The observed k_{gDE} was macronutrient-specific, which is in agreement with previous studies on barramundi (Glencross *et al.*, 2017), Nile tilapia (Schrama *et al.*, 2012) and rainbow trout (Rodehutscord and Pfeffer, 1999)</style><style face=”italic” font=”default” size=”100%”>Oncorhynchus mykiss</style></title><secondary-title>Aquaculture</secondary-title></titles><periodical><full-title>Aquaculture</full-title></periodical><pages>95-107</pages><volume>179</volume><number>1</number><keywords><keyword>Rainbow trout</keyword><keyword>Digestible energy</keyword><keyword>Partition</keyword><keyword>Maintenance requirement</keyword><keyword>Energy utilisation</keyword><keyword>Multiple regression</keyword></keywords><dates><year>1999</year></dates><isbn>0044-8486</isbn><urls><related-urls><url><style face=”underline” font=”default” size=”100%”>http://www.sciencedirect.com/science/article/pii/S0044848699001556</style></url></related-urls></urls><electronic-resource-num><style face=”underline” font=”default” size=”100%”>https://doi.org/10.1016/S0044-8486(99. This can also indicate the k_{gDE} dependent on the trophic level because of the metabolic mechanism specilised differently among carnivore, omnivore and herbivore. High values of k_{gDE} in the protein-rich diet and the lipid-rich diet confirm snakehead to utilise these macronutrients (i.e., protein and lipid) as efficiently as rainbow trout (Rodehutscord and Pfeffer, 1999)</style><style face=”italic” font=”default” size=”100%”>Oncorhynchus mykiss</style></title><secondary-title>Aquaculture</secondary-title></titles><periodical><full-title>Aquaculture</full-title></periodical><pages>95-107</pages><volume>179</volume><number>1</number><keywords><keyword>Rainbow trout</keyword><keyword>Digestible energy</keyword><keyword>Partition</keyword><keyword>Maintenance requirement</keyword><keyword>Energy utilisation</keyword><keyword>Multiple regression</keyword></keywords><dates><year>1999</year></dates><isbn>0044-8486</isbn><urls><related-urls><url><style face=”underline” font=”default” size=”100%”>http://www.sciencedirect.com/science/article/pii/S0044848699001556</style></url></related-urls></urls><electronic-resource-num><styleface=”underline”font=”default”size=”100%”>https://doi.org/10.1016/S0044-8486(99 and barramundi (Glencross *et al.*, 2017). It is worth noting that dietary macronutrient variation affects energy utilisation efficiency in snakehead. Snakehead has limited capability to handle the dietary carbohydrate which is similar to barramundi (Glencross *et al.*, 2017). This study also reflects the drawback of factorial approach to assess the k_{gDE} when various ingredients are used to formulate fish feed instead of only fish meal and fish oil included.

Introduction

Reduction and replacement of marine raw materials with plant ingredients have affected the availability of minerals in Atlantic salmon feeds. Subsequently, the dietary mineral levels essential to meet the requirement have been altered with changing feed formulations. Zinc (Zn), an essential micro-mineral to fish, is low in plant ingredients and exhibits poor availability in plant ingredient-based fish feeds (Antony Jesu Prabhu et al., 2016). Therefore, efforts to optimize the inclusion level of zinc in salmonid feeds low or devoid of fish meal has gained importance (Antony Jesu Prabhu et al., 2019; Read et al., 2014). In this regard, the present study aimed to investigate the impact of dietary zinc levels in low fish meal diets to Atlantic salmon parr in freshwater (FW), smolt and post-smolt in seawater (SW).

Material and Methods

Experimental diets, comprising of plant ingredients and low in fish meal were produced at Skretting ARC and the feeding trials were conducted at Lerang research station. Atlantic salmon were fed 6-7 graded levels of dietary Zn (40 to 280 mg kg^{-1}) in two feeding trials following a regression design. In trial 1, the Atlantic salmon parr (43 g, mean weight) were fed 6 dietary Zn levels, in duplicate groups for 8 weeks in FW, transferred to SW and fed the respective diets for another 4 weeks. In trial 2, Atlantic salmon post-smolt (125 g, mean weight) were fed 7 graded levels of Zn in triplicate groups for a period of 9 weeks in SW. The fish were fed twice a day to apparent satiation and feed intake monitored. During the start and at the end of the feeding periods, length and weight were recorded; samples collected for whole-body and tissue (plasma, vertebrae and liver) mineral status and feces samples were collected by stripping to assess apparent availability. The mineral analyses of the feed and fish samples were performed by ICP-MS.

Results

Dietary Zn did not have a significant impact on the growth of Atlantic salmon parr and post-smolt in trial 1 and trial 2, respectively. In trial 1, the fish grew to a mean weight of 71 ± 4 g after 8 weeks in FW and reached 87 ± 6 g at the end, 4 weeks post SW transfer. In trial 2, the mean weight across groups was 304 ± 12 g at the end of 9 week feeding. The data presented in the Figure 1 corresponds to the Zn status in the whole-body (A) and in the vertebrae (B) of Atlantic salmon post-smolt as affected by dietary Zn levels. Test of linearity showed that, both whole-body and vertebrae Zn status in Atlantic salmon post-smolt showed highly significant linear trend with increasing dietary Zn levels ($p<0.0001$), with no indication of non-linearity ($p>0.5$). The Zn status of Atlantic salmon parr in FW and smolt 4 weeks after SW transfer from trial 1 are being analyzed.

Discussion and conclusion

Despite the lack of growth differences, the Zn status in the whole-body and vertebrae of post-smolt Atlantic salmon in SW was significantl influenced by dietary Zn levels. However, neither of the Zn status indicators showed signs of saturation in the range of dietary Zn level examined. Atlantic salmon fed the basal diet, with lowest dietary Zn supply were able to cope without compromising on growth despite their whole body and vertebrae Zn status declining by 100%, compared to the fish fed highest dietary Zn level. The final whole-body Zn concentration of 33 mg kg^{-1} wet weight achieved with the highest Zn level (280 mg kg^{-1} feed) corresponds to the recent data reported by Åsgård et al. (2018), however, is lower than the level reported by Shearer et al. (1994). Considering the existing EU legislation on maximum permitted total Zn level of 180 mg kg^{-1} feed for salmonids (EC, 2016) and an EFSA (2017) scientific opinion suggesting a further decrease to 150 mg kg^{-1} feed, the present results are of high significance The findings will be presented in this context along with further data from ongoing analyses.

SEX, AGE AND BACTERIA: HOW THE INTESTINAL MICROBIOTA IS MODULATED IN A PROTANDROUS HERMAPHRODITE FARMED FISH

M.C. Piazzon*[1], F. Naya-Català[2], J.A. Calduch-Giner[2], P. Simó-Mirabet[2], A. Picard-Sánchez[1], A. Sitjà-Bobadilla[1] and J. Pérez-Sánchez[2]

Introduction

Intestinal microbiota is key for many host functions, such as digestion, nutrient metabolism and absorption, disease resistance and immune function. With the growth of the aquaculture industry, there has been a growing interest in the manipulation of fish gut microbiota to improve welfare and nutrition (Egerton et al., 2018). However, a long road lies ahead to establish the baseline parameters to guide this manipulation. Intestinal microbiota varies with many factors, including host species, genetics, developmental stage, diet, environment and sex. The aim of this study was to compare the intestinal microbiota of adult gilthead sea bream (GSB, *Sparus aurata*) from three groups of age maintained under the same conditions.

Materials and Methods

One-, 2- and 4-year old GSB (Y+1, Y+2, Y+4) were kept in the same open-flow system and fed the same diet for more than 6 months. After 2-days of fasting, 10 fish per group were sacrificed and the anterior intestinal portion was dissected, opened and washed to remove non-adherent bacteria. Intestinal mucus was scrapped off and immediately used for DNA extraction. The V3-V4 region of the 16S rRNA of each individual sample was amplified and sequenced by Illumina MiSeq. After quality filtering, taxonomic assignment was performed with a custom-made pipeline using the RDP database. Alpha diversity was calculated using Phyloseq and beta diversity using PERMANOVA and PLS-DA models. Metagenome prediction and pathway analysis were performed using Piphillin.

Results

All Y+1 individuals were males, while the ones belonging to Y+2 and Y+4 age classes were females. A total of 686461 high quality reads (22882/sample) were assigned to 846 OTUs (97% identity). Almost 30% of the OTUs were classified up to the level of species.

Microbiota diversity and richness did not differ among age groups; however bacterial composition did (Fig. 1), highlighting the presence of *Photobacterium* and *Vibrio* only after 2 years of age and a higher presence of *Staphylococcus* and *Corynebacterium* in Y+1 animals. The core microbiota was defined by 14 OTUs and the groups that showed more OTUs in common were Y+2 and Y+4. PLS-DA analysis (Fig. 1) showed a clear separation by sex (component 1) and age (component 2), with bacteria belonging to the phyla Firmicutes, Proteobacteria and Actinobacteria driving the separation. Pathway analysis performed with the inferred metagenome showed significant differences between Y+1 and Y+4, with

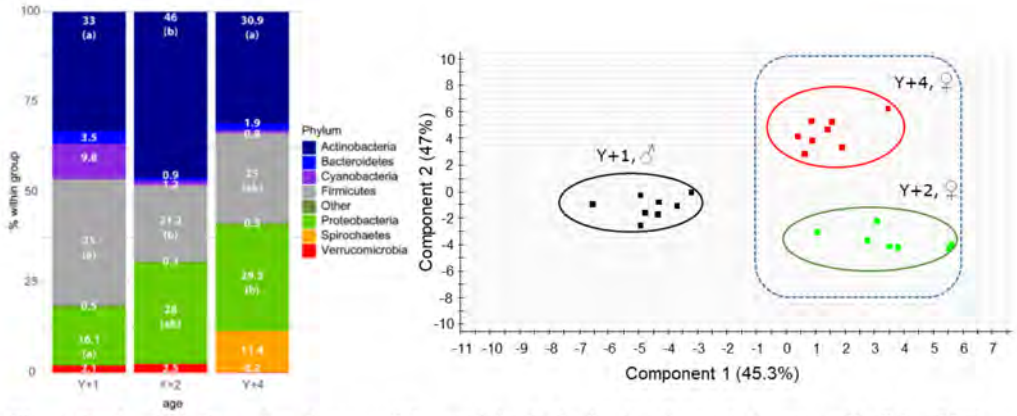

Fig. 1. Left: Relative abundance of bacterial phyla in 1-, 2- and 4-year old fish. Right: Discriminant analysis (PLS-DA) of the bacterial composition of the different groups.

(Continued on next page)

an increase with age of pathways related to cell death, motility, biofilm formation, environmental response, infection, metabolism of lipids, secondary metabolites, ansamycins biosynthesis and nitrotoluene degradation. Carbohydrate and lipoic acid metabolism and atrazine degradation were down-regulated with age.

Discussion and conclusion

The effect of host age on the intestinal microbial diversity has been previously studied in other fish species finding an increase in diversity with age (Zhang et al., 2018). However, these studies mainly focused on early life stages of the fish. Nonetheless, it is clear that the intestinal ecological niche matures with age leading to changes in the associated microbiota (Stephens et al., 2016). The dominance of the phyla Proteobacteria, Bacteroidetes, Firmicutes and Actinobacteria has already been reported in several studies on carnivorous marine fish, including GSB (Estruch et al., 2015). The current results highlight a gradual increase of Proteobacteria abundance with age with the consequent decrease of the other phyla. *Photobacterium* and *Vibrio* were previously described as the dominant genera in GSB posterior intestine (Piazzon et al., 2017) and it is noteworthy that in the current study these genera are absent in the anterior intestine of Y+1 fish, becoming more dominant with age. These two genera include many pathogenic and opportunistic species, but others are important symbionts, assisting in the breakdown of dietary components (Egerton et al., 2018). Overall, changes in microbial composition drive changes in metabolic pathways, as the up-regulation of infection-related pathways, nitrotoluene degradation and sphingolipid metabolism, and the down-regulation of carbohydrate metabolism pathways, which seem to indicate an inflammatory profile in the intestines of older fis

Introduction

Aquaponics is a technology combining both aquaculture and hydroponics. The first aquaponic systems has been developed in the late seventies. Then after, aquaponics has been rapidly adopted by education sector and urban communities. During the last decade, thanks the apparition of different aquaponic farms, aquaponics became a professional activity. Nevertheless, aquaponics is facing the drawback of innovative technologies. Firstly, the lack of advanced education dedicated to aquaponics limits the availability of technicians and engineers trained to aquaponics. Secondly, the absence of references and tools specifically dedicated to aquaponics makes the conception and monitoring of aquaponic system quite complex. In order to overcome these limitations and to foster the development of aquaponics among local communities and the corporate sector, the Interreg project Smart Aquaponics is developing an online training program, a decision support tool and a monitoring tool. These tools will be accessible within an application (smartphone and PC).

The training program will be composed of a serious game and several theoretical modules. The game will allow the user to handle virtual aquaponics systems with different levels of complexity and experiment an extensive range of events occurring in real aquaponics systems. The target groups are technical secondary schools, colleges, universities and local communities.

The decision support tool will allow users to compose virtual aquaponics systems and perform simulations. These simulations will estimate the yield, efficiency and stability of the systems and, finally allow fine-tune the design

The monitoring tool will monitor the status of the different component of an aquaponics system and propose some prediction of the future status of the aquaponic system in order to (i) anticipate potential problems (ii) maintain the parameters in an optimal range. The monitoring is based on connected sensors (pH, t°, nitrogen, …) and will be compatible with small and semi-professional systems.

Materials & methods

The three tools will be based on a model that predicts the evolution of different parameters (oxygen, nitrogen, plant and fish growth, …) of an aquaponics system. The specific nature of this model lies in its ability to model aquaponics systems of different sizes and designs. Beside, the project is also developing a data acquisition chain able to connect the sensors present both in the aquaculture and hydroponic compartment to the application.

(Continued on next page)

The calibration of the model, the evaluation of the data acquisition chain and the beta testing of the application will be achieved in three steps. First, in 2019, seven aquaponic systems belonging to the Smart aquaponics partners will be used to test the data acquisition chain. The data collected will enable a first calibration of the model. Secondly, in 2020, a panel of beta testers including professionals and hobbyists will be invited to test the data acquisition chain and the beta version of the application. The data collected with this panel will enable a second calibration of the model. The panellists will also provide a feed back on the application for improvement. Third, after the release of the application (2021), all the data collected by the application will enable further calibration of the model. In fine, the accuracy of the model and of the prediction of the application will increase with the number of users.

Results

In 2021, the Smart Aquaponics project will release an application including a training program, a decision support toll and a monitoring tool. Smart Aquaponics will also propose a data acquisition chain able to connect the sensors present in the aquaponics system to the application. Due to two years of testing, the prediction of the model will be accurate, the data acquisition chain reliable and the application user friendly.

In fine, these tools should facilitate both the design and the monitoring of new aquaponic systems. This associated with the online training program should facilitate the emergence semi-professional and professional aquaponics system.

NEW INSIGHTS INTO THE APPETITE GENE REGULATION IN COMMON CARP (*Cyprinus carpio*)

Constanze Pietsch*[1], Andreas Seitz[1], Nicola Rhyner[1], Marcel Arter[1] and Linda Tschirren[1]

[1]Fish Welfare Group, IUNR, Zurich University of Applied Sciences,
P.O. Box, Campus Grüental, 8820 Wädenswil (Switzerland)
E-Mail: constanze.pietsch@zhaw.ch

Introduction

Stress is known to influence feed intake of fish. But the differential effects of different stressors on this essential process in detail are not known. To investigate effects of different stressors on the appetite gene regulation in common carp (*Cyprinus carpio*) brain, quantitative polymerase chain reactions (qPCR) were used.

Methods

Prior to the application of the different stressors, the fish were acclimatized in an experimental tank and were trained to a feed reward applied at the same time of the day for 6 weeks. After that the fish were reared in groups of two fish each and the different stressors were applied. These included the use of the feed reward as well as the exposure to air for 1 min. The blood and brain samplings were performed after 10, 30 and 60 min after the stress applications. Reference groups were included in the experimental set-up. All experimental procedures were conducted according to the regulative permissions for animal experiments. The individual blood samples were used for cortisol quantification by means of high-performance liquid chromatography. For the gene expression analyses, the individual brains were subdivided into telencephalon, optical tectum, cerebellum and hypothalamus to allow investigations of gene regulation in different brain areas. Relative quantification of appetite gene expression was achieved using a set of validated reference genes

Results & Discussion

The results showed that the highest blood cortisol levels were observed in fish 10 minutes after exposure to distress, and the plasma cortisol concentrations decreased over time. Thus, the experiments proved that the experimental design resulted in the expected stress response patterns. Compared to this the cortisol response in the feed-rewarded group and the sham-treated fish was much shorter than in the distressed fish. Different regulation of appetite gene expression was also observed in the fish exposed to the di ferent stressors and will be discussed during the presentation.

AQUAPONIC PRODUCTION OF *Salicornia ambigua* AND PACIFIC WHITE SHRIMP IN BIOFLOC SYSTEM UNDER DIFFERENT SALINITIES

Isabela Pinheiro*, Ramon Carneiro, Matheus Rocha, Angela Kugelmeier, Claudia Machado, Felipe Vieira and Walter Seiffert

Marine Shrimp Laboratory, Aquaculture Department, Federal University of Santa Catarina. Florianópolis, SC, Brazil
E-mail: isabelapinheiro@outlook.com

Introduction

Aquaponics has been presented as an innovative and sustainable alternative as it combines aquaculture with hydroponics in a system that recirculates water and nutrients in order to promote the growth of aquatic organisms and plants in an integrated way. However, to apply this system to marine crops, it is necessary to use plants that have commercial value and are tolerant to salinity so that they can develop in the saline effluent (Buhmann and Papenbrock, 2013). Many species of halophytes are able to have their growth stimulated by the presence of salt and retain high Na^+ and Cl^- concentrations (between 25% and 30% of their dry weight), especially in shoots (Kudo and Fujiyama, 2010). However, some species differ in their degree of tolerance to salinity, and the ideal concentration for the development of these plants is that equal to or less than that of seawater (Ventura et al., 2014). Thus, the aim of this study was to evaluate the relationship of salinity to the integrated performance of Pacific white shrimp (*Litopenaeus vannamei*) and *Salicornia ambigua* in an aquaponic system using biofloc technolog .

Material and Methods

The experiment consisted in evaluating four different salinities in the cultivation of shrimp *L. vannamei* and *S. ambigua* in aquaponics: 8psu, 16psu, 24psu and 32psu, with three replicates. Each experimental unity was constructed and operated according to Pinheiro et al. (2017), and consisted of a BFT culture tank of 800 L, with titanium heaters, aeration and artificial substrates. It was coupled to this tank a settling chamber with 40 L volume and a hydroponic bench for 12 plants (40 plants.m^{-2}). Each tank was filled with 400 L water from a biofloc matrix tank (salinity 20psu) and then stocked with 240 shrimps with average weight of 1.6±0.1g (300 shrimp.m^{-3}). Posteriorly, the shrimp were slowly acclimated, and tap water and filtered seawater were added to the tanks to reach the desired salinity and the useful volume in each treatment at a rate of 2psu per hour. Shrimp were fed 4 times a day with commercial feed with 38% crude protein and was supplied according to the feeding table proposed by Van Wyk (1999). After 57 days of cultivation the production indexes of shrimp and *Salicornia* were calculated. All data were submitted to second-order polynomial regression analysis (α=0.05), and the maximum and minimum points were estimated by deriving the quadratic equation.

Results

The shrimp production data are presented in Table I. Salinity affected only the survival of the shrimps, with maximum values found at salinity of 25.7psu. The results of final mean weight and weekly weight gain were not affected by the salinities evaluated. For the production indexes of *S. ambigua* no salinity relationships were detected with any of the analyzed parameters (p>0.05). Productivity was 0.46±0.12kg.m^{-2}, 0.61±0.12kg.m^{-2}, 0.46±0.05kg.m^{-2} and 0.38±0.05kg.m^{-2} in the treatments 8psu, 16psu, 24psu and 32psu respectively.

Discussion and conclusion

Litopenaeus vannamei inhabits natural environments with variation of salinity of 1 to 50psu (Davis and Roy, 2013). In this experiment, a direct relationship was found between the reduction of salinity and the increase in shrimp mortality. This low survival may be related to the mineral composition of the water since, although it is an eurihaline species, to ensure satisfactory survival and growth of *L. vannamei* in low salinity the proportions of ions such as sodium, potassium and magnesium should be close to those found in seawater (Roy et al., 2010). Also, the maximum survival point was found at salinity 25.7psu, and is near the isosmotic point of *L. vannamei* (24.7 to 26psu) (Castille and Lawrence, 1981).

Although there was no significant relationship between plant performance and salinity, the highest yield was achieved in the 16psu treatment and the maximum productivity and final weight were estimated at salinities close to that (17.5psu and 16.4psu respectively). Halophytes of the Amaranthaceae family, such as *S. ambigua*, have their growth stimulated in the presence of NaCl, with the salinity being between 150 and 300 mM NaCl ideal for their development (approximately 8 to 17psu) (Ventura and Sagi, 2013).

The cultivation of *L. vannamei* integrated with *S. ambigua* can be performed between salinities of 16 and 24psu since the performance of the shrimp is not impaired and the growth of the plants are favored in this salinity range.

(Continued on next page)

Table I. Production indexes of *Litopenaeus vannamei* cultured in aquaponic system under different salinities during 57 days.

