCP projections for coastal winds, river discharges and solar irradiance were downloaded from the EURO-CORDEX MPI-ESM-LR model. We have generated 1000 bootstrap realizations of 3-year cycles for each environmental driver for the observed conditions and future decadal projections to feed the growth model.

We have simulated the growth of mussel seed (initial shell length = 15mm) during 450 days considering different seeding periods: winter (February), spring (June), summer (September), autumn (November). We have simulated the impact of climate change on mussel growth in terms of the time needed to reach the optimal market size (target flesh weight = 8g)

Results and discussion

SST projections vary across climate models. SST barely increases according with POLCOMS-ESM, suffers approximately a 1ºC increase according with CSIRO, and increases gradually up to 1.5-2ºC in 2046-2055 under RCP8.5 according with NorESM. The MPI-ESM projections predict a decrease in solar irradiance during summer and a subtle increase in spring and autumn. Finally, we do not predict any climate related change in food availability during the next 3 decades.

Fig. 1 highlights the important role of the seeding time on mussel growth. Mussels seeded in February need less time to reach the target weight than those seeded in summer and autumn, while those seeded in June have the largest culture length. Fig. 2 shows that the culture length shall suffer a slight increase under POLCOMS conditions but shall decrease with CSIRO and NorESM projections. However, climate change has a minor impact on mussel growth in comparison with the seeding schedule.

Our results suggest that climate change shall barely affect mussel growth in the Galician rias over the next three decades. However, a proper analysis of the impact of climate change on mussel aquaculture requires addressing other factors, such as seed availability and harmful algal blooms, which determine the seeding and harvesting schedule. The settlement cycle is controlled by solar irradiation (Fuentes-Santos et al., 2016), which shall not suffer relevant changes in the next decades. Thus, we may not expect significant shifts on seed availability. Harmful algal blooms, which cause harvesting closures of culture areas, may have an important negative impact on production. Álvarez-Salgado et al. (2011) found that rainy springs produce long-lasting closures in summer and windy summers favour long-lasting closures in autumn. A preliminary analysis of future wind regimes and continental runoffs in the area suggest that harvesting closures shall decrease by 10% in summer and increase by 10% in autumn.

THE CRITICAL SUCCESS FACTORS OF AN OPEN OCEAN FARMING OPERATION

Langley Gace *

Innovasea Systems, Inc.
425 Ericksen Avenue NE
Suite 101
Bainbridge Island, WA 98110
LGace@InnovaSea.com

Innovasea Systems Inc. delivers a wide array of equipment and services to the aquaculture industry. Offerings range from land-based hatchery/nursery technology, wireless instrumentation collection, and analysis to open ocean farming platforms. Innovasea supports its clients from egg to harvest. With a staff of more than 200, some with 20+ years' experience, Innovasea has witnessed a range of successes through their clients and industry. As a result, the company has identified several critical success factors required for a productive open ocean farm as well as a phased approach business model.

Decisions such as site selection and choice of species in the nascent stages of a greenfield venture will significantly impact managing costs in a commodity price-driven industry. Prudent staffing decisions, adhering to best management practices, reliable sources of feed and finally access to quality fish health support are crucial to averting disasters which can escalate quickly in a hatchery or open ocean farm. Equipment suitable for the environments of the farm is vital to the longevity of the operation. Hatcheries must be designed with the final requirements in mind. Farming equipment must be able to withstand the rigors open ocean yet provide for reliable operations such as stocking, feeding, mortality retrieval, and harvesting.

Finally, the startup must be adequality capitalized to support the inevitable learning curve. Innovasea works with existing and potential clients on a three-stage growth model that enables a phased approach to build out a new farm. The incremental investment provides validation of systems, processes and the market at each phase. Phase one demonstrates site viability, costs, the effectiveness of the team, processes and market demand. Phase two proves the scalability of the farm and market. Phase three provides volume and profitability based on lessons learned in the two earlier phases

NUTRITION MEETS GENETICS: GROWTH COMPARISON OF EIGHT RAINBOW TROUT *(Oncorhynchus mykiss)* STRAINS DEPENDING ON PROTEIN SOURCE OF THREE DIFFERENT EXPERIMENTAL DIETS

J. Gaehrken*, J. Tetens and S. Wessels

University of Goettingen, Department of Animal Sciences, Division of Aquaculture and Water Ecology, Albrecht-Thaer-Weg 3, 37075 Goettingen (Germany)
E-mail: jgaehrk@uni-goettingen.de

Introduction

In times of often depleted wild fish stocks and increasing consumer awareness, research is being carried out on protein sources that are suitable as an alternative to fish meal in animal feeds for carnivorous fish species (Naylor et al., 2009). However, high proportions of fish meal substitutes, such as plant and insect proteins, can have a negative impact on growth and fish health. Selective breeding of fish populations for adaptation to fish meal-reduced or fish meal-free diets could make a valuable contribution to the more sustainable production of high-quality edible fish. Le Boucher et al. (2012) were able to show that after only one generation of selection for adaptation to pure plant diets in rainbow trout, an improved survival rate and biomass was achieved. In the present study, a communal testing design was used to investigate the impact of different protein sources on growth in the offspring of several rainbow trout strains.

Materials and methods

The offspring (average weight 31.2g; age 262 days post fertilization) of 28 full-sib families from eight different rainbow trout strains were distributed equally among nine uniform tanks. Three experimental groups were fed in triplicates for 90 days with one of three experimental diets. All diets were administered at the same percentage of biomass. The isoenergetic and isonitrogenic experimental diets were based on either fish meal, microalgae meal or insect meal. All experimental fish were individually tagged using PIT-tags. Body weight and length were individually recorded at the beginning and the end of the experiment. Based on the individual weight gain, the performance of families was ranked within the different environments (diets) and examined for an existing genotype-environment-interaction. Breeding values for weight gain were estimated for each sire based on offspring performance. In addition, heritability was estimated.

Results

Preliminary results show high correlation coefficients between the rankings of genotypes (families) within the observed environments (Table I).

On average of all experimental diets, rainbow trout exhibited a weight gain of 84.3g ± 28.4g over the entire trial period. Breeding values indicated significant differences in performance between the families (figure 1), which seemed to occur independently of the experimental diet administered. Estimated breeding values for weight gain ranged from 14.42g to -23.23g. Heritability for weight gain was calculated as 0.38 (standard error = 0.06).

Discussion and conclusion

None of the observed rank correlation coefficients fall below the threshold of 0.8 for a possible genotype-environment interaction as defined by Robertson (1959). These observations suggest that the adaptability to the experimental diets used, with their different protein sources, is well developed and to a large extend regardless of genetics. Thus, breeding values might be considered consistent irrespective of the feed protein source used during performance testing, which would greatly facilitate breeding. The breeding values calculated under this assumption show a clear variability between the families. The investigated genotypes are subject to a pure conservation breeding without any selection - this likely contributed to the high heterogeneity in performance. Nevertheless, the proportion of weight gain attributable to genetics seems high with a heritability of 0.38 (SE 0.06). The type of protein source in the experimental diets used was insignificant for the observed performance levels of the different genotypes. Therefore, fish meal was well substitutable under experimental conditions. The exchange of further components of industrial aquafeeds such as fish oil should be included in the future in order to assess the possibilities of breeding rainbow trout for adaptation to aquafeed which is independent of marine capture fisheries input.

Introduction

Constant usage of fossil fuels resulted in considerable ecological and economic problems. Because of the fossil fuels non-renewability, rapid acceptance of renewable energy sources as their replacement is of the pivotal importance. Third generation biofuels, which are also represented by microalgae-derived biodiesel, are a partial solution to the mentioned problems. A direction towards the sustainable development of microalgae-derived biodiesel is development of feasible strategies responsible for microalgal lipid accumulation (Zhu et al., 2016). It has been shown that microalgae have the capability to alter their lipid biosynthetic pathway under unfavorable environmental conditions towards the neutral lipids accumulation (Sharma et al., 2013). The objective of this study was to evaluate the potential application of sodium selenite as neutral lipid inductor in marine microalgae *Dunaliella tertiolecta* which could favor the production of potential microalgae derived-biodiesel.

Materials and methods

Sodium selenite (Na_2Se0_3) stress experiment was performed according to the OECD 201 (2011) guidelines. Microalgae *D. tertiolecta* were grown under different Na_2SeO_3 concentrations (0.0, 1.8, 3.6, 7.2, 14.4, 28.9, 57.8, 115.6 and 231.3µM) 15 days of exposure. Microalgal growth was monitored by optical density measurements (680 nm). Lipid peroxidation was determined in the context of malondialdehyde (MDA) quantity (Pancha et al., 2015), while a Nile red method was used for quantitative measurement of neutral lipids in *D. tertiolecta* (Yilancioglu et al., 2014). Oil bodies (droplets) in algal cells were observed under a fluorescent microscope using blue light as the excitation wavelength

Results

At selenite concentrations up to 28.9µM algal growth rate were similar to the control group during 15 days of exposure. With selenite increase to 57.8µM at the 15th day of exposure algal cell number dropped by 35% compared to control indicating an inhibition in cell growth. The MDA levels were significantly higher in 115.6 and 231.3µM Na_2SeO_3 at the 15th day of exposure (0.39 and 1.39µM OD^{-1}) compared to control (0.22µM OD^{-1}). The highest lipid productivity (6.16 10^5 cell^{-1} day^{-1}) was obtained on 115.6µM Na_2SeO_3 at the 15th day of exposure (Fig 1; a). Neutral lipid content (yellow fluorescence) increased with the increase of Na_2Se0_3 concentration (Fig 1; b).

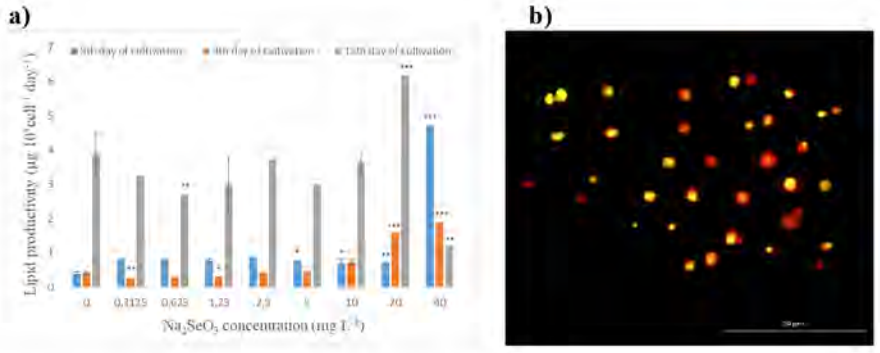

Fig 1. (a) Effects of different sodium selenite (Na_2SeO_3) concentration on neutral lipid productivity of *D. tertiolecta*. (b) Nile Red fluorescence of *D. tertiolecta* with 115.67µM of Na_2SeO_3 at 15th day of exposure. Values are expressed as means±SD. Asterisks indicate a significant difference (*p<0.05, ** p<0.01 and ***p ≤ 0.01).

(Continued on next page)

Discussion and conclusion

Selenium, as an important trace element, acts either as an essential micro-nutrient or as a toxicant which depends on the dose in biological systems (Zhong and Cheng, 2017). This study showed that *D. tertiolecta* in comparison to other tested microalgae (Sun et al., 2014) has different sensitivity to selenium, suggesting that selenium tolerance can vary significantly between different microalgal species (Sabatini et al., 2009). Increased MDA concentration is an indicator of membrane lipid peroxidation which implies an increase of reactive oxygen species concentration. Results obtained using Nile Red method pointed out that exposure of microalgae cells to different concentrations of Na_2SeO_3 had a remarkable effect on neutral lipids accumulation in *D. tertiolecta*. Since lipid accumulation is partly mediated by oxidative stress (Yilancioglu et al., 2014) it can be concluded that oxidative stress induced by Na_2SeO_3 is an effective factor for neutral lipid induction in *D. tertiolecta*, which can be utilized in biodiesel production.

Introduction

Brachionus plicatilis and *Artemia* are commonly used in aquaculture as live food for fish larvae. However, these preys are deficient in long chain polyunsaturated fatty acids (LC-PUFA) and need to be enriched in order to improve their nutritional value. These fatty acids (FA), particularly docosahexaenoic acid (DHA), are essential nutrients for the normal development of several larval tissues, especially nervous system (brain and visual perception). However, they are readily oxidable, being susceptible to suffering lipid peroxidation due to the presence of free radicals causing oxidative stress. During both, early stages of larval development and live prey enrichment protocols, there is a pro-oxidant environment due to the high metabolic activity and the aeration systems, respectively, compromising the appropriate supply of LC-PUFA to fish larvae (Viciano et al., 2017). Algae are rich in omega-3 LC-PUFA and bioactive compounds with antioxidant potential, such as carotenoids. Thus, new potential enrichment products obtained from microalgae and macroalgae were tested in the presence or absence of a pro-oxidative LC-PUFA environment in order to evaluate their potential as enrichment and antioxidant compounds.

Material and methods

Three different enrichment experiments were carried out. In the first one (E1) rotifers and *Artemia* were enriched with a commercial lipid emulsion based on DHA (Incromega DHA500) without supplementation (C) or supplemented with an astaxanthin rich commercial product (NatuRose®; NR); a fucoxanthin extract from *Lobophora variegata* (>97% purity) (FU); or a spray-dried *Isochrysis galbana* (ISD). In the second experiment (E2), different emulsions based on Incromega DHA500 (*B. plicatilis*) or on a DHA-rich marine lecithin (LC-60) (*Artemia*), were assayed without supplementation (C) or supplemented with ISD or three different formats of *Navicula salinicola:* fresh (NFRE), frozen (NFRO), or spray-dried (NSD). Finally, in a third experiment (E3), baker yeast or PhytoBloom Prof were used as controls (C) for *B. plicatilis* and *Artemia*, respectively, adding as experimental enrichment products: *I. galbana* fresh (IFRE), frozen (IFRO) or ISD. After 6 (E1 and E2) or 24 (E3) hours of enrichment, survival rate, peroxides index (PI) (Shantha and Decker, 1994) and malondialdehyde (MDA) content (TBARS) (Ohkawa et al., 1979) were determined.

showed the lowest PI and TBARS (15.05±3.85; P=0.014 and 1.76±0.16; P=0.013, respectively) in E3.

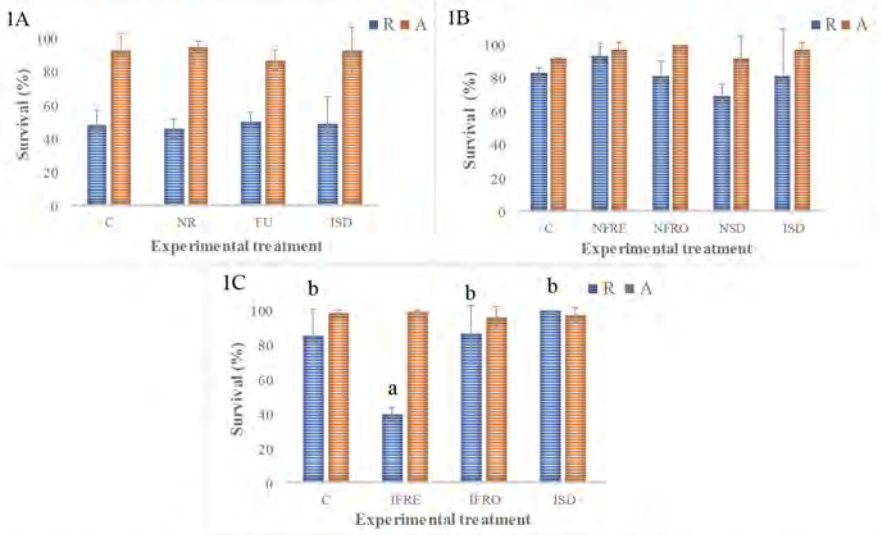

Fig. 1. Survival (%) of *Artemia* (A) and rotifer (R) in E1 (A1), E2 (A2) and E3 (A3). Different letters denote significant differences (P<0.05)

(Continued on next page)

Results

Regardless of the enrichment experiment, survival of live preys was not affected by the treatment, although it was higher in *Artemia* than in rotifers. Only IFRE treatment negatively affected *B. plicatilis* survival (P=0.001) (Figure 1). Overall, E1-PI ($mEqO_2$ kg^{-1}) was lower in the crustacean (17-41) and surprisingly high for ISD-rotifers (170.27±15.51), whereas E1-TBARS (nmol MDA mg $protein^{-1}$) remained stable between treatments in both species. E2-PI and E2-TBARS did not differ between treatments in *Artemia* (35-44 and 0.84-0.96, respectively) while rotifers given ISD showed the lowest MDA content (1.14±0.90; P=0.001). Interestingly, ISD-*Artemia* showed the lowest PI and TBARS (15.05±3.85; P=0.014 and 1.76±0.16; P=0.013, respectively) in E3.

Discussion and conclusion

According to the obtained survival rates, the new ingredients formats and concentrations assayed as single enrichment products or in combination with lipid emulsions, do not adversely affect the population status compared to the control commercial treatments. The generally lower survival rate of E1-rotifer could be related to the higher culture density used in this trial compared to that of E2 and E3 (470 *vs* 200 and 87 ind mL^{-1}, respectively). Both PI and TBARS were lower in *Artemia* than in rotifers, with the E3 ISD treatment showing even reduced amounts than the commercial product. This is probably due to the higher content of the carotenoid cantaxhanthin in the crustacean (D'Abramo et al., 1983), which may have been acting as an antioxidant in this specie. The main objective of live prey enrichment studies is the improvement of their nutritional value. In this sense, it is much easier to modify the FA profile of rotifers because of theirs passive filter feeder condition, whereas *Artemia* rapidly modifies the dietary FA profile (Viciano et al., 2017). However, the lower PI and TBARS in *Artemia* seems to indicate a better antioxidant defense and a higher potential for the effective use of the micro and macroalgae products of this species. Marine larval feeding experiments employing the best treatments of the current study will be developed in the near future.

Introduction

Vaccination is considered crucial in world aquaculture for being one of the most important methods of preventing and controlling illness. Every year, millions of farmed salmon are vaccinated to prevent different bacterial and viral diseases. However, the control of some infections still remains the main problem affecting the top salmon producing countries: Norway, Canada and Chile. Piscirickettsiosis has been infecting Chilean salmon for almost 40 years and is currently considered the main bacterial threat to this industry. *Piscirickettsia salmonis* is an intracellular bacterium that vaccines have failed to control in Chile. *P. salmonis* causes hematocrit decrease, pale liver, pale and enlarged kidneys and spleen, and necrosis of all lymphoid tissues, resulting in high mortality rates.

There are 33 vaccines commercially available against piscirickettsiosis including, inactivated bacterial vaccines, live attenuated vaccines and vaccines based on recombinant proteins. Protection failure of vaccines against this bacterium has been proposed as the cause of the increased use of antibiotics in Chile. The reason for the failure of these vaccines is currently unknown, but it has been hypothesized to be the result of the decline of circulating levels of antibodies over time and coinfection with sea lice *Caligus rogercresseyi* (Figueroa et al. 2017). In this study, we provide evidence that supports that the effectiveness of a commercial vaccine against *P. salmonis* in Atlantic salmon mainly depends on the host's genetic variation.

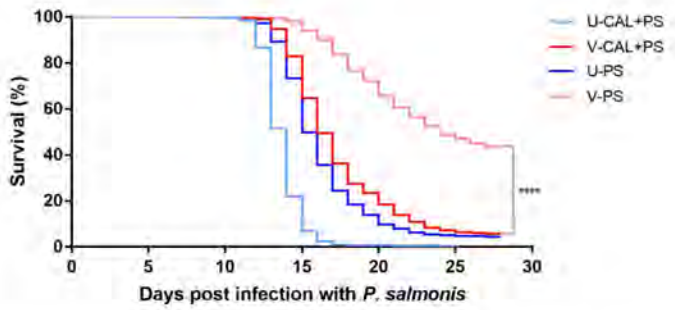

Fig. 1. Atlantic salmon survival curve after challenge with *P. salmonis*(PS) or *C. rogercresseyi*(CAL) plus *P. salmonis* on vaccinated (V) or unvaccinated (U) fish.

Table I. Heritability of resistency against *P. salmonis* and Coinfection *P. salmonis* and *C. rogercressegy* in two populations of Atlantic salmon. For abbreviations see fig. 1.

Population	U-PS	U-CAL+PS	V-PS	V-CAL+PS
1	0.48 ± 0.06	0.23 ±0.06	0.38 ± 0.07	0.65 ± 0.07
2	0.34 ± 0.06	0.26 ± 0.04	0.36 ± 0.07	0.50 ± 0.06

(Continued on next page)

Materials and Methods

This study was carried out in accordance to the guide for the care and use of experimental animals of the Canadian Council on Animal Care. Fish from two populations were challenged against *P. salmonis* and *C. rogercresseyi* as described by Figueroa et al. (2017). Of the total, 2.926 fish were vaccinated and 2.816 were not. The fish were intraperitoneally vaccinated using two commercial vaccines, one being Pentavalent, vaccine against IPNV (infectious pancreatic necrosis virus), ISAV (infectious salmon anaemia virus), *Aeromonassalmonicida*, *Vibrio ordalii*, and *P. salmonis*; and the other, Live attenuated vaccine against *P. salmonis*. Control fish were injected with PBS (phosphate-bu fered saline).

Results

Preliminary results showed that vaccinated fish challenged with *P. salmonis* (V-PS) had an optimal RPS_{60} of 84.8 % and a mortality of 9.8 % at day 16 post infestation. Conversely, vaccinated fish under a coinfection challenge (V-CAL+PS) had a RPS_{60} of 89.1 % and a mortality of 5.3 % at day 13 post infestation (Fig. 1). Nevertheless, at the end of challenge at day 27, the RPS and mortality rate dramatically decreased for V-PS (41.2 % and 56.3 %, respectively) and for VCAL+PS (5.8 % and 94.2 %, respectively, Fig. 1).

We state that there is high family variability in the response to vaccination in two domesticated populations of Atlantic salmon as illustrated in table 1. A positive genetic correlation but of medium magnitude was observed between natural resistance and resistance mediated by vaccines (range rg= 0.30-0.60), so that both processes are not totally synergistic as previously hypothesized. Low response to vaccination was associated with high mortality, lower growth, higher bacterial loads, and higher clinical signs, particularly when fish were co-infected with the sea lice *Caligus rogercresseyi*. Conversely, high response to vaccination was associated with low mortality, lower bacterial load, better growth performance and reduced clinical signs of the disease.

Discussion

The manufacture of vaccines for salmon should move towards a strategy of precision medicine, including the genetic variation of the host as a key element for the development of effective vaccines against *P. salmonis*.

ROBUST SALMON SKIN – IS THERE A GENETIC COMPONENT?

Jacob Seilø Torgersen, Jørgen Ødegård, Tim Martin Knudsen and Trina Galloway*

AquaGen AS, P.O Box 1262, 7462 Trondheim, Norway
Email: trina.galloway@aquagen.no

Introduction

Wound related problems account for large losses in Norwegian Atlantic salmon aquaculture and is commonly linked to fish management procedures or pathogens, including lice (Takle et al. 2015). The delicate outer mucosal barrier of fish is made of living cells and is easily damaged during mechanical handling, which may facilitate entry of pathogens or cause osmotic problems. Fish skin morphology and function is affected by more than 500 genes in zebrafish (*Danio rerio*) (Li et al. 2011), but little is known about this for Atlantic salmon. Minuscule damage to the outer epithelial layer of the skin has previously been linked to winter ulcers in salmon, caused by *Moritella viscosa*. In this study we have investigated the effect of genetics on wound healing and resistance to this bacterium, in order to improve skin robustness in Atlantic salmon.

Materials and methods

A total of 1800 Atlantic salmon (mean weight of 105g) from the AquaGen breeding nucleus were transported from Kyrksærterøra to VESO Vikan (Norway) in September 2018. Upon arrival, the fish were distributed evenly to two tanks with 34ppt sea water. After one week of acclimatization, all fish in tank 1 were anaesthetised and a 2.75 mm circular wound was made in their tail fin with an ear punch pincer (considered a gentle handling procedure). The fish were left to heal for one week before images of the wounds were captured with a stereo microscope. All fish in both tanks were subjected to a *Moritella viscosa* bath challenge test (Karlsen et al. 2017) 16 days post arrival. Dead and moribund fish were collected from the tanks daily, and the challenge test was terminated after 20 days.

Wound healing (tank 1) was measured as the difference in size between the original hole and the hole after 7 days (Fig. 1) and resistance to *Moritella viscosa* (both tanks) was measured as survival time (time until death) after the onset of the challenge test. In total 1645 fish were genotyped, of which 884 were from tank 1 and 761 from tank 2. The parents of these fish had previously been genotyped, enabling calculation of heritability for the di ferent traits.

Results

Wound healing and survival time in the challenge test varied significantly between families. Heritabilities were moderately good for wound healing (h^2=0.18±0.06) and for survival time (h^2=0.16±0.06). There were no significant genetic correlations between the two traits. Cumulative mortality during the challenge test was higher (95.5%) in tank 1 than in tank 2 (84.9%).

Discussion and conclusion

Wounds are caused by mechanical injuries and/or pathogens and create welfare issues for farmed fish and economic problems for fish farmers (Takle et al. 2015). The present study showed that even gentle handling increased the pathogenicity of *Moritella viscosa*, as seen by a higher cumulative mortality in tank 1 than in tank 2.

The present study also showed that healing of mechanical wounds and *Moritella viscosa* mortality can be improved by breeding (h^2 0.16-0.18). However, no correlation was found between wound healing and *Moritella* resistance. The results are very promising and will be supplemented with genomic selection, fine mapping and transcriptome studies, and studies of the combined effects of genetic selection, optimal diets and optimal vaccines on improved salmon skin robustness.

MOLECULAR APPROACHES FOR THE GENETIC MANAGEMENT OF OYSTERS ALONG THE SOUTH COAST OF BRAZIL

M. S. N. Galvão*, J. R. Monteiro, F. S. Fonseca, H. L. A. Marques, A. W. S. Hilsdorf

Fisheries Institute - Aquaculture Research Center - APTA/SAA. Av. Virgilio Baggio, 85 – 13641-004 – Pirassununga – SP – Brazil
E-mail: margalvao@pesca.sp.gov.br

Introduction

Oysters represent an important fishery and aquaculture resource worldwide and are an important source of income for the coastal communities. In Brazil, the main native oyster species economically important for fisheries and mariculture are *Crassostrea brasiliana* (= *C. gasar*) and *C. rhizophorae*. Currently, *C. brasiliana* is the one use in aquaculture operations due its higher size. However, the presence of exotic oysters in native oyster banks are jeopardized the native oyster genetic resources. This study aimed at identifying native and exotic species in the estuarine areas of Southeast coast of Brazil as well as to develop a panel of microsatellite loci of *C. brasiliana* by next generation sequencing for further studies on genetic diversity and population structure of this native oyster.

Material and Methods

The oysters were collected in mangrove roots and rocks in three estuaries of Southeast Coast of Brazil (Paraty, Bertioga and Cananeia). Due the high plasticity phenotypic in oyster, we used 16S and COI sequences and PCR-RFLP to identify unambiguously the different oyster species. The DNA of *C. brasiliana* was employed to develop microsatellite markers by next-generation sequencing (NGS). A genomic library was constructed following the manufacturer protocol of Illumina® Nextera DNA Library Preparation kit and the sequencing was conducted in a HiSeq2500 (Illumina, San Diego, USA). The reads were analyzed in *CLC*^{Bio} software with seven covers, generating contigs above 300bp. The reads were cleaned with *Seq Clean* and *Perl Script-Velvet* tool. Microsatellite loci were identified from dataset by *BatchPrimer3 V.10.* Primer sets were designed in the same software and selected using *OligoAnalyzer 3.1 IDT*. After selection, the PCR conditions were standardized for each pair of primer.

Results

Among 233 samples collected in the three estuaries, 55 were *C. brasiliana,* 54 *C. rhizophorae* and 124 were *Saccostrea* sp., an exotic species. *C. brasiliana* was found nor in Bertioga neither in Paraty. *Saccostrea* sp. comprised 92%, 65% and 15% of the sampled individuals collected in Paraty, Bertioga and Cananeia, respectively, while *C. rhizophorae* 8%, 35% and 41%. The PCR-RFLP using the *Alu*I enzyme was effective to discriminate *C. brasiliana* and *C. rhizophorae*, two cryptic species, while *Saccostrea* sp. was easily identified by its shell's morphological characteristics. The largest fragment generates by *Alu*I have 410bp for *C. rhizophorae* and 205bp for *C. brasiliana*

Microsatellite markers were isolated and selected from a genomic library obtained by NGS. After a first selection, we identified 359 loci, of which 157 are dinucleotides, 45 trinucleotides and 157 tetranucleotides. The dinucleotides motives more abundant were AG/TC with 72%, followed by AC/TG (16%) and AT/TA (12%). Among trinucleotides prevailed the AAT/TTA motif with 53%. The repeat number ranged from 6 to 34, 4 to 8 and 3 to 9 for di, tri and tetranucleotides, respectively.

A set of 30 primers were selected, 10 for each repeat type (di, tri and tetranucleotides) based on size of PCR product, primers size, melting temperature, content of CG and formation of secondary structures. Thirty primers were synthesized and the conditions for PCR were established for each pair of primer (annealing temperature 56 – 60ºC and $MgCl_2$ concentration 2,0 – 2,5 mM).

Discussion and conclusion

The first record of *Saccostrea* sp. date on June 2014, in Bertioga, SP (Galvão et al., 2018). Over the last past years, this species has expanded along the coast as shown herein. *C. brasiliana*, otherwise, has decreased in places where it used to be abundant as in Bertioga and Paraty locations. In Cananeia, a relevant area for native oyster's production, local fisher and oyster farmers reported the presence of *Saccostrea* sp. in the later 2017. These facts raise the concern about its invasive potential, becoming a threat to native populations.

(Continued on next page)

A rapid cutback of population size has serious consequences on population health and survival. This reduction may induce the loss of genetic diversity (Frankham et al., 2014).

The impact of the expansion of this exotic species in the long-term survival of the native oyster should be investigated. Against this background, this new novel of microsatellites (SSR) markers will be useful to assess genetic variability in remaining populations.
The PCR conditions were standardized for 30 loci SSR developed by NGS in the present work. After polymorphism analysis in a capillary sequencer 4300 *DNA Analyser Li-Cor* and validation of selected primers, they will be used to evaluate the genetic diversity and structure of wild populations of *C. brasiliana* oysters of the Southeast coast of Brazil.

This study will contribute for further studies on hatchery production associated with genetic improvement programs as well as in restoration programs (Hornik and Plough, 2019). As verified in this work, *C. brasiliana* has been reduced in number and almost disappeared in places where it was abundant in the past. Therefore, the reestablishment of the natural population with their genetic variability will be crucial for the continuing sustainable use of their marine genetic resources.

BIOFILM AS TOOL TO EVALUATE ORGANIC AND CHEMICAL DISPERSION FROM MARINE FISH FARMS

N. García-Bueno [a*] and A. Marín [a]

[a] Departamento de Ecología e Hidrología, Facultad de Biología, Universidad de Murcia, Spain
Email: nuria.garciab@um.es

Introduction

Marine biofilms are organized communities of mixed micro-organisms, typically surrounded by a matrix of extrapolymeric substances (EPS) which facilitates the attachment of the community to any surface (Characklis and Marshall, 1990). Diatoms and bacteria constitute the major components of biofilms occurring in the marine environment. The moment a clean surface is submerged in the sea, biofilm-forming micro-organisms rapidly colonize and form highly complex, dynamic three-dimensional (3D) surface structures (Davey and O'Toole, 2000). Using these communities on artificial surfaces facilitates the direct comparison between sites without confounding environmental and physical variables (Webster and Negri, 2006). The analysis of biofilms in test substrates enables medium term (days) rather than momentary states of the studied ecosystem (Brummer et al., 2003). The aim of this work was to: (1) quantify fish farm particulate organic carbon, particulate organic nitrogen and total phosphorus, and (2) to correlate them with the structural, trophic and element accumulation changes in the biofilm community at an o fshore fish farming zone from Mediterranean

Materials and methods

The Western Mediterranean case study of the TAPAS Project Horizon 2020, offshore Fish Farming Zone of San Pedro del Pinatar (Murcia, Spain), is one of the most aquaculture intensive areas in Spain of gilthead sea bream (*Sparus aurata*) and sea bass (*Dicentrarchus labrax*) production, with an average production of around 11.000 tonnes per year. The fish farming is exclusively carried out in open sea cages. The changes in the biofilm community due to organic matter enrichment and trace elements contamination derived from fish farming were studied. The biofilm biomass and chlorophyll *a* were quantified along an environmental gradient of fish farm wastes. Total organic carbon (TOC), total organic nitrogen (TON), total phosphorus (TP), trace elements and stable isotopes ($\delta^{13}C$ and $\delta^{15}N$) were measured. The field assays were performed using glass slides as the artificial substrate for biofilm community development. Glass slides were supported by slide holders. The slide holders, in turn, were maintained 3 m below the water surface by an anchoring system and a buoy. Particulate sedimentation rates were measured by means of sedimentation traps composed of four attached cylinders (100 cm height and 12 cm diameter). Each cylinder had a funnel at the bottom, which guided the particulate matter into a 250 ml polyethylene tube. Biofilm slides and sediment traps were deployed from fish cages located at the edge of the fish farms facility along horizontal transects at 0, 25, 75, 175, and 650 m from the fish cages.

Results

Our results indicate that organic pollution influenced carbon and nutrient accumulation of biofilms as it has been previously reported. PCA analysis grouped stations following the environmental gradients, indicating that the accumulation pattern of trace elements in biofilm was consistent along the fish farm influence. Cu, Zn and Cd were the main metals released to the environment due to fish farm, which had similar accumulation dynamics as TOC, TON and TP along the environmental gradients. Concentration of these chemicals in biofilms showed higher values for samples close to the fish cages. The isotopic signatures clearly differentiated the biofilm communities along transects (Fig. 1). Diatom abundance, biomass,

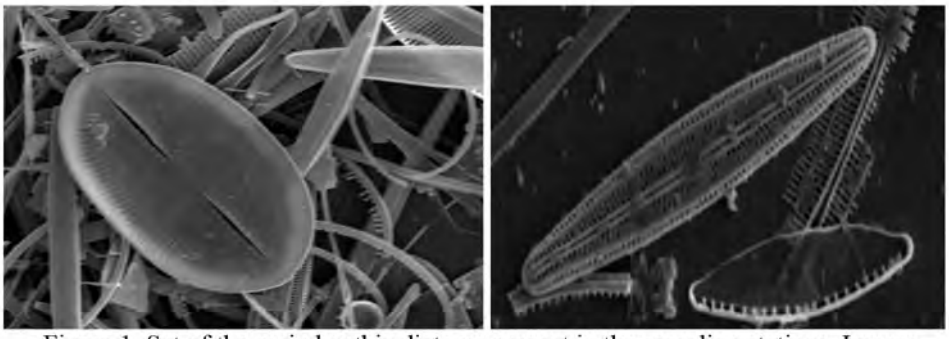

Figure 1. Set of the main benthic diatoms present in the sampling stations. Images captured by scanning electron microscope

(Continued on next page)

species richness and H´ showed a very similar trend with distance, greatly increasing close the fish farm and stabilizing further from the fish farm. The nMDS plot of diatom assemblages showed an environmental gradient between sampling stations, and that the within-station similarity among samples increased with distance from the fish farm. The regression model showed that the community structure descriptors reached their asymptotic point further from the fish farm than the POC, PON and TP sedimentation rates.

Discussion and conclusions

Benthic diatoms that grow on hard substrates represent the type of community and, therefore, are potential bioindicators (Desrosiers et al., 2013). The results of this study suggest that benthic diatoms are potential indicators to detect the emission of antibiotics in the marine environment. Therefore, it is suggested the incorporation of benthic diatoms incubated in hard substrates in coastal waters monitoring programs, as they are a simple and easy method to evaluate changes in water quality.

STUDY OF SEDIMENT ALONG AN ENVIRONMENTAL GRADIENT TO EVALUATE THE IMPACT OF MARINE FISH FARMS

N. García-Bueno [a*] and A. Marín [a]

Email: nuria.garciab@um.es

Introduction

In recent decades, seafood production from marine aquaculture has undergone almost exponential growth worldwide in terms of cultured biomass and is expected to follow the same trend in the future (FAO, 2007). A combination of factors, including production levels, feed characteristics and feeding efficienc , influences the quantity and quality of the wastes released by fish farming (Islam, 2005). The main negative impact of finfis aquaculture is the resulting organic enrichment derived from these wastes, which mainly consist of fish faeces and uneaten food and which may spread from tens to hundreds metres from the fish farm (Brown et al., 1987, Hall et al., 1990, Iwama, 1991). Such wastes take two forms: particulate and dissolved. In the water column, the levels of dissolved wastes rapidly reach background levels, whereas particulate wastes tend to sink and accumulate on the seabed. This process may produce important changes in sediment geochemistry and in the benthic communities (Brown et al., 1987, Weston, 1990, Karakassis et al., 2000, Holmer et al., 2005).

Materials and methods

The Western Mediterranean case study of the TAPAS Project Horizon 2020, offshore Fish Farming Zone of San Pedro del Pinatar (Murcia, Spain), is one of the most aquaculture intensive areas in Spain of gilthead sea bream (*Sparus aurata*) and sea bass (*Dicentrarchus labrax*) production, with an average production of around 11.000 tonnes per year. The fish farming is exclusively carried out in open sea cages. The changes in the biofilm community due to organic matter enrichment and trace elements contamination derived from fish farming were studied (Fig.1). Sampling stations were located close to the mooring system of the sediment traps (~2 m) used for measuring waste dispersion (0, 20, 120 and 600 m). All distances were sampled once during the period that the sediment traps were deployed, taking four replicates at each sampling station. The top 2 cm of the sediment were used for the physico-chemical analyses. Macrofaunal samples were taken using a hand grab (400 cm2) that penetrated to a depth of ~10 cm.

From the cores taken at each sampling station the following parameters were measured. Four cores were used to measure the redox potential with an Orion ORP 91-80 electrode that was previously calibrated using a redox buffer solution (220 mV at 25 °C). The same cores were used to measure the rest of the physico-chemical parameters. Sediment grain size was assessed by dry-sieving with a mechanical shaker through a series of sieves (2, 1, 0.5, 0.25 and 0.064 mm mesh), in accordance with the Wentworth scale (Wentworth, 1922). The fine fraction of the sediment (i.e. silt/clay) was taken as the sediment percentage that passed through the 0.064 mm mesh. The organic matter content was measured by weight difference after heating the dried sediment at 450 °C for 5 h. POC, PON and TP percentage of the sediment were determined following the same protocol as used for the samples from the sedimentation traps.

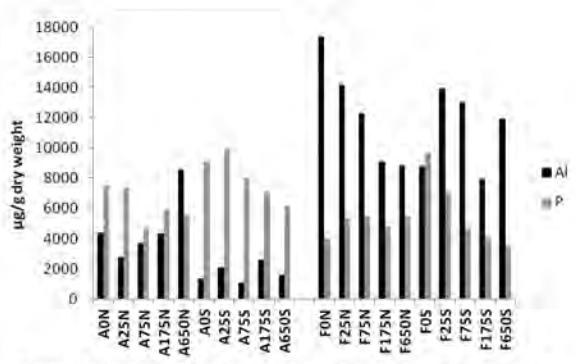

Figure 1. Al and P concentration in the sediment measured along an environmental gradient of two fish farms

(Continued on next page)

Macrofauna was used as a surrogate of the ecological benthic status. For the macrofaunal analysis, sediment samples were washed through a 1 mm sieve with sea water. The remaining sediment was fixed in a 4% formalin buffered solution, separated into major faunal groups and stored in a 70% alcohol solution for later identification. The determination of benthic groups was made to the lowest possible taxonomic level using a binocular dissecting lens. Macrofauna ash-free dry biomass was determined separately for each of the four sediment samples taken for the macrofaunal analysis at each station by weight difference after drying to constant weight at 60 °C and subsequently heating at 450 °C for 5 h.

Results

Trace elements on sediment below an open water fish farm were obtained. Fish farming modified the benthos not only in a physico-chemical and biological way, but also functionally, lowering the number of trophic groups and the evenness among them.

Discussion and conclusions

The present study demonstrates that fish farming not only influences physico-chemical and biological parameters but also alters the functioning of the ecosystem from a trophic point of view, affecting mainly the grazers and the evenness among the trophic groups.

REGULATION OF DIGESTIVE AND ABSORPTIVE PROCESSES IN TWO MEDITERRANEAN FISH: GILTHEAD SEA BREAM AND SEA BASS

I. García-Meilán*, A. Gallardo.

Introduction

One of the greatest costs incurred during fish aquaculture is that of the feed, especially in carnivorous fish species. Replacing fish meal and oil by plant feed affects digestive and absorptive processes and has an impact on growth. Therefore, different ingredients of plant origin have been tested for decades. Better knowledge of how those processes are regulated would help in the design of high-quality diets leading to optimal growth and food efficiency; minimizing food loss and contributing to sustainable aquaculture. In this communication, we report different compensatory mechanisms in sea bream and sea bass that we believe could help maintain growth in response to changes in raw materials, time of food administration, dietary composition and rations.

Material and methods

Gilthead sea bream and sea bass at different stages of growth (from juveniles to adults) were fed diets in which fish meal or oil were substituted for plant-based ingredients in different percentages (from 38% to 100%) and under different culture conditions. Activity of digestive enzymes (pepsin, alkaline protease, amylase and lipase) was analysed, the trypsin/chymotrypsin activity ratio was characterized, activity of enzymes present in the intestinal membrane (aminopeptidase and alkaline phosphatase) was measured, and the capacity for absorption of essential and non-essential amino acids and D-Glc in different regions of the intestinal tract (pyloric caeca, proximal intestine and distal intestine) was determined under both post-prandial conditions and 24 h after ingestion. The SPSS Statistics 22.0 software was used to perform statistical analysis.

Results and discussion

Gilthead sea bream and seabass are capable of modulating their digestive and absorptive processes in such a way that their growth is maintained when they are fed diets in which protein of fish origin is replaced by either plant proteins or lipids and starch, as long as the diet meets their nutritional requirements and the animals can tolerate the antinutritional factors present (García-Meilán, 2015). The mechanisms reported for this modulation are dependent on the main composition of the diet, the ingredients used in its formulation and the quantity in which it is supplied, as well as the administration method (satiety, controlled or restrictive) (García-Meilán, 2015). Here, we report three levels of regulation of the digestive and absorptive processes: 1) fish modulate intestinal digestive activity and nutrient absorption capacity, 2) they regulate the increase of pancreatic enzyme synthesis and secretion and 3) as necessary, they increase voluntary feed intake.

Proteolytic activity is affected by an excess or deficit of protein in the diet, which causes an increase in anticipatory activity, and may alter the trypsin/chymotrypsin ratio during digestion (García-Meilán et al., 2013; 2016b). Modifications of this ratio affect the availability of certain amino acids, dipeptides and tripeptides, the capacity the fish have for the absorption of which is up-regulated in different intestinal regions; with up-regulation of distal absorption capacity being an indicator of a compromised situation for the fish (García-Meilán et al., 2016a, b). Proteolytic activity is also affected by increased lipid and starch content of the diet: lower protease activity while the trypsin/chymotrypsin ratio is unaffected (García-Meilán et al., 2014; 2016b).

α-Amylase activity is less sensitive to changes in diet composition than protease; although it also responds to them. Thus, a diet with a low starch content causes an increase in the synthesis of α-amylase and in its activity, possibly as a compensatory mechanism to balance the low availability of glucose. This mechanism is normally accompanied by an increase in the capacity to take up this monosaccharide (García-Meilán et al., 2013; 2014; 2016b).

(Continued on next page)

Modulation of lipase activity due to dietary composition is more controversial. Some experiments show an increase in this enzyme activity depending on lipid or fibre content and due to a high protein content (García-Meilán et al., 2013, García-Meilán, 2015); while other experiments produce no changes in lipase activity. Meanwhile, fish fed low-energy diets showed an increase in lipase synthesis and anticipatory activity, accompanied by up-regulation of capacity to absorb D-Glc and L-Ala. In diets with a very low lipid content (12%), even the α-amylase activity increased depending on fis development and energy requirements (García-Meilán et al., 2016b).

It has also been found that length, morphology and intestinal histology are strongly influenced by both diet and eating habits, affecting the activity and distribution throughout the intestine of nutrient absorption mechanisms. Thus, the presence of plant ingredients or the general composition of the diet tends to increase intestinal transit rate. In such a situation, sea bream digestion processes are improved by an increase in the anticipatory release of pancreatic enzymes. This compensation mechanism may be accompanied by a post-prandial increase in enzyme release and even an increase in the relative intestinal length. Despite the increase in intestinal transit, all this allows the absorption of nutrients necessary to maintain growth, while saving protein whenever possible (García-Meilán et al., 2013; 2014; 2016 a, b).

Moreover, in sea bream, dietary inclusion of highly digestible carbohydrates improves digestion and absorption processes when they are administered in the morning, leading to a protein-sparing effect and producing growth comparable to that of fish fed with a commercial diet (García-Meilán et al., 2014). In addition, it has been reported that in gilthead sea bream the pH of the intestinal content, digestive activities and nutrient absorption capacities all decrease as the animals grow (García-Meilán et al., 2016a).

Finally, the dietary fatty acid profile also modulates digestive and absorptive processes. Juveniles are not capable of adapting their digestive or absorptive activities to changes in this profile in the short term (4 weeks), while adult animals can adapt (García-Meilán et al., 2016a).

Introduction

Many economically important traits in aquaculture selection programmes, such as disease resistance and slaughter traits, cannot be directly recorded on the selection candidates. For these traits, recording is typically performed on the sibs of the candidates (and so they are known as sib traits). Selection is based on sib performance and thus, the within-family variation is not taken into account when phenotypic or standard BLUP evaluation are performed. In contrast, with genomic evaluation, selection can take into account both between and within family variation and thus the accuracy of evaluation and the response to selection can be increased (Meuwissen et al., 2001; Nielsen et al., 2009). However, given the large number of selection candidates and tested individuals involved in aquaculture breeding programmes, standard population-wide genomic evaluation may be too expensive to be applied if the low economic value of selected fish is considered.

A particular cost-efficient genomic evaluation approach for aquaculture breeding programmes proposed by Lillehammer et al. (2013) is within-family genomic evaluation (WFGE). With this approach only the within-family genetic component of the breeding value is estimated using molecular information. Then the estimated within-family component is combined with an estimate of the family breeding value that can be obtained from traditional BLUP. With WFGE, the marker density required for obtaining higher accuracies than with BLUP is much lower than the density required for population-wide genomic evaluation, given the high levels of linkage disequilibrium that exist within families, reducing thus the genotyping costs.

Using computer simulations, Lillehammer et al. (2013) found up to 15% of benefits with WFGE (using 50 or 100 SNPs per Morgan) than with BLUP for salmon breeding programmes with large family size (200 fish per full-sib family). However, given that the genomic evaluation is performed only within families the accuracy of this approach would depend on the family size that for species other than salmon is usually much smaller.

The objective of this study was to predict, through stochastic simulations, the genetic gain for schemes with small family sizes when WFGE is applied. Selection was for two traits including a candidate and a sib trait that mimicked growth and disease resistance, respectively.

Material and methods

The base population was created in a two-step process. Firstly, a large population in mutation-drift equilibrium was generated by randomly selecting 500 males and 500 females across 4,000 discrete generations. The genome was composed of 20 chromosomes and the total genome size was 15 Morgans (approximates that of seabream, seabass and turbot). Each chromosome carried 10,000 evenly spaced biallelic loci that included 10, 50 or 100 SNPs per Morgan. Initial frequencies were 0.5 for all loci. Once the equilibrium was reached, 200 males and 100 females per replicate were sampled and mated (each female with 2 males) at random to create a base population with family structure.

Table I. Cumulative genetic gain for the index at generation five from BLUP and within-family genomic evaluation (WFGE) using different number of SNP markers per Morgan (n_{SNP}), for schemes with different numbers of tested fish for the sib trait (n_{ts}).

		WFGE		
n_{ts}	*BLUP*	$n_{SNP} = 10$	$n_{SNP} = 50$	$n_{SNP} = 100$
5	3.90	3.95	3.97	3.98
10	4.01	4.08	4.11	4.10
20	4.24	4.30	4.35	4.39
40	4.38	4.44	4.49	4.53

(Continued on next page)

Two uncorrelated traits were simulated and both were affected by 1,000 loci that were randomly sampled from all loci at t = 0. The initial phenotypic variance (V_p) was 1 for both traits and the heritabilities (h^2) were 0.4 and 0.2 for growth and disease resistance, respectively. Phenotypic values were obtained by adding a normally distributed individual environmental effect with mean zero and variance V_E to the genetic value. All selection candidates were recorded only for growth. The disease resistance trait was recorded on the sibs and the number of sibs tested varied across scenarios (5, 10, 20 or 40 per family). Thus, the total number of fish created per generation was 6,000 (the selection candidates) plus 1,000, 2,000, 4,000 and 8,000 fish recorded for disease resistance

Two different evaluation methods were considered: standard BLUP and WFGE. In WFGE schemes, EBVs are combinations of a conventional family estimated breeding value and a genomic within-family breeding value. In particular, the EBV for individual i of family l is $EBV_{il} = ½\ EBV_{si} + ½\ EBV_{di} + w_{il}$. The composite term ($½\ EBV_{si} + ½\ EBV_{di}$) was estimated as the average EBV for family l obtained from standard BLUP using the full data set. The within-family breeding value w_{il} was obtained from SNP-BLUP evaluation using only information from family l. Different scenarios varying in the density of markers (10, 50 and 100 SNPs per Morgan) used in WFGE were considered. The GS3 software (Legarra et al., 2011) was used for carrying out genomic evaluations.

The EBVs for growth and disease resistance were combined in a selection index that gave the same weight to both traits. Each generation the 200 males and the 100 females with the highest index value were selected. Each selected female was mated with 2 males producing 30 fish per mating (i.e., the schemes had 200 full-sib families). Selection was practised for 5 discrete generations. A total of 100 replicates were simulated.

Results and discussion

Table I shows the cumulative genetic gain for the index obtained from both evaluation methods. Increasing the number of markers used in WFGE had a very small effect in genetic gain. In agreement with the results of Lillehammer et al. (2013), 50 SNPs per Morgan seem to be enough to fully benefit from this genomic method. Doubling the marker density from 50 to 100 SNPs per Morgan increased genetic gain by less than 1% at t = 5. The cumulative genetic gain for the index increased when the number of tested sibs increased. The benefit of WFGE over BLUP was 3 - 4% at t = 5.

Introduction

Modern aquaculture tried maximizing productive yield of the installation, but usually induces chronic stress that affected growth, immunological status and reproduction of the cultivated specimens. In addition, the use of antibiotics in aquaculture has become abusive inducing a negative impact on the environment and generating antibiotic-resistant pathogens. For this reason, the inclusion of additives in cultivated fish food are been proposed to compensate stress states as well avoid antibiotic use. The essential oil extracted from *Cymbopogon nardus* has a high content of geraniol and citronellal. Citronellal is used as a basic material for the synthesis of important chemical compounds called ionones. This oil presents insect repellent activity, fungicidal and bactericidal action.

The objectives of this study are to determine the effects of inclusion of *C. nardus* essential oil in the gilthead sea bream (*Sparus aurata*) food, with the following specifics objectives: i) to assess its effect on growth, and ii) to establish its influence on metabolism. In addition, our study also evaluated the antimicrobial potential of this essential oil as a method of control of bacterial diseases in aquaculture.