Parameter	Treatment				*p*-value
	8psu	16psu	24psu	32psu	
Survival (%)	56.3 ± 4.7	83.3 ± 1.2	82.6 ± 4.3	84.0 ± 4.0	0.0389
Final average weight (g)	12.7 ± 0.3	11.5 ± 0.4	11.6 ± 0.2	11.8 ± 0.5	0.3082
Average weight gain ($g.week^{-1}$)	1.4 ± 0.0	1.2 ± 0.0	1.2 ± 0.0	1.2 ± 0.1	0.5242

KNOWLEDGE FLOW WITHIN AQUACULTURE CLUSTER PROJECTS: THE HIDDEN ADDED VALUE

S. Pinna[1], D. Vallainc[1], D. Cabana[1], G. Brundu[1], P. Graham[1], G. Giménez Papiol[1], M. Baroli[1]

Introduction

Aquaculture, as one of the pillars of European Blue Growth agenda, should aim at sustainability in a broad way, both reducing the impact on natural stocks and environment while keeping the economic and social growth. Aquaculture commercial production usually includes a culturing step in natural conditions, such as shellfish facilities in coastal areas and lagoons, or fish cages offshore. This practice reduces the costs associated to the production of food (i.e. microalgae for shellfish) and keep the water quality in indoor facilities, but exposes the production to environmental changes and threats. The production activity also impacts the natural area in which it is located.

Managing all these layers of interactions, crossed impacts and goals requires knowledge-based strategies. Cluster projects, in which the triad government, academia and industry are closely involved from the preparation stage, allow the convergence of different knowledges and actors able to provide outcomes beyond the specific subject, activity or area of the project. The challenge is to overcome communication barriers, design information flows and boost the interaction between all the stakeholders. This type of intervention is in favour of the sustainable management of fish resources to limit and contain their overfishing. Fisheries policies must guide activities to reduce the level of exploitation of biological resources on levels that guarantee renewability in the medium and long term, also to protect the strategic functions of fishing (food, economy, employment, conservation of traditional activities and cultures, etc.). The definition of the technical measures must be the result of a process of sensitive evaluation of the local realities in the dimensions often evoked (ecological, economic, social, juridical), realities that have different criteria of judgment and that also require an integrated treatment.

Materials and methods

A local ecologic knowledge (LEK) approach (Azzurro 2018) has been included in the communication and technology transfer activities planned in two cluster projects, "Valorizzazione della produzione sostenibile delle ostriche nel sistema produttivo della molluschicoltura in Sardegna – (Enhancement of the sustainable production of oysters in the mollusc farming production system in Sardinia)" (OSTRINNOVA) and "Trasferimento alle aziende operanti in laguna delle tecniche di riproduzione e di allevamento in ambiente controllato di *Mugil cephalus* – (Transfer to the companies operating in the lagoon of breeding techniques in a controlled environment of *Mugil cephalus*)" (TECNOMUGILAG). Both projects have been funded by Sardinian Region as part of its regional development strategy, and Sardinian fishermen cooperatives working in coastal lagoons are the main Industry partners' profile. OSTRINNOVA aims at developing *Crassostrea gigas* culture in Sardinian lagoons, while TECNOMUGILAG is based on transferring the aquaculture production of *Mugil cephalus* for restocking its natural populations. The LEK approach is based on semi-structured questionnaires that will be conducted by vis a vis interviews with local fishermen. The interview protocol consists of a successful methodology that has been widely used across several Mediterranean countries (Azzurro et al., 2018).

Knowledge flow (Figure 1) is based on: 1) Group meetings organized by Academia participants convening Industry participants, 2) one-to-one meetings between an Academia and an Industry participant, and 3) participant-tailored LEK interviews.

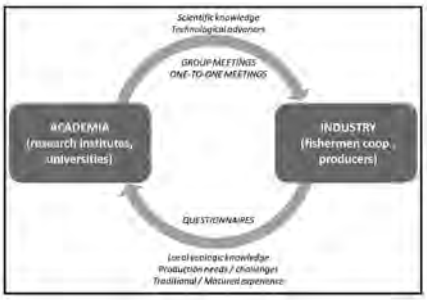

Figure 1. Knowledge flow between Academia and Industry participants in cluster projects. Italic capital letters: communication activity; Italic minor letters: knowledge type flowing.

(Continued on next page)

Results

Group meetings allow the exchange between participants of similar profile, and prompt the debate within the project, but are difficult to implement because they should fit with Industry economic activity, calendar and workload. Despite several attempts to find suitable meeting days, the final success, in terms of number of participants, is scarce: 6% of OSTRINNOVA Industry and 42% of TECNOMUGILAG Industry has participated. One-to-one meetings require more organization and time investment but have been more effective, with 100% of both cluster Industry participating; these meetings allow a more active interaction between Academia and Industry, the quality and quantity of information is higher, and facilitate the implementation of LEK approach.

Discussion and conclusion

Cluster projects are aimed at transferring the scientific knowledge to the productive sector. The knowledge flow has been usually identified as unidirectional, the transfer of scientific knowledge and technological advances from academia to industry. The reverse, from industry to academia, has usually been overlooked. Knowledge gathered from industry, ranging from matured experience at larger scale production to local, even traditional knowledge on the specific area in which aquaculture production is planned, is a unique and too often unexpected outcome. The integration of this knowledge with that generated from academia is the most valuable result for government stakeholders in order to design and implement a knowledge-based management of coastal areas and aquaculture production development. The potentialities of LEK have just started to be explored in the Mediterranean area and its importance for environmental monitoring and natural resources management is expected to grow, empowering the voices and the observational potential of people living in intimate relationship with the natural environment (Azzurro 2018).

INFLUENCE OF WATER TEMPERATURE AND FEEDING REGIME ON THE INCIDENCE OF EARLY SEXUAL MATURATION IN ATLANTIC SALMON (*Salmo salar* L.) POSTSMOLTS DURING THE FRESHWATER STAGE

E. Pino Martinez*, P. Balseiro Vigo, M. Braanaas, V. Tronci, C. Pedrosa, N. Gharbi, S. O. Handeland and T. O. Nilsen

Introduction

The current trend in salmon aquaculture towards intensification and Closed-Containment Systems (CSS) brings along some undesired effects, among which male early sexual maturation in the freshwater stage has been identified as one of the most challenging (Good and Davidson, 2016). During maturation salmon stop feeding, resulting in poor FCR and reduced growth rate (McClure et al., 2007). In addition, mobilization of resources for gonadal development highly affects flesh quality, making fillets not marketable (Aksnes et al., 1986). Finally, mature postsmolts cannot be easily identified in freshwater and often end up in the sea stage (Good and Davidson, 2016). Overall, this leads to high economic losses for the industry (McClure et al., 2007) and compromise the economic feasibility of these production systems. Factors identified as likely causes for early maturation in freshwater include photoperiods, temperature, diets, growth rate or size, among others (Good and Davidson, 2016). This study aimed to assess the effect of temperature and diet on early sexual maturation.

Materials and methods

Experimental design

This experiment consisted on a 3x2 factorial design that combined three temperatures (8, 12.5 and 18°C) and two feeding rations (Full and 67%), producing six experimental groups that were reared in duplicate at the flow-through facilities of the Department of Biological Sciences (BIO, Bergen). On 27 September 2018, 1800 Atlantic salmon parr (mean weight 26g), were transferred from a commercial RAS (Bremnes Trovåg, Norway) and randomly distributed among 12 freshwater tanks of 0.5m^3 (n=150/tank). Conditions set included water temperature 12.5°C, specific flow rate 0.5 $l.kg^{-1}.min^{-1}$ and LD24:0 photoperiod. Initially all tanks were fed a full ration and were allowed to acclimate for a week, after which temperatures were gradually adjusted to 8 and 18°C in two pairs of tanks per feeding group, while the third pair was maintained at 12.5°C. When temperatures were stable, feeding ration was reduced in six tanks to 67% by fasting every third day, while the remaining six were maintained at a daily full ration. Fish were fed appropriate commercial feeds (Biomar®) provided by Bremnes Seashore AS (Norway). The LD24:0 photoperiod was maintained for the first four months to ensure maximum fish growth, after which, on 4 February 2019, was reduced to LD12:12 to provide the fish with a winter signal for smoltification. After 5 weeks winter signal, photoperiod was set back to LD24:0 and maintained until the end of the experiment.

Samplings and statistical analysis

Seven samplings were performed until submission of this abstract, in which six males per tank were collected to record fork length, body weight, sex, gonad weight and liver weight. Gonadosomatic Index *GSI(%) = Gonad weight*100/Body weight* was used to assess maturation status. Four categories of maturity were established based on literature (Peterson and Harmon, 2005; Thorpe, 1994) and gonad visual inspection: "Immature" (GSI =< 0.06), "Early stage" (0.06 < GSI =< 0.1), "Maturing" (0.1 < GSI =< 1) and "Mature" (GSI > 1). In order to find differential trends in early gonadal development among groups, GSI during the first six months with no maturation was modelled as a function of temperature, feeding regime, time and their interactions. This analysis was performed by fitting a GLMEM using the package "nlme" in the statistical software R. A significance level α=0.05 was used

Table I. Mean body weight (g), GSI (%) and percentage of maturation found for groups *18°C-Full* and *18°C-67%* during samplings 6 and 7. Body weights and GSI (%) are displayed ± standard deviation. Maturity categories have been defined as follows: "Immature" (GSI =< 0.06), "Early stage" (0.06 < GSI =< 0.1), "Maturing" (0.1 < GSI =< 1) and "Mature" (GSI > 1). Percentages are calculated per row (experimental group).

				Maturity categories (%)			
Sampling	*Group*	*Body weight (g)*	*GSI (%)*	*Immature*	*Early stage*	*Maturing*	*Mature*
6	18°C-67%	280.1 ± 78.1	0.153 ± 0.278	53.3	20.0	20.0	6.7
	18°C-Full	336.3 ± 93.7	0.168 ± 0.133	21.4	7.1	71.4	0.0
7	18°C-67%	343.8 ± 109.4	2.480 ± 0.661	33.3	16.7	25.0	25.0
	18°C-Full	410.8 ± 117.7	2.820 ± 0.807	25.0	8.3	41.7	25.0

(Continued on next page)

Results

First obvious signs of sexual maturation appeared in males from groups *18°C-Full* and *18°C-67%* during the 6th sampling in early April. Maturation skyrocketed two weeks later in the same groups during the 7th sampling, with an increase in mean GSI greater than 15-fold (Table I). Mean GSI for immature fish across all samplings was consistently low 0.035 ± 0.009%. However, the GSI model for early development showed a significantly higher GSI in both 18°C groups during the period without maturation (p-value< 0.01), regardless of feed ration. Also, a significant positive effect on GSI was found due to the interaction 18°C*Time (p-value< 0.001), occurring from almost sampling 2 in mid-December. Feeding regime showed no significant e fect on GSI.

Percentages per maturity category displayed in Table I show that in both samplings, the proportion of immature fish and the proportion of individuals caught at early stage of maturation was higher in 67% ration group. In contrast, the percentage of individuals engaged in advanced stages of maturity was much higher in the Full ration, although advanced stages were clearly present in both groups.

Discussion and conclusions

Our results clearly point at high temperature as the main driving factor for early maturation of salmon postsmolts in freshwater. Although no maturation occurred for the first 6 months, results from the statistical analysis performed on the first five samplings suggest that individuals in 18°C may have already started to physiologically develop for sexual maturation as early as late December, three to four months before any signs were observed. This is in accordance with authors stating that the decision to mature may occur very early (Berrill et al., 2003; Thorpe, 1994) and warns the industry that high temperatures during an uncertain period in early development might be problematic for aquaculture production. The fact that maturation occurred in both 67% and Full ration groups, although not to the same extent, suggests that the feeding regime did not play a crucial role on sexual maturation while still having some influence. The percentages shown in Table I suggest that feeding restriction partially delayed sexual maturation and decreased its incidence, although this restriction was not enough to impair sexual development. The mechanisms by which high temperature promotes early maturation are not well understood and will be the main aim of this project.

It is uncertain whether maturation would have occurred to the same extent or at all if no winter signal had been given. Many authors have stated that a photoperiod cue is required for Atlantic salmon to commence reproductive development (Berrill et al., 2003; Good and Davidson, 2016; Peterson and Harmon, 2005; Thorpe, 1994), which is consistent with the timing in which the first signs of maturation appeared in our experiment (4 to 6 weeks after the end of 12:12 winter signal). Further research may help elucidate whether high temperature alone without photoperiodic cue could trigger maturation.

Introduction

Among IMTA techniques, the integration of fish and seaweed cultures in recirculating systems (IMTA-RAS) is currently one of the most promising strategies, in order to achieve diversification and sustainability in aquaculture activities. Macroalgae of the genus *Ulva* (*Ulvales*, Chlorophyta) have shown to be especially suitable for use as biofilters in IMTA-RAS systems. Combining *Ulva* spp. with sole (*Solea senegalensis*) is based on the matching of ecophysiological requirements for both cultures, the simplicity of cultivation and the high growth rate of *Ulva*, as well as the commercial interest of sole, whose cultivation on an industrial level has been recently developed and mainly performed in inland facilities.

The natural populations of *Ulva* seem to be well adapted to conditions of light heterogeneity and this population behaviour could suggest the involvement of quorum perception mechanisms. Since the bacterial communities associated with *Ulva* spp. play an important functional role both in the morphogenesis and in the reproduction of *Ulva* -considering the macroalga and its associated microbiota a singular functional entity or holobiont- it is important to know the role that microbiota plays in the mentioned mechanisms. On the other hand, light intensity can have influence on the maintenance of *Phaeobacter* biofilms in *Ulva*, as well as on the production of the antagonist compound (TDA), regulated by quorum-mechanisms.

Thus, the hypothesis of the ULVAPRO research project, funded by the Spanish government, is that the intensity and heterogeneity of light can affect both the physiology and the population behaviour of *Ulva*, its associated microbial communities and the colonization by *Phaeobacter* bacteria, and that quorum-sensing chemical signalling could mediate the response to those factors.

Material and methods

The verification of the hypothesis will be approached from a multidisciplinary perspective, including di ferent objectives:

1) Demonstrate the existence of biochemical communication by quorum sensing in *Ulva* populations in response to light heterogeneity and to identify the chemical signals which would mediate that communication, and the possible role of epiphytic microbiota on it.
2) Define the responses of *Ulva* epiphytic microbiotal comunities to light intensity and heterogeneity.
3) Determine the influence of light intensity and heterogeneity on the experimental colonization and maintenance of *Phaeobacter* bacteria on *Ulva* and the production of TDA, oriented to its application as a bacterial control strategy in IMTA-RAS systems.

Results

Verifying this hypothesis from a multi-disciplinary approach (from -omic techniques to the engineering of IMTA-RAS systems) will allow i) to understand the mechanisms underlying the behaviour of *Ulva* populations both in nature and in culture (main Objective of SubProject 1) and ii) to provide important guidelines for the design and operation of *Ulva* culture, towards the optimization of production and capacity of biofiltration as well as bacterial control in IMTA- RAS, as well as the safety and nutritional quality of the biomass produced (main Objective of SubProject 2).

Introduction

Feeding protocols for gilthead seabream (*Sparus aurata*) larvae normally envisage the introduction of live-prey during the first 30 days after hatching (DAH), with full weaning to commercial microdiets occurring during the second month of development. Despite challenging, developing a microdiet to offer at first-feeding would be extremely advantageous for hatcheries, although at this stage larvae have reduced preying and digestive capacities. Since microdiets tend to be poorly accepted and less digestible than live-prey, especially in what concerns complex proteins, it is imperative to account for these constraints when formulating a microdiet. For instance, these factors can be attenuated by including protein hydrolysates in microdiet formulations, enhancing its attractability and leading to a further maturation of larval digestive tract (Cahu and Infante, 1995). A microdiet for first-feeding seabream needs to be comprised of small particles (approx. 100 µm) with a high surface-to-volume ratio, what leads to excessive leaching nitrogen compounds resulting from protein hydrolysis to the rearing water. Microencapsulation offers the possibility of controlling leaching of these water-soluble nutrients, increasing the nutritional value of microdiets upon ingestion. This control seems paramount for a successful introduction of microdiets in first-feeding seabream.

This study aimed at developing a microencapsulated prototype able to reduce leaching of a protein hydrolysate commonly used in microdiets for fish larvae. This prototype was subsequently added to the formulation of a commercial microdiet at 8.5 and 30 % and its biological efficacy was tested by evaluating gilthead seabream growth and survival from the onset of exogenous feeding until 34 DAH.

Materials and methods

A protein hydrolysate and a protein concentrate mixture was spray-dried, with resulting microencapsulated powder being evaluated for leaching of water-soluble proteins.

Three dietary treatments were tested: in the Control treatment, a commercial microdiet was used. In the remaining treatments, the microencapsulated prototype was used at 8.5 (CAP8.5) and 30 % (CAP30), replacing the protein fraction of the microdiet used in the Control treatment. All microdiets were introduced in the feeding regime of gilthead seabream at first-feeding (3 DAH), being offered close to satiation and maintained until the end of the experiment (34 DAH). Along with microdiets, larvae were initially co-fed with enriched rotifers until 13 DAH. Compared to a standard feeding regime comprised by live-prey only, the quantity of rotifers provided to all treatments was initially reduced by 20 %, gradually decreasing to 40 and 85 %, from 7 to 13DAH, respectively. From 12 to 23 DAH, a residual amount (0.3 nauplii mL^{-1}) of *Artemia* AF was maintained in the rearing tanks, with larvae feeding on the microdiets alone from 24 to 34 DAH. Larvae were reared at an initial density of 120 larvae L^{-1} in triplicate 100 L conical-cylindrical fibreglass tanks set in a partially-closed water recirculation system. Larvae were sampled at 2, 12, 20, 27 and 34 DAH for dry weight and total length. Larval survival was determined the end of the trial. Microdiet particles and live-prey present in larval digestive tract were assessed by visual inspection throughout the experiment.

Results

Following two hours of immersion in seawater, the novel microencapsulated prototype released only 25 % of its content in water-soluble protein, 65 % less than values obtained in the reference curve (90 % of leaching during the same period).

At 12 DAH, a higher number of seabream larvae was observed with microdiet in the digestive tract than with live-prey. At this age, a significantly higher larval dry weight was observed in CAP8.5 and CAP30 than in the Control treatment (Fig. 1). At 34 DAH, larvae from the CAP8.5 were significantly larger than larvae from the CAP30 treatment. No significant differences were obtained between the former treatments and the Control. Larval survival was not influenced by the microdiets (4-7% in all treatments).

(Continued on next page)

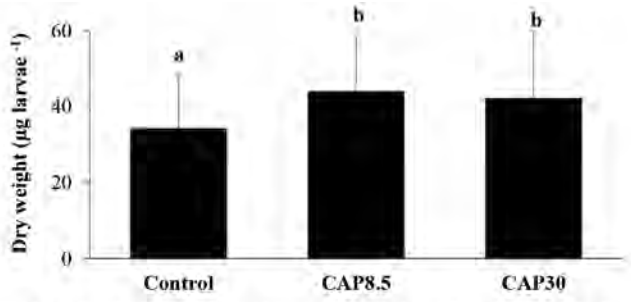

Fig. 1. Dry weight of 12 day-old seabream reared under different dietary treatments. Results are expressed as means ± standard deviation ($n = 60$).

Discussion

This study showed that seabream larvae benefited from the dietary inclusion of a microencapsulated prototype able to reduce leaching of water-soluble proteins during the first days of development (CAP8.5 and CAP30). Yet, in comparison with the Control, only larvae from the CAP8.5 treatment maintained a good performance at the end of the trial. These findings suggest that high dietary protein hydrolysate levels may not be adequate for seabream following the first two weeks of development, as reported previously for Senegalese sole larvae (Canada et al., 2017). Furthermore, growth in all treatments was very similar to findings published by Mata-Sotres et al. (2016) for seabream fed on live-prey only. Therefore, although there is still room for technological improvements in commercial diets, an early weaning and high live-feed replacement during the first weeks of development may now be as an avenue to explore in gilthead seabream hatcheries.

Introduction
Oyster culture is one of the most economically productive sector of Portuguese aquaculture (INE, 2019).

The primary species, of oyster, cultured in Portugal is the Pacific oyster, *Crassostrea gigas*, and the most common methods of culture are mesh bags attached to tables (Conte and Moore, 2001). The portuguese oyster, *Crassostrea angulata*, was historically locally abundant in portuguese estuaries, but now it is present only in relatively few locals of the Iberian Peninsula (Ruano, 1997; Fabioux, 2002), like Mira and Sado estuaries. This species is mainly found in wild beds, with distinct edaphoclimatic conditions, than those found in production nurseries. Those wild beds are usually found in areas upstream of estuaries where oysters are subject to particular unfavorable ecological conditions. In contrast, in ocean-influenced farms, oysters are subject to other unfavorable conditions, typical of production sites

There was a significant change in bivalve mollusc production. Initially, in Portugal, it was choosed exclusively for semi-intensive production in large areas, at this moment there is a intensification of production in less land area, increasing the animal density. This option took to changes that were described in other places, which had result in lower growth rates, lower product quality, lower fertility rates and epizootic diseases (Grizel et al., 1987).

Materials and Methods
Two population of oyster, Portuguese oyster (n=30) from Sado estuary and Pacific oyster (n=30) from Alvor lagoon, were surveyed. An anatomohistopathological examination was performed. The tissue samples for histopathology were fixed in Davidson's fixative for 48h, dehydration, embedding in paraffin and cutting with a microtome in sections less than 5 µm thick, then stained with Hematoxylin and Eosin (H&E).

Results
The macroscopic lesions were recorded in the specimens collected in wild beds (*C. angulata*) and farmed oysters (*C. gigas*). In samples of wild beds oysters there was observed 20% with mud blisters, mainly caused by *Polydora sp*., 33% with gills lesions and 10% with foot diseases. In farmed population there was observed only 10% with mud blisters. The histopathology showed, that of portuguese oysters sampled, 30% had *Trichodina sp*. in gills and mantle epithelium. Similarly, 20% contained *Ancistrocoma sp*. in the digestive gland tubules. Of the farmed oysters sampled, 23% had *Trichodina sp*. and 27% had *Ancistrocoma sp*. Copepods (*Mytilicola sp.*) were observed within the intestine of oysters at prevalences of 17% and 3% for wild and farmed oysters, respectively.

Concerning tissue lesions and morphological alterations, 27% of wild oysters showed metaplasia in digestive gland and 36% hemocyte inflammation, mainly in connective tissue. Regarding to farmed oysters, 6% showed metaplasia and 13% showed hemocitosis. No other serious morphological changes or lesions were detected.