Materials and methods

Immature juveniles of gilthead sea bream (*S. aurata*, N = 162, 10,2 ± 0,3 g body mass) were provided by *Servicios Centrales de Investigación en Cultivos Marinos* (SCI-CM, CASEM, University of Cádiz, Puerto Real, Cádiz, Spain; Operational Code REGA ES11028000312) and were randomly distributed into nine 80-L tanks (for each tank N = 18), with flow-through water system at 18-19 °C, under natural photoperiod (May-July 2017). Three feeds containing different doses of citronella oil were tested: i) control, ii) dose 1.0ml.kg^{-1} feed, iii) dose 2.0ml.kg^{-1} feed in triplicate during 60 days. All fish were fed a daily ration of 2.0 % body mass distributed in two meals. Biometric analyzes (length and weight measures) were performed every 15 days, and, at the end of the experiment, blood and liver samples were collected and the weight of the liver was taken. Hepatosomatic index was determined as: HSI = 100*(liver weight/body weight). Plasmatic and hepatic metabolites levels were performed. Differences were tested by one-way ANOVA ($p<0.05$). To determine the *in vitro* antimicrobial potential of citronella essential oil its capacity to inhibit three fish pathogens (*Vibrio harveyi*, *Photobacterium damselae subsp. piscicida* y *Aeromonas hydrophila*) was evaluated. The potential toxicity was calculated by the observation of the decrease of the bioluminescence of *Vibrio fischeri*.

Table I: Biometric, plasmatic and hepatic parameters assessed in different experimental groups. Different letters indicated significant differences (one-way ANOVA ($p<0.05$).

	Parameters	Control	Dose 1	Dose 2
Biometric	Initial length (cm)	10.4 ± 0.05	10.4 ± 0.05	10.3 ± 0.05
	Final length (cm)	13.3 ± 0.07	13.2 ± 0.09	13.1 ± 0.07
	Initial weight (g)	17.2 ± 0.3	18.5 ± 0.3	16.9 ± 0.3
	Final weight (g)	44.8 ± 0.9	44.5 ± 1.0	44.2 ± 0.8
Plasma	Glucose (mM)	3.1 ± 0.2	3.6 ± 0.2	3.3 ± 0.2

Results and discussion

The addition in the feed of citronella essential oil was tolerated by *S. aurata* specimens without affecting (positively or negatively) growth parameters. Also, the addition of this essential oil did not cause alterations or significant changes on metabolism of *S. aurata* specimens (Table I).

However, this oil appears to modulate lipid metabolism, reducing plasma and hepatics levels. Similar data have been found in *Oreochromis mossambicus* fed with ginger oil (Immanuel et al., 2009) and in *O. niloticus* fed with essential oil of *Citrus sinensis* (Metwally, 2009) and garlic oil (Acar et al., 2015). Our results suggest that the inclusion of citronella oil could be beneficial by modulating lipid metabolism

The citronella essential oil inhibited the bacterial growth of *V. harveyi*, *P. damselae subsp. piscicida* at a concentration of 31.25µl.ml.-1 and *A. hydrophila* at 62.5µl.ml.-1. The median effective concentration (EC50) to inhibit the bioluminiscence of *V. fischeri* was 0.766µl.ml.-1. The *in vitro* tests confirmed that the citronella essential oil possess antimicrobial activity against several fish bacterial pathogens (Singh et al., 2011), although it is necessary to carry out *in vivo* studies to verify if these potential remains without generate adverse effects on fish

Introduction

Yellow perch, *Perca flavescens* (Michill, 1814), is one of the most abundant species of the *Percidae* family in the inland waters of the northern regions of the North American continent. It is a highly valued food fish in the United States with additional markets in Canada and Europe. Yellow perch commands a high market value for meat texture and taste, low percentage of fat and phospholipids, long shelf life, resistance to freezer damage and for its traditional popularity around the Great Lakes region. The market demand is for product of only a 150 gram harvest weight. The reduction in the wild catch due to overfishing and devastation of the natural habitat (Clapp and Dettmers, 2004) has resulted in an increased interest in research of the biology of this species, and the development of appropriate culture technologies. To date, significant impediments have limited the commercial production of yellow perch in the United States. The limited duration of seasonal optimal ambient conditions for pond and cage culture in the Great Lakes region was found to be unacceptable for commercial production. Grown at ambient temperatures, most of the females of this fish reaches sexual maturity at the end of the second year, when their medium weight is greater than 60g. Males can be sexually mature by the end of the first year, while weighing only about 15g (Malison, 1999). The development of the gonads has a negative effect on somatic growth, as also reported in the European perch (Rougeot, 2003). Controlled conditions within recirculating systems, without seasonal temperature fluctuations, enhance growth and inhibit sexual maturation (Melard et al., 1996). The prolongation of the daylight period also inhibits the development of the gonads, especially in males (Jourdan et al., 2000). The aim of this study is to identify and quantify the advantages of controlling photoperiod and temperature to suppress the gonadal development of yellow perch.

Materials and Methods

Yellow perch fingerlings were raised from 16.5 grams to market size in an indoor recirculating system. For the purpose of this study, a total of 6000 fish were divided into two separate tank units. Fish were raised at constant temperature of 24-25^{o}C. Dissolved oxygen level was maintained at saturation using oxygen injection. Calcium hardness was maintained between 80-150 mg/l using calcium chloride, and pH was maintained between 7.2 and 7.4 with the addition of sodium bicarbonate. During the entire experimental period perch were fed continuously with commercial slow sinking pelletized feed ("Ziegler Brothers", PA), containing 45% of crude protein and 12% fat, using automatic belt feeders. Fish were fed 5% of their body weight per day in the first month, 4% in the second, 3% in the third and fourth, 2.5% in the fifth and sixth month, and 1.5% in the last four months of the growing period (Jug-Dujakovic and Van Gorder, 2002). Both groups were kept at constant temperature of 25-26°C and a diurnal photoperiod of 16 hours at 300 lux. At the end of the experimental period, the total weight of the fish as well as that of the gonads and the gonadal somatic index was determined using a Mettler balance.

Results and Discussion

Yellow perch grew from 16.82 and 16.13 g respectively to 181.21 and 173.49 grams in eight months. At the end of the experiment most of the fish gonads were in the initial stage of development, with an average weight of 3.28 and 3.14 (Table 1). The gonads account for 1.81% of the body weight in both groups. In the natural environment, gonads can account for 20-30% of the total weight in females and 8-15% in males. (Melard et al., 1996), significantly affecting the growth and dress-out percentage.

Table 1. Growth of yellow perch during eight months of the experiment, and the weight of gonads at the end of experiment

Tank	Initial weight (g)	Final weight (g)	Gonads (g)
1	16.82	181.21	3.28
2	16.13	173.49	3.14

(Continued on next page)

Grown at ambient temperatures, most of the female American perch reach sexual maturity at the end of the second year, when their medium weight is greater than 60g. It has been shown that under natural conditions, females grow faster than males (Piferrer, 2001). In natural conditions of lower temperature in late autumn and early winter, more energy is used for the development of the gonads than for the somatic growth (Henderson et al., 2000). If the gonads are not fully developed, 150g Yellow Perch will yield 55-60g of edible flesh (Malison,1999)

Maintaining a one-year production cycle at constant temperature and prolonged photoperiod slows down the development of the gonads and increases the percentage of the edible portion of the fish (Malison, 1999; Jug-Dujaković and Van Gorder, 2002). The culture of yellow perch within indoor controlled-environment recirculating aquaculture systems with continuous prolonged photoperiod and constant temperature elevated to 24-25°C can result in improved growth rates and the subsequent grow-out of yellow perch to harvest size within an acceptable time frame, and an increased dress-out percentages.

Introduction

European perch is being described as a candidate species for European aquaculture diversification due to high market demand especially in Alpine countries. In past decades, the species has been well adapted in recirculating aquaculture system (RAS) allowing year-round intensive production (Policar et al., 2015). However, bacterial diseases by *Aeromonas* sp. are frequently causing low growth and mass mortality in intensively cultured fish including European perch (Rupp et al., 2019). Based on geographic origin, it can be expected that individual populations have been exposed to different pathogenic pressure in their localities, which in turn has led to different sensitivity to the bacterial or viral diseases. To test this hypothesis, we tested the extent of the immune response in different populations of European perch populations following the stimulation with gram-negative *Aeromonas hydrophila* bacterium.

Materials and methods

In present experiment, we used juveniles (body weight 93.03±25.05 mg) from six European perch populations originating from: **FV**, Valkea-Kotinen Lake (61° 14′ 32.1″ N, 25° 03′ 47.1″ E Finland); **PS**, Stary Dwór Lake (53° 44′ 51.6″ N, 20° 27′ 11.8″ E Poland); **IS**, Sorgà Pond (45°11’02.5”N, 10°59’59.8”E Italy); **CN**, Nové Hrady Pond (48° 47′ 33.8″ N, 14° 48′ 32.3″ E Czech Republic); **SV**, River Váh (49° 07′ 29.7″ N, 18° 27′ 26.2″ E Slovakia); and **SL**, Liptovská Mara Reservoir (49° 5′ 20.1″ N, 19° 34′ 38.3″ E Slovakia). Fish were kept in 60-L light grey tanks (tank size of 22.5 × 30 × 89 cm) at 23 °C ± 0.5 set up in RAS. Oxygen saturation (> 90%) and pH level (7 ± 0.5) were monitored twice a day with a multimeter (Hach Lange HQ40d, Germany); photoperiod was constant at 12L:12D. During the experimental period (7 days) fish were not fed.

At the start of the experiment, we injected 15 individuals per population with PFA inactivated *A. hydrophila* saline solution. In addition, one group (15 individuals from SL, noted as **C**) was used as a negative control and injected with saline solution only. At each sampling day (1, 3, and 7), peritoneal leukocytes were isolated from five individuals per population and their total number and ratio of myeloid and lymphoid leukocytes were analyzed by flow cytometry and microscop .

Results

The increase in the number of peritoneal leukocytes indicates early onset of peritoneal inflammation accompanied by dramatic changes in the ratio of white blood cell lineages. In general, one day after injection of the inactivated *A. hydrophila*, 1-7 million leukocytes were isolated from the peritoneal cavity of European perch. The first day was also the only time point, where most of the cells were of myeloid character *i.e.* neutrophilic and monocytes (approximately 55-66%). Following days, the number of cells gradually decreased and 7 days after injection ranged from 1 to 4 million cells of which 80-90% were lymphocytes. In the C group, we recorded no increase in the number of cells.

With respect to different European perch populations, it can be noted that the *A. hydrophila* injection induced two types of reactions. While the fish originated from FV, SL and SV showed a dramatic influx of leukocytes during the first 24 hours (approximately 6-7 million cells; 4 million myeloid cells), the fish from CN, IS, PS reached only 1-2 million. However, in these fish populations most of these cells were neutrophil and monocyte lineages. Remarkably, while the fish from FV, SL, and SV group reduced myeloid cell amount to just 500,000 on the third day, the fish from PS, IS and CN were up to three times higher (1-1.5 million). In contrast to the apparent polarity in myeloid cell response, no significant differences between groups were observed in lymphocyte numbers.

(Continued on next page)

Discussion and conclusion

The ability to eliminate a pathogenic agent and prevent its spreading through the body is critical to the infection survival. Knowledge from other fish models (*i.g.* rainbow trout) suggests that pathogens are recognized by the resident macrophages, which recruit neutrophils and monocytes. These cells eliminate the threat through phagocytosis and subsequent respiratory burst. The acute phase of inflammation is followed by activation of acquired immunity, particularly a population of B cells. The rate of acute inflammation induction as well as the number of cells which need to be recruited into the infected tissue, provide insights into the body's ability to defend itself against infection. In our pilot experiment, we demonstrated that peritoneal activity undergoes remarkable changes. During the first 24 hours after injection, the highest influx of leukocytes was found in perch populations from FV, SL and SV, where neutrophils and monocytes were dominant. Our preliminary results represent the first comprehensive description of the inflammatory processes in the peritoneal cavity of European perch, and present important information for future selective-breeding programs.

Conventional agricultural practices are often pointed out for their heavy environmental burdens such as soil and water pollution, greenhouse gas emission and natural resource depletion. Reducing these impacts is one of the main issues to ensure sustainable food production in a near future. Thanks to the efficient use of water and the nutrient recycling and valorizing, aquaponics is usually presented and perceived as an environmentally sustainable method to produce fish and vegetables.

Indeed, the combination of these two food productions bring up noteworthy advantages and limits the effluent discharge in a local environment, however, it does not erase the drawbacks inherent to culture intensification associated to aquaculture production in RAS or hydroponic culture in closed environments. The main environmental impacts of aquaponics are linked to high energy use (electricity), fish feed addition and infrastructure needs (Boxman et al., 2017; Forchino et al., 2017; Jager et al., 2019). These categories could also be responsible for the main operational economic burdens.

According to the life cycle approach, the Life Cycle Assessment (LCA) and the Life Cycle Costing (LCC) represent flexible and performant tools to assess both the environmental and economic sustainability of a given process. These tools were previously performed on the set-up phase of an indoor aquaponic system, giving a picture of the economic and environmental burdens associated to the construction of a pilot production facility (Forchino et al., 2018).

This coupled aquaponic system (total volume: 19 m³), hosted in a 104 m² building, produces tilapia (with an expected yearly production of 1 t), lettuce, rocket salad, basil, coriander and parsley (expected vegetable yearly production: 2 t).

The aim of this study is to evaluate both the environmental and economic sustainability of fish and vegetable production in this aquaponic system through the combined application of LCA and LCC.

Giving a comprehensive vision of the environmental impacts of the aquaponic production, the results will highlight bottlenecks and efficient development levers to improve the system. Moreover, this study will be coupled with a mass balance analysis to assess the nutrient flows between the different compartments of the system and measure the efficiency of nutrient recycling. This functional analysis would help to put into perspective the environmental impacts of the production with the internal functioning of the system and effluent discha ge.

Finally, the economic approach will enable a scaling-up simulation to evaluate the opportunity to generate profits

REAL-TIME BASED AUTOMATED BIOMONITORING FOR FOOD AND WATER QUALITY CONTROL

Gerhardt, A.

Aquaculture represents an increasing market worldwide including both freshwater and marine fish, cruastaceans, molluscs and other species. Next to sharp regulations on fish health food safety and quality as well as water quality monitoring are important issues in aquaculture farming.

The Multispecies Freshwater Biomonitor (MFB) is a so-called real-time based automated online biomonitor recording quantitatively the fitness of all types of aquatic animals in a continuous manner. Changes in fitness, e.g. due to changes in water quality can be detected immediately and countermeasures taken at the earliest to prevent economic failures in food production. The MFB has successfully been used to monitor rivers (e.g. Rhine), wastewater treatment plants and waterworks.

The application in aquaculture is new. Therefore, we tested different freshwater and marine fish (e.g. *Sparus aurata*) and crustaceans species regarding their signal quality, handling and performance in the MFB. Toxic pulses were simulated (e.g. acid stress, metal stress) and the responses of shrimps (Marine: *Crangon crangon*; freshwater: *Macrobrachium lanchesteri*) studied. Fig. 1. shows the immediate response of increased avoidance in *C. crangon* to stepwise pH-downshifts in seawater.

Moreover, the MFB was tested in situ, such as at the effluent f a wastewater treatment plant with *Poecilia reticulata* and in a shrimp farm with *Penaeus monodon* (both in India).

The first results demonstrate the great potential of future application of the MFB in the aquaculture sector

Introduction

Harmful algal blooms (HABs) are worldwide deleterious ecological phenomena that can severely impact shellfish ecosystems, fisheries, and human health. Several species of the genus *Dinophysis* are known to produce lipophilic toxins, which can accumulate in suspension feeding bivalves and intoxicate consumers of contaminated shellfish. A striking feature of the *Dinophysis* toxic events documented along the French Atlantic coast in the last decades was the low concentration of *Dinophysis* in seawater samples (Delmas et al., 1992; Belin and Soudant, 2018), which prevented its observation from satellite remote sensing. Since *Dinophysis* is an obligate feeder of *Mesodinium rubrum*, the detection of *M. rubrum* could be used as an early warning system. *M. rubrum* is a globally-distributed mixotrophic marine ciliate known to form ephemeral and massive red tides in coastal areas, such as estuaries, fjords, and upwelling zones. Detection, sampling, and quantification of such red tides is notoriously challenging, however, due to the speed at which the ciliate can grow, swim, aggregate, disaggregate, and/or be consumed. Here, we present a novel detection and quantification method based on high spatial resolution satellite remote sensing.

Materials and methods

A culture of the cryptophyte *Teleaulax amphioxeia* was used to feed the mixotrophic ciliate *M. rubrum* (Fig. 1). The inherent optical properties of *M. rubrum* were measured from the culture, and a radiative transfer model was used to simulate its optical signature in terms of remote sensing reflectance (R_{rs}), which is the optical parameter available from satellite data. A detection and quantification algorithm was then developed based on the optical signature of *M. rubrum*, and applied to a three-year archive of high-resolution satellite data over a shellfish farming area located along the French Atlantic coast.

Results and discussion

The particulate absorption and backscattering coefficients of *M. rubrum* were characterized for the first time using laboratory cultures, and were consistent with *in situ* observations (Guzmán et al., 2016). Radiative transfer simulations allowed us to characterize the optical signature of *M. rubrum*s over a wide range of chlorophyll-*a* concentrations. The simulated R_{rs} spectra exhibited unique spectral features, including a near-infrared (NIR) peak associated with the presence of chlorophyll-*a* and a green trough associated with phycoerythrin absorption. An algorithm based on the amplitude of these spectral green and NIR anomalies was then proposed and applied to the archive of Sentinel-2 data from 2017 to 2019 over a shellfish farming area located in southern Brittany (France). Several red tides were successfully detected, allowing us to study the spatio-temporal dynamics of *M. rubrum* blooms at high spatial resolution (20 m) over a wide coastal area (Fig. 2). Massive blooms of other species (e.g., *Lepidodinium chlorophorum*) were also observed in shellfish farming sites, and successfully discriminated. Our results demonstrate the advantage of using Earth Observation, not only to monitor HABs in aquaculture sites, but also to better understand their spatiotemporal dynamics, and link their formation and duration to environmental forcing mechanisms.

E-mail: Jan@cfeed.no

Ballan wrasse as a cleaner fish for sea lice is becoming more and more popular in the Norwegian salmon industry. Never the less, the industrial cultivation of this species still has challenges and the availability of high quality juveniles remains a major bottleneck during the production cycle.

Two key challenges are faced during juvenile production. One being the first feeding of the larvae and the second being the weaning on dry pellets.

To tackle these challenges, a multifactorial experiment with three different feeding regimes and four different commercial micro diets was conducted. All feeding regimes were based on Copepods (*Acartia tonsa*, C-Feed AS) as start-feed. Approximately 200 000 Ballan wrasse larvae were equally distributed among 24 60-liter tanks and reared for 55 days. Eight treatments (three replicate tanks per treatment) were included and split in four early weaning treatments and four late weaning treatments.

In the early weaning treatments Copepods were fed to the larvae from 4-24 days post hatching (dph). A co-feeding period of 4 days followed, in which four different commercial micro diets (one for each treatment: Otohime, Reed Mariculture; AgloNorse Extra, Trofi; Molofeed; Gemma Micro, Skretting) were introduced to the experimental tanks.

In the late weaning treatments live feed was fed from 4-37 dph. Two of the four treatments were fed with Copepods while the other two treatments were fed with enriched (Multigain, BioMar) Artemia. A co-feeding period of 7 days followed until 44 dph when two commercial micro diets (Otohime, Reed Mariculture and AgloNorse Extra, Trofi) were introduced.

Larval length and weight were assessed for 15 larvae per Tank every fifth day. Furthermore, daily mortalities were counted individually per tank. At the end of the experiment, all remaining larvae were counted. Additionally, 25 individuals per Tank were sampled for malformation analyses.

All early weaning treatments had reduced survival rates, compared to the late weaning treatments. This was likely due to a mortality peak two days after the last Copepod feeding at ca.30 dph. Never the less groups fed with Trofico and Skretting showed the best growth performance in the early weaning approach.

In the late weaning treatments, the overall survival rate was higher, compared to the early weaning treatments. The long fed Copepod groups had an improved survival rate, resulting in twice as many surviving larvae at the end of the experiment compared to the late weaning group fed with Artemia. This result could be linked to a mortality peak in the Artemia fed groups shortly after they were weaned on the micro diets. Pure Trofi feeding reduced the mortality slightly but was still increased in comparison to almost no mortality in the weaned Copepod group.

However, the growth of the larvae exclusively fed with Copepods was reduced between 35-45 dph due to reduced Copepods prey size. This deficit was superseded by an increase in growth of the larvae in both Copepod treatments, as soon they were fed with micro diets.

REGULATION OF THE RHYTHMICITY OF PROTEOLYTIC DIGESTIVE FUNCTION IN GILTHEAD SEABREAM UNDER DIFFERENT DAILY FEEDING PROTOCOLS

Introduction

Digestion consists of a group of complex processes, involving physical, chemical, and biochemical transformations of the ingested food. All of them are interdependent and finely tuned by a number of molecular, hormonal, and nervous signals, many of which are driven by the circadian system. This system is composed of several interconnected oscillators, for which light-dark and feeding-fasting cycles are the most powerful synchronizers. An increased knowledge of Food Anticipatory Activity (FAA), an out of Food-entrainable oscillators (FEO), may help to optimize the utilization of nutrients by a given species adapting feeding protocols to these internal rhythms. The present work aimed to evaluate the rhythmicity of some of the gastrointestinal tract (GIT) factors that are related to digestive efficiency in gilthead seabream (*Sparus aurata*) juveniles as well as to determine how these factors are affected by different feeding protocols.

Materials and methods

Juveniles of *Sparus aurata* were randomly distributed into four groups with three replicates (for each group N = 124, body mass 17.91 ± 0.2 g), in 250-L tanks, with flow-through water system at 19.5 ± 1.0 °C, and a photoperiod of 11L/13D. All groups were fed a daily ration of 2.5 % body mass, with the same experimental diet but different daily feeding protocols (P) during the daylight: P1) one meal at 08:30 h (local time); P2) three meals at 08:30, 13:30, and 18:30 h; P3) five meals at 08:30, 10:00, 13:30, 16:00, and 18:30 h; and P4) continuous feeding from 8:30 to 18:30. After two-weeks, fish were sampled (six individuals, two per tank) every 4 hours during a 24 h cycle. Relative expression of genes related to appetite regulation (ghrelin, *ghrl*), nutrient transport (Peptide transporter 1, *slc15a1*), and circadian rhythms (period circadian

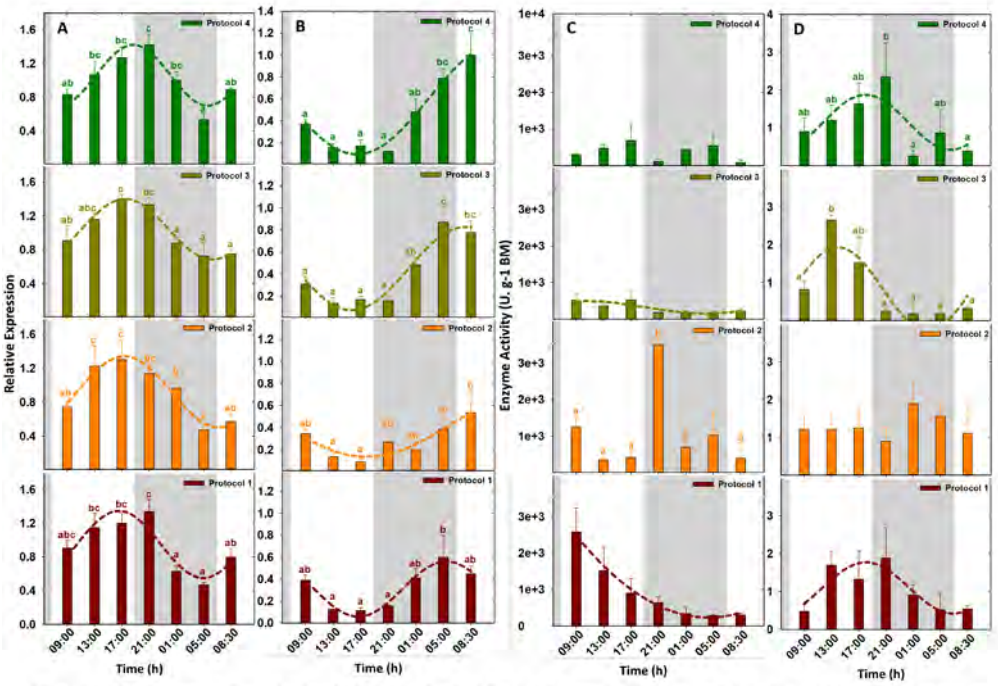

Fig. 1. Daily pattern of *clock* (A) and *slc15a1* (B) expression, and pepsin (C) and trypsin (D) activity in *S. aurata* with different feeding protocols. Different letters denote significant differences among sampling times within each protocol. Dashed lines exhibit significant circadian rhythms ($p < 0.05$). Grey areas indicate the dark period.

(Continued on next page)

protein homolog 3, *per3*; circadian locomotor output cycles protein kaput, *clock*) were quantified in the whole GIT tissue using the $\Delta\Delta C_T$ method. Pepsin and trypsin activity, as key proteolytic enzymes, were assessed using hemoglobin (pH 2.0) and BAPNA (pH 8.5) in the stomach and intestine, respectively. Besides two- and one-way ANOVAs, data were subjected to a cosinor analysis (EL TEMPS®) to test for circadian rhythms ($p < 0.05$).

Results

Significant influence of feeding protocol and/or sampling time was obtained in all the studied parameters. P2 and P1 had the lowest, while P4 and P3 had the highest *slc15a1* and *per3* expression levels. Nevertheless, P3 and P4 showed the lowest, while P2 and P1 showed the highest pepsin activity. In all protocols, expression of *clock* and *per3* had significant daily rhythms with almost opposite patterns. Except for *slc15a1*, other studied factors did not exhibit daily rhythms in all the feeding protocols (Fig. 1).

Discussion and conclusion

Rhythmicity of GIT expression of clock genes under all the tested daily feeding protocols, without major phase shift, indicated a strong light synchronization rather than food entrainment. It is speculated that entrainment of endogenous clocks by feeding-fasting cycles is mediated by hormones, metabolites, and other sensor molecules, through alterations in the family of *period* genes. Interestingly, in our study, *per3* was the only circadian gene that was significantly influenced by the feeding protocol. The strong correlation between *per3* and *slc15a1* expression and, to a lesser extent, between *clock* and *ghrl* expression in this work, supported the previously reported role of clock genes in daily organization of biological functions such as nutrient transport and appetite control, or could underline a putative interactive role of these parameters in entrainment of FEOs (Isorna et al., 2017). Activity of proteolytic enzymes, especially trypsin, showed rhythmic daily patterns that were mostly synchronized by food availability in GIT in most of the experimental protocols. Overall, higher incidence of daily rhythmic patterns in the studied parameters and a higher expression of *slc15a1*, as a marker of protein absorption function, may suggest a better digestive efficiency in P3 and P4. On the other hand, highest enzymatic activity in P2 might be a strategy to compensate the absence of daily rhythmicity in some of the studied parameters.

Introduction

Cholecystokinin (CCK) is a peptide hormone that plays an important role in intestinal phase of the digestion process, by being involved in the regulation of pancreatic enzyme secretion among others (Rønnestad et al., 2017). Peptides and free amino acids in the chyme act as signals that initiate the release of CCK, which in turn causes the release of pancreatic digestive enzymes into the gut lumen. Daily fluctuations of CCK and trypsin activity has been addressed especially in fish larvae. However, daily interaction of this hormone with pancreatic enzymes in juvenile fish under different feeding schedules has been scarcely studied. Therefore, the aim of the present work was to evaluate the influence of different feeding protocols, in terms of timing and frequency, on daily rhythm of CCK hormone and two pancreatic enzymes in juveniles of Senegalese sole (*Solea senegalensis*).

Materials and methods

Senegalese sole juveniles were randomly distributed into four groups with two replicates (for each group N = 118, initial body mass 51.61 ± 0.9 g), in 250-L tanks, with flow-through water system at 19.5 ± 1.0 °C, and a photoperiod of 11L/13D. All groups were fed a daily ration of 2 % body mass, with the same experimental diet but different daily feeding protocols (P): P1) one diurnal meal at 08:30 h (local time); P2) six diurnal meals at 08:30, 10:00, 12:00, 14:00, 16:00 and 18:00 h; P3) six nocturnal meals at 20:00, 22:00, 24:00, 02:00, 04:00 and 06:00 h; and P4) 12 meals during 24 h (at all times mentioned for P2 and P3). After two weeks, fish were sampled (four and five individuals for CCK and enzymatic activity measurements respectively) every 4 hours during a 24 h cycle.

CCK concentration was measured in epithelial tissue of the proximal intestine using the Fish CCK8 ELISA Kit (MyBioSource, Cat. No. MBS069488). Trypsin and chymotrypsin activity were assessed in the proximal intestine using BAPNA and GAPNA as substrates (pH 8.5), respectively. Besides One-way ANOVA, data were subjected to a cosinor analysis (EL TEMPS®) to test for circadian rhythms ($p < 0.05$).

Results

Fish with a single diurnal (P1) and 12 diurnal-nocturnal (P4) meals had maximum and minimum daily average CCK levels, respectively. While, P1 and fish with exclusively nocturnal meals (P3) showed the minimum and maximum daily average trypsin activity, respectively (Table I). Trypsin and chymotrypsin daily activity patterns were similar in all the experimental protocols. Only in P1, cosinor analysis showed significant daily rhythm for all the studied parameters, with acrophase at 13:33, 13:36, and 13:46 h, for CCK, trypsin and chymotrypsin, respectively. However, a general phase shift was obtained in the rest of the feeding protocols, with CCK peaks preceding the maximum enzymatic activity levels (Fig. 1).

Discussion and conclusion

The inverse relationship in total quantity and temporal displacement of daily CCK and digestive enzyme activity patterns supports the involvement of CCK in the pancreatic proteases secretion and the existence of a regulatory loop between these parameters. Moreover, this displacement depended on the feeding protocol; increasing the feeding frequency led to longer delay between CCK secretion and proteases activity peaks. In all the experimental protocols, expect for P1 with a single daily meal, two daily CCK and the subsequent protease activity peaks were obtained.

Introduction
Feeding efficiency requires an adequate nutrient composition and an efficient digestive process. Feed formulation has been the target of many studies; however, the actual digestive capacity of farmed fish, with pre- and post-prandial responses, is largely unknown. Besides, few studies have focused on designing optimized feeding schedules. Therefore, the aim of the present work was to evaluate the effect of two daily feeding frequencies on growth and daily fluctuations of parameters related to the circadian and digestive physiology in gilthead seabream (*Sparus aurata*) juveniles.

Materials and methods
Juveniles of *S. aurata* were randomly distributed into two groups in duplicate (each group N = 96, initial body mass 22.7 ± 0.6 g), in 500-L tanks, with flow-through water system at 19.5 ± 1.0 °C, and a photoperiod of 11L/13D. All groups were fed a daily ration of 2.5 % body mass, with the same experimental diet but different daily feeding protocols (P) during the daylight: P1) three meals at 08:30, 13:30, and 18:30 h, and P2) five meals at 08:30, 10:00, 13:30, 16:00, and 18:30 h. The experiment was carried out in a period of almost five months (139 days), over which the Specific Growth Rate (SGR), and Feed Efficiency (FE) were analyzed regularly. At the end of the experimental period, fish were sampled (eight individuals, four per tank) every 4 hours during a 24 h cycle. Expression of clock genes (*bmal1*, *clock*, *per3*, *cry1*) and genes related to appetite control and food intake (leptin, *lep*; ghrelin receptor, *ghsr1b*; glucocorticoid receptor, *nr3c1*) were quantified in the liver ($\Delta\Delta C_T$ method). Trypsin and chymotrypsin activity were analyzed in the proximal intestine (BAPNA and GAPNA as substrates, respectively). Besides t-test and ANOVAs, data were subjected to a cosinor analysis (EL TEMPS®) to test for circadian rhythms ($p < 0.05$).

Results
Final body mass, SGR, and FE were 123.7 ± 1.8 g, 1.22, and 1.23 in fish with three (P1) and 124.6 ± 2.1 g, 0.76, and 0.78 in fish with five daily meals (P2), respectively. No significant differences were obtained neither for final body weight nor for any other studied parameter between protocols. However, most of the variables demonstrated significant fluctuations along the daily cycle and in some cases, their patterns depended on the experimental protocol (Figs. 1 to 3).

Higher trypsin activity during light period in P2, coincides with the food ingestion and could lead to a more efficient alkaline protein digestion in this group (Fig. 1). Daily changes of the *lep* and *ghsr1b* are in accordance with their putative anorexigenic and orexigenic function, respectively. Circadian pattern of *lep* and *nr3c1*, with their peak at the transition of light-dark period, can imply their possible role in entrainment of peripheral oscillators through modification of clock genes expression (Fig. 3). Finally, due to the daily changes of the studied parameters, when estimating the fish digestive capacity or comparing the response to different diets or feeding protocols, decisions that are based on a single sampling time are incomplete and could lead to misleading conclusions.

CRYPTIC INTROGRESSION: WILL PLASTICITY AND NATURAL SELECTION MASK THE EFFECTS OF GENE-FLOW FROM DOMESTICATED ESCAPEES ON NATURAL POPULATIONS?

Kevin A. Glover* and Monica F. Solberg

Institute of Marine Research, Nordnesgaten 50, 5218, Bergen, Norway
kevin.glover@hi.no

Farmed Atlantic salmon are domesticated, and where significant interbreeding with wild conspecifics occurs, this may lead to changes in fitness traits, and ultimatel , less productive wild populations (Reviewed by Glover *et al.* 2017).

Thus far, there are few data demonstrating direct evidence of life-history and fitness changes in native populations resulting from interbreeding with domesticated conspecifics. While the reasons behind this are many, including the fact that investigating native populations is logically demanding, in this talk we speculate whether plasticity, and natural selection, may combine to mask some of the life-history changes that could be expected in native populations following spawning intrusion of domesticated escapees.

The talk to a large degree bases itself on recently published work demonstrating the plasticity and selection can mask genetic changes in native populations (Glover *et al.* 2018), and the result of modelling work conducted via IBSEM (Castellani *et al.* 2018).

A FULLY INTEGRATED SIMULATION MODEL OF MULTI-LOOP AQUAPONICS: PUTTING THEORY INTO PRACTICE

S. Goddek [1], O. Körner [2], A. Joyce [3], and K.J. Keesman [1]

email: alyssa.joyce@gu.se

Introduction

Decoupled multi-loops aquaponics systems allows for co-cultivation of plants and fish in a circular system that can take advantage of nutrient, water and energy cycling. Sizing of systems is important so that wastes from the RAS component can be utilized effectively within the hydroponic (HP) system, based on parameters such as plant growth rates, evapotranspiration and species-specific plant nutritional needs. However, in order to create the optimal fit between RAS and HP, the temporal responses of the underlying processes need to be optimized so that water and nutrient flows are always synchronised. We have therefore created an aquaponics-sizing simulator based on deterministic mathematical models that are transferrable to various environmental conditions with simple parameterisation. Model outputs of this simulator allow us to further understand system dynamics under different environmental conditions, while also allowing us to perform parameter estimation, optimization and control for each location where output from the RAS systems can be estimated, greenhouse specifications can provide known growth rates for the desired species, and appropriate seasonal weather data is available.

Materials and methods

Two independent model systems, for (1) the greenhouse, incorporating HP and climate control biofeedback and (2) the aquaculture facility as illustrated in Fig. 1, were developed in the modelling and simulation environment MATLAB. The combined model system is a compilation of technical and biological sub-models, including greenhouse macro- and microclimate, energy consumption and crop growth that are thoroughly calibrated and validated (e.g. Körner et al., 2007).

Results

The simulation outcomes let us size the system and also determine the required flows in between the respective sub-systems (Goddek & Körner, 2019). The simulations, with the respective flow rates provide a good indication with respect to nutrient concentrations within the RAS system under different environmental conditions (Fig. 2).

The peaks in NO3-N concentration for tomatoes are a result of a lower crop-specific evapotranspiration rate of young plants during the winter (i.e. lower solar radiation). The uptake of NO3-N is linear related to transpiration rates of the crop, resulting in a higher accumulation of NO3-N in the RAS system in cooler regions. Unlike lettuce that is consecutively planted and harvested year-round (resulting in a homogeneous crop all the year), tomatoes are usually re-started with young plants once a year. Thus, season, geographical location and cropping practices alter the leaf-area, which in turn is the driving force for transpiration.

Discussion and Conclusion

Based on the results, the model makes it possible to gain a better understanding with respect to water and nutrient dynamics in an aquaponics system. More importantly, the simulation outputs also includ yield predictions for both plants and fish, energy (thermal and electricity) and water requirements for the system, thus allowing for economic feasibility calculations. The model uses small time-points of 5-min for the plant sub-modules, in order to simulating the faster dynamics within the HP system, while the slower RAS dynamics are simulated with daily time-points. We are currently applying this simulation model in both Namibia and Saudi Arabia, where different desert climates prevail (semi-hot and semi-humid, hot and dry). In order to fit RAS and HP to extreme climate conditions, where the choice of greenhouse construction and equipment is of particular importance.

Introduction

The pikeperch (*Sander lucioperca* L., 1758) belonging to the *Percidae* family is on its way to become an attractive aquaculture species in the western world. The aquaculture of this so far only rarely domesticated fish species confronts breeders with numerous challenges in breeding and keeping. The only poorly researched biology of pike-perch with regard to the behavior during and after periods of stress or the defense against infectious pathogens in aquaculture leads to high mortalities in the larval and juvenile stages of development, particularly during feed conversion. Multiparametric analyses with genome biological approaches in combination with classical stress-analysis methods and targeted fish monitoring contribute to the understanding of the biology of pike-perch with regard to aquaculture and to the development and optimization of breeding approaches. The project presented here on the genome analysis of pike-perch will boost the development of genomic tools for the aquaculture of pike-perch. Grants for this project (MV-II.1-LM-001) come from the European Maritime and Fisheries Fund (EMFF) and the Ministry of Agriculture and the Environment Mecklenburg-Vorpommern.

Material & methods

A male pikeperch was used for genome analysis. DNA sequencing was performed with different sequencing platforms. Long DNA fragments were sequenced with PacBio Sequel SMRT technology and short fragments with Illumina HiSeq 2500 (2 x 150 bp paired end fragment size). The ongoing genome analysis of another 394 pikeperches with the Illumina NovaSeq sequencing technology serves to identify and validate informative single nucleotide polymorphisms (SNP) and to create an initial linkage map for the pike-perch. For this, the software GATK (Genome Analysis Tool Kit) are used. Based on initial RT-qPCR gene expression analyses (Biomark HD system, Fluidigm 48.48 IFC chip or Roche LightCycler96, 96-well plates), key genes associated with growth, stress and immunity were validated with respect to animal welfare and performance under rising water temperatures, hypoxia or pathogen impact.

Results

PacBio sequencing of the pike-perch genome size was based on in average 20 kb DNA fragments and resulted in a 41-fold genome coverage whereas the paired end sequencing by Illumina resulted in a 373-fold coverage of the genome. The genome assembly analysis resulted in a first highly continued draft genome assembly for pike-perch. The assembled total length of the genome is 900 Mb covering 88% of the 1014 Mb estimated genome size. (More information can be found on our pikeperch genome poster.) We also sequenced 394 pike-perch by Illumina NovaSeq with a coverage between 25 and 30 per fish.

While the investigations on the ontogenesis of pike-perch and on some of the above mentioned animal-welfare-relevant characteristics are still ongoing, a network of interacting thermomarker genes has already been identified reflecting the response of pike-perch to rising water temperatures. Based on this, a molecular biochip for temperature stress analysis was developed. (Detail on these data are given in separate posters.)

Discussion and conclusion

The pike-perch genome sequence presented for the first time together with the genome data of nearly 400 individual animals provides an excellent basis for the further and more precise assembly of the pikeperch genome. Furthermore, it helps to identify the protein-coding and other gene sequences and provides the prerequisites for detailed molecular analyses in the five known sander species and future genome-based breeding approaches. The functional analyses revealed detailed information on optimized fish keeping with regard to essential basic parameters such as temperature and oxygen saturation.

INHERITANCE AND EXPRESSION OF RED-EYE KOI MUTATION IN KOI (*Cyprinus carpio*) x GOLDFISH (*Carassius auratus*) HYBRIDS

B. Gomelsky*, J. Warner, N. Novelo, A. Kramer and B. Thomas

Aquaculture Research Center, Kentucky State University, 103 Athletic Road, Frankfort, KY 40601, USA
E-mail: boris.gomelsky@kysu.edu

Introduction

Appearance of red eyes in fish is usually connected with the action of albino mutations. In contrast, Gomelsky et al. (2016) showed that appearance of red eyes in ornamental koi carp (*Cyprinus carpio*) is caused not by albino mutation but by another, dominant demelanization mutation (*R*), which has partially decreased the quantity of melanin in both the skin and eyes. The purpose of the present study was to investigate inheritance and expression of red-eye koi mutation in koi x goldfish *Carassius auratus*) hybrids.

Materials and methods

The general scheme of experiments included crossing of goldfish males with normal black eyes with koi females with either normal black or red eyes followed by analysis of segregation in progenies with regard to eye color and body pigmentation in swim-up larvae and 5-month-old juveniles. All progenies were obtained by artificial spawning; one male and one female were used for production of each progeny. Significance of difference between observed segregation and the 1:1 theoretical ratio was determined using a Chi-square test.

Results

A total of five progenies were obtained and analyzed (able I).

Table I. Segregation of fish in progenies obtained by crossing of goldfish (GF) males with koi females with normal black or red eyes. Different superscript letters indicate significant difference (P<0.05) between observed segregation and the 1:1 theoretical ratio.

Progeny no.	Parents		Segregation of larvae (n)		Segregation of juveniles with regard to body color (n)			
	Male	Female	Light body and lenses	Dark body and lenses	Yellow	Brown	Yellow + Brown	Wild Type
1	GF	Black-eyed koi	0	77	0	0	0	452
2	GF	Black-eyed koi	0	82	0	0	0	809
3	GF	Red-eyed koi	38[a]	33[a]	46	96	142[a]	148[a]
4	GF	Red-eyed koi	52[a]	43[a]	71	150	221[a]	271[b]
5	GF	Red-eyed koi	18[a]	25[a]	149	104	253[a]	326[b]

(Continued on next page)

Fig.1. Juveniles of koi x goldfish hybrids with wild-type, yellow, and brown colors (from top to bottom); bar = 1cm.

In progenies 1 and 2 obtained by crossing goldfish males with black-eyed koi females all larvae were dark and had normal black eye lenses while all juveniles had a wild-type color and black eyes. In progenies 3, 4 and 5 obtained by crossing goldfish males with red-eyed koi females, two types of larvae were observed: larvae with light body color and light eye lenses and larvae with dark bodies and black eye lenses; in all three progenies segregations of larvae did not differ significantly from the 1:1 Mendelian ratio. Three types of juveniles with regard to body color were observed in these progenies: wild-type, yellow, and brown. All juveniles had normal black eyes. As an illustration, juveniles of these three types from progeny 3 are shown in Figure 1. The cumulative proportion of colored (yellow + brown) juveniles varied in different progenies from 43.7 to 49% (Table I); in progeny 3 segregation of colored and wild-type juveniles did not differ from the 1:1 Mendelian ratio while in progenies 4 and 5 this difference was significant.

Discussion and conclusion

The results of the study show that the dominant mutation *R* causing appearance of red eyes in koi resulted in the occurrence of unpigmented larvae with light lenses in hybrids obtained by crossing goldfish males with red-eyed koi females. The 1:1 ratio of dark and light larvae in progenies indicated that goldfish males had genotype *rr* while red-eyed koi females were heterozygous (genotype *Rr*). At the juvenile stage, this mutation caused only partial demelanizanion of the body, which resulted in the appearance of yellow and brown fish with black eyes. A statistically significant deficit of colored juveniles in the two progenies was observed, apparantly because some hybrids with *Rr* genotype were indistinguishable from wild-type fish with genotype *rr*.

IMPROVEMENT OF FAECES STABILITY THROUGH DIETARY MANIPULATION IN STARTER FEEDS FOR SEABASS (*D. labrax*) AND SEABREAM (*S. aurata*) REARED IN RECIRCULATION SYSTEMS

Pedro Gómez-Requeni*, Kim Schøn Ekmann, Kyla Meagan Zatti

BioMar A/S, Mylius-Erichsensvej 35, Brande, Denmark
Email: pgr@biomar.com

Introduction

In the recent years there has been a tendency of seawater (SW) hatcheries to prolong the growth of the fry in land-based facilities before transfer to sea cages. Most of the new coming developments in this area will be done in recirculation systems (RAS) and due to water usage constraints, pathologies, stability of temperature and other rearing parameters a great majority of the existing pre-growing units will change into RAS as well. The first step in RAS is the solid removal. Depending on the stability of the faeces produced by the fish this step can be simple or quite complex. As a result, there is a market need for starter feeds designed for RAS with special emphasis on enhancing the faeces stability in the water.

This project aimed to develop a BioMar ORBIT starter feed product range for SW fish in the range within 0.2 – 15 g, especially for seabass (*D. labrax*; SBA) and seabream (*S. aurata*; SBE). Therefore, this development was focused on providing enhanced faeces stability without jeopardizing fish performance and gut health

Materials and methods

Four diets (D1, D2, D3 and D4) varying in what we named *BioMar ORBIT package* were tested in quadruplicate tanks (V=100-120 L) using 2 RAS systems placed in CTAQUA (Cádiz, Spain). System water renewal in each RAS was set at 5-10 % renewal per day after stabilization of the biofilte . The biofilter consisted of a submerged and a trickling filter with different plastic media. Temperature was 21 ± 1 ºC for SBA and 22 ± 1 ºC for SBE. Photoperiod was 12 L / 12 D (light/dark). Fingerlings had an initial body weight of 1.16 ± 0.02 g (SBA) and 0.90 ± 0.04 g (SBE).

Table 1. Difference (%) in the volume and area of the faecal particles released to the water by fish fed with the experimental diets D2, D3 and D4 compared to D1 (n=4)

	VOLUME OF FAECES (μl/L)

(Continued on next page)

Faecal samples were collected using a modified Guelph system over a period of 17-18 h. Faecal particle size distribution analysis (PSD) was performed by means of a LISST-Portable|XR particle size distribution analyser (Sequoia Scientific Inc) based on Brinker *et al*. (2005). Analyses were carried out in duplicate per tank. Samples of liver and intestine were also taken and preserved in buffered formalin for further histological analyses. Samples of distal intestine were trimmed, processed and embedded in paraffin wax and the tissue blocks were cut at 5 µm and stained with hematoxylin and eosin (H&E), and Alcian blue, by Fish Vet Group (Inverness, UK). Each slide was digitalized at 40x magnification using a ScanScope AT Turbo slide scanner (Leica Biosystems, USA). The digital slides were examined using ImageScope Version 12.3.2 (Leica Biosystems, USA). Transverse sections of the intestine were scored using six parameters, and all parameters were scored on a scale of 1 to 4.

Results

At the end of the trials, we did not find any significant differences in the growth rates, performance, survival or the distal intestine architecture of fish fed with the experimental diets. However, the faecal assessment determined by measuring the particle size distribution did show statistically significant differences between the experimental diets in both species (Table 1).

Discussion and conclusion

In general, the addition of the *BioMar ORBIT package* in D2, D3 and D4 reduced the volume and area of faecal particles within each particle size range (<30 µm / 30-60 µm / >60 µm) when compared to D1, and this effect was more evident in SBE. Furthermore, D3 and D4 reduced the volume and area of the particles even more, in the range between 30-60 µm, when compared to D1. Therefore, with the purpose of improving the removal of solid waste as early as possible in the process, the results from this trial recommend the addition of the *BioMar ORBIT package* to starter feeds to be used in RAS systems in, at least, the levels of D3 in both SBE and SBA.

Introduction

There is a constant request to intensify the aquaculture production to fulfil the growing need of the market. In Norway farmed salmon has become a significan source of national income with the excess of 1 million tons produced every year (MOWI, 2018). The expansion of the industry and the diversity of materials used to build and maintain the aquaculture systems have paralleled the development of synthetic polymers over the last decades. Synthetic fibers ropes offer greater strength and durability than natural fiber ropes, they are cheaper, durable and easier to handle compared to their natural counterparts. All plastic material within an aquaculture site is maintained and controlled for chemical degradation, biofouling and corrosion, and are regularly inspected to ensure strength and stability. Lost gear, broken and fragmented equipment, release of debris because of intense use are sources of plastic emission from aquaculture at global and local level (Astudillo et al., 2009; Lusher et al., 2017;). However, the estimation of the level of contribution remains a knowledge gap that needs to be estimated (Haave et al., 2018; Gomiero et al., 2019). It is therefore crucial to look at the challenges and solutions related to the release of microplastics from the aquaculture industry. Therefore, the aim of the present project aims at : a) to identify the sources of emissions of plastic and micro-plastic in the sea from aquaculture facilities; b) to determine and quantify the contributions from aquaculture operations in the immediate vicinity of sea farms; c) Identify which processes within the seafood production is largely responsible for plastic discharge and suggest measures to reduce eventual emissions; d) encourage an active exchange of information and discussion between academia, industry and stakeholders for a common solution towards marine plastic pollution.

Materials and methods

To discriminate any production step-dependent contribution in the plastics enrichment of the final fish food product samples from raw materials (n=8) and from different steps in the fish food pellet production (n=4) have been collected together with the information on the products (origin, date of production, supplier, etc). As in the fish production phase produced pellets are high pressure transported to the cages by plastic pipes, such technique has been speculated to create a significant abrasion of the plastic thus possible environmental release of plastic particles of unknown size distribution. An ad hoc autosampler has been engineered to collect, quantify and characterize the plastic debris coming out from the hose of a standard feeding system before and during its operative phase. Furthermore, the occurrence of plastic fragments in different environmental compartments potentially affected by aquaculture production activities such as marine sediments, seawater, suspended matter and biota (farmed Atlantic salmon) at increasing distances from an active aquaculture facility is performed. Van Ween grab devices, multi-sieving collectors and sediment traps where used on 8 sites placed on two orthogonal sampling transects and compared to a control site not affected by the aquaculture production. 10 individuals of wild salmon (control) as well as farmed salmons were collected during the production phase and analysed for total content and polymers composition in the gut line and in the gills. The extraction and purification method trust in a combination of a multistep enzymatic-strong alkali-oriented purification followed a density-based separation to extract plastic fragments from digestates was performed. Extracted samples were size fractionated in four size classes (D1:500-300 µm; D2:300-150 µm; D3: 150-10 µm; D4: 10-1 µm; D5: 1 - 700 nm). D1 representing a fraction with large fragments was quantified by ATR-FTIR. The finer fractions D2 – D4 were analysed first by a µFTIR microscopy and finally by GCMS-pyrolysis technique. Eight among the most commonly used plastic polymers such as: polyethylene - PE, polypropylene - PP, polystyrene - PS, polyvinyl chloride - PVC, polyamide - PA66, polymethyl methacrylate - PMMA, Polycarbonate - PC and polyethylene terephthalate - PET of purity >99% were investigated.

(Continued on next page)

Results and discussion

Occurrence of microplastics in the fish food production: preliminary results indicate negligible levels of microplastics contamination in most of the analyzed raw materials. Limited amounts of plastics in the range of few µg/g of PE and PA66 in fish meal and PP in the wheat gluten source were observed. Further investigations on the wheat gluten production line helped to identify part of the industrial process responsible to the PP release.

Occurrence of microplastics in selected environmental matrices: PE, PP, PVC and PA66 were observed in all investigated matrices with highest levels, in range of tens of µg/g, for each of the addressed polymers, reported in sediments and in suspended matter. The site targeted as reference in the study showed a similarly represented pool of polymers but with different accumulation levels. The observed preliminary results point out the complexity of the polymers distribution interpretation hampered by the multiple input source in the aquatic environment.

Conclusions

The ongoing project has so far helped to identify some industrial process responsible to the release of small amounts of plastics. Some solutions were successfully placed to reduce the potential impact of microplastics on the environmental footprint of Atlantic salmon farming. Part of the analyses are still in and will be presented during the conference.