(Continued on next page)

Discussion and conclusion

In the present study, two *Crassostrea sp.* population were sampled with the objective to evaluate the sanitary condition of these population. The lesions can be a consequence of factors such as pathogens, seasonality, temperature, reproductive cycle, host density and general state of the hosts. Most of the parasites found among 60 oysters examined are commonly observed in oyster populations worldwide and are usually of negligible or minor significance as pathogens, but when there are massive infestations of these parasites, they can lead to host weakness (Ruano and Dias, 1994; Ruano, 2008). No organisms potentially pathogenic to humans were identified

Organic lesions, such as metaplasia and hemocytosis, may reflect physiological stress, contaminants or the presence of large parasitic loads. (Ruano and Dias, 1994)

The identification, the characterization and the registration of pathologic processes in oysters constitutes important measures for sanitary control.

Introduction
The culture of bivalve molluscs is an activity with high expression in Portuguese aquaculture. It represents 55% of whole production, being the main species, clams, oysters and mussels. Oyster culture is an important production in Portuguese aquaculture, accounting for about 17% of the total production in this sector (INE, 2019). The primary species cultured is the Pacific oyster, *Crassostrea gigas*, and the most common methods of culture are mesh bags attached to tables (Conte & Moore, 2001).

Materials and Methods
We surveyed a population of Pacific oyster from Alvor lagoon, south coast of Portugal, cultivated in a strong ocean-influenced environment. Those farms use high densities during the production cycle which could induce unfavorable conditions for animal welfare.

We took a sample of this population (n=30) for gross lesions and histopathological examination. The tissue samples for histopathology were fixed in Davidson's fixative for 48h, dehydration, embedding in paraffin and cutting with a microtome in sections less than 5 µm thick, then stained with Hematoxylin and Eosin (H&E). Morphological changes and pathogens were recorded.

Results
In the population sampled we observed 10% with mud blisters (mainly caused by *Polydora sp.*). The histopathology showed the presence of protozoan ciliates, 23% *Trichodina sp.* and 27% of *Ancistrocoma sp*. Copepods (*Mytilicola sp.*) were also present in the intestine lumen at prevalences of 3%.

Concerning tissue lesions and morphological alterations, 6% of the animals showed metaplasia in digestive gland and 13% showed hemocitosis, indicating an inflammatory process, mainly in connective tissue. We also observed that most animals sampled had destruction of the cover epithelium of diverticula of digestive gland and necrosis of hemocytes.

Discussion and conclusion
In the present study a population of *C. gigas* were sampled with the objective to evaluate the sanitary condition of this population with an historical of severe mortalities. The lesions can be a consequence of several biotic and abiotic factors such as pathogens, seasonality, temperature, life cycle, host density, and general state of the hosts. The parasites found are common in oysters and usually are not a risk, unless in massive infestations that can lead to host weakness (Ruano e Dias, 1994; Ruano, 2008). Lesions of the internal organs, such as metaplasia, may reflect physiological stress, contaminants or the presence of large parasitic loads (Ruano, 1994). The destruction observed in the epithelium of the diverticula of the digestive gland, the hemocytic infiltration and necrosis are usually associated with an inflammatory process that could be related with the presence of the virus and associated bacteria, such as *Vibrio splendidus* and *Vibrio aestuarianus*.

ASSESSMENT OF FOULING COMMUNITIES ON OFFSHORE AQUACULTURE STRUCTURES IN MADEIRA (EASTERN ATLANTIC)

L. Png-Gonzalez*, P. Ramalhosa, S. Álvarez, I. Gestoso, J. Canning-Clode, N. Nogueira

Centro de Maricultura da Calheta/ARDITI, Edif. Madeira Tecnopolo, Piso 2. 9020-105 Funchal, Portugal
E-mail: lydiapng@gmail.com

Introduction

The archipelago of Madeira (Portugal) is located in the Eastern Central Atlantic and belongs to the biogeographical region of Macaronesia (Madruga et al. 2016). The aquaculture industry is an emerging activity in the island, accounting for 60% of national sea bream production. Given the physical and oceanographic features of this outermost region, and the lack of information regarding environment and ecosystem management, there is a need to characterise and update the faunal database. Therefore, the present study serves as a prior assessment to identify the epifaunal communities on offshore aquacultures structures.

Materials and methods

The study was performed in two aquaculture facilities rearing gilthead sea bream (*Sparus aurata*), located in the south coast of Madeira. Experimental units consisted in PVC plates (10x10cm) hung at the seacages, facing down to the bottom and sustained by bricks. All replicates (n=36) were submerged at -1m depth on the external ring of the floating structure, avoiding any contact with the net and surrounding ropes. Sampling was repeated monthly, by means of photographs, in order to assess the structure and dynamics of fouling communities. After four months, the remaining sets were translated to the laboratory to sort and identify macrofaunal organisms.

Results

Organisms were sorted and counted into main phyla, including arthropods, annelids, molluscs and other fauna. Preliminary results suggest significantly larger abundance of arthropods in both aquaculture operations. Major groups within arthropods were identified as amphipods, copepods, decapods, isopods, tanaids and pycnogonids. Amphipods were considered the outstanding group, since their abundance was represented by ~87% of the overall. However, non-significant differences were found between installations, even if the geographical location and oceanographic conditions at each location differ.

Discussion and conclusion

Epifaunal assemblages, namely amphipods, play an important role as trophic resources for fish populations (Vázquez-Luis et al. 2009). In this sense, amphipods respond to habitat alterations and can be used as indicators of environmental impacts (Png-Gonzalez et al. 2014). Moreover, the periodic sampling of the fouling community helps to understand the dynamics and detect further impacts (Greene and Grizzle 2007), such as aquaculture pollution (Sliskovic et al. 2011), by the presence/absence of sensitive species.

Given the different location of both aquaculture facilities (closed bay *vs.* open sea) and, therefore, the oceanographic characteristics at each location, significant differences in the fouling abundance were initially assumed. The lack of proper evidences suggests good management practices according to the fish production and the carrying capacity of the local environment.

SALINITY REDUCTION BENEFITS EUROPEAN EEL LARVAE: A REVIEW

S.N. Politis*, E. Syropoulou, E. Benini, S.R. Sørensen and J. Tomkiewicz

Danish Technical University, National Institute for Aquatic Resources, Lyngby, Denmark
Email: snpo@aqua.dtu.dk

Introduction

European eels (*Anguilla anguilla*) are euryhaline species that undertake a catadromous reproductive migration resulting in eel offspring naturally occurring in a hypo-osmotic environment in the ocean. Here, plasma osmolality is lower than the environment and offspring need to maintain osmotic balance through desalting processes to counteract osmotic water loss. Interestingly though, reducing salinity during early life history rearing in aquaculture results in better growth and survival (Okamura et al., 2009; Politis et al., 2018). Here, we overview three studies on effects of salinity reduction on captively produced European eel larvae, in the quest to elucidate functionality and timing of osmoregulation related processes affecting larval performance and assess optimal conditions for rearing European eel larvae.

Materials and Methods

First investigations focused on European eel offspring reared in 1L beakers throughout the yolk-sac stage. Here, larvae reared at 36 psu (control), representing the salinity occurring in the natural spawning area in the Sargasso Sea, were compared to larvae reared under conditions where salinity was decreased on 0 or 3 days post hatch (dph) and at rates of 1, 2 or 4 psu/day, resulting in seven different salinity treatments (con, 01, 02, 04, 31, 32 and 34). Secondly, at actual hatchery level, eel larvae were reared in replicated 8L Kreisel tanks connected to Recirculating Aquaculture Systems (RAS) under four different salinity reduction protocols: i) 4 psu/day step-wise (fast treatment) or ii) 24h drip-wise (slow treatment) reduction regimes as well as iii) an extreme reduction on day6 from 36 to 18 psu (drastic treatment) *vs* iv) a control treatment, where salinity was kept constant at 36 psu. As such, also the possibility of applying a more efficient salinity reduction, requiring only two stable RAS engines, was further explored. Finally, a third study investigated at which stage this salinity change should be implemented in order to counteract the high mortality observed during the first 6 days post hatch (dph). Here, larvae reared in constant 36 psu (control) were compared to larvae experiencing an extreme change in salinity from 36 to 18 psu either on day 1 (drastic 1), day 2 (drastic 2) or day 3 (drastic 3), respectively.

Results and Discussion

In all experiments, larval mortality was highest when salinity was kept at 36 psu (control), which resembles the salinity regime larvae would naturally encounter in the oceanic spawning area in the Sargasso Sea. Earliest results show that the earlier and faster salinity is reduced, the higher the larval survival. Reducing salinity, especially on 0 dph and at 4 psu (fastest reduction) resulted in reduced mortality (Fig. 1), increased body area, higher growth, reduced oil drop utilization and improved growth efficienc . However, starting salinity reduction on 3 dph can result in a more balanced mortality/deformity ratio. The applicability of the gained knowledge was then tested on an actual hatchery level. Here, larval survival was improved up to 50% when salinity was reduced slow, representing a physiologically gradual and gentle salinity reduction, for both eel larvae and the RAS biofilte . Fortunately, larval survival was equally improved when salinity was reduced fast, which represents a salinity reduction protocol in line with previous experimental findings. Considering a full-scale hatchery production, this is a more realistic and cost-efficient approach - reducing the need for dedicated RAS for each batch produced. Thus, the fast salinity reduction approach can be applied using a few RAS engines already set at the desired salinity steps, ensuring the water quality stability of each system and microbial equilibrium of each biofilte , respectively. Moreover, the larvae of the drastic treatment showed similar survival to the control, as they were also reared at 36 psu until day6, but were astonishingly able to cope with the extreme physiological change when they were then drastically moved into 50% reduced salinity. As such, a new question raised was at which stage or age this drastic change should be applied in order to counteract the high mortality observed during the first 6 dph. Here, the final study showed that the earlier the drastic salinity regime was introduced, the higher the larval survival. These results prove that a drastic salinity reduction can be applied, also resulting in 50% increased larval production by applying the most cost efficient salinity reduction, requiring only 2 stable RAS engines. Results relating to larval performance will be presented including morphological and physiological measurements substantiating insights and defining optimized rearing protocols.

(Continued on next page)

Conclusion

We conclude that salinity reduction benefits European eel larvae in terms of lower mortality and improved growth efficienc , which is likely facilitated by an energy surplus associated to lower osmoregulation demands. At the same time, we established the technically most efficient salinity reduction methodology from a hatchery cost-benefit point of view. Hence, the overall knowledge gained adds to our understanding of underlying biological mechanisms during early life history of European eel and provides a promising step towards optimized rearing conditions in the strive for sustainable aquaculture of this species.

All mentioned studies were most notably funded by the Innovation Fund Denmark under grant agreements no. 5184-00093B (EEL-HATCH) and 7076-00125B (ITS-EEL).

Introduction

The majority of harvested sea cucumbers are exported to Asian seafood markets, primarily as a dried product called *beche-de-mer*. The intensive exploitation of this resource has contributed to deplete natural populations of several species (Meloni and Esposito, 2018; Purcell et al., 2018). Aquaculture production of sea cucumbers has expanded rapidly in recent years but mainly in Asian countries. In Europe, the aquaculture production of these echinoderms is non-existent, reflecting the low scientific production on the topic. In Portugal, like in Mediterranean countries, there are native species with high commercial value, which can be potential candidates for aquaculture. However, there are very few studies of larval development of European species from broodstock harvested in the natural environment (Domínguez-Godino et al., 2015; Domínguez-Godino and González-Wanguemert, 2018; Rakaj et al., 2017) and none for matured broodstocks in captivity. The control over the reproductive cycle is an important tool for rearing success, which, in turn, decreases the pressure over natural stocks. The present work studied the influence of three diets administered to *Holothuria tubulosa* Gmelin, 1971 broodstocks on the viability of larval development.

Materials and Methods

Holothuria tubulosa (N=100) were harvested in January 2018 in the coastal zone of Arrábida (38°28.011'N08°59.374'W). The sea cucumbers were randomly distributed in three tanks (N=30 per tank) in a recirculating aquaculture system (RAS) at 15.8±1°C and salinity 33±1. Afterwards, *H. tubulosa* were fed for 120 days with different diets: diet 1 - frozen microalgae mix; diet 2 - live microalgae mix; diet 3 - live microalgae and dry extruded feed. The gonadosomatic index (GI, % ± SE) was assessed at the beginning (N=10) and at the end of the trial (N=10 per diet). Histological analysis was performed to evaluate the gametogenic development stage of *H. tubulosa* fed with each diet. At the end of the trial, the spawning of *H. tubulosa* was induced by thermal stimulation, raising the water temperature by 5°C for 2 hours (Domínguez-Godino et al., 2015; Domínguez-Godino and González-Wanguemert, 2018; Rakaj et al., 2017). The larval development, from all batches, occurred at the temperature (mean ± SD) of 21±1°C and salinity (mean ± SD) of 33±1. The larvae were fed with a mix of *Isochrysis galbana* and *Phaeodactylum tricornutum* during 27 days. Daily, samples were collected to evaluate the survival and the larval development.

Results

At the beginning of the trial, the GI was not quantified because the gonads were not present. In the end of the trial the GI was higher in individuals fed with the diets 2 (9.9 ± 2.5%) and 3 (9.5 ± 2.5%) than in *H. tubulosa* fed with the diet 1 (4.1 ± 1.2%), although without statistically significant differences (p>0.05). At the end of the trial, the broodstock fed with diet 1 were immature (30%) and mature (50%). The broodstock fed with diet 2 and diet 3 were immature (50% in both batches), mature (40% e 10%, respectively) and spawning (10% in both batches). The embryonic development occurred in the first 72 h post fertilization in larvae from all the broodstocks. In the larval rearing from broodstock fed with diet 2, total mortality was observed after the onset of mid auricularia stage at day 7. The late auricularia and doliolaria stages appeared first in larval rearing from broodstock fed with diet 1 (on day 17 and 25 post fertilization, respectively) while in larval development from broodstock fed with diet 3 appeared two days later (on day 19 and 27 post fertilization, respectively). The first larvae in the pentactula stage were observed on day 27 in larval rearing from broodstock fed with diet 1 and diet 3.

(Continued on next page)

Discussion and conclusion

The histological analysis allowed evaluating the gonadal maturation stages in captivity. Broodstock fed with diet 2 and diet 3 presented *H. tubulosa* in the spawning stage while the broodstock fed with diet 1 presented only immature and mature individuals. Even so the thermal shock treatment used was an effective method that allowed obtaining larvae from the different broodstocks fed with the three diets. The larval cycle *H. tubulosa* was consistent with that of holothurians reared previously; however, the duration of the larval stages differs from other species (Domínguez-Godino et al., 2015; Domínguez-Godino and González-Wanguemert, 2018). In this study, with a controlled temperature of 21°C, the late auricularia stage was achieved 3 days earlier than previously recorded in a study regarding the same species, with a controlled temperature of 24°C (Rakaj et al., 2017). This was observed in the larval development from the broodstock fed diet 1. However, Rakaj et al. (2017) achieved the doliolaria and pentactula stages one day before us. The pentacula stage was obtained from broodstock fed with diets 1 and 3 suggesting that this species can accept different types of diets as frozen microalgae mixes or live microalgae and extruded feeds. These diets can be used for *H. tubulosa* broodstock conditioning with hatchery production purposes. Nevertheless, varying the broodstook diet can yield differences in larval survival and development of *H. tubulosa*.

Introduction

Sea urchin roe is becoming an extremely appreciated delicacy in occidental gastronomy. Besides that, it also has a high nutritional value, being rich in of protein, lipids, fatty acids (mainly ω3-PUFA), carotenoids, vitamins and minerals. The high commercial value and the continuously growing market demand are starting to cause the decline of sea urchins natural stocks in Europe, namely of *Paracentrotus lividus* (Lamarck, 1816). Thus, the interest in sea urchin aquaculture has increased in the last decade and it is possible to do gonadal enhancement. For this purpose, harvested adult sea urchins are maintained in captivity and fed with artificial diets, to improve gonad yield and quality. This study aimed to assess the gonad yield and nutritional quality of *P. lividus* maintained in captivity and fed with a jellified diet in comparison to wild individuals. This assessment was performed with different duration of the gonadal enhancement period.

Materials and Methods

Adult *P. lividus* (N=120; test diameter >35mm) were collected in intertidal rocky pools from the coast of Peniche (Portugal). Initially, 40 animals were sacrificed, in order to collect biometric data and determine their gametogenic stage through histology. The remaining sea urchins (N=80) were maintained in a recirculating aquaculture system (RAS), at ambient temperature, with a 12h photoperiod. They were fasted for a week. Afterwards, *P. lividus* were fed *ad libitum*, with a jellified diet (maize, spinach, pumpkin and agar), during two different periods: 6 weeks (Aqua1) and 12 weeks (Aqua2). At the end of these periods, sea urchins' test diameter (TD), total wet weight (TWW) and gonad wet weight (GWW) were measured, the gonadosomatic index (GI) and the gametogenic stage were evaluated, as well as the total protein (Lowry et al., 1951), lipid (Bligh and Dyer, 1959), carotenoid content (Symonds et al. 2007) and fatty acids profile (Lepage and Roy, 1986) of the gonads. The same analyses were done also to wild individuals (N=40) collected from the same original population, at the end of each gonadal enhancement period (Wild1; Wild2).

Results

Regarding somatic growth of the sea urchins, it was verified an increase in TD (Aqua1: 6.40% and Aqua2: 3.33%) and TWW (Aqua1: 18.70% and Aqua2: 8.51%). However, biometric results showed that GI was higher for wild *P. lividus* (10.17%) compared to enhanced individuals from both periods (Aqua1: 8.59%; Aqua2: 4.90%), even though Aqua1 did not present statistical differences when compared to Wild1 (Aqua1 *vs* Wild1: p-value>0.050; Aqua2 *vs* Wild2: p-value<0.001). The ideal gametogenic stage for consumption is the pre-maturation, which was achieved by half of the sea urchins in Aqua2 and only 30% of those from Aqua1, in comparison to 40% in Wild2 and 35% in Wild1. In general, biochemical composition of gonads was similar between wild and enhanced *P. lividus*, with protein content (Aqua1: 67.93; Aqua2: 83.54; Wild1: 61.39; Wild2: 106.69 $mg.g^{-1}$) higher than lipid content (Aqua1: 14.65; Aqua2: 21.67; Wild1: 12.88; Wild2: 16.02 $mg.g^{-1}$). The exception was the ω3:ω6 ratio, which was higher in wild sea urchins compared to each gonadal enhancement period (Aqua1 *vs* Wild1: p-value<0.050; Aqua2 *vs* Wild2: p-value<0.050). Comparing both periods, Aqua2 reached a higher lipid content (p-value<0.050), but a lower ω3:ω6 ratio (p-value<0.050). In terms of carotenoid content, an approximate mean value of 10mg per 100g of gonads was assessed for enhanced and wild sea urchins, without significant differences (p-value>0.050).

(Continued on next page)

Discussion and conclusion

The lower GI values obtained in enhanced sea urchins could be related with the fact that the temperature was not maintained constant during the trial. In further investigation, it should be maintained a constant temperature (13-15˚C), in order to increase gonad yield without promoting maturation (Spirlet et al., 2000). Regarding nutritional quality, the results were in accordance with other authors. The protein content was much higher than lipid content (Prato et al. 2018; Rocha et al. 2019). In terms of fatty acids profile, it was obtained a lower ω3:ω6 ratio for enhanced sea urchins, which might be related with dietary input of PUFA resulted from the jellified diet. Even so, the mean values of the ratio were always higher than the recommended value of 1 (Chow, 2007). For that, it could be concluded that wild and enhanced *P. lividus* gonads have a good lipid quality and consequently it can be considered beneficial for human nutrition. Since sea urchins are not capable of *de novo* synthesis of carotenoid pigments (Matsuno, 2001), it can be assumed that the vegetable-based diet used during the trial, which contained low (but detectable) levels of carotenoids, was capable of producing gonads with an acceptable carotenoid content and, consequently, a suitable colour.

Acknowledgements

This project has the financial support of Operational Programme MAR2020, through the project 16-02-01-FMP-0004: Ouriceira Aqua: Aquaculture and Enhancement of Gonad Production in the Sea Urchin (*Paracentrotus lividus*). Also, this study had the support of Fundação para a Ciência e Tecnologia (FCT), through the strategic project UID/MAR/04292/2019 granted to MARE - Marine and Environmental Sciences Centre.

Introduction

The sea urchin *Paracentrotus lividus* (Lamarck, 1816) represents an important economic resource, since its reddish-orange gonads are long considered a luxury food item, with a high nutritional content, particularly in carotenoids. Given the overexploitation of the natural stocks and the high market demand for roe throughout the year, the development of a sustainable and reliable echinoculture is mandatory. In this context, aquaculture is turning to alternative products to be used in formulated feeds, in particular land vegetable products or by-products, allowing the recycling of unprocessed agricultural discards into biomass of high commercial value. Gonads of wild *P. lividus* range from pale yellow to dark brown, both colours considered inappropriate for consumption (Symonds et al., 2007). A bright red-orange range represents the ideal colour for market acceptance and high-priced gonads, as an indication of a high-quality product (Shpigel et al., 2006). The present work studied the influence of three diets on the colour and carotenoid content of the *P. lividus* gonads.

Materials and methods

Wild *P. lividus* adult individuals were collected in Peniche, Portugal (39°22'12.7"N, 9°23'08.2"W) and were starved for 30 days. Three jellified diets were developed, using agar as binding agent: maize and spinach (diet A); maize, spinach and the macroalga *Laminaria digitata* (diet B); maize, spinach and the pumpkin *Cucurbita maxima* (diet C). These diets were given to three different groups of sea urchins for 90 days. Gender identification was made through histological analysis. For colour evaluation, 12 individuals from each diet (6 males and 6 females) were randomly selected. Total carotenoids were extracted in duplicate using acetone (10:1, v:w). Total carotenoid content was determined by UV-Vis spectrophotometry, at a wavelength of 454 nm (Guzman et al., 2010), using an extinction coefficient ($E^{1\%}_{1cm}$) of 2200 (Pocock et al., 2004). For colorimetric analyses, one gonad from each individual was photographed in controlled conditions and photos were converted to CIE L*a*b* (CIELAB colour space, defined by the International Commission on Illumination in 1976). The a* parameter was used to define the "redness" of each gonad, which is usually highly related to carotenoid concentration (Hatlen et al., 1998).