Acknowledgements. The project TRACKing of PLASTtic emissions from aquaculture industry (TrackPlast) has been granted by Fiskeri- og havbruksnæringens forskningsfinansiering (FhF) as part of the strategic plan aiming at evaluating the environmental and industrial impact of plastic litter.

NUTRITIONAL REQUIREMENTS OF EUROPEAN LOBSTER (*Homarus gammarus*, L.): EFFECT OF PROTEIN, LIPID, AND CARBOHYDRATE DIET CONTENT ON METABOLIC POSTPRANDIAL RESPONSE

R. Goncalves*, I. Lund, M. Gesto, P.V. Skov

Technical University of Denmark, DTU Aqua, Section for Aquaculture, The North Sea Research Centre, DK-9850 Hirtshals, Denmark
E-mail: rego@aqua.dtu.dk

Introduction

The general decline of European lobster (*Homarus gammarus*) natural stocks has been counteracted with the release of hatchery-reared juveniles in the wild. However, growth and survival rates in lobster culture are still low. Moving away from live/frozen feed and embracing the use of dry formulated diets can support simpler and more reliable production considering their more stable storage and consistent nutritional quality (Powell *et al.*, 2017)which impact on larval survival, development and growth. For early-stage European lobster, Homarus gammarus larvae, feeding ecology and body composition are largely unknown. We initiated four progressive feeding experiments (novel feed types, feeding regime and feed size and cannibalism effects. The development of a balanced diet requires species-specific information on their nutritional requirements. Some nutritional studies have been conducted in *H. gammarus* (Glass and Stark, 1995, Powell *et al.*, 2017)"id":"ITEM-1","issue":"3","issued":{"date-parts":[["1995"]]},"page":"424-433","title":"Carbohydrate digestion in the European lobster Homarus gammarus (L. but appropriate requirement levels are still to be defined. The postprandial metabolic cost, commonly referred to as specific dynamic action (SDA) is dependent on several factors including animal size, meal composition and quantity. Therefore, SDA quantification is a useful metric of the overall nutritional performance of an animal (Secor, 2009)such as the mahi-mahi (Coryphaena hippurus. Understanding the species- and diet- specific postprandial metabolic costs can be used in the evaluation of formulated feeds. In an attempt to define appropriate requirement levels of protein, and the role of non-protein energy, the present work evaluated the metabolic response of lobster juveniles fed six experimental dry feeds, differing in macronutrient composition. SDA, feed intake, and growth performance were determined and their significance discussed

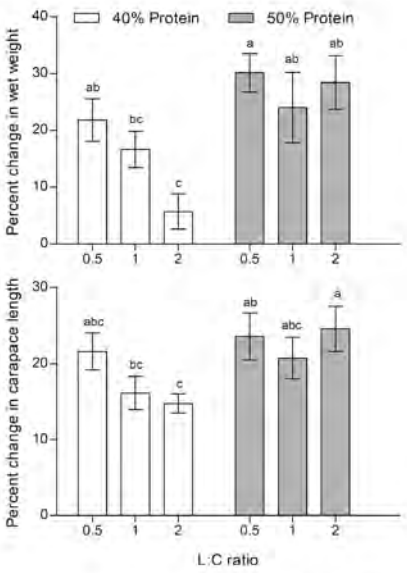

Fig. 1. Mean percent growth gain of E. lobster at the end of respiratory trials. Letters in superscript indicate significant differences between means.

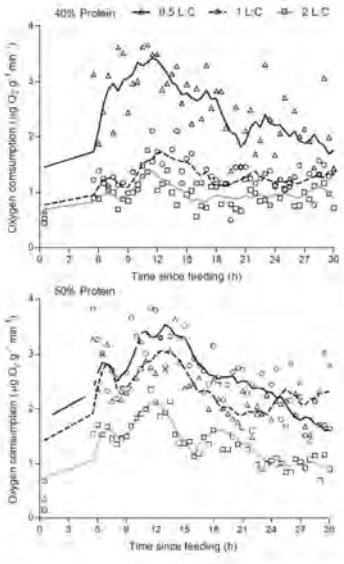

Fig. 2. Plots of postprandial metabolism over time in each diet.

(Continued on next page)

Materials and Methods

Lobster juveniles (1.0±0.1g) were individually acclimated in a recirculation system for 4 weeks to the experimental diets before respiratory trials (18±0.5˚C temperature, 34±1 psu, >7mg/L dissolved oxygen, <0.1mg/L NH_4), under a 8L:16D photoperiod. During acclimation they were fed their diets in excess each morning for 4h. Six formulated diets were evaluated in this experiment with two fixed protein levels (400 and 500 g/Kg) at 3 lipid (L) - carbohydrate (CHO) energy ratio (0.5, 1, and 2 L:CHO): Oxygen consumption rate (MO_2) was determined in individual metabolic chambers over a 96h period in 30min measurement loops. Standard metabolic rate (SMR) was determined from the first 48h of measurements on fastened individuals. After 48h, chambers were opened and 1 pellet offered to each lobster. After a 2h feeding period, remaining pellets were carefully removed and MO_2 postprandial measurements continued for 48h. Following each respiratory trial, each lobster was transferred to a 100 ml container and offered a pre-weighted pellet for 2h. The uneaten fraction was collected, filtered, and dried for feed intake estimation. Wet weight and carapace length of individual lobsters were measured at the end of the experiment.

Results:

Individuals were attracted to all experimental diets and actively fed. Protein content had a significant effect on the growth rate. In the group of animals fed 40P diets, a larger contribution of carbohydrate energy resulted in significantly better growth than when non-protein energy was mainly derived from lipid (Fig. 1). Higher protein levels in the diets prolonged the time to reach peak SDA, although no statistical differences were detected in the duration, peak, or magnitude of the SDA. There was a tendency for lower values in animals fed low protein and high lipid diets (Fig. 2), possibly as a result of significantly reduced feed intake in these groups

Discussion:

The positive effect of protein content on SDA response agrees with previous studies showing that SDA increases with the relative protein content of a meal (Whiteley *et al.*, 2002). Also, the smaller the size of the meal, the lower the assimilation and digestion metabolic costs (Secor, 2009)the metabolic response that accompanies meal digestion has been characterized, theorized, and experimentally studied. Historically labeled \"specific dynamic action\" or \"SDA\", this physiological phenomenon represents the energy expended on all activities of the body incidental to the ingestion, digestion, absorption, and assimilation of a meal. Specific dynamic action or a component of postprandial metabolism has been quantified for more than 250 invertebrate and vertebrate species. Characteristic among all of these species is a rapid postprandial increase in metabolic rate that upon peaking returns more slowly to prefeeding levels. The average maximum increase in metabolic rate stemming from digestion ranges from a modest 25% for humans to 136% for fishes, and to an impressive 687% for snakes. The type, size, composition, and temperature of the meal, as well as body size, body composition, and several environmental factors (e.g., ambient temperature and gas concentration. Therefore, feed intake observed for low protein - high L:CHO ratio diets would explain not only the lowest performance in terms of growth but also the smaller SDA response. Moreover, the decreased SDA response in 40P diets could be indicative of a decreased digestibility and assimilation of those diets. Growth and SDA results from this study corroborate the hypothesis that juvenile European lobster requires a minimum of 500 g/Kg protein content in their diet. This level agrees with the dry matter protein content reported by Powell *et al.* (2017) supporting the idea that diets should meet the organism biochemical composition. Our study showed that it is viable to grow E. lobster juveniles on formulated dry feeds without compromising their metabolism and growth. High protein is a requirement; however, its inclusion can be reduced when compensated with moderate carbohydrate levels. Reducing protein inclusion is particularly important taking into account the need for more sustainable formulated feeds.

THE DEVELOPMENT OF AQUACULTURE IN THE CANARY ISLANDS: NEW PERSPECTIVES AFTER THE PUBLICATION OF THE "PROAC" AND THE "NEW CANARY AUTONOMY STATUTE"

Inmaculada González Cabrera, Elena Proietti, Ricardo Haroun Tabraue

University Professor in Law, ULPGC (TOTMA)
Proietti, Elena
Doctor-Researcher MarSP Project (TOTMA)

Aquaculture is an economic activity that is sustainable and respectful of the marine environment, since, in its exploitation, it favours regeneration, the development of fishery resources, the protection of marine protected species and human health (against plastic pollution that affects fish in the open sea).

In fact, thanks to aquaculture it is no longer necessary to catch or kill fish in the open sea, which may affect, even accidentally, to those others fish that are trapped in nets and are not suitable for food, especially those species that are protected. On the other hand, thanks to the cultivation of fish, aquaculture can satisfy the human needs of food (the average consumption of current marine products is 23.1 kg per person, of which 24% comes from aquaculture).

Despite the previous statement, an **orderly planning** is necessary because both the inadequate and lack of planning can generate a degeneration or imbalance of marine ecosystems motivated by the organic waste released from the cages and other facilities that are located in the sea, as well as, by the interference of human activity in the natural development of the marine environment. Because of that, it is essential to make an adequate aquaculture planning in the Canary Archipelago.

In the scope of the MarSP Project, indeed, an important part is reserved for the management of the aquaculture of the **Canary Sea**, with the aim of developing a respectful planning **of the principles and environmental limitations of the Directive n. 89/2014 (EU)** and, at the same time, **appropriate to the interests of entrepreneurs and researchers**.

In this line, **it is appreciable the effort of the Canary Islands Regions to renewal and adaptation to European demands**, thanks to regulatory changes of great interest such as the approval of **the new Statute of Autonomy of the Canary Islands** and the enactment, also, of the new **Regional Plan of Ordination of the Canary Islands Aquaculture** (PROAC). In this framework, the foundations are laid for a new scenario more current and adapted to the new reality.

In spite of this, however, the new ordination does not manage to solve with agility the problems encountered by entrepreneurs to access the aquaculture sector, basically because the new regulation is linked to the existing one, without clarifying its coherent application and clarity, and without the adequate responses to the new needs that arise in this sector. As it will be shown, indeed, the procedures are complex, long in time and above all, at times, contradictory to each other.

These problems will be the object of analysis in the present work, taking into account **the great opportunity that this sector supposes for the Canary Islands**, given its strategic geographical position and its vast marine resources, in order to be able to develop it in an increasingly constant and efficient way, so that this region can become a standard-bearer of this type of company internationally.

Legal Framework: Aquaculture in the Canary Islands

The Autonomous Community of the Canary Islands has such competence in accordance **with article 131, paragraph 3, of the Organic Law 1/2018, of November 5, of the reform of the Statute of Autonomy of the Canary Islands (hereinafter EAC),** according to which corresponds to the Autonomous Community of the Canary Islands competence in matters of activities in the maritime areas defined in Article 4 of the same Statute, which includes, in any case, the planning, management, management of shellfish and aquaculture, as well as the facilities destined to these activities. It is the responsibility of the Island Councils to perform executive functions in aquaculture and marine farming (Article 70.2 ñ of the EAC).

According to **article 131.4 of the EAC**, the Autonomous Community of the Canary Islands, without prejudice to those that may correspond to the State, has the exclusive competence in internal waters to delimit and declare protected areas of fishing interest, as well as to establish zones of special interest for shell-fishing, aquaculture and recreational, sports and ecotourism activities.

(Continued on next page)

In particular, with regard to aquaculture, the aforementioned **Law 17/2003 establishes that the Regional Plan for the Management of Canarian Aquaculture** (PROAC; *Plan Regional de Ordenación de la Acuicultura de Canarias*; original name) will be configured as an instrument for the management of aquaculture activity in the Autonomous Community of the Canary Islands, and will to be prepared by the Ministry of the Canary Islands Government responsible for fisheries

This norm was developed **by Decree 102/2018, of July 9,** which definitively approves the Regional **Plan for the Management of Aquaculture of the Canary Islands** (hereinafter, PROAC), norm that currently establishes the general management of aquaculture in the Autonomous Community of the Canary Islands and, specificall , the zones and species of interest for marine crops, the areas and prohibited species, as well as, the technical characteristics and the conditions of the exploitations.

Regarding the authorization procedures or concessions for the development of the aquaculture activity, it is necessary to take into account **the Decree 182/2004, of December 21,** which approves the Regulation of the Fisheries Law of the Canary Islands, as it is which continues to regulate the procedure for granting aquaculture concessions and the procedure to obtain the pertinent authorizations, the procedures can be activated by the stakeholders.

Therefore, and in response to what has been said, in practice the aquaculture activity in the Canary Islands is regulated in accordance with the following rules:

1) Regarding the authorization procedures or concessions for the development of the aquaculture activity, the **Decree 182/2004, of December 21, which approves the Regulations of the Fisheries Law of Canary Islands**, that continues regulating the procedure of granting aquaculture concessions and the procedure to obtain the pertinent authorizations.

With respect to the obtaining of the concession and/or authorization qualifying titles, the above-mentioned **Decree 182/2004, of December 21**, establishes, in its Title IV:

- The procedure for granting aquaculture concessions (Chapter I)
- The procedure for granting authorizations (Chapter II);
- The area of occupation (Chapter III);
- The constitution and composition of the Regional Aquaculture Commission (Chapter IV);
- The Register of Aquaculture Holdings (Chapter V).

2) Considering the location of the cages, the arable species and other technical measures specifically related to the aquaculture companies, it is necessary to take into account the **PROAC which, for its part, orders**:

- Areas and species of interest for marine crops;
- prohibited areas and species and technical characteristics;
- the conditions of the farms.

The PROAC regulates the areas and the keys species for the marine cultures, the areas and the prohibited species, and the techniques features, and the farms conditions.

According **to art. 22 of the PROAC**, in general, for the establishment of an establishment for aquaculture, will be mandatory:

* The delimitation of a Zone of Interest passes the Aquaculture (Z.I.A.);
- Ordering in detail the area by delimiting parcels. In addition, it will be necessary to specify the maximum productive capacity per parcels and the area of occupation of each of them, the species to be cultivated and the type of establishment, these two last determinations being of nature.
- However, for the cases of aquaculture authorizations for research/experimentation and/or training in the Z.I.A., they may be granted without the need for detailed management;
- Obtaining qualifying licenses and / or authorization, required by the Fisheries Law of the Canary Islands depending on the purpose intended; marketing, research / experimentation, training or repopulation.

Problems and possible solutions

The final part of our intervention will focus on identifying the main problems of the Canarian legislation thus conceived and proposing some possible solutions.

(Continued on next page)

In general, we can point out that the procedure required for entrepreneurs interested in investing in aquaculture in the Canary Sea seems well structured and updated (as far as the PROAC is concerned), but it is a bit complicated.

A. On the one hand, it is necessary to request authorizations or concessions according to legislation dating back to 2004. However, at the same time, in order to decide where the aquaculture companies can be installed and which species to grow, a compatibility *favourable report* between the project to be developed and the PROAC is indispensable.

We must also point out that within the PROAC, further authorizations or certificates are required (among them, the *environmental impact assessment*) for certain forms of aquaculture business, aggravating the procedure required of businessmen with the addition of many other complex formalities.

The regulatory options seem to be coherent, but, in any case, it would be desirable that the Canarian legislation be updated also with regard to the authorization procedures, to simplify the structured procedure and divided into different sectors, and as regards the new European targets set in the Directives enacted in recent years on biodiversity, the environment and the fight against climate change

B. It should also be noted that after the publication of the new **EAC, the boundaries of the Canary Sea were modified (Organic Law 1/2018, of November 5, article 4, second paragraph).** This means that it would be advisable to update the aforementioned Law 17/2003 and Decree 182/2004 on the basis of the new frontiers, especially in those articles that delimit the space dedicated to aquaculture, so that there is no confusion in the application phase current.
C. Another problem is about the difficult of introducing new cultivable species not included in the PROAC. It would be desirable to establish the formulas and procedures to evaluate the introduction of the cultivation of new species that are not included in the PROAC, provided, of course, that they do not generate any danger to the ecosystem, as demonstrated by the new scientific advances
D. Finally, we have received proposals from entrepreneurs interested in constructing aquaculture plants in the open sea, but it seems that the current legislation foresees this possibility, which is having a great result abroad.
E. Finally, we must insist on the effects of the environmental impact study required by **Law 9/2006, of April 28, modified and updated in 2013,** but in which the necessary coherence with this modification is not appreciated, due to the documents and annexes of the PROAC are calibrated in accordance with the 2006 law.

NOVEL INSIGHTS INTO SEX-RELATED GENES IN THE COMMON LITTORAL SHRIMP *Palaemon SERRATUS* BY GONADAL TRANSCRIPTOMIC ANALYSIS

Inés González-Castellano[1]*, Chiara Manfrin[2], Alberto Pallavicini[2], Ana M. González-Tizón[1], Andrés Martínez-Lage[1]

email: ines.gonzalez.castellano@udc.es

Introduction

The common litoral shrimp *Palaemon serratus* is an economically important decapod resource in some European communities (Fahy et al. 2006). Aquaculture practices prevent the genetic deterioration of wild stocks caused by overfishing and at the same time enhance the production. The biotechnological manipulation of sex-related genes has the proved potential to improve the aquaculture production (Ventura and Sagi 2012). However, since the lack of genomic data about *P. serratus* hinders the application of any genetic manipulation-based technique, a depth-understanding about the genetic factors underlying the sexual and reproductive development of this species is mandatory. The aim of this study was to reveal candidate genes featured in sex determination, sex differentiation and gonadal development processes using a high-throughput sequencing approach.

Material and methods

Gonads from three adult females and three adult males were removed and total RNA was extracted to prepare three ovary and three testis cDNA libraries, i.e. three biological replicates per sex. Libraries were sequenced using the HiSeq 4000 PE100 platform (Illumina). A reference gonadal transcriptome was obtained by *de novo* assembly both ovary and testis clean reads together. Functional annotation of the resulting transcriptome was conducted and differential expression analyses were performed between the ovary and testis samples to identify sex-related genes with sex-biased or sex-specific expression patterns.

Results

A total of 224.5 and 281.1 million paired-end reads were produced from ovary and testis samples, respectively. *De novo* assembly yielded a transcriptome with 39,186 transcripts. The 29,57% of the transcriptome retrieved at least one annotation and 11,087 differentially expressed genes (DEGs) were detected between ovary and testis replicates. 6,207 genes were up-regulated in ovaries meanwhile 4,880 genes were up-regulated in testes. Candidate genes to be involved in sex-determination, sex-differentiation/differentiation and gonadal development were found in the transcriptome. These sex-related genes were discussed taking into account whether they were up-regulated in ovary, up-regulated in testis or not DEGs between gonads and in the framework of previous findings in other crustacean species

Discussion and conclusion

This work encompasses the first large-scale RNA-Seq and comprehensive transcriptome analysis of *Palaemon serratus* gonads. This dataset will surely facilitate further research into the reproductive biology of this shrimp. Specificall , a wide inventory of candidate sex-related genes is discussed, being the first time that sex-related genes have been addressed in a *Palaemon* species. Relevant findings that might shed light about the evolution of sex-regulators in crustaceans are reported. Moreover, we highlight some genes that could be targets towards investigating future aquaculture applications for *P. serratus*, mainly doublesex- and mab-3-related transcription factor 1 (Dmrt1), insulin-like androgenic factor (Iag) or vitellogenesis genes such as vitellogenin (Vg) or vitellogenin receptor (VgR) among other candidates.

Introduction

Early maturation of Atlantic salmon *Salmo salar* has been a major source of economic loss for farmers (Good and Davidson, 2016), as precociously developed fish often exhibit decreased growth and feed conversion efficiency (McClure et al., 2007), reduced product quality (Aksnes et al., 1986), and increased susceptibility to opportunistic microorganisms (St-Hilaire et al.,1998). The initiation of sexual maturation can be difficult to prevent, given the numerous factors, such as photoperiod, temperature, fish size, growth rate, nutritional status, and genetics, that can influence the onset of puberty (Taranger et al., 2010). Early sexual maturation has been particularly problematic in land-based, closed containment recirculation aquaculture system (RAS) facilities raising Atlantic salmon to market size (Good and Davidson, 2016), with reported early maturation ranging from 2% to 100% of the salmon populations raised at seven RAS facilities. With increased investment in land-based smolt and post-smolt production facilities, and with a recent focus on carrying out land-based salmon production in freshwater (versus brackish or seawater), it is critical to gain a solid understanding of the environmental influences of maturation in freshwater RAS

Materials and methods

In a series of three long-term studies, we investigated various photoperiod regimes, feeding rates, and ploidy (i.e., diploid vs. triploid) as Atlantic salmon were raised in freshwater systems from fry to 1,000 g in size and beyond. Briefl , in *Study 1* we investigated three photoperiod regimes – LD24:0 (i.e., 24 hours light, zero hours dark), LDN (simulated natural photoperiod, Bergen latitude), and LD12:12 beginning at 100 g. All fish were initially cultured in 12 replicate 0.5 m^3 tanks in a flow through system, prior to transfer to a partial reuse system consisting of three 10 m^3 circular dual-drain culture tanks, microscreen filtration and gas conditioning (stripping tower, low-head oxygenator) after fish achieved a mean weight of 100 g. Each culture tank received the aforementioned photoperiod treatments until fish reached a mean weight of 1,000 g, after which all fish were marked and stocked into a single semi-commercial scale RAS under LD24:0 and raised to a harvest size of 4 kg. In *Study 2*, we assessed LD24:0 and LDN photoperiods in factorial combination with 100% (full ration, FR) and 60% (half-ration, HR) feeding regimes. Treatments were applied in 12 replicated 0.5 m^3 tanks in a flow-through system, prior to marking and transfer of all fish at 500 g (mean weight of best performing group) to a single partial reuse system under LD24:0, FR conditions, where fish were raised to 1,000 g mean weight. In *Study 3*, we carried out a second factorial-design study investigating S_0 vs. no-S_0 winter photoperiods and ploidy (diploid vs. triploid) in all-female Atlantic salmon. Diploid and triploid salmon either received or did not receive a winter photoperiod (6 weeks LD12:12, followed by a return to LD24:0) while cultured in 12 replicated 0.5 m^3 tanks in a flow-through system. All fish were transferred to a partial reuse system and raised to 1,000 g, after which they were marked and transferred to a single semi-commercial scale RAS under LD24:0 photoperiod. At the time of abstract submission, these fish are approximately 3 kg mean weight, and will be raised to 4-5 kg harvest size.

(Continued on next page)

Results

At the time of abstract submission, results of numerous physiological analyses remain forthcoming. Major results available at this time include: *Study 1* LDN photoperiod was associated with reduced growth rate up to 600 g, and all photoperiods demonstrated high levels of maturation by harvest size, with the least maturation observed in the LD24:0 treatment group; *Study 2* FR groups demonstrated superior growth performance, with best condition factor and growth observed in the LD24:0/FR group and poor condition factor observed in both HR groups; and *Study 3* no maturation has so far been observed in triploid cohorts, while all-female diploid salmon are demonstrating approximately 20% maturation based on morphological signs (presence of ovipositor, ventral softness). A comprehensive assessment of maturation including gonadosomatic index quantification will be carried out at harvest. Full results for all three studies will be presented at Aquaculture Europe 2019.

CARBON DIOXIDE STUNNING OF RAINBOW TROUT (*Oncorhynchus mykiss*): THE EFFECTS OF DIFFERENT SEASONAL TEMPERATURES AND THE RELIABILITY OF VISUAL INDICATORS OF CONSCIOUSNESS

J. Bowman, P. Hjelmstedt, N. Van Nuland, & A. Gräns*

Department of Animal Environment and Health, Swedish University of Agricultural Sciences, Box 461, 405 30 Gothenburg, Sweden
Email: albin.grans@slu.se

Introduction

Humane slaughter requires that the fish is stunned before being bled. The ideal stunning method before slaughter is one that induces instantaneous and long-lasting unconsciousness that allows staff sufficient time to kill the animal (Van de Vis et al. 2003). A fundamental limitation when assessing the effectiveness of different stunning methods used for fish is the difficulty of determining when consciousness is lost (Kestin et al., 1995; Lambooij et al., 2010). The overall objective of this study was to monitor how animal welfare is safeguarded during the stunning of rainbow trout (*Oncorhynchus mykiss*) at different acclimation temperatures using narcosis with carbon dioxide (CO_2). Specificall , we investigated if the time it takes for a fish to lose consciousness is affected by the seasonal temperature and how reliable visuals indicators are at identifying the moment when a fish loses consciousness

Material & Methods

For this, we visited a Swedish fish farm and recorded visual indicators of consciousness (*i.e.* loss of equilibrium, ventilation and eye-roll reflex) in rainbow trout during narcosis in a water bath fully saturated with CO_2. This was done on three different occasions over a year so that fish acclimated to 2, 8 and 14°C were included in the study. In addition, a complementary laboratory study was conducted to verify that the behavioral indicators in part 1 of the study did indeed function as reliable indicators of unconsciousness in rainbow trout. Here, we used a newly developed non-invasive technique that allows measurements of brain activity by electroencephalography (EEG) in rainbow trout with electrodes attached to the head of the fish with a silicone cup. EEG allowed us to monitor visual evoked responses (VERs) from light stimulation that are present while a fish is conscious and gradually dissipate as brain activity (*i.e.* consciousness) is lost (Kestin et al., 1995). By monitoring brain activity via VERs and behavioral indicators of consciousness simultaneously we investigated how accurate different visual indicators are at determining the loss of brain function in rainbow trout during CO_2 narcosis.

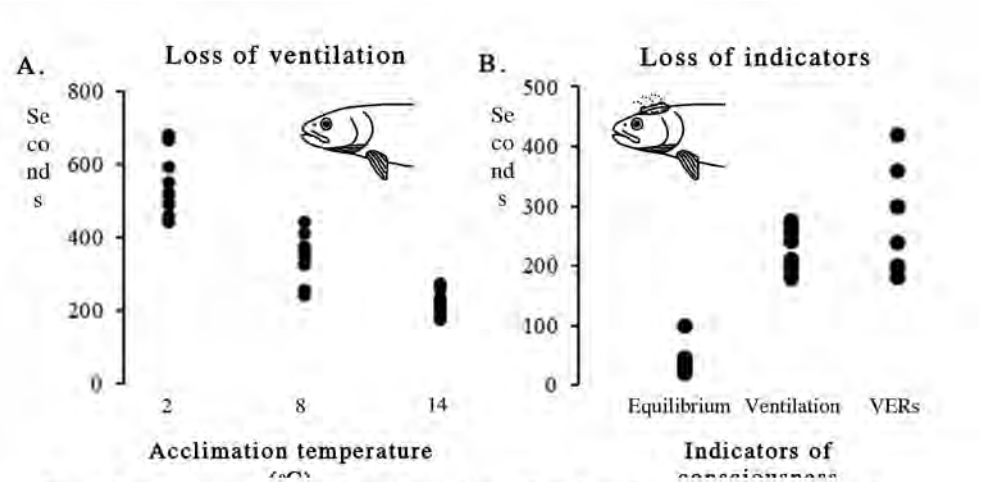

Fig. 1. Loss of consciousness during stunning with carbon dioxide. Times until ventilation is lost for individual fish at three different season temperatures (A). Times until the behavioral indicators (equilibrium and ventilation) and brain activity (Visually Evoked Responses on the EEG) are lost for individual fish (B).