Results

Total carotenoid content in gonads was highest for diet C, considering all individuals (387.3 ± 147.0µg.g^{-1} DW) or males (382.0 ± 199.0µg.g^{-1} DW) and females (392.6 ± 88.6µg.g^{-1} DW) in separate. Diet B led to the lowest carotenoid content for the whole set of individuals (330.2 ± 85.4µg.g^{-1} DW) and for females (343.8 ± 49.4µg.g^{-1} DW), with an intermediate result for males (316.7 ± 114.8µg.g^{-1} DW). Diet A promoted an intermediate carotenoid content, regardless of gender (345.6 ± 108.5µg.g^{-1} DW), as well as for females alone (386.8 ± 72.8µg.g^{-1} DW), but registered the lowest value for males (304.3 ± 128.4µg.g^{-1} DW). In general, females presented higher total carotenoid content (374.4 ± 71.3µg.g^{-1} DW) than males (334.3 ± 147.8µg.g^{-1} DW). Regarding the gonads colour analysis, individuals fed with diet C, with an average a* parameter

(Continued on next page)

of 143.9 ± 6.8, presented more reddish gonads than diet A (139.6 ± 5.9) and B (139.4 ± 6.3). Diet C also promoted higher values than other diets, when considering only males (142.2 ± 8.9) or females (145.6 ± 3.8). Overall, females presented more reddish gonads (143.1 ± 3.6) than males (138.7 ± 8.0). A strong positive correlation (r = 0.8) was found between a* parameter levels and total carotenoid content, when considering all individuals.

Discussion and conclusion

Gonad colour in sea urchins derives mainly from carotenoid pigments (Vizzini et al., 2015), in particular, echinenone and β-carotene (Symonds et al., 2007). Increasing echinenone content is normally correlated with an intense and acceptable gonad colouration (Shpigel et al., 2006). In maize and spinach, predominant in diet A, lutein represents the major carotenoid source (Janick-Buckner et al., 1999; Bunea et al., 2008). In *Laminaria* spp., present in diet B, β-carotene only accounts for 4-6% of total carotenoids, with all-trans fucoxanthin representing 80% (Haugan and Liaaen-Jensen, 1994). The main carotenoid in pumpkin (>80%) is β-carotene, with lower levels of lutein, lycopene and α-carotene (Seo et al., 2005). These factors may partly explain why diet C was the most successful in promoting higher *a values (gonad redness) and carotenoid levels in all analyses. Since echinenone is not commercially available to be used in a formulated feed (Symonds et al., 2007) and there is the need to reduce the dependency from wild macroalgae, this study emphasized the efficacy of accessible vegetable sources, particularly pumpkin, for colour enhancement.

Introduction

Controlling the planktonic larval development represents one of the key bottlenecks for commercial echinoculture. Particularly, the transition from planktonic larvae to benthic juveniles, the metamorphoses, the settlement rates and survival are the most critical stages for full cycle production. For this reason, significant improvements are needed regarding the rearing of early life stages (Carbonara et al., 2018). The provision of suitable food and larval nutrition are key factors for successful larval culture. The diet selected have high impact in larval plasticity, competency, metamorphosis, development rates, deformations and mortality. Moreover, the selection of specific cues will improve settlement rates of competent larvae, decrease mortality and improve the growth of the post-settlement juveniles. The present study was carried out aiming to 1) optimize the larvae survival during rearing phase through the choice of an optimal diet; and to 2) identify of reliable metamorphosis-inducing cues to induce settlement of *Paracentrotus lividus* larvae.

Material and Methods

The larval culture methods were adapted from Castilla-Gávillan et al. (2018) and Carboni et al. (2012). Larvae were cultivated in closed aquatic systems, at a density of 4ind.mL^{-1}, using 50L conical tanks in triplicate. During the experiment, larvae were kept at a salinity of 35, an average temperature of 19.5°C, continuous light and gentle aeration. Three experimental diets were tested: 1) *Rhodomonas baltica* (diet R), 2) *Phaedactylum tricornutum* (diet P) and 3) a mixed diet of these two species (1:1; diet C). Microalgae were fed to the larvae every two days, during their exponential growth phase. The diet ration was calculated according to the larval stage of development: larvae with two, three, four pairs of arms and rudiment were fed with 1000, 3000, 6000 and 12000cells.mL^{-1}, respectively. The microalgae rations were standardized for equivalence between cell volume and number of cells for each treatment, according to the known microalgae biovolume. Larval body length (BL), body width (BW), post-oral arm length (PAL) and rudiment length (RL) were measured to characterize growth and morphology of larvae fed with different diets. Larval survival was assessed volumetrically every two days.

The settlement experiments were conducted by testing the effectiveness of Detrital Urchin Shell Particles solution (SUP), Ground Ulva Solution (GUS) and Sea Urchin Waterborne (SUW) as metamorphosis-inducing cues. The three metamorphosis-inducing cues were tested with competent larvae reared in each of the diet treatments (diet R, P and C) in a balanced orthogonal experimental design. When the rudiment was equal or larger in length than the stomach, larvae were considered to have reached competence for settlement and were submitted to settlement tests. For each tank, 30 larvae were transferred into petri dishes containing the tested metamorphosis-inducing solutions. The petri dishes containing the competent larvae were incubated at 22°C in the dark and the experiment run in triplicates. Larval settlement and metamorphosis rate were checked at 24h and 48h. Thus, attached larvae with well-developed spines and tube feet were considered properly settled.

Results

For all treatments, BL and BW showed a continuous increase until the age of competence, however in treatment R (BL: 724.74±102.88µm; BW: 664.31±128.29µm) were significantly higher than on the other diets. Diet C also showed body length and width (BL: 666.32±52.89µm; BW: 583.75±60.35µm) higher than diet P (BL: 599.26±48.57µm; BW: 583.75±57.21µm). The results also showed that for diet R and diet C, PAL increased until day 16 post-fertilization and then decreased. For diet P, the PAL increased until day 20 DPF.

(Continued on next page)

The rudiment was observed for the first time on day 14 DPF for diet R, whereas in diet C it was only observed by day 17 DPF, and finally in diet P, at day 20 DPF. The RL for diet P was significantly higher, reaching a maximum RL of 294.44±58.55µm, at day 25 DPF, when compared to the other diets. Competence was first reached by larvae fed with diet R at 20 DPF, followed by larvae fed with diet C at 23 DPF and diet P at 28 DPF, showing that the development of the rudiment was not synchronized between treatments. Larvae fed with diet P showed higher survival at the end of the experiment (17%), when compared to diets R (16%) and C (15%).

The percentages of metamorphosed larvae obtained in response to exposure to SUP, GUS, and SUW were different for larvae fed with different diets. For larvae fed with diet R, SUP showed metamorphosis rates of 46% after 24h of exposure, while diet C only 0.6% of the larvae were induced to metamorphosis. After 48h, SUP induce metamorphosis in diet P (<2%). For both diets R and P, GUS induce metamorphosis at least 7% (24h), while no metamorphosis was found in diet C (after 24h and 48h). For all diets, SUW was the cue with the lowest percentage of metamorphosed larvae (< 4%) after 24h and 48h. While, SUP produce settlement only in diet C (<2%) after 24h and 48h. GUS induce settlement for diet C at least 0,6% after 24h. No settlement was found in diet R and P for SUP and GUS. However, settlement was achieved for all diets for SUW but with a low percentage (<3%).

Discussion and conclusion

Larval survival rates obtained in this study (15-17%) were comparable with the results obtained by Castilla-Gávillan et al. (2018) (13-25%). In the present study, *P. lividus* larvae fed with the *Rhodomonas baltica* (R) diet showed better growth performances, with faster development and longer and larger larvae at 20 DPF. This difference may be explained by a high PUFA content (22:6n-3 and 20:5n-3) that is essential for larvae development (Castilla-Gávillan et al., 2018). It would be expected that *Ulva* sp. solution (GUS) would be the best metamorphosis-inducing cue, however it presented the lowest metamorphosis rates (<7%), both for the larvae of treatment R and P, which was a poor result when compared to 80% obtained for Carbonara et al. (2018). Adapting the use of an inorganic inducer of metamorphosis and settlement from Castilla-Gávillan et al. (2018), SUP showed the highest metamorphosis levels for the larvae fed with diet R. This study highlighted that the microalgae diet influences metamorphosis and settlement of *P. lividus* larvae. The low settlement rates obtained can be explained by the absence of a grazing substrate. Thus, further experiments must be carried out to optimize metamorphosis and settlement post-larvae, as well as metamorphosis-inducing solutions.

Introduction

Among the biologically active substances with antioxidant and adaptogenic effects, which have a stimulating effect on metabolism, selenium can be distinguished. The use of selenium, which is part of a number of hormones and enzymes in the feeding of farm animals in recent years has become increasingly popular, as studies conducted in this direction in various sectors of livestock and fish farming, show positive results (Levina, 2017; Metallo , etc., 2013a, 2013b).

Selenium stimulates growth and development of animals, increases their productivity, fertility. The increase in productivity under the influence of selenium is a consequence of its adaptogenic e fect to various stresses.

Correction of selen – unprofitable states increases nonspecific resistance and normalize nitrogen metabolism, reduces morbidity.

Selenium compounds are able to protect the body from the toxic effects of heavy metals. The presence in the body of a sufficient number of substances involved in antioxidant protection is very important for fish rich in unsaturated easily oxidized fatty acids. Since selenium, vitamin E, methionine are essential nutritional factors and are not synthesized in the body, they should come with food.

An indicator of the security of the body of fish with selenium can serve as the activity of glutathione peroxidase, which it is part of. The maximum activity of glutathione peroxidase in trout plasma was found at the content of selenium in the diet in the amount of 0.15-0.38 mg/kg. Various combinations of selenium and vitamin E can prevent signs of selenium deficienc . Thus, trout has a high content of selenium (0.9 mg/kg) and a relatively small concentration of vitamin E (41mg/kg), or salmon against the background of low levels of selenium in the feed (0.1 mg/kg) increased vitamin E – 500 mg/kg. For channel catfish, the selenium level of 0.25 mg/kg was equivalent to 30 mg/kg vitamin E in feed. These norms were sufficient for normal fish growth and glutathione peroxidase activi .

In high amounts, selenium is harmful. 3- 15 mg/kg are called as toxic doses (Ostroumova, 2012). However, it is known (Lovell, 1996) that in some fish, such as trout, excess selenium is easily excreted through the gills and urine. Consequently, it does not accumulate in the body like heavy metals, but this apparently does not prevent to have a toxic effect on fish at high concentrations in the feed.

Despite the existence of a variety of information in the literature is not enough data on the impact of selenium on the physiological and biochemical processes of mature sturgeon in the reproductive period, in which there are significant hormonal changes.

Materials and methods

The research was carried out in the laboratory of aquatic bioresources and aquaculture on the basis of the experimental aquarium complex "Kagalnik" (Kagalnik, Rostov region) of the Southern scientific center of the Russian Academy of Sciences using a unique bioresource collection. The object of the study was the producers of the hybrid sterlet × beluga. Feeding of breeders was carried out with granulated feeds, introduction of selenium into the feed was carried out by irrigation, pre-diluting the drug E-selenium with water at a concentration of 1:50.

(Continued on next page)

Results

The dynamics of blood parameters was studied to assess the effect of vitamin and mineral supplements of E-selenium in the feed for sturgeon.

Hematological parameters during the entire period of the study were within normal limits. In females of the experimental group, the concentration of hemoglobin, serum protein and beta-lipoproteins at the end of the study was higher in comparison with the control group fish

Analysis of the data on the maturation of females showed that in the experimental group there was a positive dynamics of the transition to the final stages of maturity of gonads. Thus, in the experimental and control groups at the beginning of studies, only 5% of females were at the IV stage of gonad maturity. In the group of fish grown using feed with the addition of the drug E-selenium, for fish at the IV stage of maturity gonads was 30% of the total, in the control group this figure did not exceed 15 %.

Discussion and conclusion

Based on the above, it can be concluded that the use of sodium selenite in combination with vitamin E, first of all, has a positive effect on reproductive function in breeders who have a violation of lipid metabolism.

Additional studies will be conducted to better assess the effect of E-selenium on fish in the pre-spawning period

BIOCHEMICAL ANALYSIS OF SERUM FROM AFRICAN CATFISH *Clarias gariepinus* RAISED IN BIOFLOC SYSTEMS

Omoniyi M. Popoola, Samuel T. Oguntade, Temitayo O Oyesiji and Olajumoke E. Ajibola

Department of Fisheries and Aquaculture Technology, Federal University of Technology, Akure, Nigeria
Email: ompopoola@futa.edu.ng

Introduction

Biofloc, being new in aquaculture systems, has been found useful in recent years. Its principle involves the microbial conversion of nutrient waste in aquaculture systems (ammonia) into microbial biomass which can be reused by the cultured organisms as a food source (Crab et al., 2012). Apart from improvement in feed efficiency and reduction in the nutrient waste, studies have shown that biofloc systems improve fish immunity (Cardona et al., 2016). The study was carried out to assessed the effects of biofloc technology (BFT) application on African catfish (*Clarias gariepinus*) fingerling production with emphasis on its health status using heamatology and biochemical analysis as indices.

Materials and Methods

Two biofloc (Rice bran and Cassava flour C/N = 10) were prepared. The regular additions of organic carbon source (Rice bran and Cassava flour ratio of 10) was adopted to induce the growth of heterotrophic microbial biomass as constituent of biofloc, where no carbon sources were added is the control systems. Nine hundred (900) of *Clarias gariepinus* juveniles (8.89±0.3g) were purchased from Bond farm in Ibadan, Nigeria. Experimental fishes were divided into three groups with replicated as Control, Biofloc rice bran (BR) and Biofloc cassava (BC) respectively. Fishes were fed with 42% crude protein commercial pelleted feed at 5% body weight for 72 days. Water quality parameters in the culture tanks were monitored daily. At the end of 72 days, pooled blood serum was collected from the experimental fish for biochemical analysis. The biochemical parameters examined are Alanine phosphatase (ALP), Aspartase aminotransferase (AST), Alkaline aminotransferase (ALT), Albumin, Globulin, Total protein, Glucose and Cholesterol

Results

The results show that the biochemical parameters measured differed significantly ($p<0.05$) between the treatments (bioflucs and control). (Table 1).

Discussion and Conclusion

Aspartase aminotransferase was observed to be relatively higher in the serum of fishes reared in the control tanks than it is in the fishes raised in the biofloc system this implies that severe tissue damage must have occurred which results in more of the mitochondrial enzyme being released.Increased activities of aminotransferases indicated amplified transamination processes. This occurs due to amino acid input into the TCA cycle in order to cope with the energy crisis during toxicant-based stress (Philip et al., 1995). The significant changes in the activities of AST and ALT enzymes in blood plasma indicate tissue impairment caused by stress experienced in the control treatment (James et al., 1991; Svoboda, 2001). In this research, it was observed that the concentration of glucose in the serum of fishes raised in control tanks are higher than that of bioflocs tanks indication that biofluc improved the rearing stress. Therefore, this study revealed that fish raised in a biofloc systems are able to stand the stress of density and also revealed that fish immunity is improved through the use of biofloc

Introduction

Earth Observation data represents an important and free source of information, which can be used in site selection of shellfish farm and AZA (Allocated Zone for Aquaculture) identification. For instance, as shown in Brigolin et al. (2017), Sea Surface Temperature (SST) and Chlorophyll a can be used for mapping potential biomass yield: these maps can be combined with other selection criteria and constraints by means of multicriteria methodologies, in order to obtain suitability maps. To this regard, mapping the risk of bacterial contamination in coastal areas in relation to the intensity and duration of precipitation can provide an important additional criterion for shellfish farm allocation. In fact, according to the current European legislation (Reg. 854/2004; Reg. 2073/2005; Reg. 2285/2015) areas where the harvesting of live bivalve molluscs is authorised are classified as type A if the product may be collected for direct human consumption. Samples of live bivalve molluscs from these areas must not exceed, in 80% of samples collected during the review period, 230 *Escherichia coli* per 100g of flesh and intravalvular liquid. The remaining 20% of samples must not exceed 700 *E. coli* per 100g of flesh and intravalvular liquid. Furthermore, the competent authority, based on a risk assessment, can decide to disregard an anomalous result exceeding the level of 700 *E. coli* per 100g of flesh and intravalvular liquid. For producers, it is therefore very relevant to operate in areas where the probability of exceeding the above threshold is very low and, should that happen, to be able to provide to competent authorities evidence that the sample was an outlier. In fact, should an A area be reclassified as B at the end of a review period, a producer would have to face depurations costs, leading to a marked decrease of profits. The aim of this study is therefore twofold: 1) to map the risk of faecal bacteria contamination related to rainfall events; 2) to include these maps as additional selection criteria and apply the Spatial Multi-Criteria Evaluation methodology for mapping the suitability of bivalve marine aquaculture (i.e.: *Mytilus galloprovincialis*) in the Veneto regions (North Adriatic Sea - Italy). This approach, if validated, besides providing a valuable input to the planning of aquaculture activities within the framework of the Maritime Spatial Planning Directive, will also allow the application of an early warning alert system, aimed at optimizing the sampling effort of the agencies to which the implementation of the above Regulations is entrusted.

Materials and methods

Faecal bacterial contamination has a terrestrial origin and is usually caused by a malfunctioning of waste water treatment plants, which may occur in presence of heavy precipitation. Ocean colour and temperature data could then be used for assessing the probability that a given location in a coastal area which, on average, is not affected by river plumes, can be reached by freshwater during such events: this probability can be taken as a proxy of the risk of faecal bacteria contamination. This methodology was tentatively applied to the coastal areas off the Veneto region, Northern Adriatic Sea, where mussel farming is a relevant economic activity. In this preliminary application, time series of the main river flow rates (*e.g.*: Po, Piave, Brenta and Adige) were analysed in order to identify discharge peaks after heavy precipitation events (95th percentile). Remotely sensed data detected just after these events were then processed for mapping Total Suspended Matter (TSM) and Sea Surface Temperature (SST). Landsat 8 images, with a resolution of 15, 30 and 100 meters, respectively for the panchromatic, multispectral and thermal bands, were used to estimate the TSM and SST. TSM maps were produced using the Gordon model (Gordon, 1988) for the Landsat 8 Band-4 (Red-Band), while for the SST analysis the Landsat 8 Thermal Bands (Band-10) was used. The satellite images were analysed using Google Earth Engine Code editor software and database, implemented with a Java-script to correct the images, masking the cloud presence over a 20% limit, and selecting the region of interest. The TSM and SST were mapped using QGIS and, in order to evaluate the river plume effects, the shellfish farms were mapped

(Continued on next page)

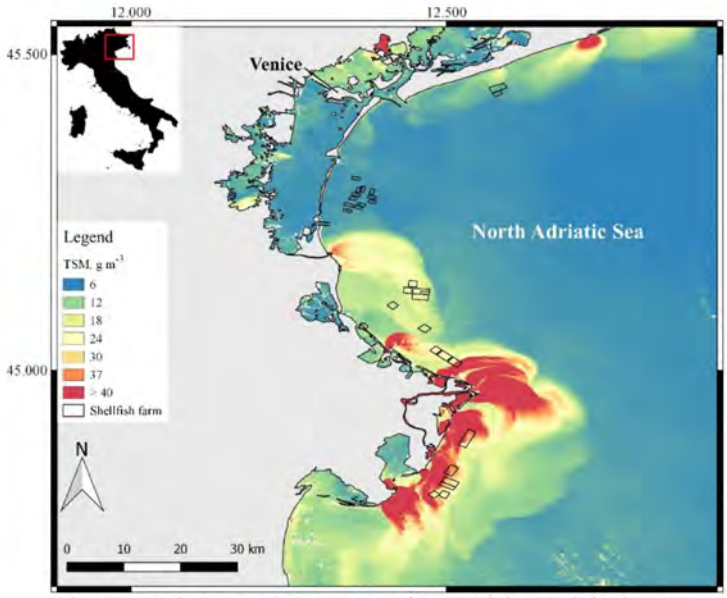

Fig 1. Total Suspended Matter after a high precipitation event (19/11/2014) in the study area.

Results and discussion

The spatial distribution of TSM 2 days after a high precipitation event occurred on 19/11/2014 is show in Fig. 1. As one can see, the river plumes reached shellfish farms located South to the Lagoon of Venice: these areas are more vulnerable to faecal bacteria contamination, with respect to the northern ones.

Based on these findings, satellite data available for the last decade will be processed, in order to estimate the frequency that a given farm is reached by a river plume. The methodology applied will be validated using data of faecal contamination collected in situ and sampled within the studied area immediately after high precipitation events.

After normalization, these frequencies will be used as proxies of faecal bacteria contamination risk. The resulting map will be added to the criteria used in Brigolin et al. (2017) in order to improve suitability maps.

Introduction

Aquaponics is a system that integrates the productions of aquatic organisms and plants, of which the majority of the nutrients (> 50%) that contribute to vegetable growth comes from the wastes of fed aquatic organisms (Palm et al., 2018). Aquaponics represents a sustainable alternative to produce food in a more environmentally friendly manner due to the use of low volumes of water, the diversification of production and the offering of chemical-free products (fertilizers and antibiotics) (Diver and Rinehart, 2010; Hundley and Navarro, 2013; Pinho et al., 2018). In Brazil, aquaponics is still considered a new activity. No organization exists for commercial aquaponics activities or knowledge of the realities related to production. The knowledge of the economic status of aquaponics in Brazil is necessary to encourage the expansion of the activity. The characterization of the production system enables a better understanding of the activity, allowing the prediction of how this activity will evolve and identifying the distribution of the productions in the country and the time in which the aquaponics farms were established. This information can be used to identify the structures, products and processes appropriate for the particularities of each region. In addition, this information may reveal the constraints in the production process that are unknown to Brazilian aquaponic participants and may lead to improvements. This work aims to identify aquaponics production facilities in the Brazilian national territory and characterize the productions.

Material and Methods

An online questionnaire was developed using the Google Forms platform, with questions related to: producer identification; geographic distribution; major animal and vegetable species produced; monthly productions; destinations of production; motivation for production; purpose (research, subsistence, commercial, hobby etc.); amount of resources and infrastructure used. The questionnaire was made available from July to September of 2018 and distributed through social media, educational institutions, research, extension, and in all known professional platforms and discussion groups related to the topic. The data obtained were a descriptive analysis of the general characteristics of aquaponics in Brazil.

Results

The questionnaire received 41 responses, 39 of which completed the questionnaire. The groups of producers identified by the data survey are located mainly in the Southeast (35.9%) and South (30.7%) regions, with no records of this production system in the North (Figure 1A). They are inserted mostly in urban areas (64.1%), with the main purpose of subsistence (30.9%) and commercial/business (30.8%). The first aquaponics enterprise started operations in 2006 and, over a ten-year period (until 2016), there were only 16 new units of production created. However, from 2017 to 2018 there were 11 new aquaponics enterprises per year, with 56.4% being established in less than three years. Since these farms are operating for a short time, 71.8% of the properties perform some experimental trials to improve the production systems and to adapt it to their realities. The coupled production system is predominant (76.9%), the vegetable beds are mainly horizontal NFT (28.2%), semi-dry substrate (28.2%) and hybrid systems (23.1%). There were 39 groups/varieties of vegetables identified, out of which the more prominent were lettuce (84.6%), chives (51.3%), tomatoes (48.7%), arugula (35.9%), strawberry (30.7%), basil (33.3%), parsley (33.3%). There were 21 groups/species of aquatic organisms identified, consisting of the Nile tilapia (66.7%), common carp (28.2%), ornamental fishes (23.1%) and lambari *Astyanax* spp.) (23.1%).

Discussion and Conclusion

The first initiative to identify the groups working with aquaponics in Brazil was carried out between October 2015 and February 2016 by Emerenciano et al. (2016). From the publication of this article to the present day, 22 new aquaponics initiatives were created, with growing interest for commercial purposes, which have already matched those of subsistence. In other words, 61.7% of the aquaponics in Brazil is no longer for research or hobby purposes. Love et al. (2015) identified only one commercial aquaponics in Brazil, much different from the current reality. The high diversity of plant and animal species used in the systems indicate that producers seek to adapt their production for the different regional demands and characteristics, which may hamper the standardization of a technological package, since there is a need to meet the requirements of several species. However, the current scenario demonstrates the potential that aquaponics has as an integrated multi-trophic aquaculture system, to suit different realities.

OYSTER PRIMARY CELL CULTURE: DEVELOPING TOOLS TO UNDERSTAND DISEASE

Robert Potts*, Alejandro Gutierrez, Tim Bean, Ross Houston

The Roslin Institute, University of Edinburgh, Midlothian, EH25 9RG
Email: r.potts-1@sms.ed.ac.uk

Introduction

Pacific oysters (*Crassostrea gigas*) are one of the most important aquaculture species globally. Sustainable production of oysters is hampered by outbreaks of mass mortality caused by Oyster Herpes Virus (OsHV) (Degremont et al. 2019. Understanding of OsHV pathogenesis is limited, and experimental replication of the virus requires serial passage through live oysters. This is partly due to the lack of a relevant immortalised cell line. Establishing an immortalised pacific oyster cell line is a key goal for several research fields including ecotoxicology, virology, immunology, and genetic resistance to disease (Yoshino et al. 2013). The aim of the current study was to establish primary cell cultures from multiple pacific oyster tissues using an optimised culture method, with a view to future cell culture and live oyster disease challenge experiments to better understand host response and resistance to OsHV.

Materials and methods

Live pacific oysters were obtained from a UK oyster farm. Tissues were dissected and sterilized using antibiotic and antifungal treatments under sterile conditions. Tissue explants between 2 mm and 10 mm across were transferred to cell culture well plates pre-coated with matrigel. Sterile filtered media for all cultures was prepared using Leibovitz's L15 media and artificial seawater with antifungal and antibiotic treatments. Plates were sealed and incubated at 22 ºC, and media was refreshed regularly to promote cell proliferation.

Results

Using this optimised method, axenic primary cell cultures from heart, mantle, gill, adductor muscle, gonad and hemolymph have been successfully established (e.g. Figure 1). The cell cultures demonstrate highly confluent and varied cell assemblages demonstrating that the culture technique can be successfully applied to all these tissues without modification. Successful culture of oyster muscle cells has been achieved, which has not been reported previously.

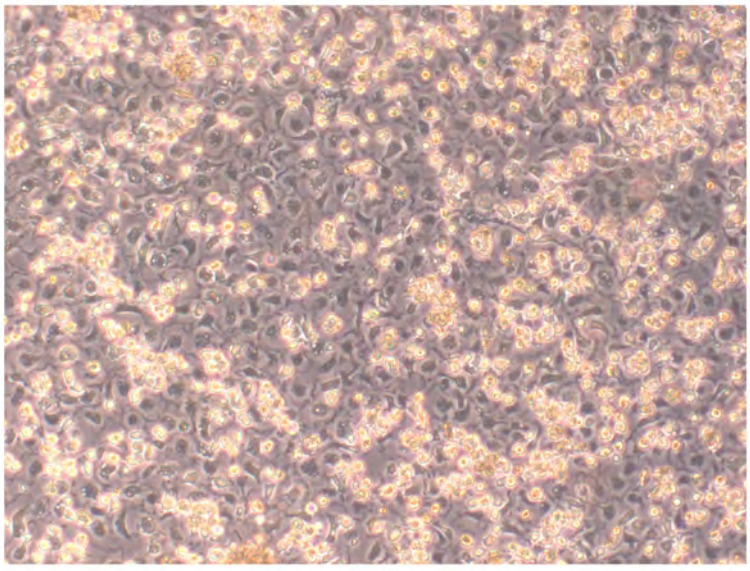

Figure 1) Primary culture of oyster heart cells with multiple morphologies and high confluency. Scale bar = 100 µm

(Continued on next page)

Discussion and future work

The methods developed have produced primary cell cultures that can potentially be used for a range of applications, including the establishment of an immortalised cell line in the future. There are multiple approaches for immortalisation, but these are generally optimised for mammalian cell culture. The immortal gastropod mollusc *Biomphalaria glabratra* cell line was established by careful maintenance and sub-culturing of primary cells (Hansen 1976), which is currently underway with the *Crassostrea gigas* lines. Furthermore, these primary cultures present an opportunity to replicate OsHV in the laboratory, which will be trialled in the future. It is anticipated that these cell cultures will provide tools to improve our understanding of host response and genetic resistance to OsHV in Pacific oysters

Introduction

Hatcheries are nowadays the best alternative to sustain the aquaculture of bivalves, producing the seed needed, increasingly difficult to obtain from natural beds. Unfortunately, these installations are threatened by frequent episodes of larval and post-larval mortalities, which compromise the production and economic viability.

The aetiological agents of these outbreaks have been identified mainly as bacteria belonging to some species of the genus *Vibrio*, opportunistic pathogens naturally associated to the system and lethal when they proliferate under suitable conditions.

In this work, we report the recurrent detection of the pathogen *Vibrio europaeus* in a hatchery along the larval season, affecting five bivalve species cultured

Materials and methods

Different bivalve species are cultured along the year, following the procedures in Centro de Cultivos Mariños de Ribadeo (CIMA, Consellería do Mar, Xunta de Galicia): *Ensis magnus*, *Polititapes rhomboides*, *Ruditapes philippinarum*, *Ruditapes decussatus* and *Donax trunculus*. Microbiological protocols have been implemented for seawater and phytoplancton (food) circuits. A new protocol of microbiological control of larval cultures is being developed, in early stages yet.

Larvae were directly sampled from mesh sieves at the changes of seawater, using sterile loops, and spread on TCBS. Bacterial isolation, preservation and identification of isolates followed the methodologies described in Prado et al. (2014).

Results

The pathogen *Vibrio europaeus* was identified in di ferent cultures of five bivalve species along the season

In March, *V. europaeus* was simultaneously found in initial samples (2-3 days post-fertilization, dpf) of larval cultures of the sword razor *E. magnus* and the banded carpet shell *P. rhomboides*. None of the cultures survived, reaching only 13 and 17 dpf, respectively.

Two months later, the pathogen was isolated from Manila clam *R. philippinarum* larvae (3 dpf). This batch reached settlement, with 53% of larval survival.

In August, *V. europaeus* appeared associated to new species: the wedge clam *D. trunculus* and the grooved carpet shell *R. decussatus*.

In the grooved carpet shell, it was found in initial samples (5 and 1 dpf, respectively) of two batches obtained two weeks apart. Both cultures failed, though in the second one a few number of larvae completed the larval development, being later eliminated.

In the wedge shell clam, *V. europaeus* was found during the settlement of two simultaneous spawns, from broodstock with different geographical origin. Both batches were eliminated at days 34 and 62. In the first one, *V. europaeus* appeared suddenly 29 dpf and only 5 days later the culture failed completely. In the second one, it appeared in samples 31 dpf and it was detected again 36 dpf. The culture recorded heavy mortalities, being successively eliminated the sub-batches (38, 43 and 48 dpf) until the complete discard at day 62.

(Continued on next page)

Discussion and conclusion

Vibrio europaeus was present along the season in the hatchery, acting as a non-host-specific microorganism. The differences in the geographical origin of the broodstock, between and in each bivalve species, and the simultaneous emergence in different moments, pointed to the hatchery as a reservoir. This could also explain its recurrence in the installation.

Regarding to its effects, the bivalve cultures did not complete the larval/post-larval development, with the only exception of Manila clam. However, it should be noted that this bacterial species was initially isolated from episodes of mortality affecting larval cultures of *Ostrea edulis* and small spat of *R. philippinarum* in Galicia hatcheries (Prado et al., 2005; Prado et al., 2015).

Once the microbiological control of larval cultures has been established, and the batches are regularly monitored, complete information will be obtained, about the recurrence and dynamic of the pathogen in the installation, as well as the real effect of its presence in larval cultures.

Introduction

The bivalve hatchery, from a microbiological point of view, may be considered a whole, with a continuous flow of microorganisms between compartments. In many cases, the microbiota is innocuous or even beneficial/necessary for the development of cultures. However, there is a risk of proliferation of opportunistic pathogens. These are mainly bacteria of genus *Vibrio* (Prado, 2006). And, though only a few species cause mortalities in hatchery, and the genus is a common component of marine microbiota, protocols of control based on the presence of vibrios have been useful.

One of the "compartments" is the live food, the microalgae. These cultures are a direct source of bacteria, with a high and constant load of marine heterotrophic bacteria throughout the year. Vibrios may be occasionally detected, being their presence related with environmental and production factors (Dubert et al., 2015). Furthermore, high levels of vibrios seemed to be indicators of problems.

Minihatcheries are small, and relatively low cost, installations designed to obtain individuals suitable for pre-ongrowing. In this work, we present the results of microbiological control of phytoplancton cultures in a Minihatchery, the detection of vibrios and their persistence in surfaces of storage tanks.

Materials and methods

Routine microbiological control of phytoplancton is being implemented in the Minihatchery located on IGaFA (A Illa de Arousa, Galicia, NW Spain). Samples are taken weekly in different points of the circuit of production and distribution of live food. The bacteriological medium Thiosulphate-Citrate-Bile-Sucrose (TCBS) is used to detect the presence of vibrios, with the aim of preventing their transmission to bivalve cultures, as well as indicator of problems in the microalgae. Processing, bacterial isolation, preservation and identification of isolates were performed following Prado et al. (2014)

Results

Routine control showed the presence of vibrios in the phytoplancton stored in the "Harvest-tank" (HT). This tank contains the mixture of different species of microalgae from the continuous culture in 400 l. bags. The tank was cleaned, following the protocol of the installation.

In the next two weeks, the samples of HT continued to show growth in TCBS (presumptive vibrios), although in lesser numbers. The third/fourth weeks, the routine control showed a sharp increase of vibrios in HT and their distribution through the feed circuit. The bags in harvest were sampled. Cultures of *Phaeodactylum* were identified as the source and they were removed.

In the following controls, despite elimination of the sources, the samples of HT continued to show vibrios. Complementary samples of the phytoplancton, just before it reached the tank, demonstrated that the cultures were not the source. The possibility of persistence of vibrios associated to the surfaces of tanks was evaluated. In this case, TCBS contact plates, specially designed by us, were used. Samples were taken from bottom and walls of the tank.

Representative colonies from the samples were isolated and identified. The results showed that two different vibrios (type I and II), initially presented in the phytoplancton, were able to persist weeks associated to the surface of HT, even after their disappearance from the sources, the original cultures.

The Type I was related to the first episode of detection, while the Type II was found in the second episode and the *Phaeodactylum* cultures. Interestingly, both types were isolated from bottom and walls of the HT, after the elimination of vibrios from the harvested phytoplancton and the standard cleaning of the tank.

(Continued on next page)

Discussion and conclusion

The results showed the potential of phytoplancton cultures as source of vibrios in hatcheries. Moreover, the microalgae seemed not affected by these bacteria, being thus "asymptomatic carriers". If the appropriate microbiological controls are not established, the vibrios may be distributed through the installation with the risks implied.

By other hand, the persistence of vibrios in the surfaces of tanks should be taken into account. It is known that many microbes persist attached to surfaces with a structured biofilm ecosystem, where they function as an integral part of a population, obtaining ecological advantages, such as protection from desiccation (Ophir and Gutnick, 1994), or resistance to toxic substances such as antibiotics, chlorine and detergents (Costerton et al., 1987). The present study showed the persistence of vibrios, even after 6 weeks of the first detection in the case of Type I, associated to the surfaces of HT. During this period the tank had been regularly cleaned and treated with chlorine. Hence, the occasional presence of vibrios in the microalgae could lead to their recurrent distribution across the hatchery. Once again, routine microbiological protocols are imperative if we want to control the dynamic of potential pathogens in the installation.

Introduction

Slaughter yields are traits of high economic value especially for fish species sold in the processed form. Common carp is now more and more offered as headless carcass or fillets. However, genetic improvement of slaughter yields is tricky and alternatives are either sib selection based on slaughtered fish, or indirect selection on correlated traits recorded *in vivo* (Kause et al., 2007; Haffray et al., 2013; Vandeputte et al., 2017). In a previous study we combined external (phenotyping, 2D imaging) and internal (ultrasound imagery) measurements to study their phenotypic and genetic relationship to the real slaughter yields of market size Amur mirror carp (Prchal et al., 2018). In the present study, the similar approach was applied but for external measures a 3D digitizer was used to collect body landmarks directly on the fish body, instead of 2D digitizing from images. Thus, the aim of this study was to i) determine best morphological predictors of slaughter yields using combination of 3D landmarks and ultrasound imagery, ii) estimate genetic parameters of slaughter yields predictors, and iii) predict and compare potential genetic gain based on slaughter yields predictors.

Materials and methods

The experimental stock was established by a partial factorial design of 20 dams and 40 sires of broodstock of Amur mirror carp, and 1553 progenies were assigned to their parents using 12 microsatellites. The stock was reared communally until market size under semi-intensive pond conditions. Fish were phenotyped for body weight, standard length, muscle fat content and slaughter yields (headless carcass and fillet yield). External measures were performed using 3D digitization (MicroScribe G2LX) and fifteen coordinates of morphological points were digitized. These coordinates were used to calculate lengths, heights, areas and volumes. Five internal measurements were collected through ultrasound imagery (Hospimedi LC1000, 7.5 MHz). Slaughter yields were calculated as log-log residuals of the regression with body weight, and their predictors were estimated using a multiple linear regression model including 3D external and ultrasound imagery internal morphometric variables using the reg.best function of the FactoMineR of R software. Heritabilities and genetic correlations were calculated using an animal model with software DMU with a fixed effect of sex. Genetic gains were calculated using breeder's equation (Falconer and McKay, 1996) for theoretical mass selection (MS), full-sib selection (FSS) and indirect selection (IS) with 10% and 30% proportions of selected individuals.

Results

The accuracy of the phenotypic prediction was high for headless carcass yield ($R^2 = 0.59$) and intermediate for fillet yield ($R^2 = 0.49$). Heritability of predicted slaughter yields (0.46 – 0.56) was high and highly genetically correlated with the real yields ($r_g = 0.86 – 0.88$). Besides, three individual predictors (P_1, P_2, and P_6) included in the prediction models showed high heritability estimates ($h^2 = 0.40 – 0.66$) and moderate to high genetic correlations to the slaughter yields ($r_g = |0.44 – 0.80|$). The expected genetic gain (with 10% and 30% proportion selected) per generation calculated for fillet yield using model-predicted fillet yield was 0.65% and 0.43%, respectively. The best individual predictors achieved expected genetic progress for fillet yield in range of 0.41% – 0.48% for a proportion selected of 10 % and 0.27% – 0.32% for a proportion selected of 30%.

(Continued on next page)

Discussion and conclusion

Heritability estimates of predicted slaughter yields and individual predictors using 3D landmarks were similar to previous study on common carp using 2D landmarks (Prchal et al., 2018) but higher than in other fish species (Haffray et al., 2013; Vandeputte et al., 2017). Genetic correlations of model-predicted yields and the best individual predictor (P_2) were slightly lower when compared to 2D-based predictors (Prchal et al. 2018) as well as regarding the expected genetic gains using indirect selection on predictors for fillet yield improvement. In conclusion, 3D predictors also have a solid potential for genetic improvement of slaughter yields in common carp. While such predictors are not better than 2D predictors, they are much more convenient and faster to collect in the field, as they do not imply post-processing of images. These practical aspects should be taken into account in the future carp breeding program.

Introduction

The mussels *Mytilus galloprovincialis* and *Perna perna* are species of aquaculture interest distributed along the Moroccan coast. Despite interspecific hybridization is a naturally occurring process between congeneric species, barriers to hybridization are strong, numerous and often prevent the movement of genes from one species to the other (Arnold, 1996). DNA based molecular methods using polymerase chain reaction (PCR) allow nowadays the identification of those two species and their hybrids from overlapping zones. Hybrids are of upmost interest in mytiliculture for they gather properties of the parental species and are a priori genetically neutral to the environment.

Materials and methods

More than one thousand blue mussels (*M. galloprovincialis*) and green mussels (*P. perna*) were sampled from the Moroccan coast and their DNA was extracted and purified with the method FENOSALT (Pérez and Presa, 2011). Enzymatic digestions were carried out separately on genes 18S, ITS1, and ME, and reactions were incubated for 4h at 37ºC. Differentiation between both species and their hybrids was done upon diagnostic allele sizes for each species. Additional sequencing of mtDNA Cytochrome-C Oxidase subunit I gene was performed in an ABI Prism 3100 capillary sequencer using the BigDye Terminator Cycle Sequencing Standard (Applied Biosystems). Phylogeny and molecular evolutionary analyses were conducted using MEGA 5.1 software (Tamura et al., 2011) using maximum likelihood computation on 10000 bootstrap replications and applying the "General Time Reversible Model" for substitutions.

Results and discussion

Individuals belonging to genus *Mytilus* showed two bands from 18S-RFLP restrictions (68bp and 169bp) while just one band (237bp) from *Perna* mussels. Hybrids showed three bands (68bp, 169bp and 237bp). Such RFLP technique revealed 46% *M. galloprovincialis*, 33% *P. perna* and 21% hybrids from overlapping zones. The mitochondrial Cytochrome C Oxidase subunit I gene sequenced was also a powerful marker for species discrimination, i.e. 59% were *Mytilus*, 39% were *Perna*, and only 2% exhibited an unambiguous recombinant gene molecule between *Perna* and *Mytilus*. Interbreeding between *M. galloprovincialis* and *P. Perna* can take place at cytoplasmic level (mtDNA) as has also been observed at nuclear level (18S rDNA) but no mechanism explains satisfactorily the recombination of uniparentally or double uniparentally inherited mitochondrial genome of those species. Independent of mechanistic mtDNA genomic arrangements which need further hypotheses testing on in vitro crosses, hybrids can be of great interest in aquaculture for their novel properties and propagative safety.

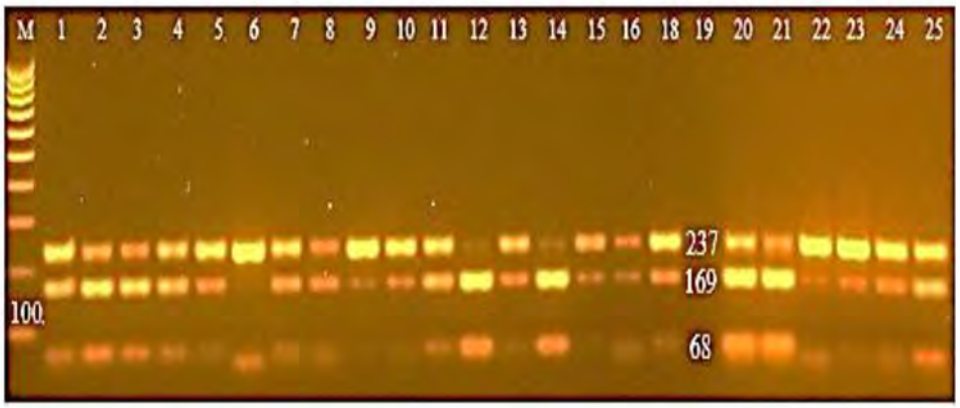

Fig. 1. Agarose gel pic showing profiles of 18S rDNA RFLP patterns on mussels from the *M. galloprovincialis* (68+169bp) - *P. perna* (237bp) overlapping zone and their hybrids (68+169-237bp).

MOLECULAR IDENTIFICATION OF A NEW GROUPER SPECIES *Polyprion* spp FROM SOUTH AFRICA

P. Presa[1*], A. Pita[1], N.R. Matusse[2] and M. Pérez[3]

[1]Laboratory of Marine Genetic Resources, Faculty of Biology, University of Vigo, 36310, Spain

E-mail: pressa@uvigo.es

Introduction

The systematics of *Polyprion* spp in the Southern Hemisphere is far from resolved due to records of sympatric congeneric species. For example, early records of *Polyprion* in South Africa were assigned to *P. americanus* (Rowan and Rowan, 1955) but some evidence suggests that they might correspond to *P. oxygeneios* (Andrew et al., 1995). Preliminary distinctive mtDNA profiles and microsatellite genotypes allowed hypothesizing that a third species of *Polyprion* might exist in the Indian Ocean waters off South Africa (Ball et al., 2000). The clarification of *Polyprion* systematics is key for the management of wreckfish fisheries as well as for its aquaculture development (Matusse et al., 2016) provided its good flesh qualit , large size and high market price .