Discussion & Conclusion

(Continued on next page)

Results

Low water temperatures significantly delayed the time it took for all visual indicators to be lost (figure 1A). When stunned with CO_2 during winter (2°C) it took up to 2.25, 6.0 and 11.3 min for the trout to lose equilibrium, eye-roll reflex and ventilation, respectively. While during summer (14°C) these times were shorter with only 1.4, 2.5 and 4.6 min required for loss of equilibrium, roll reflex and ventilation, respectively. Furthermore, our laboratory study, conducted at 10°C, showed a poor relationship between the visual indicators of consciousness and loss of brain function (VERs). The VERs were lost up to 6.5 and 3.5 min after the fish had lost equilibrium and ventilation, respectively (figure 1B). In both experiments, trout exhibited immediate aversive reactions after being submerged in the CO_2 water bath, including violent escape attempts and rapid swimming, which continued until equilibrium was lost.

Discussion & Conclusion

Our results show that CO_2 narcosis is not an ideal stunning method before slaughter as it does not induce instantaneous unconsciousness and causes aversive behaviours and that these problems are even further aggravated by low environmental temperatures. These results are not surprising considering that CO_2 narcosis was deemed unacceptable as a stunning method for fish by the European Food Safety Authority (EFSA) already in 2004. Yet, in Sweden, it is still the dominating method used for rainbow trout and other species. Furthermore, our results show that the visual indicators of consciousness that are currently used to assess if fish are unconscious are unreliable and if used risks that subsequent exsanguination and evisceration occurs in paralyzed but conscious animals. The results highlight that behavioral indicators are not sufficient to determine unconsciousness in trout during CO_2 narcosis. To safeguard the welfare of fish during stunning it is crucial to evaluate stunning methods using EEG to detect unconsciousness rather than relying on visual indicators alone.

FISH FARM SENSORS AND THE INTERNET OF THINGS

J. Grant[1], R. Filgueira[2], M. Burke[1], C. Stockwell[1], E. Milos[3], L. Torgo[3], F. O Donncha[4]

Precision aquaculture ((Føre et al 2018) involves a variety of sensors used to gain insight into the farm environment, make decisions which optimize fish health, growth and economic return, and reduce risk to the environment. This trend parallels developments in agriculture (Wolfert et al. 2017) where sensors and other observing technologies lead to enhanced insight into crop health as well as animal welfare. For aquaculture, this includes sensors specific to monitoring of oceanographic conditions as well as technology such as acoustic fish tags to detect fish movement and behaviour. Aquaculture has become part of the Internet of Things defined as interconnected sensors which store and serve data, interact with other sensors and devices, and provide decision support. Sensor networks produce huge volumes of information or Big Data. We have initiated extensive research in this area with multiple partners including fish farmers (Cooke Aquaculture; Cookeseafood.com) and the ocean technology company RealTime Aquaculture (rtaqua.com). In addition, a new research network DeepSense (deepsense.ca) has been established at Dalhousie in partnership with IBM to provide analytics to ocean industries (Fig. 1). We are also investigators in Horizon 2020 project GAIN (Green Aquaculture Intensification; unive.it/pag/33897), in which similar sensor deployments are underway in Spain, Scotland, and Norway. Hundreds of sensors have been deployed in Canada at multiple salmon farms. Sensors are primarily observing oxygen and temperature with data provided in real time to the cloud and to mobile devices. Additional data on fish position is provided by the CageEye acoustic system (cageeye.no) as well as individually tagged fish. Our research objectives include resolving (a) scales of variation in sensor deployment, (b) management of Big Data and use of data analytics to mine predictions related to fish growth and health, (c) development of additional sensors for understanding the aquaculture ecosystem, and (d) integration of data into coastal information portals and wider metrics of coastal health. Since we are in the initial stages, an overview of the ongoing research is presented as well as initial results of sensor outputs at Nova Scotia fish farms

RISK ASSESSMENT OF NORWEGIAN SALMON FARMING – A NEW APPROACH

Ellen Sofie Grefsru [*1], Terje Svåsand[1] and Lasse Berg Andersen[2]

[1]Institute of Marine Research, Nordnesgaten 50, 5218, Bergen, Norway
[2]Prendo, PO Box 8034, 4068 Stavanger, Norway
E-mail: ellens@hi.no

Norwegian salmon aquaculture has since its pioneering days in the 1970s, grown into a significant industry. Of the total aquaculture production of nearly 1.3 million tons in 2017, Atlantic salmon counted for 94.5% and is one of the country's largest export industries by economic value.

A total of 1325 active licenses, including production of eggs and juveniles and open-cage production, is distributed along most of Norway's coastline. In 2018 the standing biomass in the salmon farms varied between about 600 000 and 800 000 tons during the yearly production cycle. Such substantial amount of fish represents on one hand a potential hazard to the environment but on the other hand constitute an efficient method for producing valuable seafood. Understanding the risk situation is essential for both local and national authorities to enable knowledge-based governance.

Annual risk assessments of the environmental impacts of Norwegian salmon farming have been conducted by the Institute of Marine Research and collaborators since 2010, and have evolved over time in parallel with increased knowledge of the risk factors. This includes effects of salmon lice and other diseases on wild salmonids, genetic introgression of farmed salmon in wild salmon populations, local and regional impacts of nutrients and organic loads, effects of contaminants and drugs, environmental impacts related to the use of cleaner fish in salmonid aquaculture, ecological impacts on wild fish populations and mortality as well as fish welfare of the farmed fis

Several different approaches have been suggested and discussed for risk analysis of marine ecosystems and marine aquaculture activities. Risk analysis, as a scientific field is young, not more than 30-40 years old. Risk assessment in the aquaculture industry is, however by comparison still in its infancy. The approaches adopted to analyse aquaculture-risk are for the most part driven by statistical analyses of available hard data where inclusion of expert knowledge and opinons are thought to introduce subjectivity and uncertainty to the end risk results. Lack of hard data is common and may thus lead to inability to perform a risk assessment on the subject at all. The objective of risk assessments is, however, not to accurately calculate risk, but to provide the best foundation for risk-based decisions.

A new risk assessment framework is needed that is tailor-made for risk-based governance of aquaculture and in line with the new perspectives on risk analysis. Documenting knowledge strength, evaluating assumptions and systematizing risk sources, consequences and associated uncertainties in hierarchical and intuitive structures contributes to risk understanding and improved decision making. Bayesian Networks allow combinations of hard data and expert knowledge on the input side and highlights and documents the results in terms of hierarchical structures of risk sources and consequences.

Contrary to some other methods such as deep learning or purely data-driven methods, Bayesian networks combines data and expert knowledge as well as support explanation of results. The graphical nature of the models is intuitive to the domain experts and other stakeholders and it is possible to explain why a specific result is produced by the model. Due to the modular construction of the model, it can be adjusted using local changes only.

In this talk we present the method used for the risk assessment of environmental impact of fish farming in Norway in 2019.

EXPLORATION OF THE QUALITY OF REARED VS. WILD GILTHEAD SEABREAM: PROFILING THE SENSORY DIFFERENCES OCCURING BETWEEN POPULATIONS

Niki Alexi[1*], Derek V. Byrne[1] & Kriton Grigorakis[2]

[1] Food Quality Perception & Society, Department of Food Science, Aarhus University, Kirstinebjergvej 10 DK-5792 Årslev, Denmark
*niki.alexi@food.au.dk
[2] Institute of Marine Biology, Biotechnology and Aquaculture, Hellenic Centre for Marine Research, Anavyssos, 19013, Athens, Greece

Introduction

Gilthead seabream (*Sparus aurata*) is one of the main fish species cultivated in EU, accounting for approximately 14% volume of the total finfis aquaculture production. Due its great share in EU aquaculture, research has focused in exploring the quality features of reared counterparts, using as a reference for comparison wild ones, since consumers perceive wild fish as having a favourable quality to reared ones. While the research in this area is quite extensive, it mainly focuses in the nutritional quality while only scarce data exist in terms of the sensory differences of reared and wild gilthead seabream (Grigorakis, 2017). However, acquiring a full assessment of the sensory profile is considered crucial, since it has been shown that small changes in aroma and flavour modalities can have a higher impact in consumer preferences, than that of fish texture modality (Alexi, Byrne, Nanou, & Grigorakis, 2018). The aim of the current study was to explore the proximate composition, fatty acid (FA) profile and provide a full sensory profile, including aroma, taste, flavour and texture, of reared vs. wild gilthead sea bream.

Materials and Methods

Study design & sampling: The wild and reared gilthead seabream groups consisted of 12 specimens each. For each specimen, one fillet was kept for proximate composition and FA analyses (-20°C) and the other for sensory analysis (-80°C). The average weight of the wild and reared seabream fillets was 21g (±4.8) and 55.1g (±8.9), respectivel .

Analyses: Proximate composition analyses were performed according to the standard AOAC (2005) methods. FA composition was analysed after methylesterification by GC-FID. The oven-cooked fish samples were profiled via sensory generic descriptive analysis (DA). Details on the sample preparation and DA processes can be found in Alexi, Nanou, et al. (2018). Final evaluation of samples was performed in duplicates, in individual sensory booths by 7 expert panellists in fish evaluation, using a 15cm scale for the evaluation the attributes' intensities.

Results

The proximate and FA composition of the fillets is presented in Table I.
All proximate composition variables varied significantly (P <0.05), whereas significant variations were found in all FA groups with the exception of polyunsaturated FA (PUFA).

The odour, taste, flavour and texture profile of the reared and wild gilthead seabream specimens is presented in Figure 1. Specimens of different rearing origin were discriminated by their odour and texture, whereas the taste profiles were similar between wild and reared specimens. Some differentiations were identified between the flavour profiles of counterparts of different rearing origin, however the variations were not found significant

Discussion-Conclusion

Higher fat and protein content in reared seabream counterparts, compared to wild

- No differentiation in PUFA proportions between reared and wild counterparts. Higher ARA, EPA, DHA proportions and n-3/n-6 ratio in the wild specimens
- Distinctive shrimp odour in wild gilthead seabream specimens. Reared specimens characterized by boiled potato/ vegetable aroma and fish oil aroma as well as a juicier texture and oil coating sensation, when compared to wild

(Continued on next page)

Table I: Mean Values and standard deviation of fillet proximate composition and FA profile of wild and reared gilthead seabream. Variable significance is calculated by 1 way ANOVA performed with Tukey post-hoc test at 95% confidence level.

Introduction

Branched-chain amino acids (BCAAs), consisting of Valine (VAL), Leucine (LEU), and Isoleucine (ILE), are a group of dietary essential amino acids (EAA) (NRC, 2011). In humans, BCAAs have been linked to an increase in muscle growth and performance, and reduction in muscle loss (Holeček, 2018). The metabolism of BCAA in other vertebrates show they are metabolised differently to other EAA with the first step in catabolism occurring in extrahepatic tissue. This poster will be examining the digestibility of the experimental diets enhanced with BCAAs and the post-prandial plasma responses of free amino acids (fAAs) in *Salmo salar* (Atlantic salmon) over a 24h period.

Materials and methods:

Five extruded isoenergetic and isonitrogenous diets (4mm ø) were formulated and manufactured. The basal diet was supplemented with 20g kg^{-1} of each BCAA (LEU, ILE, VAL) in a crystalline form and yttrium oxide (2g kg^{-1}), as a marker for digestibility analysis. Thirty-five Atlantic salmon post-smolts, averaging 263.13g (±24.52), were stocked in each tank and allowed to acclimatise for one week on their allocated diets. Fish were fed to apparent satiation, with uneaten feed being collected to estimate the daily intake in each tank. Fish were starved for 24 hours prior to assessment of their postprandial responses. Two hours before feeding, three fish were euthanised to establish baseline. Feeding resumed on test diets at 1.25g fis $^{-1}$. Blood and tissue samples were then taken at 2h, 4h, 8h, and 24h postprandially from three fish per tank at each time point. In addition, at the 8hr time point, all but three fish were anaesthetised with MS222 to manually strip faeces for further assessment of diet digestibility. This entire procedure was conducted three times over a three-week period to obtain replication through a blocking approach, where fish were randomly reallocated amongst the five tanks

Blood samples were taken from the caudal vein and centrifuged, after which the plasma was removed and stored at -70°C. An adapted method was used in the analysis of the plasma fAAs. Samples were then derivitised according to the Waters AccQ•Tag derivitisation method. The AA composition in feeds was analysed using an adapted Waters feed hydrolysis method and run at two varying temperatures on a CEM Mars 6 microwave digester Results were statistically analysed using analysis of variance (ANOVA), followed by a Fishers LSD planned comparisons post-hoc test.

Results and Discussion

Initial AA analysis of the experimental feeds confirmed the expected levels of increased BCAAs specific to each diet. The basal diet values comprised of LEU 4.42%, VAL 2.43% ILE 2.22%. In contrast, the LEU diet contained 5.86% VAL diet 4.00% and ILE diet 3.68%. The mixed BCAA diet contained LEU 4.90% VAL 2.23% and ILE 1.98%. No significant differences in feed intake were observed between the different treatments during the acclimation periods. The preliminary plasma fAAs results demonstrated that the BCAAs had a post-prandial peak concentration in the plasma at the 4h sampling point before then subsiding to just above baseline by 24h. The treatment plasma fAA levels were compared against that of fish fed the basal diet, allowing for visualisation of the treatment specific fAA effects (Figure 1). The sudden and elevated peak times of plasma concentrations may be due to the inclusion of the crystalline AAs (cAAs) and rapid absorption times. Other studies have shown peak times of 12h with returns to baseline up to 48h post-feeding. As found in this study, supplementation of ILE in *Oncorhynchus mykiss* (rainbow trout) increased concentrations of VAL and LEU for up to 24hr post-feeding in other trials (Tantikitti & March 1995).

The levels of each of the added crystalline AAs peaked at 4 hours. This was similar to the peak time response seen in a study of the postprandial plasma fAA profile of *Lates calcarifer* (barramundi) when fed supplemental crystalline methionine (Poppi *et al.* 2019). However, in our study no significant variation in feed intake was observed among experimental diets, which contrasted observations of Comesaña *et al.* (2017) who reported significant variations in feed intake, with higher intake observed in VAL diets in comparison to a decrease in LEU diets.

Introduction

There is increasing focus on the effects of organic wastes produced by intensive aquaculture, and on solutions to reduce the pollutive impacts of marine farms worldwide. Integrated Multitrophic Aquaculture (IMTA) offers a natural means of converting the organic wastes of aquaculture activities into food inputs for the production of lower-trophic-level crops of commercial value, increasing both the environmental and economical sustainability of aquaculture (Troell et al., 2009).

The present study evaluated, for the first time, the potential co-culture of the sea cucumber, *Holothuria tubulosa,* and the sea urchin, *Paracentrotus lividus*. These species are good candidates for co-culture in IMTA systems, considering their feeding habits and high market value. Indeed, omnivorous animals, such as sea urchins, are traditionally considered to be relatively low-input and thus more sustainable market species. Instead, sea cucumbers are deposit feeders which are able to ingest sediment with organic matter produced by farm activities. *P. lividus* and *H. tubulosa* are two of the most commercially exploited echinoderms in Mediterranean regions and they are considered a delicious food with high market value. *P. lividus* gonads ("*roe*" or "*uni*") are luxury sea food, reaching prices of over 150 € kg^{-1}. *H. tubulosa*, as other sea cucumbers, is dried and exported to Asian countries where it is considered a culinary gourmet food reaching prices of above 100 € kg^{-1} (Purcell et al., 2012; Carboni et al., 2014). Therefore, this study was designed to evaluate an integrated mutitrophic aquaculture between these two species, directly feeding only the sea urchins a land-vegetable diet. The aim of this study was to demonstrate the possibility of developing a viable aquaculture of commercially important species of echinoderms in IMTA, with *P. lividus* as the primary species and *H. tubulosa* as an extractive species.

Materials and Methods

Thirty-six specimens of *P. lividus* and *H. tubulosa,* collected at S. Marinella in the central Tyrrhenian Sea, were employed in this experiment, which lasted three months (15 March-20 August 2018). The experiment was run in three aquaria of a RAS (Recirculating Aquaculture System). This rearing system, connected in tandem, guaranteed similar physio-chemical parameters: temperature (20±1°C); salinity (36±1‰); pH (8.20±0.12), and natural photoperiod. Each experimental aquariam contained 12 specimens of *P. lividus*, kept in holding baskets, under which we placed 12 specimens of *H. tubulosa* marked individually with micro tags. In this way, the sea cucumbers were free to ingest the sea urchin waste on the bottom of each aquaria, and we were able to monitor each specimen as a single statistic unit. During the experiment the same procedures were carried out on a daily and monthly basis. The daily routine consisted of feeding the sea urchins *ad libitum* with entire and raw land-based vegetables, such as soy, maize and carrots; however, before this feeding, we siphoned off

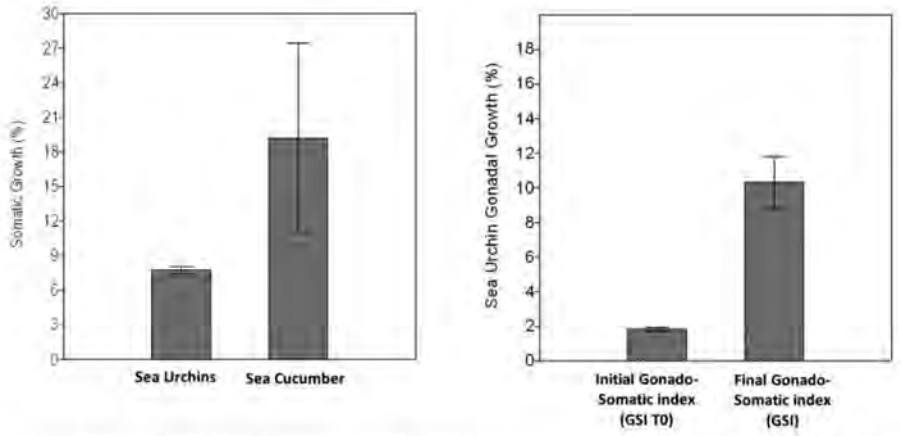

Figure. 1. Results of Gonadal Growth and Somatic Growth in *P.lividus* and *H. tubulosa*

(Continued on next page)

any leftover food and faeces produced the previous day. Every month, we measured the wet weight of each individual specimen of both species. At the end of the three month-long experiment, the efficiency of the diet in terms of **Somatic Growth Yield (SG%)**, for both sea urchins and sea cucumbers, and in terms of **Gonado-Somatic Index (GSI%)**, for sea urchins, were determined.

Results

During the three months of experiment, no mortality occurred in any aquaria and significant growth was obtained in the specimens of both species. In fact, positive somatic growths were achieved both for *H. tubulosa* and for *P. lividus*, at the end of the experiment (respectively 15.88% and 15.50%; Fig.1). Moreover, in *P. lividus,* the final wet weight of the gonads, calculated as GSI, was significantly higher (9.66%) than their initial wet weight (2.00%), estimated by a sub-sample at T0.

Discussion and Conclusion

Our study demonstrated that culturing the *P. lividus* sea urchin, using the *H. tubulosa* sea cucumber as an extractive-species in IMTA, is a promising avenue for developing a sustainable and profitable aquaculture. The results of this study highlighted that *H. tubulosa* is able to consume and assimilate sea urchin faeces waste when the latter were fed with vegetable foods. We obtained promising results in terms of survivorship and growth for both species, demonstrating the potential use of vegetables as an environmentally and economically viable alternative for co-culture of these species. The multitrophic integrated aquaculture among *P. lividus* and *H. tubulosa* showed, in this preliminary study, would have showed a potential for success in large scale co-culture of aquaculture applications. For example, the rearing of sea cucumbers and sea urchins in IMTA land-based systems could become cost effective due to for their high market price. In fact, the use of sea cucumbers could save reduce the treatment costs of sea urchin waste and, at same time, produce, at same time, high value sea food.

Introduction

In the last few decades there has been increasing interest in the development of sea urchin aquaculture as a sustainable alternative to satisfy market demand and preserve natural populations worldwide. Although the sea urchin's life cycle is already controlled in captivity, echinoculture is still largely dependent on wild-caught sea urchins (Baião et al., 2019). The main limiting factor for these farming activities is the slow growth rate: it takes 4-5 years for reared sea urchins to reach commercially viable size (Sartori and Gaion, 2016). Therefore, the future success and sustainability of commercial sea urchin aquaculture strongly depends on the development of suitable and cost-effective diets, specifically designed to maximize growth rate at the various stages of sea urchin's life cycle (Fernandez and Boudouresque, 2000). In this study, we investigated the effects of land-based vegetable diets, enriched with different ratios of fish meal (0%; 20%; 40%) in order to evaluate the best performance of three size classes of sea urchin *Paracentrotus lividus.* The aim of the experiment was to define, for each size classes of sea urchin, the best form of food (whole or extruded) and the best aliquots of fish meal to add as a nutritional integrator in terms of somatic and gonadal growth.

Materials and Methods

144 specimens of *P. lividus* - 48 in each size class - were employed in this four-month experiment (15 May - 20 September 2018). Size classes were composed of sea urchins falling into three different test diameter ranges: 15 - 25mm (juveniles); 25 - 35mm (sub-adults) and 45 - 55mm (adults). The experiment was run in a RAS system made up of 12 aquaria of 30 l each connected in tandem (4 for each size class). This rearing system guaranteed a flow rate of 120 l h^{-1} and ensured similar physico-chemical parameters: temperature (20±1°C); salinity (36±1‰); pH (7.95±8.05), and natural photoperiod. Sea urchins were individually marked with micro tags, so that each specimen could be monitored as a single statistic unit. The 48 sea urchins of each size classes were divided in 4 groups of 12 specimens, and each group was fed daily *ad libitum* with one of the four experimental diets: DVI (100% whole) vegetables, DE-0 (100% extruded vegetables), DE-20 (80% extruded vegetables, 20% fish meal), DE-40 (60% extruded vegetables, 40% fish meal). In each condition the leftover food and the faeces produced were collected daily, whilst the wet weight and test diameters were measured monthly. Gonads were collected in a sub-sample at the start of experiment and at the end were harvested in all sea urchins in each condition. From the four months of experimentation, it was possible to determine the efficiency of each diet in terms of Somatic Growth (**Total Somatic Growth (SG))** and Gonad Production (**Gonad Somatic Index (GSI)).**

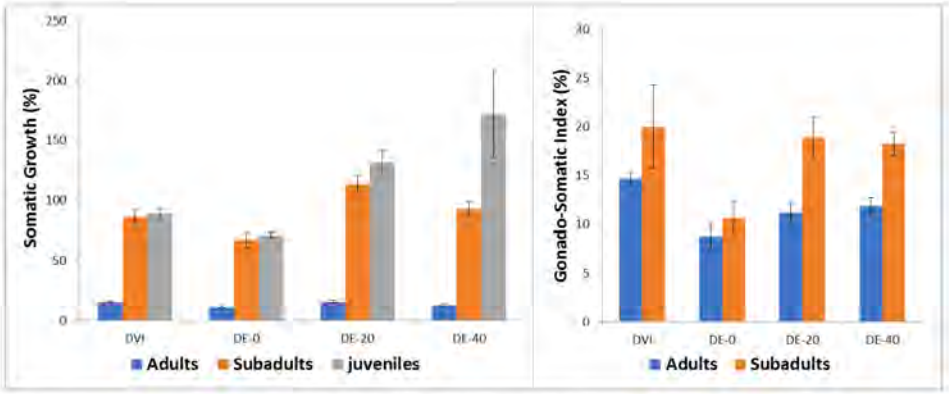

Figure. 1. Somatic and gonadal growth of the three size classes among the four different diets

(Continued on next page)

Results

Somatic and gonadic growth resulted in significant differences among the different diets and for the different size classes. Indeed, a significant difference in SG and GI was obtained between whole and completely extruded vegetable diets (DVI and DE-0) in all size classes. The highest somatic growth was obtained: in the juveniles with DE-40, and in both the sub-adults and the adults with DE-20 (Fig.1). Regardless of the size class, the somatic growth was lower with vegetable food than in the two fish meal-integrated diets. Conversely, the gonadal growth was largest in sea urchins fed on the vegetable (DVI) and low-fish diet (DE-20). In fact, the maximal gonad growth was obtained with DVI both in sub-adult and adult sea urchins (Fig.1).

Discussion and Conclusion

Terrestrial vegetables such as soy, corn and carrots proved to be a sustainable and economic basic food source for *P. lividus* aquaculture. Moreover, it was possible to estimate the optimal amount of fish meal necessary to achieve the best performance in terms of somatic and gonadic growth among the three size classes of *P. lividus*.

Sea urchin juveniles showed the best performance in both somatic and gonadic growth with the feed containing a high concentration of animal proteins (40%). This demonstrates that conditions with a high protein content are suitable for promoting a fast somatic growth during this stage. The sub-adult stage, where a repartition of somatic and gonadal growth energy is required, the best performance was found when using an intermediate level of fishmeal (between 20% and 40%). Finally, the adult sea urchins performed better when fed on whole vegetables food and low fish meal extruded food (20%).