Materials and methods

Thirty-seven Cytochrome Oxidase I sequences from *Polyprion* spp. individuals sampled worldwide were obtained at CACTI facilities (University of Vigo). Maximum Likelihood phylogenetic tree (ML) were inferred upon the 37 sequences plus nine from *P. americanus* and six more from *P. oxygeneios* deposited in BOLD database. Additionally, the relationship between COI haplotypes from both species was appraised from a Neighbor-Joining tree built with the Recombination Detection Program – RDP4. The divergence time between species was inferred using a standard mtDNA-clock (Avise et al., 1998).

Results

The ML tree comprised 3 well-supported clades: one group comprised *P. americanus* from the Atlantic North, South America and the South Indian Ocean and Oceania. The second clade comprised all samples of *P. oxygeneios* and the third clade comprised all specimens from South Africa. The NJ tree based on eight COI haplotypes showed two main supported clades, one comprising three haplotypes of *P. oxygeneios* and the other one comprising four haplotypes of *P. americanus*. A specific haplotype from South African samples formed a well supported intermediate clade between the two major clades of *P. americanus* and *P. oxygeneios*.

Discussion and conclusion

While current NJ dendrogram is largely consistent with previous UPGMA on microsatellite variation (Ball et al., 2000), the position of the South African sample within the *P. americanus* cluster contrasts with its position outside *P. americanus* and *P. oxygeneios* using mtDNA COI phylogenies. Those contrasting results suggest that wreckfish specimens caught in South Africa belong to a distinct mitochondrial lineage within *Polyprion*. The support of the South African COI haplotype as phylogenetically intermediate between *P. americanus* and *P. oxygeneios* strongly suggests a hybrid origin of the South African wreckfish. Based on conventional molecular clock of 2% divergence among COI sequences per My (0.69% - 3.00% molecular fork in fishes, Avise et al., 1998), the South African *Polyprion* divergence from parental species would date back to 1.4 My (0.92My – 4.00My). Such temporal fork comprises the advent of glacial cycles and cold-water upwelling around South Africa some 2.5My ago (Shannon, 1985).

INGESTION RATE AND NUTRITIONAL REQUIREMENTS OF JUVENILE RED SEA URCHIN Loxechinus albus FROM THE XII CHILEAN REGION

P. Presa[1]*, M. Martínez[1], M. Palacios[2]

[1]Marine Genetic Resources Laboratory, Faculty of Biology, University of Vigo, 36310 Vigo
E-mail: pressa@uvigo.es
[2]Programa de Doctorado en Ciencias, Mención en Ecología y Evolución, Universidad Austral de Chile, Independencia 641, Valdivia, Chile

Introduction

The Chilean red sea urchin *Loxechinus albus* (Molina 1782) is one of the world most important echinoidean species in terms of exportation and landings (Andrew y Agatsuma, 2002). Massive and viable production of juveniles is presented as the most suitable option for the recovery of the stocks, currently depleted by overfishing (Cárcamo et al., 2005). This work aims to progress on optimizing and dimensioning the production of early juveniles after metamorphosis. That aim is addressed both, through estimates of nutritional needs according to body size and by optimizing control of culture parameters regarding previous assays. A feed intake test was assayed in four body size-class urchins placed on benthonic *Nitzschia* diatoms films at 13°C and standard photoperiod (12h light) which are representative of the average latitudinal conditions in the range of *L. albus* and are also applicable to the aquaculture of the red sea urchin in the southernmost Chilean region.

Materials and methods

In order to determine the average environmental conditions in the range of the species distribution, the equinoctial photoperiod and the average value of 13ºC were chosen upon paleoclimatic and oceanographic records. Other culture conditions followed Bustos and Olave (2001). The selected food was a cultivated strain of *Nitzschia* sp. Three trials were carried out. First, a test of ingestion rate (FI) on 4 size classes (range 0.78 – 2.44 mm) was carried out to estimating daily intake upon the microalgae reduction regarding the control. Second, a quantitative (dry weight) and qualitative (bromatological) assessment was performed on the food supplied. In third place, an experiment of stabling and fattening of juveniles was enforced under the selected culture conditions to check for the system efficienc . Growth progress was assessed upon optimal health criteria (Hernández and Russell 2010) as well as upon both, the mortality rate and the effective growth of individuals.

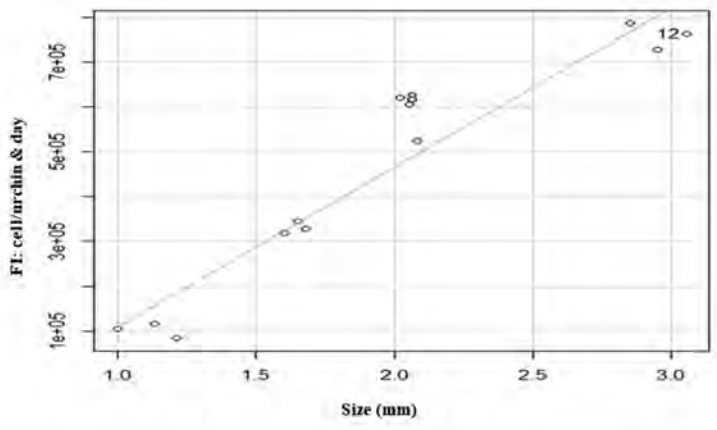

Fig. 1. Linear regression model between the cephalic perimeter and ingestion rate (FI)

(Continued on next page)

Results

Feed intake assessed per total dry weight, per nutritional component and per size-class, exhibited a linear regression model between cephalic perimeter and FI (r = 0.9175) in the size range assayed (figure 1).

Discussion and conclusion

The stabling test showed low mortality rates (<3% monthly), good health and a growth rate (GR) of 0.533mm/month, i.e. lower than that observed (0.7mm/month) on a similar body size (Zamora and Stotz 1994), a fact attributed to the use of an average range temperature during the pre-fattening period. Therefore, such environmental conditions are valid for the austral region but should be optimized upon latitude.

IFISHIENCI: WILL INCREASED EFFICIENCY THROUGH THE USE OF BREAKTHROUGH INNOVATIONS AND PRINCIPLES OF CIRCULAR ECONOMY TRANSLATE INTO IMPROVED SUSTSAINABILITY FOR EUROPEAN AQUACULTURE?

S. Prescott* and T. Bardócz

AquaBioTech Group
Email: SGP@aquabt.com

Introduction

The iFishIENCi project aims to contribute towards the sustainable development of European aquaculture by developing novel technologies based upon artificial intelligence and the Internet of Things. Additionally, new feed ingredients are being developed to replace the inclusion of fishmeal and oil, which are limited in supply. These novel ingredients, such as microalgae, are being produced using nutrient wastes from aquaculture as a substrate for growth; an approach in line with the EU strategy of adopting circular economic principles. However, it cannot be assumed that increases in efficiency achieved through these developments will translate into improved sustainability. For this reason, Life Cycle Assessment (LCA) is being used to explore how technological innovations developed by the iFishIENCi project may affect the sustainability of the aquaculture production species and systems to which they are applied. However, the use of LCA for aquaculture production is challenged by difficulties in comparing the sustainability of competing, alternative and eme gent species.

Method / Approach

Whereas most types of environmental assessment focus on one or only a few impacts of a specific economic activity, LCA estimates a variety of environmental impacts produced by all stages of a products value-chain. LCA plays a vital role in allowing us to identify situations where reductions in environmental impacts are achieved through innovation at the cost of increasing contributions towards other impacts. Utilising aquaculture effluent as a substrate for algal production may both reduce nutrient related impacts whilst reducing pressure upon limited fishmeal and oil resources. But doing so will introduce a new chain of economic activities, involving infrastructure production, electricity use, and possibly nutrient emissions from distal stages of the value-chain. By assessing the potential environmental impacts associated with the activities of this circular economic approach, the iFishIENCi project aims to understand if the reduction of aquaculture effluents and decreased dependence on wild fish stocks can be realised without unintended impacts in other areas of environmental concern. The project will use LCA to critically assess issues of sustainability relating to the adoption of Artificial Intelligence and the concept of 'Internet of Things': will these technological advances increase the efficiency and competitivity of European aquaculture at the expense of contributing to environmental problems such as climate change?

Clearly, the concept of sustainable aquaculture development is inextricably linked with food security (Prescott, 2017). Food security depends upon the availability of nutrition essential for good health. Thus, we need to compare the relative sustainability of different aquaculture products and systems within the context of their respective contribution to nutritional supply. To do this, the nutrient content per weight of species can be calculated. Then, the environmental impacts of producing the weight required to deliver a set quantity of nutrient content will be calculated for each species. The life cycle impacts can then be compared between different fish species produced in different systems and using various technology, within the context of food security. However, different species differ, sometimes drastically, in their nutrient profile, each containing different nutrients combined in different ratios. Thus, a variety of nutrient based units of comparison will be used for the comparative assessments.

Expected results

The LCAs will allow a critical evaluation of trade-offs between the various environmental impacts resulting from the application of technological innovations and circular economic principles, to produce several cultivated species. Comparing the environmental impacts of different products using various unit of comparison based upon nutrient content, will likely produce conflicting results. This will provide valuable insights and provoke challenging discussions about how we understand sustainability within a globally important food production sector. It should be particularly relevant for policy makers who seek to promote and shape the development of a competitive European aquaculture industry capable of delivering a sustainable contribution towards nutritional security.

MUSSEL CULTIVATION IN THE BELGIAN NORTH SEA

Ajie B. K. Pribadi*, L. Donatini, E. Lataire

Maritime Technology Division, Ghent University, Ghent, Belgium
E-mail: ajiebramakrishna.pribadi@UGent.be

Introduction

A research project to examine the feasibility of growing mussels off the coast was initiated within the project named Edulis. The suspension culture (Danioux *et al.*, 2000; Morse and Rice, 2010) is considered for the study. The floating system consists of buoys, anchors and a long line that supports suspended ropes to which mussels are grown (figure 1). Two test setups were installed within the wind turbine park of Belgian North Sea. Bio line was installed in May 2017 to study the growth of mussel whereas Force line was installed later in November 2017 to measure forces and positions of the mussel line system. Numerical calculations were performed with a lumped-mass based open source software, namely MoorDyn (Hall and Goupee, 2015). Adaptations are made to the code, mainly to cope with 3 degree of freedoms cylindrical buoy, horizontal seabed frictions and environmental loads of wave and current. The results are validated and new proposed configuration will be proposed based on numerical calculations.

Materials and methods

A measuring device is installed in the Force line, logging the coordinates of two spar buoys at each end of the long line. Haversine formula (Van Brummelen, 2013) is used to calculate the relative positions of the buoys changing in time with South West (SW) anchor as the origin (0,0) in the Cartesian frame. On the other hand, adapted MoorDyn is used to perform numerical calculations. Tidal current of 13 hours range changing in direction, magnitude and elevation is used as the input for the simulation. The results are compared with measured buoys' positions of the same time frame as the input for the simulation.

Results

In figure 1, preliminary result shows that calculated positions as well as pattern of system displacements are comparable to those found in measured data (6% of error at the highest discrepancy of buoy's position). Both simulation and measurement logged new positions every 1 second. However, measured data shows more thickness in the plot, this is due to the wave induced load causing the system to oscillate in a higher frequency compared to the tidal current. The preliminary calculation only consider current induced load.

Discussion and conclusion

As a large portion of chains are laying down on the seabed, modelling of seabed contact gives a significant influence on the numerical model. The seabed friction model used in the simulation does not take into account soil displacement and accumulation. Simplification also made by assuming flat seabed. Model test will be conducted to obtain hydrodynamic coefficient of the mussel collector lines, which currently is based on a model test for a dropper line type (Plew, 2005). This will further improve the validation results as the drag force is mainly driving the displacement of the system. Further investigation will be conducted with wave input to compare force amplitudes. Validated software will be used to design a new proposed configuration consists of multiple mussel line systems

Introduction

Growth in bivalves is influenced by both endogenous and environmental factors. It is well established that the temperature and the nutritional environment are the most influencing environmental factors in bivalves growth, whereas the interindividual differences in the growth rate in populations maintained under the same environmental conditions has a genetic basis. The physiological differences between fast (F) and slow (S) growing individuals living in the same environment relies upon a higher acquisition capacity, higher metabolic efficiency and/or lower costs of maintenance of the F specimens (Bayne et al. 1999). Recently, Tamayo et al. (2016) suggested that the environment conditions could determine the physiological differences between fast and slow growing individuals. In other words, the phenotype arising as fast grower is determined by the requirements of the living environment and the capacity of such phenotype to maximize growth. The present work aims to analyze the influence of the rearing environment in the physiological parameters determining fast growing. For that aim, mussels were reared under 5 different nutritional conditions and 2 distinct water temperatures. In addition, the gill transcriptome of F and S mussels reared in different nutritional conditions was analysed to ascertain the genetic basis of fast growing.

Materials and methods

Juvenile seeds of *Mytilus galloprovincialis* mussel were gathered from a natural population of an intertidal rocky shore. At the laboratory, mussels of similar live weight and shell length were selected and divided in seven groups of approximately 150-200 individuals. Each group was placed in a different rearing condition to test the effect of the nutritional environment and the temperature on the physiological basis of fast growing. 5 groups of mussels were maintained at 16 ºC and at different food availability conditions, as follows: i) Continuous immersion and continuous feeding of a diet dosed below the pseudofaeces threshold (1) ; ii) Continuous immersion and continuous feeding of a diet dosed above the pseudofaeces threshold (2) ; iii) Discontinuous immersion and continuous feeding of a diet dosed below the pseudofaeces threshold (3) ; iv) Discontinuous immersion and continuous feeding of a diet dosed above the pseudofaeces threshold (4) and v) Continuous immersion and discontinuous feeding of a diet dosed below the pseudofaeces threshold (5). The remaining 2 groups of mussels were reared at vi) 10 ºC (6) and vii) 20 ºC (7) under continuous food supply conditions, dosed below the pseudofaeces threshold.

After the rearing period the largest and the smallest individuals from each group were selected and denoted as fast (F) and slow (S) growers. Thus, 14 experimental groups were obtained (7 maintenance conditions * 2 growth conditions). Individuals belonging to these groups were used in a series of different feeding and thermal experiments and the physiological parameters determining the energy balance were measured. Once the experiments were performed, mussels were dissected and the gill-surface area was determined. In addition, the gill transcriptome of (1) and (2) mussel groups was analysed using a microarray.

Results

Feeding experiments showed that, when mussels were reared under good food availability conditions, faster growth is based on the significantly higher food acquisition rates and preingestive selection efficiencies of F individuals. However, when mussels were reared under severe food restriction conditions, the main physiological difference promoting a differential growth rate between F and S is the significantly lower standard metabolic rate of F individuals.

Thermal experiments showed that, in agreement with the feeding experiments, faster growth relies on the higher food acquisition rates of F mussels at both warm and cold temperatures. However, differences in the thermal compensation capacity between mussels from both rearing temperatures were found: F and S mussels reared at 20 ºC showed a similar thermal compensation capacity, but among mussels reared at 10 ºC, only F individuals were found to partially compensate the water warming effects on the physiological parameters.

(Continued on next page)

Irrespective of the maintenance condition F individuals were found to have significantly larger gill-surface areas (standardized to a common weight) than their slow growing counterparts.

Gene expression analysis revealed 117 genes differentially expressed by the fast and slow growing mussels. The F individuals overexpressed genes involved in i) growth; ii) maintenance of the structure and functioning of extracellular matrix; iii) filtration and ciliary activity; iv) aerobic metabolism and v) the immune-system. In contrast, S individuals overexpressed a different series of genes from the immune system along with genes involved in the response to cellular stress as well as anaerobic metabolism.

Discussion

The repeatedly observed existence of large interindividual differences in growth rate of juvenile mussels that were maintained in a broad variety of homogenous and stable nurture conditions indicates the existence of a strong endogenous (genetic) component in the growth rate variability usually found in the populations of the mussel *Mytilus galloprovincialis*.

The obtained results have evidenced that variations in the thermal or the nutritional regime can modify the physiological basis underpinning interindividual growth rate differences. Thus, it seems that rather than relying upon a single physiological process, interindividual differences in growth rate are caused by multiple physiological traits and that the contribution of each physiological trait to growth rate differences depends on the rearing environment.

The potential to develop a high gill-surface area is a key factor determining the interindividual growth rate differences in the mussel *Mytilus galloprovincialis*.

The transcriptomic results suggest that the gills of F mussels are well equipped to maintain higher filtering activities that enable fast growing mussels to maximize food acquisition and sustain fast growth rates. In contrast, slow growing individuals might need to spend higher rates of metabolic energy to fight against exogenous stressors, thus reducing the scope for growth of the organism.

Introduction

Humic substances (HS), a class of compounds resulting from decomposition of organic matter, are the most common form of organic carbon (Islam et al., 2005) and comprise the majority of dissolved organic matter in freshwater ecosystems (Steinberg et al., 2004).

Recently, these substances have been used as alternative feed additives in animal husbandry practices to improve animal (dairy cows, pig, poultry, etc.) production (Islam et al., 2005). Beneficial effects of HS on growth rates, feed efficienc , health of gastro-intestinal tract, inhibition of bacterial and fungal growth, or reduced production of stress causing hormones were observed (Gao et al., 2017; Islam et al., 2005). Besides, HS are promising natural immunostimulants which may be an alternative to 'traditional' chemical therapeutants to fish (Lieke et al., 2019). However, the effects of dietary supplementation with HS have not been widely researched in aquaculture yet, and information in relation to aquatic animals is limited (Gao et al., 2017).

Therefore, the present study assessed the effect of HS feed additives on growth performance and health status of *Clarias gariepinus* (Burchell, 1822), as one of the commercially important fish species for intensive freshwater aquaculture

Material and Methods

A 56-day feeding experiment was conducted to determine the effect of dietary HS supplements (pure Siberian Leonardite containing of 80% humic acids) on growth performance and health status of juvenile *C. gariepinus*.

Fish (initial weight of 32.3±0.8g) were stocked into four separate recirculation aquaculture systems (RAS; 26.8±0.6°C, 61.3±13.4% O_2, 6.8±0.3 pH) and fed with four experimental diets (0, 1, 3, and 6% content of HS) in five repetitions (90 fish tank). Feeds (recommended ratio of 3–4%) were supplied to fish using automatic feeders twelve-times a day. Temperature, pH and oxygen concentration were checked twice a day. Each 14 days, fish growth (biomass gain, individual weight, body length) and mortality was measured in all experimental tanks (20 fish/tank).

At the end of experiment, blood and tissue samples were collected (10 fish/group) for biochemical analysis. Selected somatic and production indices were calculated. Data were statistically evaluated by the program Statistica 12.0.

Results

In the present study, growth performance including final weight (W), body size (TL) and specific growth rate (SGR) was not significantly affected ($P>0.05$) in juvenile *C. gariepinus* that were fed with different HS supplement (0, 1, 3, 6%) for 56-day period. However, coefficient of variation (CV) significantly varied among tested groups ($P<0.05$) after 56 days of rearing. The significantly highest CV (48.4±4.6) was observed in control group (0% HS) compared to other three groups (41.4±0.9) fed with HS supplements (1, 3, 6%). Condition factor (CF), hepato-somatic and splenic-somatic indices were not significantl affected with use of HS in this study. Also, mortality of fish was not significantly ($P>0.05$) affected with HS supply during whole experiment.

(Continued on next page)

Furthermore, biochemical analysis revealed no significant differences in ALT, AST, cholesterol, triglyceride, total plasma protein and LDH between groups after 28 and 56-day exposure. Only glucose level significantly differed between groups. It decreased from 6.2 to 3.9 $mmol.l^{-1}$ with higher HS feed supply (from 0 to 6%, respectively).

Discussion and Conclusion

In the present study, significantly positive effect of HS feed supplement on growth performance was not confirmed in juvenile *C. gariepinus* after two-month exposure, although other studies reported enhanced growth (Gao et al., 2017; Islam et al., 2005).

Generally, glucose is one of the most common stress indicators. Present results indicated that probably more-stress resistant fish were in HS supplemented groups, compared to control group where glucose levels were significantly higher. Meinelt et al. (2008) explained that, although HS are not too strong as 'traditional' therapeutics, they may show advantages in repairing secondary, stress induced damages in fish

Further research on longer exposure to HS feed supplements may reveal other, or deepen current, positive effects of HS on *C. gariepinus*. Therefore, we decided to prolong this experiment until fish will achieve market size, and evaluate also immunology, gut microbiology, mid-intestine histology, and sensory analysis as they may provide new information on the effect of HS on fish.

CITYFOOD: ASSESSING AQUAPONICS WITHIN THE URBAN FOOD-WATER-ENERGY NEXUS

Gundula Proksch*, Alex Ianchenko

College of Built Environments, University of Washington, 3950 University Way NE
Seattle, WA 98195
E-mail: prokschg@uw.edu

Introduction

The world's cities are growing - by 2050, 68% of the global population will reside in cities (United Nations, 2018). By the same time, global food demand is projected to increase by 59-98% compared to 2005 (Valin et al., 2014). Combined with growing concerns about the destructive effects of climate change on wildfish capture and the significant role of the agricultural sector in perpetuating resource depletion, these figures paint a daunting outlook on impending urban food insecurity. Conventional food supply networks exert pressure on energy and water sectors through increasing demand for irrigation, storage, processing, transport and operating industrial equipment.

Aquaponics has been recognized as one of "ten technologies which could change our lives" by merit of its potential to revolutionize how we feed urban populations (Van Woensel et al., 2015). Funded through the Sustainable Urbanisation Global Initiative/ Food-Water-Energy Nexus call, the project CITYFOOD addresses the interdependence of urban food, water, and energy systems by evaluating the potential of aquaponic farms for urban integration and as a sustainable solution.