Introduction

β-glucans are considered an immunostimulant that acts on fish non-specific defense mechanism. To date, several immunomodulatory influence of β-glucans has been documented on fish by many authors. However, very few studies have studied the effects of β-glucans administration on the fish skin mucosal immunity. As is known, skin of teleost fish represents one of the first barriers of defence against environmental factors like microorganisms, toxins and pollutants (Raeder et al., 2007) and since most of pathogens start the process of infection in the mucosal surfaces, the mucosal immune response plays an essential role in the course of the infection. In fact, the protective role of the skin mucus has been evaluated in several fish species with economic interest to aquaculture after bacterial challenge. However, few studies have reported the effect of β-glucans diets on the fish innate immune response after bacterial challenge. Therefore, the present *in vivo* study attempts to describe the immunostimulatory impact on several immune-related enzymes and bactericidal activity in plasma and skin mucus after bacterial challenge with *Aeromonas hydrophila* in Pacific red snapper fed diets supplements with glucans derived from *Yarrowia lipolytica* (N6), *Debaromyces hansenii* (Dh004) and *Saccharomyces cerevisiae* (Zymosan A as positive control) during 4 weeks.

Material and methods

Healthy Pacific red snapper (*Lutjanus peru*) (98 ± 18 g mean body weight and 16.3 ± 0.9 cm mean length) were obtained from hatched eggs and reared to the juvenile stage in the larviculture laboratory at CIBNOR. Fish were randomly distributed into twelve identical tanks (12 fish per tank) where the following groups were established in triplicate: 1) non-supplemented diet (control); 2) N6, diet supplemented with 500 mg Kg^{-1} of β-glucan N6 from *Yarrowia lipolytica*); 3) Dh004, diet supplemented with 500 mg Kg^{-1} of β-glucan Dh004 from *Debaromyces hansenii*; and 4) Zymosan A, diet supplemented with 500 mg Kg^{-1} of β-glucan Zymosan A from *Saccharomyces cerevisiae*. The fish were fed at a rate of 2% body weight day^{-1} during 4 weeks. Subsequently, the fish were challenged with a sublethal dose of *A. hydrophila* (1 x 10^8 cfu ml^{-1}). For that purpose, fish from each experimental group were anesthetized and intraperitoneally (i.p.) injected with 100 µl either PBS or *A. hydrophila*. Afterwards, injected specimens were reallocated and distributed into eight identical tanks (12 fish per tank) where four groups were established in duplicate (unchallenged and challenged) according to dietary treatments. Six fish were then sampled from each tank for blood (for plasma compilation) and skin mucus collection at 24 and 48 h after i.p. injection. The methodology of all immune-related activities is described in detail elsewhere (Guardiola et al. 2014; Reyes-Becerril et al., 2018).

Results

Our results revealed that the protease and antiprotease activities were unaffected by bacterial challenged in skin mucus of fish fed all experimental diets. Regarding SOD and CAT activities in skin mucus, the values of SOD activity decreased in challenged fish at 24 hours post-challenge respect to unchallenged ones whilst CAT activity not showed alterations between experimental groups. Interestingly, the bactericidal activity against *A. hydrophila* showed a decrease of challenged fish fed β-glucans supplemented diets respect to challenged fish fed control diet at 24 hours post-challenge. However, these alterations were reduced at 48 horas where any significant variations was observed. Skin mucus bactericidal activity against *Vibrio parahaemolyticus* not showed variations at both experimental times. However, the bactericidal activity against *Photobacterium damselae* exhibited a decrease in skin mucus of challenged fish fed β-glucans supplemented diets respect to control diet at 48 hours post-challenge.

(Continued on next page)

Regarding humoral immune-related enzymes, antiprotease activity not showed variations between experiments groups whilst protease activity decreased in challenged fish fed N6 and Zym A diets compared to unchallenged ones at 48 hours. Contrarily, peroxidase activity increased in challenged fish fed N6 and Zym A diets respect to the unchallenged ones at the same experimental time. Similarly, nitric oxide (NO) production increased in challenged fish fed N6 and Dh004 diets compared to the fish injected with PBS (unchallenged) at 48 hours post-challenge. The values of SOD activity decreased in challenged fish fed β-glucans supplemented diets respect to challenged fish fed control diet at 24 hours post-challenge whilst CAT activity not showed any variation between challenged and unchallenged groups. In the case of lysozyme activity, the values increased in the challenged fish fed control and N6 diets at 48 hours post-challenge respect to unchallenged ones. Finally, bactericidal activity against *A. hydrophila* and *Vibrio parahaemolyticus* increased in plasma from challenged fish fed all experimental diets at both sampling times.

Discussion and conclusions

These results confirm that β-glucans tested in this study, mainly the β-glucan N6 (from *Yarrowia lipolytica*), modulate positively the immune-related parameters measured in plasma and skin mucus of Pacific red snapper. Therefore, both β-glucans are beneficial for increasing the innate immune response and enhancing resistance against *A. hydrophila*, an opportunistic pathogen that severely restrict the development of aquaculture.

Introduction

Nodavirus (NNV) causes the viral encephalopathy and retinopathy disease (VER) in fish and represents one of the most serious problems in the modern aquaculture, producing high mortalities in larvae and juvenile stages in several fish species and being maternally transmitted to the progeny (Munday et al., 2002). Among the immunological pathways involved in fish viral defence most studies have dealt with the interferon pathway and much less with the cell-mediated cytotoxic (CMC) activity. The innate CMC is played by the nonspecific cytotoxic (NCCs) and natural killer (NK) cells whilst the specific CMC is played by cytotoxic-T lymphocytes (CTL), which are characterized by the presence of the CD8 coreceptor (reviewed by Fisher et al., 2006). In the NNV-susceptible orange-spotted grouper (*Epinepheluscoioides*), the NNV infection resulted in increased *cd8* mRNA levels as well as the number of CD8$^+$ circulating lymphocytes and the specifi CMC activity against NNV-infected cells, in a process that was dependent on the MHCI (Chang et al., 2011). By contrast, the expression of T cell receptor (*tcr*) and *cd8* genes in European sea bass (*Dicentrarchus labrax*) and Atlantic halibut (*Hippoglossushippoglossus*) after NNV infection was unaltered, suggesting that this specific CMC activity is not generated in all the fish species (Scapigliati et al., 2010; Patel et al., 2008). Based on this lack of gene regulation upon NNV infection in the European sea bass, one of the most important fish species for Mediterranean aquaculture and highly susceptible to NNV, we aimed to study the implication of the CD8 cells in their defence. Thus, we have generated a polyclonal antibody against the European sea bass CD8a and, after validation of the antisera, we evaluated the localization, distribution and abundance of CD8a$^+$ cells in naïve sea bass tissues as well as after NNV infection.

Material and methods

Synthetic peptide of European sea bass CD8a was produced and used to immunize mice to obtain polyclonal antibodies. Sea bass tissues were used to validate the antiserum by both western blot and ELISA (Santana et al., 2013). Once validated, antiserum was used to localize CD8a$^+$ cells in thymus, head-kidney and spleen tissues from naïve specimens of European sea bass by routine indirect immunohistochemistry (IHC). Localization, distribution and abundance of CD8a$^+$ cells was also studied by IHC in the brain, the target NNV tissue, and the gonad from juveniles infected with NNV (Chaves-Pozo et al., 2012) and compared to mock-infected specimens. In addition, peripheral blood (PBL), head-kidney (HKL) and spleen leucocytes were isolated and the percentage of CD8a$^+$ cells evaluated by flow cytometry during a NN infection.

Results

Firstly, the western blot revealed a band of less than 25 kDa, very similar to the predicted 24 kDa of the mature sea bass CD8a. In addition, the ELISA also demonstrated that the signal was completely abrogated when the synthetic peptide was used to pre-adsorb the antiserum. These two techniques served to validate the specificity of the generated polyclonal antiserum. In addition, IHC revealed a strong staining in the cytoplasmatic periphery of discrete cells. As expected, the number of CD8a$^+$ cells in the thymus was very high, followed by the head-kidney and no detection was observed in the spleen.

(Continued on next page)

Focusing on NNV-infected European sea bass tissues, we firstly identified by IHC few scattered $CD8a^+$ cells in the brain, the main target tissue for NNV, and in the gonad, a tissue that is also colonized by NNV and used to be spread to the progeny. Upon infection, we observed an important increment in the number of $CD8a^+$ cells in both tissues. We also quantified $CD8a^+$ cells present in immune tissues through an infective process by flow cytometry. Interestingly, we found two distinct positive populations according to the staining intensity observed that depends on the presence of CD8a in the cells. Thus, populations were named $CD8a^{low}$ and $CD8a^{hi}$. Thus, NNV infection resulted in general decrease of $CD8a^+$ cells 3 days post-infection in the HKLs and PBLs but unaltered in the spleen. As the infection progressed, 7-15 days, the percentage of $CD8a^+$ cells significantly increased in all the tissues analyzed when compared to mock-infected specimens. Interestingly, the greatest increment was observed in the case of the $CD8a^{hi}$ population.

Discussion and conclusions

Our results showed the anti-CD8a serum as a valuable tool to characterize the $CD8^+$ lymphocytes in European sea bass and their role in immunity. This antibody is an important tool to investigate the fish acquired immunity at protein and cellular levels. The increment of $CD8a^+$ cells during infection in naïve and NNV-infected tissues reveals that sea bass are able to mount a rapid cellular acquired immunity against virus, as also demonstrated in grouper (Chang et al., 2011). However, further functional studies are needed to ascertain whether these lymphocytes are effective in the infected tissues to clear the virus depending on specimen size.

Introduction

The innate immune arm is an essential component of the teleost fish immunity due to their poikilothermic nature. Until the acquired immunity is achieved, fish fighting of pathogens is completely relegated on the innate immunity. Interestingly, many antimicrobial peptides (AMPs) have been isolated from fish and exert a powerful microbicidal activity against a wide range of pathogens. AMPs are gene encoded, constitutively expressed in most of the tissues studied to date, modulated upon infections and directly involved in microbicidal functions and immune regulators of the innate and acquired immune responses (Valero et al. 2018). Amongst them, some studies have pointed to the anti-bacterial, -viral and -parasitic role of NK-lysin (Nkl) in fish (Lama et al. 2018, Pereiro et al. 2017, Wang et al. 2018). Unfortunately, very little is known at functional level and nothing in the case of the European sea bass (*Dicentrarchus labrax*), one of the most important cultured fish species in the Mediterranean Sea. Thus, the aim of this work was to evaluate the antiviral function of synthetic sea bass Nkl peptides against the most important fish viruses *in vitro* as well as their potential protective *in vivo* actions in European sea bass juveniles upon nodavirus (NNV) infection.

Material and methods

Three different European sea bass Nkl peptides (Nkl1, Nkl2 and Nkl3) were synthetized and purified by high-pressure liquid chromatography (HPLC). For the *in vitro* antiviral activity, synthetic peptides were incubated with NNV, viral septicaemia haemorrhagic virus (VHSV), infectious pancreatic necrosis virus (IPNV) or spring viremia carp virus (SVCV) as major virus for European sea bass, salmonids and cyprinid fish species. Viral samples incubated with phosphate buffered solution (PBS) served as controls. Afterwards, viral suspensions were incubated for infectivity determination onto cultures of the E-11 cell line, in the case of NNV, and in the EPC cell line for VHSV, IPNV and SVCV at their respective optimal growing conditions. Cultures were evaluated by phase contrast microscopy for the presence of cytopathic effect (CPE) and virus titters determined (Reed and Müench, 1938). Viral infectivity was presented as inhibition of viral titter respect to the controls.

For the *in vivo* trial, European sea bass juveniles (15± 3 g mean body weight) were divided into groups and received a single intramuscular injection of 0.1 mL of PBS alone (control) or containing 1 µg Nkl peptides g^{-1} fish. After 3 days fish were intramuscularly injected with a pathogenic dosage of NNV and the mortality recorded during 1 month. The relative percent survival (RPS) was determined and expressed as %.

Results

Our results *in vitro* demonstrated that Nkl peptides have a clear antiviral role but it depends on the peptide sequence and the virus. Thus, treatment of NNV with Nkl1 reduced the viral infectivity 68.5%, respect to the controls or untreated viral stocks, while both Nkl2 and Nkl3 peptides did at 99%. In the case of VHSV, viral viability was equally reduced by the three peptides reaching a 97-98% of viral reduction. For IPNV, Nkl1 reduced the viral infectivity up to 90% while the other two peptides virtually cleared all the virus since the viability was lower than 0.01%. By contrast, SVCV infectivity was the less affected by the synthetic sea bass Nkl peptides. While Nkl1 and Nkl2 incubation reduced the infectivity 53% the Nkl3 failed to have any impact on viral CPE respect to the controls.

(Continued on next page)

In the *in vivo* exposure, European sea bass juveniles challenged with NNV resulted in 41.67% of mortality. Interestingly, when fish were pre-injected with the synthetic sea bass Nkl peptides the RPS for Nkl1-, NKl2- or Nkl3-treated sea bass juveniles was of 34, 21 or 40%, respectively.

Discussion and conclusions

Our results demonstrate that the European sea bass Nkl peptides have a potent antiviral activity both *in vitro* and *in vivo* as well as activity against different types of fish virus. Since they are able to reduce the viral infectivity by the direct contact with the virus it is reasonable to suggest that Nkl is able to produce holes or pores in the viral capsid, a fact that merits further evaluation to clearly determine the mechanism of action of Nkl peptides on virus. By contrast, during the *in vivo* administration, the fish pre-injected with Nkl peptides were more resistant to NNV infection suggesting that NKl peptides might trigger the immune response although further characterization of the different responses elicit are mandatory. Thus, the immunological mechanisms behind this finding are under investigation in our laboratory. Thus, Nkl peptides are presented as valuable tools for preventing viral diseases in fish and might be potential candidates for prophylactic measures in aquaculture.

Introduction

The indiscriminate use of antimicrobials has contributed to the emergence of resistant microorganisms, an alarming problem in public and animal health, since the speed of adaptation of microorganisms is much faster than the time of production of drugs to combat the diseases (WHO, 2018). In this sense, the study of natural substances that can be used as an alternative to chemical products has increased in recent decades. Of all these alternatives, which include micronutrients and probiotics, plants are considered the most reliable source of compounds to treat infections in both animals and humans (Dotta *et al*., 2018). Guava (*Psidium guajava* L), which is a plant that grows in tropical and subtropical areas of the world, has been used in medicine with reported antimicrobial, antihypertensive, anti-inflammatory and anti-neoplastic effects in both animals and humans (Gutiérrez *et al*., 2008; Gobi *et al*., 2016). Thus, in this work we have studied the effects of ethanolic and ethanolic-aqueous extracts of guava leaf (*P. guajava* L.) against several fish pathogenic bacteria, as well as their effects on the viability and innate immune activities on head-kidney (HK) leucocytes of gilthead seabream (*Sparus aurata*).

Material and methods

Guava leaves were collected in Santo Domingo (Dominican Republic) and afterwards were dried at room temperature and crushed. Ethanolic and ethanolic-aqueous extracts were obtained according to García-Beltran *et al.* (2018). In order to evaluate the antimicrobial power of the guava leaf, a bacterial sensitivity test was performed with each of the extracts by diffusion in agar against several fish pathogenic bacteria (*Vibrio harveyi, Vibrio anguillarum, Photobacterium damselae* subs. *piscida* and *Aeromonas salmonicida*). In addition, the effects of guava leaf extracts on viability and innate immune activities was analysed in HK leucocytes isolated from gilthead seabream exposed to 4 concentrations of each extract (0.01, 0.1, 0.5 and 1 mg mL^{-1}) for 24 hours. Viability was studied by flow cytometry using propidium iodide and respiratory burst, peroxidase and phagocytosis activities were determined according to the methods optimized by our research group (García-Beltran *et al.,* 2018).

Results

The guava leaf extracts inhibited the growth of *V. harveyi, V. anguillarum, P. damselae* and *A. salmonicida*. In other hand, the viability of HK leucocytes incubated with the ethanolic extract of *P. guajava* decreased only in those incubated with the highest concentrations (0.5 and 1 mg mL^{-1}) respect to untreated cells. However, in case of the ethanolic-aqueous extract the cellular viability decreased until it was significantly lower with the higher concentration of the extract (0.5 and 1 mg mL^{-1}). Regarding peroxidase activity, levels remained similar to the control with the lowest concentrations (0.01 and 0.1 mg mL^{-1}) when using the ethanolic-aqueous extract, while no effect was seen when using the ethanolic extract. In terms of phagocytic ability, high concentrations of ethanolic-aqueous extract (0.5 and 1 mg mL^{-1}) significantly decreased this activity. Finally, only the concentrations of 0.5 mg mL^{-1} of ethanolic-aqueous extract and 1mg mL^{-1} of ethanolic extract caused a significant decrease in the phagocytic capacity of gilthead seabream leucocytes.

Discussion and conclusions

According to our results we can conclude that *P. guajava* leaf has a powerful microbicidal effect against the pathogenic bacteria tested and low or moderate concentrations of aqueous and ethanolic extracts of this plant showed immunostimulant effects in HK gilthead seabream leucocytes, obtaining the best results when using the ethanolic extract.

Introduction

In teleost, the vertebrate integument (skin), with conserved organization consisting of the epidermis, dermis, and hypodermis, is the prominent mucosal surfaces and immune barriers bear the brunt of environmental stimulation (Esteban, 2012). Fish live in aquatic environments ubiquitous with pathogens and allergens, which may suppose a threat to the mucosal immunity (Gomez et al., 2013). On top of it all, higher density and intensification in aquaculture system can end into skin lesions, abrasions and ulcers, which are one of the major limiting factors for aquaculture production. To be safe, the skin injured is very rapidly repaired make the case for the defensive mechanism against the external environment (Costa and Power, 2018). On the other hand, *Shewanella putrefaciens* is a strain isolated from the skin of healthy specimens of gilthead seabream (*Sparus aurata*) (Chabrillón et al., 2005) and we previously have demonstrated its potential as an immunostimulant in gilthead seabream systemic immunity. Therefore, the aim of this work was to demonstrate if this bacterium has any positive effect on gilthead seabream skin inflammation.

Material and methods

A total of 48 gilthead seabream specimens from a local farm (San Pedro del Pinatar, Murcia, Spain) with a mean initial body weight of 21.81 g (0.87 g SEM) were randomly assigned into 4 re-circulating seawater aquaria (400 L), with continuous aeration and flow-through seawater at the rate of 900 L h^{-1} at 22 ± 2 °C and 24% salinity. The photoperiod was 12 h light: 12 h dark. A commercial diet (Skretting) was used as the basic feed. Saline buffer and bacterial suspension of equal volume were added to the basic feed, formulating the control and SpPdp11 (10^9 cfu g^{-1}) diets, respectively. Twice tanks of 12 fish were fed each of these two experimental diets at a rate of 2% body weight day^{-1}. After 30 days of trail, 8 fish per tank were selected randomly for periodical sampling, and then anesthetized with 20 mg L^{-1} of clove oil (Guinama®). For gene expression analysis, skin tissues were taken and frozen in liquid nitrogen immediately and stored at −80 °C till use. The rest of the fish were sedated as mentioned above, and then wounded by a metallic circular biopsy punch (Stiekel) with a diameter of 8 mm and 2 mm depth and were fed with the same diets. At the end of the experiment (1-week post-wounding), the acquisition of skin tissues was as indicated before.

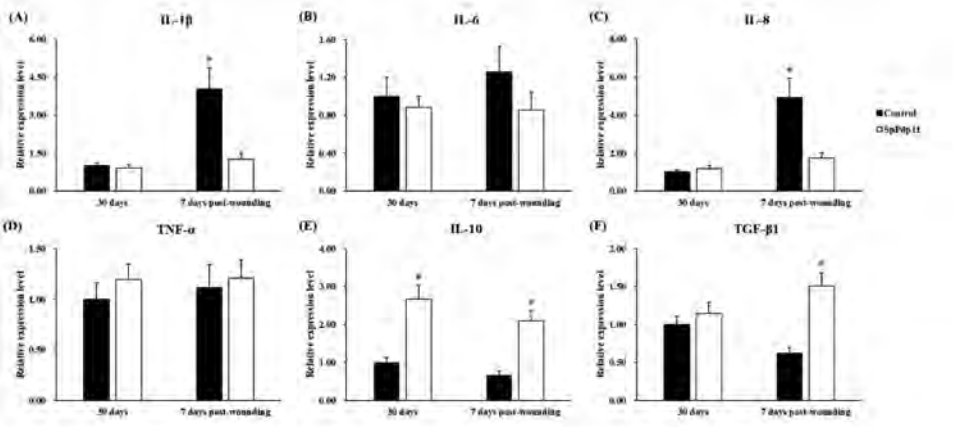

Figure 1. Relative expression level of *IL-1β*, *IL-6*, *IL-8*, *TNF-α*, *IL-10* and *TGF-β1* genes in skin samples of gilthead seabream of control and SpPdp11 group at 30 days of trial and 7 days post-wounding. Error bars of columns denote standard error of means (n = 8), asterisks denote significant differences between experimental groups ($P < 0.05$).

(Continued on next page)

The total RNA of the skin was isolated using TRIzol® reagent (Life Technologies). RNA purity and concentration were measured using Nano Drop® 2000 spectrophotometer (Thermo Fisher Scientific), and then treated with DNase I (Promega) to remove genomic DNA contamination. First-strand complementary DNA (cDNA) synthesis was reversely transcribed from 1 μg of total RNA using the SuperScriptIV reverse transcriptase (Life Technologies) with an oligo-dT18 primer (Life Technologies). All the real-time PCR analyses were performed using an ABI PRISM 7500 Instrument (Applied Biosystems) with using SYBR Green PCR Core Reagents (Applied Biosystems). The mRNA levels of these genes were normalized to the mRNA level of sea bream ef1α and the rps18, which were used as housekeeping gene. The gene expression levels were calculated using the $2^{-\Delta\Delta CT}$ method, and the relative expression level of gene in the Control after 30 days' sampling was used as a calibrator.

Results and discussion

Compared with the control group, seabream fed SpPdp11 diet showed significantly higher *IL-10* gene expression after 30 days' feeding ($P<0.05$). Besides this, 7 days post-wounding, the gene expression of *IL-1β* and *IL-8* were remarkably ($P<0.05$) declined in SpPdp11 group, while the gene expression of *IL-10* and *TGF-β1* was significantly ($P<0.05$) increased in SpPdp11 group compared to the expression level of the skin from fish belong to the control group (Figure 1)

The results revealed that gilthead seabream fed SpPdp11 diet showed a significantly reduced gene expression of pro-inflammatory cytokines (IL-1β, IL-6, IL-8, and TNF-α), and significantly enhanced gene expression of anti-inflammatory cytokines (IL-10 and TGF-β1) 7 days post-wounding. Therefore, dietary administration of SpPdp11 could significantly alleviate the skin inflammation of experimentally wounded gilthead seabream.

Introduction

Tenacibaculosis (formerly called flexibacteriosis) is one of the most common bacterial pathogens in aquaculture and can affect a wide range of species, such as sole, turbot, European eel, salmon, European sea bass, gilthead seabream, etc. (Salati et al., 2005). In the case of fish studied, gilthead seabream is one of the most important fish crops in the Mediterranean area. Recently, the statistical data showed that the production of this species in 2018 was 246,839 tonnes in Europe with a percentage of 10.7 compared to the previous year's productions. However, the relation between nutrition and the pathogenicity of Tenacibaculosis have not been studied under a low proportion of daily feeding or with low protein diets. In fact, it is well known that proper nutrition in fish can protect against pathogenic and disease episodes (Oliva-Teles, 2012), but generally in marine cages, crops can be poorly fed by bad weather or inefficient distribution of granules. This can affect some fish by preventing them from feeding with the usual or recommended feeding ratios. Therefore, the aim of the present study was evaluated the immune response of gilthead seabream fed diets with different protein and fat levels and challenged with *Tenacibaculum soleae*.

Material and methods

One hundred twenty healthy gilthead seabream (*Sparus aurata*) (12,86 ± 0,28 g initial experimental mean body weight) were obtained from a local hatchery (Águilas, Murcia, Spain). Fish were randomly distributed and acclimated prior the experiment into eight identical tanks (15 fish per tank) where the following groups were established in duplicate: Diet A (Ti3- Skreeting for Tilapia); Diet B (Mar Perla- Skreeting as gilthead seabream Control diet); Diet C (Biothesan 40); Diet D (Biothesan 70). The diets were selected by their protein and fatty acid ratios: Diet A, crude protein (Cp): 33 %, and crude oils (Co): 6,5 %; Diet B, Cp: 56 %, Co: 15 %; Diets C and D, Cp: 28,6 %, Co 6,5 %. Diets C and D were isoproteic and isolipidic, and their main protein source used was spent brewery yeast at 55 % and 62,5% of wet weight kg^{-1} inclusion, respectively. Mainly the protein and oil source was different and whilst the Diet B (control treatment) had fish meal (FM) in a 48,40 %; Diet A has only 4,4 % of FM and Diet C and D have 25 % and 20 % of FM, respectively. The proteins ratios that fish meal used as raw material brings for commercial diets are impossible to know, but the feed formulated and designed as Diets C and D used low protein ratio FM (58 %) obtained from canning and fisheries by-products.

The fish were fed at 1,5 % of daily biomass body weight day^{-1} during 62 days. After that period, 5 fish of each treatment were anesthetizes and sampled whilst 5 of each treatment was intraperitoneally (i.p.) injected with 100 µl either PBS (unchallenged group) or *Tenacibaculm soleae* (10^6 ufc ml^{-1}, challenged group). The rest of the fish (5) were recovered. After 24 hours, the fish that were injected were anesthetizing and sampled. Intestine and skin were collected and then stored for the analysis of the expression of immune-related genes (*igt*, *tcr-β*, *il-1β*, *cox2*, *tnfα*, *hep*, *β-def*, *lyz* and *c3*) using Real-Time PCR (qPCR).

Results

Our results revealed that the expression of genes studied in gut and skin was unaffected by the different assayed diets at the end of trial (62 days). Interestingly, the expression of most genes was altered after the bacterial challenge. In the case of gut, the expression of *tcr-β* and *cox2* genes was down-regulated in the fish fed Diet D respect to values found in the fish fed Diet B. A significant down-regulation of *hep* gene expression was observed in specimens fed all diets compared to fish fed Diet B. Fish fed diet C showed a down-regulated of *c3* gene expression respect to fish fed Diets A and B. In the case of skin, the expression of the most genes tested (*igt*, *tcr-β*, *il-1β*, *cox2*, *tnfα*, *β-def*, *lyz* and *c3*) was down-regulated in the fish fed Diets B, C and D compared to the expression observed in the fish fed Diet A.