This investigation connects concepts of the Food-Water-Energy Nexus framework with best practices in aquaponics to evaluate aquaponic farms' potential performance in cities based on case study research.

Aquaponics as a food source

Aquaponics provides a protein source (fish) alongside fresh produce to satisfy diverse urban dietary needs regardless of climate. Urban aquaponic farms can compete with imported perishable vegetables and fish year-round without the need for pesticides and reduced fertilizer use.

For urban aquaponic farmers, two major benefits of urban locations are a growing consumer market with an interest in fresh, high-quality, locally grown produce and the reduced need for transportation. Within inland cities that rely on imported seafood to meet inhabitants' needs, aquaponic farms can provide a fresh alternative on the market, and achieve premium pricing for locally-grown status (Quagrainie et al., 2018). Additionally, urban farms may alleviate food insecurity in vulnerable populations; for example, from 1993 to 2018, Will Allen's Growing Power has famously provided access to fresh food and education to underserved communities in the Milwaukee area.

Aquaponics within the urban water cycle

In aquaponics, the use of recirculating water infrastructure reduces overall water consumption for the production of both fish and vegetables. Situated in cities, aquaponic farms are well-poised to take advantage of alternative water sources to increase water efficiency even further, using rainwater harvested from rooftops and foundation drain water. As an added benefit, aquaponically-grown produce strives to close the nutrient cycle, thereby reducing the production of nitrogen-rich run-off from aquaculture. Through smart resource management within major environmental systems, aquaponic systems may avoid excessive water consumption and eutrophication usually created by industrial agriculture.

Aquaponics and energy supply

Urban aquaponic farms can save operational energy demand by reducing transportation distance to the consumer and reducing the need for cold storage. Due to the heat island effect, urban environmental conditions can also be advantageous for aquaponic farms in cold climates - average temperatures in cities are higher than in rural surroundings, therefore reducing the demand for space heating during colder months. Aquaponic farms that are integrated with the building systems of a host building can further utilize urban resources such as waste heat and CO_2 in the exhaust air to benefit the growth of plants as an alternative to conventional CO_2 fertilization.

Energy demand is one of the most pressing challenges for urban aquaponics, since the mechanized nature of commercial-scale aquaponics requires energy for heating, cooling, ventilating, pumping, and illuminating the space.

(Continued on next page)

Results

The results of the food-water-energy analysis described above can be used to holistically juxtapose the environmental impacts of urban aquaponics and rural aquaculture. Based on this comparison within the FWE Nexus framework, CITYFOOD aims to identify synergies unique to the city that can improve the environmental sustainability of urban aquaponic farms.

BUILDING-INTEGRATED AQUAPONICS: ARCHITECTURAL DESIGN CONSIDERATIONS FOR FUTURE FARMS

Gundula Proksch*, Alex Ianchenko

College of Built Environments, University of Washington, 3950 University Way NE
Seattle, WA 98195
E-mail: prokschg@uw.edu

Introduction

Techniques to extend the natural crop-growing season range from temporary modifications in soil-based fields to full environmental control in permanent facilities that allow year-round production. The latter strategy is also known as controlled environment agriculture (CEA) and includes greenhouses and indoor growing facilities. Most aquaponic farms are conceived as CEA since they combine fish with produce, which both require consistent growing conditions and protection from pathogens to achieve optimal yields. Additionally, CEA enables aquaponic farms to amortize high investment by providing produce to the market outside of the natural growing season.

The relationship between the aquaponic system and the surrounding envelope has the potential to be beneficial for both - an aquaponic farm can improve host building performance, while a well-designed envelope can raise farm productivity (Alsanius et al., 2017; Sanjuan-Delmás et al., 2018). Currently, aquaponic studies often omit the host building; however, including the enclosure is essential to evaluating aquaponic farms in temperate and colder climates. Understanding that the contribution of the building sector to global environmental impacts is comparable in magnitude to the agricultural sector, the deliberate architectural design for aquaponic farms becomes a critical opportunity to reimagine sustainable CEA.

Urban aquaponic farms can be designed from the built environment perspective to optimize multiple resource flows at once - primarily, the exchange of heat, CO_2, and water between the system and the enclosure (see Fig. 1). Designing aquaponic facilities with respect to the local climate and seasonal swings can create productive and sustainable farms that minimize dependence on fossil fuels (Graamans et al., 2018).

Methodology

The research team has compiled a database of 273 aquaponic farms using self-published documentation from practitioners and has developed a taxonomy of five enclosure types - passive solar greenhouses, medium-tech greenhouses, high-tech greenhouses, rooftop greenhouses, and plant factories. Each farm type is characterized by its reliance on climate control systems and envelope opacity.

The team has also selected nine plant factory case studies to analyze aquaponic and hydroponic farming through the lens of spatial arrangement (see Fig. 2).

Results

Analyzing the contextual conditions where each farm type is present, the team has found that indoor growing spaces are only favored by farms located in climates with greater seasonal variability, where the trade-off between better insulation to establish indoor air temperature and the need for artificial lighting is profitable. In almost all cases, greenhouses are preferred, signifying that using light and heat from the sun is still more sustainable and profitable than relying on artificial lighting arrays.

Using case study analysis, this project will lead to a series of spatial design guidelines with the recommendations for (1) the selection of enclosure types, (2) efficiencies of layouts of different enclosures, and (3) programmatic layout and space allocations for the different functional components of an aquaponic farm.

GLOBAL AQUAPONIC PRACTITIONER SURVEY: PRELIMINARY FINDINGS AND TRENDS

Gundula Proksch*, Alex Ianchenko

College of Built Environments, University of Washington, 3950 University Way NE
Seattle, WA 98195
E-mail: prokschg@uw.edu

Introduction

Aquaponics is catching on; many farms have opened their doors since 2013, the year of the last international survey of the field (Love et al., 2014). The Global Aquaponic Practitioner Survey has been launched by the CITYFOOD team in April 2019 to assess the state of the aquaponic field. Using information gathered in this survey, the research team aims to connect and empower aquaponic farmers, researchers, and decision-makers worldwide.

The international project CITYFOOD investigates how aquaponics can be integrated into urban food, water, and energy networks to satisfy growing food demand and minimize the environmental impact of food. A preliminary search for aquaponic farms conducted by the CITYFOOD team at the University of Washington in July 2018 shows that the number of aquaponic operations has rapidly increased over the last six years. This focused online search for aquaponic operations identified 197 active aquaponic farms and research labs worldwide (see Fig. 1). 4 out of every 5 farms in this cohort have opened their doors in 2013 or later; only 39 aquaponic farms have been in operation for more than six years.

The Global Aquaponic Practitioner Survey (GAPS) is meant to follow up on earlier surveys of the field, while recognizing that aquaponic farming is gradually scaling up as interest in commercial urban agriculture grows (Love et al., 2014; Mchunu et al., 2018; Villarroel et al., 2016).

Methodology

The GAPS is structured as two branches of a single survey - one meant for commercial aquaponic farmers, and another for researchers in the field. Many of the questions overlap to maintain comparability between labs and farms. Unlike previous surveys, the GAPS gives more focus to built environment infrastructure that houses most farms - asking respondents to identify their building type, relative footprints of farm components, and climate control systems.

The GAPS shifts focus away from aquaponic hobbyists, and towards commercial-scale facilities. To reflect this shift in focus compared to earlier surveys, the GAPS gathers minimal demographic information about the respondent but increases the number of questions about farm equipment, infrastructure, initial design, and regulatory barriers.

The CITYFOOD team has used REDCap to program and administer the survey online. Snowball sampling was used - each respondent was asked to distribute the survey to colleagues within their aquaponic network.

Fig. 1 Aquaponic operations in the United States, identified by online search in July 2018 (red = for-profit, blue = research labs, green = non-profit and hobby operations).

(Continued on next page)

Results

The GAPS is scheduled to run until June 2019, at which point all responses will be consolidated and analyzed using Tableau Prep and Tableau by the CITYFOOD team at the University of Washington. Results will indicate the current scale of aquaponic farming worldwide, as well as existing preferences for various systems and farm configurations among practitioners that can inform further research. The regulatory barriers identified by the respondents will inform further advocacy work for shaping aquaponic policy. Additionally, the GAPS will be used to create a searchable Global Aquaponic Directory for public use.

MICROBIAL COMMUNITIES IN BIOFLOC SYSTEMS FOR WHITELEG SHRIMP (*Litopenaeus vannamei*)

K. EL Arbani, E. Strauch, J. Pucher*

German Federal Institute for Risk Assessment, Max-Dohrn-Str. 8-10, 10589 Berlin (Germany)
E-mail: Johannes.pucher@bfr.bund.de

Introduction

The global demand for aquatic food products is steadily increasing. As capture fishery production is not expected to increase further, the demand in aquatic foods must be supplied by aquaculture. With key resources for aquaculture production (e.g. water, feeds, and land) being limited, growth of aquaculture production must mainly be realized by intensification and a more efficien use of key resources (Avnimelech 2015). The biofloc-technology is a novel kind of aquaculture for the production of fish and crustaceans with minimal water exchange. Supplemental input of a carbon source (e.g. glucose) as energy source and high aeration creates a highly active microbial milieu with heterotrophic bacteria in the culture volumes (Avnimelech 1999). These bacteria are binding excreted nutrients (especially nitrogen and phosphorus) and form bioflocs which are submerged in the water and can be taken up by the cultured fish or shrimps species as an additional feed resource (Crab et al. 2010; Crab et al. 2012). Consequently, biofloc systems are described as nutrient efficient and water saving systems (Avnimelech 1999; Emerenciano et al. 2017).

But, the food production in such a highly active microbial milieu leads to the question of the hygienic conditions in these systems and whether the conditions within biofloc systems are enabling potential human pathogenic bacteria to establish and pose a food safety hazard to the consumers. Within this study, the focus laid on the production of Whiteleg shrimp (*Litopenaeus vannamei*) in biofloc systems as these systems are highly intensified and low level of postharvest processing of shrimp are common (e.g. no removal of head, legs and viscera; inadequate heating before consumption).

Materials and methods

A literature study was performed by screening the databases for scientific papers on the microbial communities in different, globally applied biofloc systems for the production of Whiteleg shrimp (*Litopenaeus vannamei*). Further, the methods for describing the biofloc microbiome were collected and grouped for their level of data quality. Special emphasis was put on the occurrence of potentially human pathogenic bacteria. In summary, about 122 scientific reports were reviewed.

Results and discussion

Globally, different biofloc systems are in use for the production of Whiteleg shrimp. These systems range from highly intensive indoor tanks to outdoor ponds (Avnimelech 1999; Avnimelech 2015). Further, they differ in the use of quantities and kind of organic carbon sources, the kind of aeration (gassing or mechanic circulation of water), water exchange rates, pre-treatment of water, removal of sludge, feeding regime etc. For the biofloc culture of Whiteleg shrimp, the amounts of feed and carbon source are adjusted to a C/N ratio of 20:1 (Emerenciano et al. 2017). To establish the biofloc systems, inoculation with water from other running systems or with a specific starter microbiome are often performed.

Among reviewed publications, a limited number of studies (38) report about bacteria in terms of abundance and/or community description, with 16 studies alone recording the presence of *Vibrio* spp.. Only very few of these publications (7) are determining whether certain families or species are present. Generally, reports about bacterial species composition are rather focusing on shrimp pathogens and less on the identificat on of potential human pathogens. The identified bacterial communities show high diversity, within and between systems, which might change over time as the feeding rate and consequently also the addition of carbon sources increase. The transfer of pathogens into the production sites via water, wind, and animals can often not be excluded.

The methods to describe the different microbial communities in biofloc systems are ranging from cultivation methods, microscopy, and molecular biology techniques to genomic methods. The microbiomes are generally determined down to the level of phyla.

(Continued on next page)

Conclusion

The presence of human pathogens in biofloc systems is described in several publications. But scientific assessments of the safety of the products of different biofloc systems are scarce. The establishment of human pathogens under such conditions has not been systematically assessed, yet. Further research is needed to assess the risk of microbial contamination with human pathogens in these systems by using highly sensitive and specific methods for their detection. To describe the microbiome and the presence of potential human/shrimp pathogens, it is recommended to use metagenome analysis applying next-generation sequencing techniques which may be followed by specific PCR methods for verification. The knowledge about the dynamics of potential human pathogens in biofloc systems is essential to develop best management practices to proactively mitigate and control these food safety hazards.

Introduction

In recirculating aquaculture systems (RAS), understanding of bacteria-bacteria interactions and bacteria-fish interactions is essential for developing and optimizing practices that support fish health and economical operation of the system. Stable bacterial communities can carry out the nitrification process and maintain the balance between beneficial and the harmful strains (Rurangwa and Verdegem, 2015). Recent advantages of next-generation sequencing have made it possible to efficiently explore the genetic material associated to environmental samples, enabling characterization of the whole microbiomes. In this study, we examined bacterial community structures in the start-up phase of freshwater and salt water RAS. Our objective was to study the development the bacterial communities in different compartments of the freshwater RAS system using the 16S rRNA gene sequencing, and compare the freshwater RAS to an otherwise identical system where the water source was supplemented with 7 ppt salt.

Materials and methods

Two separate experimental scale RAS units were used, each consisting of a 500 l fish tank, waste feed collector, swirl separator, 60 µm drum filte , 125 l fixed bed bioreactor, 125 l moving bed bioreactor, trickling filter and a pump sump. Units were disinfected before the experiment using sodium hydroxide. Rainbow trout (*Oncorhynchus mykiss*) were stocked to both units (24 kg, average weight 249 g). Fish were fed constantly 240 g per day (Biomar Orbit 929) with constant make-up water of 120 l per day. Excess fish were removed weekly. Microbial samples were collected from the circulating water and biofilms from the fixed bed bioreactor, moving bed bioreactor, trickling filter and fish tank surface. The samples were collected eight times during the 23 week start-up period. DNA was extracted using commercial kits and sequencing was performed from the V4 location of the 16S rRNA gene using Ion PGM (Ion Torrent, Thermo Fisher Scientific). Water quality parameters were monitored using online probes and manual water sampling. The RAS units and online water quality monitoring system has been described more detailed by Pulkkinen et al. (2018).

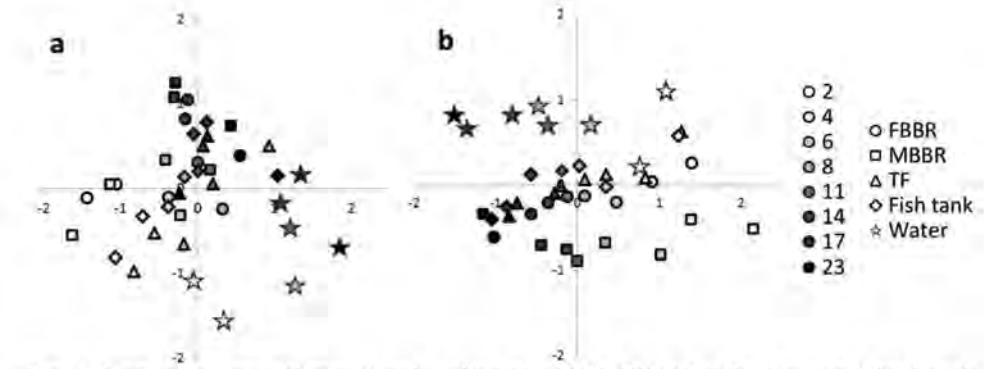

Fig. 1. Non-metric multidimensional scaling plots (NMDS) of a) fresh water RAS b) salt water RAS based on Bray-Curtis dissimilarities. Numbers refer to sampling weeks. FBBR = fixed bed bioreactor, MBBR = moving bed bioreactor, TF = trickling filter, Water = circulating water from the fish tank outlet.

(Continued on next page)

Results and discussion

Bacterial communities were different between freshwater system and salt water system, as well as between circulating water and biofilm samples (Fig 1.). The most distinct genus separating freshwater and salt water RAS was *Polynucleobacter*, which was more abundant in freshwater system. On the other hand, *Luteolibacter* was more abundant in the salt water system. In salt water, moving bed bioreactor had different communities than the other biofilm samples. Some water quality parameters may have affected the fluctuation of communities in freshwater RAS, whereas salt was a strong factor affecting the salt water RAS communities.

Nitrosomonas was the most abundant nitrifying bacterial genus in the salt water RAS. *Nitrospira*, typically classified as a nitrite-oxidizing bacteria were dominant nitrifying bacteria in the freshwater RAS. Low amount of ammonia-oxidizing bacteria might indicate that some species of *Nitrospira* observed in this system might have also ammonia-oxidizing potential (comammox) (Bartelme et al., 2017).

In the start-up phase of the freshwater RAS, development of characteristic bacterial took over 8 weeks, which should be taken into consideration when studying bacterial communities in RAS experiments.

Introduction

The term failed fish (or runt) syndrome is a synonym for a fish with impaired growth or substantially slower growth rate after sea-transfer (Skjelstad and Gu, 2016). Although observed throughout salmonid aquaculture, (typically ~10%) it is greatly increased for rainbow trout (*Oncorhynchus mykiss*) reared in full salinity where failure levels of >30% are often encountered. Rapid acclimation to increasing salinity through physiological modifications is crucial in euryhaline teleost (Guner et al., 2006). Thus, this study objective was to compare the clinical chemistry and tissue structure differences in rainbow trout pre and post seawater transfer to investigate the impacts and potential causes of this syndrome.

Materials and methods

The study took place in a fish farm, under aquaculture conditions. Blood samples were initially taken from random pit-tagged fish 4 weeks before seawater transfer. Second blood samples were taken 8 weeks post seawater transfer. Fish condition was measured and tissue samples were taken for supportive histopathological analysis in both time points. All serum samples were analysed within 3 months of freezing on the clinical chemistry analyser Daytona RX (Randox Laboratories Ltd., Crumlin, UK) using commercial kits. Routine histology was used to produce tissue sections for histological inpection of trout tissues. Statistical analysis was performed using the General Linear Model (GLM) and Linear Discriminant Analysis (LDA) to classify the two groups according to their biochemical profiles

Results

Fish serum biochemical analysis showed significant increase activity ($p<0.05$) of ALP (alkaline phosphatase) and concentration of ammonia, recorded in the fish with good condition after the transfer to seawater. In comparison, fish with retarded growth had significantly higher activity of LDH (lactate dehydrogenase), together with decreased activity of amylase and concentrations of potassium, while concentration of chloride was higher after the transfer to seawater. Interestingly, despite no statistical differences could be found for the majority of measured endpoints in freshwater environment, it is noteworthy that the parameters with potential effect on osmoregulatory balance and nutritional deficit, chloride, sodium and zinc concentrations, respectively, were identified as the variables that distinguish best these two groups at initial stage of growth. Moreover, no significant differences in fish condition were observed. Histopathological evaluation of stunted fish liver showed hepatocyte shrinkage along with marked glycogen reduction. Furthermore, tissue damage to the eye chamber was evident in form of exfoliation of cornea.

Discussion and conclusion

Results of the present study indicate that initial fish size does not have any particular role in predisposition to runt syndrome. Runt fish showed signs of poor nutritional status that was observed through serum metabolic endpoints, but also some evidence of osmoregulatory dysfunction. Moreover, there was a proof that fish from the freshwater, that later became failed in seawater, had disturbed osmoregulatory function and zinc deficienc . Cataracts induced by zinc deficiencies have been described wild and farmed salmon (Bjerkås et al., 2004). A study by Bjerkås and Sveier (2014) demonstrated that fluctuation in water salinity caused higher intraocular pressure. This could be due either to increased influx through the damaged cornea, or as increased water uptake in the whole body due to poor fluid regulation through periods of osmotic stress. In addition, another possible cause for this syndrome in trout could be reduced vision due to cataracts that prevents normal feeding and eventually led to trout emaciation and mortalities. Blood biochemistry shows excellent potential to investigate fish health status and was associated with organ/tissue damage. Further research to evaluate the genetic aspect of this syndrome and better bloodstock selection could add to improvements in sea trout aquaculture.

E-mail: rbharathi1997@gmail.com

High pressure Processing is a non-thermal process capable of inactivating and eliminating pathogenic and food spoilage microorganisms. Nowadays consumers have a growing demand for convenience food of highest quality in terms of natural flavour and taste, which are free from additives and preservatives. This demand triggered the need for the development of non-thermal approaches to food processing. Among other technology, HPP has proven to be very valuable. Pressure range between 300-600 Mpa inactivates yeast, mould and most vegetative bacteria including infectious food born pathogen and spoilage microorganisms. Thus, pressure leaves small molecule such as many flavour compounds and vitamins intact. Therefore, HPP treated food is very similar to that of fresh food products. Herein, the mini review article discuss the basic principle of HPP, pressure temperature effect, operation of the equipment, effects of HPP on microbial food safety and molecular biology. Specific opportunities are discussed that a food processor can consider to implement this new processing technology to increase their profit and product qualit .

Introduction:

High pressure processing (HPP) is one the best innovation in food processing sector. Its influence on microbial inactivation has been recognized since late 1800s and in 1900 the first commercial installation of HPP occurred. Consumers have a growing preference for minimally processed extended shelf life foods which are convenient, healthy and fresh (Aymerich et al., 2000). The sensory and nutritional characteristics of foods are best retained by HPP over thermal sterilization and pasteurization but it is currently more expensive to commercialize (Balasubramaniam et al., 2008). The use of the HPP offers novel gateway for food industry to fulfil the demand of consumers

In HPP, the intense pressure ranging between 100 – 1000 Mpa accompanied with or without heat which inactivates vegetative, pathogenic and spoilage microorganisms effectively. This processing method is used for liquid and high moisture content solid foods (Balny and Masson., 1993).

Basic principle of HPP:

According to Le – Chatelier principle: In any reaction, structural change and phase transition is accompanied by decrease in the volume by enhancement of pressure (Cheftel, 1995). The physical compression in food by pressure treatment results in volume reduction and increase in temperature and energy within food products which is sufficient to destroy the microorganisms. Since transmission of pressure is not time and mass dependent, the products are independently compressed of product size.