(Continued on next page)

Discussion and conclusions

These results suggest the diets used can modulate the susceptibility of fish to infectious diseases. Our results demonstrated that the expression of the most immune-related genes evaluated in the skin was up-regulated in the fish fed Diet A (Ti3-Skreeting for Tilapia) which is a deficit diet for the species under study. Interestingly, the expression of the genes tested not showed variations between Diet B (control, Cp: 56 %) compared to the values found in the fish fed Diet C and D (Cp: 28,6 %, mainly from spent brewery yeast). As is known, the adequate diet supplies the immune system with the amino acids, PUFA, enzyme co-factors and energy necessary to support lymphocyte proliferation and the synthesis of immune-effectors (Lall, 2000; Kiron et al., 1995). Therefore, the diets C and D, which contain a lower protein and fat proportion, seem supplies the essential requirements for cells of the immune system. This fact could mean lowering the costs involved in the formulation of diets for fish aquaculture

Introduction

Among disturbances of aquatic environments, the eutrophication of surface water seems to be accelerated throughout the world as a result of the release of nutrients under development anthropogenic activities. One of the consequences of eutrophication is a large proliferation of toxic cyanobacteria that may be present in the surface water area for a long period of time (Vieira et al., 2005). Frequently, as cyanobacteria dominate phytoplankton in temperate freshwater environments during the hotter periods of the year, and as global temperature elevations predicted from climate change models (Davie et al., 2009) suggest that Cyanobacteria will increase in frequency, duration and severity. The production of toxins by cyanobacteria such as Microcystis, which has temperature for growth and photosynthesis at or above 25 °C (Davis et al., 2009), and the frequency of blooms for the same cyanobacteria has increased in recent decades (Dziallas and Grossart, 2011).

Material and methods

Description of experimental groups. Group control: For the group, water from the treatment network of the city of Pirassununga (São Paulo) was used, which was oxygenated for 3 days to eliminate chlorine. Three aquariums are assembled, each of which is considered a replica. Treatment 1: for this treatment, dilutions of 5 ppb and 50 ppb of the extract of cyanobacteria of *M. aeruginosa* species, were used, for each concentration three aquariums were assembled, each of which was considered a replica. After the experimental periods of 48 and 96 hours, liver fragments were extracted from each of the 5 specimens collected in each aquarium (15 per group). These samples were fixed in buffered formaldehyde, dehydrated in alcohol and included historesin, for Hematoxylin-Eosin reactions, for the analysis of possible alterations in organ morphology in PAS to identify changes in glycogen accumulation and in Pearls solution for iron detection.

Results

The qualitative analysis showed that cytoplasmic vacuolations, sinusoidal capillary dilations and hyperemia. The dilatation of the sinusoidal vessels was only considered positive when the mean of its largest diameter in longitudinal sections was statistically higher than in the control group. The cases of hyperemia were identified and the percentage of individuals per group that had it. Apparently, the vacuolization present in the treatment groups is due to the accumulation of lipids, the deletion of glycogen or other substances, which do not lead to cell death since no evidence of cell death was found. The Pearls technique presented positive iron titers in the liver in the groups exposed to the toxic strain in the both concentrations tested, but only after 96h of exposure, and it was also possible to observe the accumulation of macrophages in the hepatic tissue.

Discussion and conclusions

Pham et al. (2015) and Woźny et al. (2016) who described that even exposure to a toxic strain tends to be reversed over time. However, these authors did not describe irreversible damage such as necrosis that has already been described by other authors, which leads them to believe that there would be a second hypothesis in our experiment if it were prolonged, just as in these authors the damages would tend to be diminished and reverted. This same pattern of reversal damage caused by microcystin was reported by Hou et al. (2015) in ovaries of zebrafish. This point leads us to highlight the importance of our work, since it not only focused on hepatocyte damage but also identified hyperemia and dilatation of sinusoid, hepatocyte nuclei, data that were not reversible and should be observed in experiments with microcystin a from this moment. In the work carried out by Preeti et al. (2016) we may observe hyperemia and dilatation of sinusoid vessels as in our work, however, these data were not reported by the authors..

Introduction

Plastics are a synthetic organic polymers, which are derived from the polymerization of monomers extracted from oil or gas that came out in 1909. The durability of plastics, one of the good factor for its use, it's also what makes them a potential material to harm different species and the environment, since it's highly resistant to degradation (Cole et al., 2011). Plastics can be divided in macro- (size superior to 5 nm), micro- (MPs) (size between 100 nm and 5 mm) and nanoplastics (NPs) (smaller than 100 nm) which can be found in the water and sediment of both marine and freshwater systems. In the case of MPs, several authors have reported that MPs are consumed by a great variety of aquatic organisms in multiple pathways including ingestion, adherence and trophic transfer (Wen et al., 2018). Therefore, the fish exposure to MPs can lead to multiple toxic effects in several organs and tissues, such as intestinal damage, oxidative stress, endocrine disruption, immune response and finally reduced growth and survival (Wen et al., 2018). In addition, the MPs might release chemicals that are part of their composition or that they were able to absorb when released to the environment such as metals and heavy metals, organic compounds or pharmaceutics allowing those products to enter in their bodies (Rochman et al., 2014). Therefore, the present *in vivo* study attempts to describe the single and combined effects of waterborne exposure to MPs and cadmium (Cd) on the antioxidant defence and innate immunity in European seabass (*Dicentrarchus labrax*).

Material and Methods

The bioassay was conducted in glass tanks (60 L capacity) to minimize plastic exposure, filled to 50 L. Water quality was maintained with aeration and daily water changes of 100%. The photoperiod was of 12 h light: 12 h dark and fish fed with a commercial pellet diet (Skretting, Spain) at a rate of 1.5% body weight day^{-1}. Ammonia levels in the water were measured every day using commercial kits (Palintest Ltd) and never exceeded 0.40 mg L^{-1}. During the trial, water temperature averaged 17.04 ± 0.5 ºC, salinity was maintained at 35.0 ± 1.0 g L^{-1}, and dissolved oxygen was kept near saturation (7.0 mg L^{-1}). The photoperiod was of 12 h light: 12 h dark and fish fed with a commercial pellet diet (Skretting, Spain) at a rate of 2% body weight day^{-1}.Eight specimens of European seabass (66.9 ± 13 g body weight) from a local fish farm (Cantabria, Spain) were divided into four tanks by duplicate and 4 experimental groups were established: *i)* control group (unexposed); *ii)* Cd group [exposed to Cd ($CdCl_2$; Sigma, 0.1 mg L^{-1})]; *iii)* MPs group [exposed to MPs (0.25 mg L^{-1}, red fluorescen MPs, Cospheric-Innovations in Microtechnology, USA)]; *iv)* MPs-Cd mixture group [exposed to Cd and MPs (0.1 mg L^{-1} and 0.25 mg L^{-1}, respectively)]. All experimental tank were exposed daily and therefore for each group, we had a cleaning tank that was used to transfer the fish while the experimental tanks were cleaned, allowing full renovation of the water, the addition of each contaminants and the decreasing as much as possible the decay of both contaminants (MPs and Cd). To reduce MPs adherence to plastic used on the tubes for aeration, a plastic pipette was used, since it is more inert compared to the plastic tubes. The concentrations used were ecologically relevant and the fish were allowed to acclimatise for 15 days before the start of the experimental trial. They were starved for 24 h prior to sampling and four fish per tank (8 per group) were sacrificed by an overdose of ethylene glycol monophenyl ether (Sigma-Aldrich, 1,000 ppm) for blood and liver sampling after 5 and 10 days of exposure.

Results

Our results revealed that the numbers of red blood cells (RBC) decreased in fish exposed to MPs respect to values found in the fish from Cd and Mix groups at the day 5. In the case of the number of circulating total WBC (white blood cells), a decrease was observed in all exposed fish compared to unexposed ones (control) at the day 10 of exposure. However, the haemoglobin concentration, hematocrit, MCV (mean corpuscular volume), MCH (mean corpuscular haemoglobin) and

(Continued on next page)

MCHC (mean corpuscular haemoglobin concentration) values remained unaltered. Regarding lipid peroxidation (LPO) and catalase (CAT) activity in liver, the values of LPO and CAT activity not showed alterations between experimental groups. Interestingly, the bactericidal activity against *Photobacterium damselae subsp. piscicida* (PP3 strain) showed a decrease in the plasma of fish exposed to MPs respect to values found in the plasma from fish unexposed and exposed to mixture (MPs-Cd) during 10 days. Similarly, the bactericidal activity against *Vibrio harveyi* decreased in fish exposed to MPs respect to unexposed fish at the same experimental time.

Discussion and conclusions

These results confirm that the combination of MPs with Cd not seem to increase the toxicity of this heavy metal. Interestingly, the exposure to MPs, Cd and MPs-Cd mixture caused a decrease in the number of WBC which could be related to the decrease observed in the bactericidal activity evaluated in the plasma. Regarding stress oxidative, no significant variations were recorded in LPO and CAT activity in liver of exposed fish. This fact could be related with the Cd and MPs concentrations tested (ecologically relevant) which was lower than that used in other studies (Miranda et al., 2019). Therefore, further studies should elucidate the potential risks of heavy metals and MPs combination for fish health to longer exposure times and whether this could contribute to significant e fects on the food chains by bioaccumulation.

Introduction

While in most fish species egg viability rapidly decreases after ovulation, Salmonids can hold their eggs in the body cavity for a week without any significant loss of egg developmental competence. In the body cavity, eggs are bathed in a biological fluid called ovarian fluid (OF) or coelomic fluid (CF). This fluid appears to be directly responsible for the good conservation of eggs. Indeed, eggs remain viable after several days of storage in this fluid, while their viability rapidly decreases when stored in artificial medium mimicking the mineral composition of CF. Understanding the biological properties of coelomic fluid and identifying the actors involved in this process would be of great interest for aquaculture and for further understanding the biological mechanisms preserving egg viability. It would particularly help improving egg storage conditions.

Results

We have used a proteomic approach to characterize rainbow trout (*Oncorhynchus mykiss*) coelomic fluid proteome. Proteins involved in immunity, part of the extracellular matrix, or involved in lipids metabolism and transport are the most highly present classes in this fluid. Comparison of this proteome with transcriptomic data of the PhyloFish database suggests the presence in the rainbow trout coelomic fluid of proteins specifically expressed in salmonid

To further characterize CF, rainbow trout fluid has been fractionated by HPLC on a gel filtration column. After 4 days of incubation in those fractions, trout eggs were fertilized. In some fractions, eggs exhibited a good developmental rate, even though lower than in non-fractionated coelomic fluid. Proteins present in those fractions are currently being identified. In parallel, proteomic comparison of salmonid coelomic fluids with non-salmonids ovarian fluids will allow us to identify proteins specifically present in salmonids coelomic fluid

Conclusion

Together, those experiments will help us identify potential protein candidates participating in preserving egg viability and unraveling pathways conferring this unique biological activity to salmonid coelomic fluid. The identification of those candidates could have direct applications in aquaculture and help improving the egg storage conditions.

IDENTIFICATION OF SNP MARKERS ASSOCIATED TO SOMATIC GROWTH IN THE FLATFISH SENEGALESE SOLE (*Solea senegalensis*)

Introduction

The Senegalese sole is a species with high economical value whose aquaculture production has been consolidated in Southern Europe in recent years. One unexplored way to improve growth performance is the implementation of genetic breeding programs and the use of genomics to assist in the control of reproduction and to increase the accuracy of genetic estimates. With the rapid development of sequencing technologies, the analyses of single nucleotide polymorphisms (SNPs) has become an essential tool in genetic studies to identify quantitative traits loci (QTLs) and genes associated to growth as reported in other species such as turbot (Lyu et al. 2019), catfish (Zang et al. 2019), Asian seabass (Xia et al. 2013) or golden pompano (Zang et al. 2018), among others. The objective of this work has been the identification of SNP markers associated to growth in sole. For this purpose, a set of SNPs have been identified *in silico* using a genome draft of the sole, and tested in a mid-density DNA chip using wild animals. Later, the markers were studied in F1 families of soles with different growth rates (high and low) identifying 6 genes or chromosomal regions associated to growth.

Materials and methods

The set of SNPs used in this study were detected in silico by mapping transcriptome data onto a genome draft of a *S. senegalensis* (after sequencing with Nanopore and the correction of Illumina). The scaffolds were blasted onto the *Cynoglossus semilaevis* reference genome to positioned in the genome. The SNPs were used as target sequences to design specific probes compatible with the OpenArray DNA chip platform (Thermofisher). To validate the chips, a wild population captured in the Gulf of Cádiz (Spain) composed of 83 females and 81 males was used. Blood or fin samples were taken from each individual and high-quality DNA was isolated using the Qiagen DNA kit according to the manufacturer's recommendation. The quality and quantity of DNA was measured with a Nanodrop ND-8000 spectrophotometer and agarose electrophoresis. The chips were loaded with an Opencuray AccuFill ™ System and amplified in a real-time PCR (QuantStudio12KFlex model) according to the manufacturer's instructions. For the association analysis, four families were selected according to their growth rates at harvest. The slow-growing families LG1 and LG2 averaged 159.3g and 133.7g in weight, respectively. The fast-growing families FG1 and FG2 were 518.6g and 468.1g, respectively. The disequilibrium analysis was carried out using the JLIN (Carter et al., 2006) and the genome-wide association study (GWAS) with GWASpoly package in R (Rosyara et al., 2016) and Tassel 5 program (Bradbury et al., 2007). For the analysis, both the estimated breeding values (EBV) and a binary approach were used.

Results

The in silico analysis identifie a set of 110 potential SNPs that were used to design specific probes. A final set of 60 SNPs was considered that were located in the following chromosomes: 13 in chrW, 20 in chrZ, 14 in chr14 and 13 in other 10 chromosomes using the *C. semilaevis* genome as a reference. Genotyping analysis of a wild population showed 4 monomorphic assays, 7 with abnormal amplification profiles that did not allow a clear differentiation between heterozygotes and homozygotes and a total of 49 polymorphic SNPs in Hardy-Weinberg equilibrium. The association analysis using the GLM and MLM approaches revealed 6 markers with significant differences between the high and low growth families after Bonferroni correction. These markers followed the general model, 5 for the binary weight category (explaining a 61.44% of the total variation) and 2 for the EBV data (explaining a 15.85% of the total variation). One of the markers showed significant differences for the two variables. These markers, located 4 on the chr14, 1 on the chr17 and 1 on the chr22, were associated to the gem-associated protein 8, general transcription factor 3C polypeptide 4, inactive rhomboid protein, protein FAM222A-like, ephrin-A5-like and mitochondrial fission process protein 1

(Continued on next page)

Discussion and conclusion

In this work, we have tested a mid-density SNP chip in Senegalese sole. A set of 49 assays resulted optimal to association studies. The results identified a set of 6 markers associated to growth that may be linked to genes that participate directly or indirectly in the trait. In the absence of information about the function of some of these genes in fish, we see that in mammals, for example, that the inactive rhomboid protein regulates the secretion of several ligands of the epidermal growth factor receptor and indirectly activates the epidermal growth factor receptor signaling pathway and may regulate sleep, cell survival, proliferation and migration (GeneCards). This study is still ongoing to further delve into the function of these genes.

The results obtained are useful for the current genetic selection program ongoing that can benefit the aquaculture of this species in the medium / long term.

BONE MINERALIZATION PATTERN DIFFERENTLY AFFECT PHOSPHORUS REQUIREMENT IN TAMBAQUI, *Colossoma macropomum* [a]

Introduction

The phosphorus (P) requirement in animals diverges depending on the response parameters and the models used to estimate the requirement. For instance, requirement estimates based on weight gain are lower than those estimated based on bone mineralization. The use of P requirement estimates based on WG have led to several bone deformities in salmonids imposing a threat to the welfare of fish and the quality of the final product. This assumption has been used as a rule for most of the aquacultured fish species, at least for Nile tilapia and carp aquaculture. However, limited data on other fish species are available and further extrapolations should be made with care. Therefore, we designed a trial to determine the P requirement for tambaqui juveniles (from 15 to 150g) using different response parameters. Additionally, we provide evidence that the P requirement for bone mineralization might be similar to the estimate based on WG by using a CT-scanning method associated to the bone mineralization data.

Materials and methods

A total of 192 tambaqui juveniles of approximately 17 ± 0.85 g were randomly stocked into a set of 24 70L-aquaria connected to a water recirculation system. The experimental design consisted of six treatments (1.5, 3.0, 4.5, 6.0, 7.5 and 9.0 g kg^{-1} Pdisp.) and four replications in a randomized block design. Fish were fed the six semi-purified diets twice daily for 90 days. At the end of the trial, fish were euthanized and growth performance, whole-body, vertebrae and scales mineralization, CT-scans, as well as hematological and blood chemistry were analysed. Data were submitted to ANOVA and when significant differences were observed, the multiple comparisons test of Student Newman Kews - SNK or Duncan test were used to compare the treatments. Dietary P requirement was estimated using different regression models ($P < 0.05$). Models were selected based on the least sum of squared differences between the values of the observed and predicted values of the dependent variable, the P value and the R^2.

Results

No mortality or apparent signs of P deficiency were observed. Growth performance variables were significantly affected by dietary P levels. Based on weight gain, the P requirement was 6.33g kg^{-1} diet. For adequate bone mineralization, tambaqui seems to require 6.95 g kg^{-1} P. Hematology was not affected by dietary P levels, while blood chemistry parameters were affected by the P levels, except for serum calcium.

Discussion and conclusion

P requirement based on bone or whole-body mineralization are generally higher than the values estimated based on growth. However, our results with tambaqui surprisingly showed the contrary (6.95 versus 6.33 g kg^{-1} for bone mineralization and growth, respectively). We hypothesize that the P requirement based on growth is greatly affected by the amount of mineralized structures (such as scales, operculum and fins) of the species. Comparing tambaqui with Atlantic salmon, one of the most studied species in aquaculture, tambaqui seems to have a higher number of mineralized structures and bone density than salmonids and therefore this might affect the determination of the requirement. In fact, this hypothesis was supported by our findings that fish fed the deficient diet clearly showed a reduced number of mineralized structures and the total bone volume was 2.90 HU, while fish fed adequate P levels (6.3 g Kg^{-1}) showed a great increase on total bone volume (13.34 HU) (Fig. 1). Thus, the assumption that the requirement based on the whole-body mineralization is higher than those based on growth might not be a rule for all fish species

(Continued on next page)

Taking altogether, our study demonstrated that feeding tambaqui with 6.33 g kg^{-1} digestible P on the beginning of the growth stage is adequate based on several parameters of growth and welfare. Additionally, we have demonstrated for the first time that CT-scan might be an adequate and non-invasive method to assess the P requirement or bone health of fish. Further studies on the effect of P status on lipid metabolism and other blood chemistry parameters are warranted since a profound effect of P status on these parameters was observed in this study.

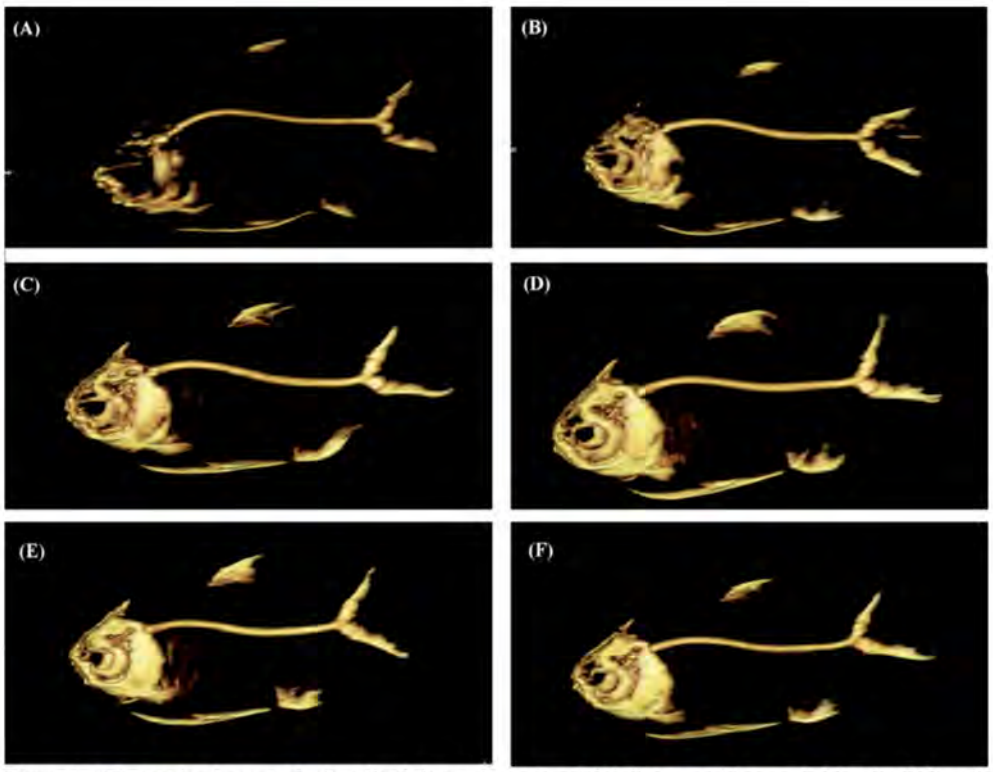

Figure 1. CT-scanning images of mineralized tissues in tambaqui fed diets containing graded levels of digestible phosphorus; Fishes fed basal diet (A), 2.5 g kg-1 dP diet (B), 4.8 g kg-1 dP diet (C), 6.3 g kg-1 dP diet (D), 7.8 g kg-1 dP diet (E), and 8.8 g kg-1 dP diet (F)

IDENTIFICATION OF FACTORS EXPLAINING THE GROW-OUT PERFORMANCE OF EUROPEAN SEABASS *Dicentrarchus labrax* AND GILTHEAD SEABREAM *Sparus aurata* IN THE MEDITERRANEAN

Benan Gulzari*, Kasper Janssen, Hans Komen

Department of Animal Breeding and Genomics, Wageningen University and Research, Droevendaalsesteeg 1, 6708 PB, Wageningen (The Netherlands),
E-mail: Benan.Gulzari@wur.nl

Introduction
Despite a rapid growth in global aquaculture, growth of Mediterranean aquaculture of European seabass and gilthead seabream stagnates. The productivity and profitability of Mediterranean aquaculture are mainly determined by the zootechnical performance of the farms.

The objectives of the present study were to quantify variation in zootechnical performance and to identify variables that explains this variation.

Materials and Methods
Data were obtained from a survey performed in the EU-project MedAID. In short, a questionnaire was distributed among the grow-out producers across the Mediterranean. Survey participants were asked for detailed zootechnical performance for multiple recent batches and rearing practices applied. Thermal growth coefficient (TGC) ($g^{2/3}$.day $degree^{-1}$), survival rate (%) and deformity rate (%) were used as key performance indicators (KPI) of zootechnical performance from the available data. Information from 6 EU (Croatia, Cyprus, France, Greece, Italy, Spain) and 3 non-EU (Egypt, Tunisia, Turkey) countries was used in the analyses.

Variation in KPIs among batches of farms was quantified. To identify factors that explain the variation in KPIs, multiple regression models were used. Non-significant variables were excluded based on backwards elimination, where the criterion for model performance was adjusted R^2 values.

Results
Descriptive statistics of zootechnical performance in grow-out farms and the amount of data used for each variable are in Table I. On average, seabass had somewhat higher TGC and survival than seabream; however, deformity rates were also higher in seabass. Deformity rates had strong positive skew, which was apparent from higher-than-mean standard deviations. Between-farm variation was greater than within-farm variation for both species.

Multiple regression models that resulted in the highest adjusted-R^2 for each KPI included different variables (Table II). Although the origin of juveniles explained the most variation in simple regression models, it was excluded from four of the multiple regression models due to singularity issues. Presence of pathologies had consistently large negative effects on survival of both species. The effect of feed related variables was not consistent across the KPIs.

Discussion and Conclusion
This study identified several variables that, when they are manipulated by farm management, have the potential to improve the zootechnical performances. Significant associations between the KPIs and explanatory variables are observational rather than causal, hence these do not necessarily reflect the biological mechanisms. The effect of deformities and feed related variables on KPIs are not immediately clear either because their effects are not consistent in the two species or they were significant in one species but not in the other. Thus, further studies are required to confirm their influence on KPIs. Variation in explanatory variables indicates that practices differ among the farms. These results may help grow-out producers to evaluate their practices and allow for improvements to be made in specific management factors.

The origin of juveniles had very high influence on performances in simple regression models; however, relative importance of origin of juveniles could not be evaluated in multiple regression models because juveniles from certain origins were used by only one producer. This prevented to distinguish the effect of origin of juveniles from the farm effects. Multiple breeding programs for seabass and seabream are active in the Mediterranean (Chavanne et al., 2016)hindering an overall evaluation of their success. Here, we report on the results of an online survey of the major aquaculture breeding companies operating

(Continued on next page)

in Europe. Six main reared fish species were targeted. A total of 31 respondents contributed to the survey, representing 75 % of European breeding organizations. Family-based breeding schemes were predominant, but individual selection was more frequently applied in marine species. Artificial fertilization is the preferred means of reproduction; however, mass spawning is often used as a fallback method. The most frequently selected trait is growth performance, but the number of selected traits has been increasing over the years through the addition of traits such as disease resistance or product quality. The use of molecular tools is now common in all programs, mainly for pedigree traceability. An increasing number of programs use either genomic or marker-assisted selection. Results related to the seed production market confirmed that for Atlantic salmon there are a few dominant players at the European level, with 30-50 % market share. Only part of the European fish aquaculture industry today fully exploits selective breeding to the best advantage. A larger impact assessment still needs to be made by the remainder, particularly on the market share of fish seed (eggs, larvae or juveniles. Although the genetic levels of strains from these breeding programs will vary, strains from breeding programs may be expected to have a superior performance relative to unselected strains (Janssen et al., 2017).