Fig 1: Represents high pressure processing equipment

(Continued on next page)

Pressure – Temperature effect:

At room temperature, for every increase in 100 Mpa, there is a 3^{o}C increase in the water temperature. Fat and oil in the food have a heat of compression value 100 Mpa at 8-9^{0}C and Protein, carbohydrates have intermediate compression values. The pressure and duration of HPP are the key factors of microbial inactivation. The pressure resistance of microorganisms is maximum at temperature 15-30^{0}C and significantly decrease at igher or lower temperature (Patazca et al., 2007).

Conclusion:

High pressure processing develops new "minimally" treated foods with high nutritional and sensory quality with increased shelf life. HPP is only alternative technology that has reached consumer with variety of new products. The main barrier for its commercialization is high cost. These can be overcome by research and studies to fill the gaps and to fully understand the process to reduce the production cost, which will eventually leads to reduction in the capital and operation cost.

STUDY ON THE APPLICATION OF HURDLES IN POST HARVEST PRESERVATION

R. Bharathipriya*., M. Satheesh ., Dr. S. Balasundari and Dr. N. Muralidharan

Department of Fish Processing Technology,
Dr. M.G.R Fisheries College and Research Institute, Ponneri.
Tamilnadu Dr. J. Jayalalithaa Fisheries University. Nagapattinam
E-mail: rbharathi1997@gmail.com

Hurdle technology was developed as a new concept for the production of safe, stable, nutritious, tasty and economical foods. The basic principle is to combine different preservation technique in order to achieve multitarget, mild but reliable preservation effects. Nowadays, consumers interest on fresh like foods which can be made by applying mild preservation techniques. Mild preservation is achieved by combining already existing traditional or novel preservation techniques with its least intensity.

Hurdle technology also called barrier technology. Each preservative factor is considered as hurdle with which microorganisms present should not be able to overcome. Commonly used hurdles are temperature, water activity (a_w), pH, redox potential, preservatives and so on. If higher the hurdles, greater influenc on microbial stability and contributes to safety of food. This concept is used unconsciously in many traditional foods. But it was re-invented some 15 years ago in food industry to design effective process for different food with minimum changes in sensory attributes.

Types of hurdles for food preservation:

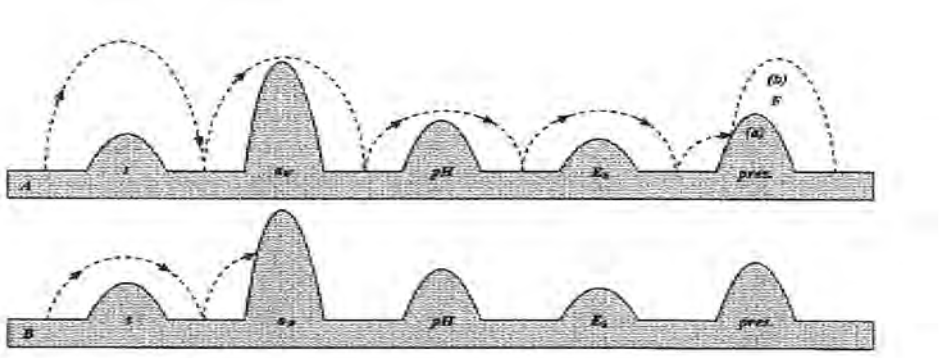
Types of hurdles	Examples
Physical hurdles	Electromagnetic energy(microwave, radiation) High temperature(blanching, pasteurization, baking) Low temperature (chilling, freezing) Packaging(active and vacuum packaging, edible film)
Physical non thermal hurdles	High hydrostatic pressure pulsed electric field and pulsed light.
Physicochemical hurdles	Co_2,O_2, O_3, Ethanol, Lactic acid, Lacto peroxidase, Low pH, Low a_w, Maillard reaction, Smoking, Nitrite/Nitrate, Sulphite and Spices
Microbiological hurdles	Competitive flora, Protective cultures and Microbial products

Mode of action:
Hurdle technology is a critical concept of mild preservation of foods. Hurdles will control microbial spoilage and food poisoning, leaving desired fermentation processes unaffected. Individual hurdles applied at lower intensities acts "synergistic" with one another in order to achieve safety and also maintains the sensory, nutritive and economic attributes of a food.

Fig.1 illustrates food containing six hurdles high temperature during processing, low temperature during storage, low water activity, acidity (pH), low redox potential (Eh) as well as preservatives. Some microorganisms can overcome a number of hurdles but none can jump over all hurdles. Finally food is stable and safe for long duration in theoretical cases.

Fig.2 illustrates hurdles are applied at different intensity like water activity and preservatives are main hurdles whereas pH, storage temperature, redox potential are minor hurdles. Intensity usage of individual hurdle is greatly reduced while combining preservative techniques. The number of hurdle application directly influence of product quality and safet .

(Continued on next page)



Conclusion:

Researchers have growing interest in designing and application of hurdle technology in food preservation. It is expected that this development will proceed in near future. Certain works on new hurdles like antimicrobial agents from plants, active packaging, processing technologies such as ultra-high pressure, high electric field pulses etc. paves the way for new invention in hurdle technology. This technology minimally affects sensory attributes of food. Innovation in hurdle technologies offer wide benefits to food industry with respect to increased product quality and assured safet .

SHORT SUPPLY CHAINS OF THE MILICZ CARP *Cyprinus carpio* IN POLAND

Magdalena Raftowicz*, Mirosław Struś, Magdalena Kalisiak-Mędelska, Izabela Kurtyka-Marcak

Institute of Economics, Wrocław University of Environmental and Life Sciences,
pl. Grunwaldzki 24a, 50-363 Wrocław, Poland
E-mail: magdalena.raftowicz@upwr.edu.pl

The carp market in Lower Silesia covers the area of 8493.265ha, where there are 48 breeding areas, including the biggest carp breeding center in Poland and even in Europe - Milicz Ponds (6114.64ha). The Milicz carp as the most recognized local product has become a key element of the economic, natural and cultural offer of the area.

Unfortunately, as a result of the intensifying processes of concentration of land and capital, strong competitive pressures and the demand for cheap food, the dominant form of carp distribution is based on long supply chains.

The factor that further stimulates the development of long supply chains is the negligible amount of local processing and the rapid development of transport as part of the global food industry network.

Shortening the supply chain and promoting year-round consumption of carp also in a new form (frozen, smoked, filleted fish, etc.) associated with the development of processing and recreational services may be crucial for maintaining the financial liquidity of farms.

The main goal of the research is to develop an optimal model of effective cooperation between producers and customers, based on short supply chains on the market of the Milicz carp.

The research was conducted on the basis of in-depth interviews among the participants of the supply chain on the market of the Milicz carp, i.e. on fishing farms, agritourist farms and among consumers

The research has shown that the effectiveness of this model requires a coherent and consistently implemented action plan, based on cooperation of participants in the supply chain and business environment institutions.

IDENTIFICATION, MOLECULAR AND FUNCTIONAL CHARACTERIZATION OF GLUTAREDOXIN-1 FROM BLACK ROCKFISH (*Sebastes Schlegelii*)

Introduction

Glutaredoxins(Grx) are versatile disulfide oxidoreductases with CXXC motifs that belong to the thioredoxin fold super-family. They can catalyze the reduction of protein disulfides, glutathione (GSH) and protein mixed disulfides via coupled reactions with NADPH, GSH and glutathione reductase. As these redox proteins serve as an inevitable member for the redox homeostasis, it is implicated as a cellular protector against oxidative stress conditions. Further, glutaredoxins involve in iron homeostasis and bind labile 2Fe–2S clusters. The present study was carried out to identify, molecular characterize, study the transcriptional modulation of rockfish glutaredoxin-1 (*SsGrx1*) upon immune challenges and ultimately examine the functional aspect of recombinant rockfish glutaredoxin-1(rSsGrx1)

Material and method

Phylogenetic tree and multiple sequence alignment were constructed to determine the evolutionary relationships and sequence homology respectively. The immune stimulation of *SsGrx1* was examined after challenging the healthy rockfish with three immune stimulants, Lipopolysaccharide, *Streptococcus iniae* and poly I:C. Blood and gill tissues were sampled from the challenged and unchallenged negative control fish at different time points. Various tissues were separately collected from five healthy fish for distribution of analysis *SsGrx1*. Those tissues were used for the RNA extraction. For both tissue distribution and immune modulation analysis of *SsGrx1*, qPCR assay was performed using the cDNA that were synthesized from the isolated RNA. The *SsGrx1* ORF was inserted into pMAL-c5x vectors and then it was transfected into BL21 expression systems. Recombinant protein was overexpressed by the IPTG treatment and the protein purification was carried out using maltose affinity chromatography. In order to study the protein activity, insulin disulfide reduction assay was performed.

Results

Amino acids sequence analysis indicated the presence of specific motifs and amino acids required for the GSH binding including $T^{69}V^{70}P^{71}$ motif, $G^{83}S^{84}D^{85}$ motif, K^{20} and Q^{58}. The phylogenetic tree unveiled that all the Grx family members were emerged from a single ancestor and affirmed the evolutionary conserveness of *SsGrx1* with the other Grx1 counterparts. *Larimichthys crocea* was identified as the evolutionary closest member. *SsGrx1* and other vertebrate Grx1 showed higher sequence homology, especially the two catalytic cysteine residues and the TVP motif for GSH binding were 100% conserved among the counterparts. Tissue distribution analysis confirmed an ubiquitous nature of the *SsGrx1* basal expression in naive rockfish tissues with the highest expression found to be in kidney. Immune challenge experiment showed a significant up-regulation of the *SsGrx1* mRNA expression in blood and gills with the injection of LPS, *S. iniae* and poly I:C. During the functional studies, rSsGrx1 was able to reduce the insulin disulphide bonds in a concentration dependent manner.

Discussion and conclusion

The conserveness of the amino acids and motifs including the TVP motif, K^{20} and Q^{58} implies the importance of the GSH mediated redox activity which was affirmed by the conservation in multiple sequence alignment. The tissue distribution of *SsGrx1* was found to have a wide range in the rockfish tissues illustrating its ubiquitous functions in different kind of cells and tissues. The significant upregulation of the *SsGrx1* after immune challenge denotes the immune relevance of *SsGrx1* to prevent the pathogenic attack. The functional study using the reduction of insulin by the recombinant protein was used as a method to assay the protein activity to show the redox potential of the purified protein. Collectively, the results obtained in this study plausibly suggest the immune relevance of *SsGrx1* and the relevance for oxidative protection.

Introduction

Today, almost 50% of global fish demand is met by aquaculture (FAO, 2018). And, although its growth has decelerated, aquaculture still is a constantly growing market worldwide. However, with increasing production volumes in net enclosures, ponds or recirculating aquaculture systems (RAS), the risk of disease outbreaks also increases. Stress due to high stocking densities and the exchange of stocking fish can facilitate the spread of diseases. Viral pathogens, whether long known or newly discovered, are therefore a challenge because there are few effective treatment options and the development of efficient viral vaccines in aquatic systems has so far been difficult to grasp (Crane and Hyatt, 2011). Other factors, such as climate change, are also contributing to the spread of known viral diseases such as pancreas disease (PD), infectious salmon anemia (ISA) and the emergence of new diseases. Through imports of Koi fish the Koi herpes virus (KHV) has been shown to spread significantly and is now carried by warmer temperatures in 28 countries (OIE, 2017). In general, industry-wide losses from aquatic animal diseases summed to over US$6 billion per year (World Bank, 2014). For this reason, vaccine development will play a central role in limiting existing and emerging viral diseases in fish (Gudding et al., 2013). Depending on the fish species and mechanism of a specific virus, different cell models are required. The establishment of new cell cultures, especially of CCApin (Rakers et al., 2018) as part of the "KHV-Vacc" project is presented as an example.

Materials & Methods

For the establishment of new cell cultures, different protocols have been used, depending on the target tissue and culture medium used. One-year old carp (*Cyprinus carpio*) were anaesthetized with clove oil and immediately decapitated. Protocols for cell isolation have undergone an ethical review process by the German Animal Welfare Law §8a. In total, eight new permanent growing cell cultures have been established. Among these cell cultures, three cultures have already been characterised in detail, whereof the CCApin culture from fin turned out to be the most promising. Therefore, cross-reactivity of mammalian-specifi antibodies has been tested and carp-specific primers for gene expression analysis by PCR have been generated. To characterise KHV replication in CCApin cells parameters such as medium, fetal bovine serum content, time of infection (TOI, cell density at virus inoculation), multiplicity of infection (MOI, ratio of applied virus particles per cell) and time of harvest (TOH) were varied. Virus replication was monitored using the 50 % tissue culture infective dose assay ($TCID_{50}$) to determine the number of infective particles. Viral DNA content was assessed using real time polymerase chain reaction (qPCR).

Results

The most successful permanent growing cell culture was derived from a preparation of carp fin and termed CCApin (*Cyprinus carpio pinnae* (lat.)). This culture was characterized in detail by proliferation studies as well as by immunocytochemistry (ICC) and gene expression of certain markers. Besides the molecular technologies, the cells have also been tested by our consortia partners for their virus replication capacity. The highest titres of 10^7 $TCID_{50}$/mL were reproducibly detected when a TOI ranging from 2x 10^4 to 6 x 10^4 cells/cm^2 was used, independently of applied MOI (from 0.005 to 3). In comparison, using lower TOI ranging from 5 x 10^3 cells/cm^2 to 2 x 10^4 cells/cm^2 resulted reproducibly in maximum titres of only 10^6 $TCID_{50}$/mL, again with no correlation to used virus load. To achieve the highest virus yields of 10^7 $TCID_{50}$/mL, low MOI (between 0.001 and 0.01) in combination with an intermediate TOI of ~3 x 10^4 cells/cm^2 were used for inoculation.

(Continued on next page)

Discussion & Conclusion

Cell models are an important building block on the road to an efficient vaccine. They not only enable the production of viruses in suitable titers, but also the manageability of the pathogens, e.g. for the observation of host-pathogen interactions *in vitro*, which can lead to improved diagnostics. As an example, new cell lines from carp that have high virus-replication capacities are urgently needed as reliable diagnostic method for KHVD and also for vaccine development. With the new CCApin cells, application of higher TOI at inoculation resulted in higher virus titres. Comparison of KHV replication in CCApin and CCB cells showed that similar titres were generated, indicating that both cell lines are equally suited for KHV replication. Replication in other, newly developed cell lines might prove successful to enable higher KHV titres, and they will help to develop more effective vaccines in the near future.

This work was financially supported by the German Federal Ministry of Food and Agriculture (BMEL) through the Federal Office of Agriculture and Food (BLE), grant number 2815HS010.

Introduction

Banana production in Canary Islands is a well stablish industry that produces 400mT per year from which generates a 10% of residues, that causes in most of the cases a problem of waste accumulation directly in the plantation. In the Life BAQUA (LIFE 15/ENV/ES/000157) project, a pilot facility has been developed to extract the fiber from the banana organic residue (banana pseudostem) to using as biodegradable materials in packaging and as natural additive for high volume production sectors like automobile industry. During pseudostem fiber extracting process, an important by-product is generated: the pulp. Moreover, the banana crops also generate other important residues like banana flowers. Different studies show the opportunity and high interest of banana crops wastes due not only to the great amount generated, but also to its high content in antioxidants (Gonzalez-Montelongo *et al*., 2010; Bhaskar *et al*., 2011), but is not much still used in human or animal products.

Materials and methods

Two raw materials from canarian banana crops waste, banana pulp (BT) and banana flower (BF), were tested at increased dietary levels in isoproteic and isolipidic diets for seabass. The experiments were carried out in two different feeding trials: for BT trial 24 fishes per tank in 12 tanks were fed with control diet (no BT), BT2, BT4 and BT8 (percentage of BT inclusion) for two months. BF feeding trial was performed for one month were 30 fishes in 12 tanks were fed with control diet (no BF), BF1, BF3 and BF6 (percentage of BF inclusion). Growth and performance parameters were taken at the end of the trials apart from biochemical composition, fatty acid and digestive and liver histology.

Results

In both experiments, the fish with the higher final weight were the fish fed with BT4 diet (23.38±1.56 g) for the banana pulp and BF6 diets (25.58±0.89 g) for the banana flowe . All the obtained results will be presented and discussed.

Acknowledgments

This study was partially funded by the European project Life BAQUA (LIFE 15/ENV/ES/000157), which aims at implementing the circular economy through spanning the value of the banana crop ensuring the use of wastes in other industries, being aquaculture and aquaculture feeds an important target objective.

Introduction

Antibiotics or antimicrobials are drugs that can kill or inhibit the action of microorganisms which is derived from either natural or synthetic source. Antibiotics should be safe to the animal, allowing their use as chemotherapeutic agents for the treatment of bacterial infectious diseases. An antibiotics are used to prevent the diseases by treating the water or fish before disease occurs. However, the heavy dosage of antibiotics in the fish/shrimp rearing systems could be leads to negative impact to the health of fish/shrimp, consumers and nature which will also increase the bacterial resistance to antibiotics. Hence more attention should be taken while using prophylactic antibiotics in fish/shrimp farming. At this circumstances role of antibiotics with respects to its positive and negative effects in culture systems were discussed for the benefits of farming communities.

Role of antibiotics in aquaculture

Among the animal protein, fish is the best source of nutrients, which flourished with PUFA, proteins, iron, calcium, zinc and etc. In the present situation, capture production is keep on decreasing, hence aquaculture is imperative to compensate the food demand. Aquaculture is the fastest growing sector meanwhile, to aiming the high profit, intensification came to existence in culture practices which leads to imbalance the host, pathogen and environment, this situation create the diseases and environmental impact. At this juncture use of antibiotics in shrimp/fish farming will minimize the diseases and maximize the production. Some of the antibiotics are being used with permissible level (to safe the animal as well as environment) in fish and shrimp farming and certain antibiotics are cause negative impact on animals as well as environment (Table 1). The antibiotics (oxytetracycline, florofenicol, sarafloxacin, and enrofloxacin) are most frequently used in aquaculture to combat bacterial diseases. Globally, other antibiotics such as chlortetracycline, quinolones, ciprofloxacin, norfloxacin, oxolinic acid, perfloxacin, sulfamethazine, gentamicin, and tiamulin are used

Certain farmers are using the antibiotics for prophylaxis and to treat the diseases, thus leads to negative effect. To conquer the problems, we have to promote the use of alternatives to antibiotics and create awareness among the farming communities regarding pros and cons of antibiotics. For sustainable aquaculture, we have to promote the organic farming and restrict the antibiotics usages.

Introduction

Aquaculture is playing, and will continue to play, a significant role in boosting global fish production and in meeting rising demand for fishery products. In 2013, fish accounted for about 17 % of animal protein consumed by the global population. A further shift towards a more pescatarian diet has the potential to reduce global agricultural greenhouse gas emissions and help prevent diet-related diseases. Such change is thus desirable from human and environmental health perspective, but this requires a sustainable growth of the fishery sector. A recent session of the FAO Committee on Fisheries stressed the increasingly key role of aquaculture in fish production for human nutrition and poverty alleviation in many rural areas. As such, there is a need to provide insights on how to ensure sustainable growth of the fishery sector but particularly of the aquaculture-fish secto .

Overall, the huge growth expected for aquaculture products makes necessary a more sustainable aquaculture development to mitigate the environmental impacts linked to this growth. Aquaculture can contribute to the overall objective of filling the gap between EU consumption and production of seafood in a way that is environmentally, socially and economically sustainable (COM (2013)229). Aquaculture is one of the pillars of the EU's Blue Growth Strategy and its development can contribute to the Europe 2020 Strategy. When practicing responsibly, fish farming can help provide livelihoods and feed a global population that will reach nine billion by 2050.

In 2013 European Commission proposes the Product Environmental Footprint (PEF) and Organization Environmental Footprint (OEF) methods as a common way of measuring environmental performance (COM2013/179/EU). To validate the methodology, a series of pilots for different products are developing, and Marine Fish was selected as one of the 11 food products. The package establishes the Life Cycle Assessment methodology methods to measure environmental performance of European Product and organizations.

This project aims to demonstrate that this integrative methodology can facilitate the evaluation and reduction of aquaculture environmental impact.

Methodology

AQUAPEF is going to promote the implementation of the PEF methodology into Mediterranean aquaculture sector by developing an integrative methodology to facilitate data availability, footprint calculation, verification, demonstration and communication. In the overall scheme of the project concept is presented.

- **Data availability:** Two main challenges could be distinguished regarding the data acquisition: a) collection of traceable primary data and b) representativeness of the background data. AQUAPEF project will ensure traceability of the primary data by i) developing a harmonized data acquisition protocol specifically oriented to the Mediterranean aquaculture value chain and by ii) collecting traceable data for marine aquaculture.

Regarding the representatives of the background data, LIFE AQUAPEF will collect main data regarding the feed types and ingredient or wastewater organic loads of the Mediterranean marine aquaculture. This challenge is fully in line with the needs of the PEF marine fish pilot working group

(Continued on next page)

- Calculation simplification and verification: AQUAPEF will provide the first software tool specifically designed for Mediterranean aquaculture sector that enables the calculation in an easy-way of a harmonized environmental impact, complying PEF methodology. The project demonstrates that the new software tool could provide to the aquaculture industry a reliable and representative ad-hoc tool to calculate their environmental impacts.

- Communication strategies: In relation to previous studies of consumer behavior associated to ecofriendly purchase, to date, several studies have pointed to the relationship between sustainability and the impact of knowledge, attitude and behavior on the consumption of sustainable or environmentally responsible products. As an example, some relevant studies carried out at European level are those of the Eurobarometer, such as the one on "European's attitudes toward the issue of sustainable consumption and production 2009". The AQUAPEF project will explore different communication strategies. However, the certification and label market has become ineffective and counterproductive. Consumers are confused by the stream of incomparable and diverse environmental information. About half of European consumers think it is not easy to differentiate between environmentally friendly and other products and only about half of them trust producers' claims about environmental performance. This also influences their readiness to make green purchase

Results and discussion

Three main results are expected from this project:

- AQUAPEF tool: A new SAAS (Software-as-a- service) is under developing to facilitate the implementation of PEF methodology in the Mediterranean aquaculture sector

- Improvement strategies: AQUAPEF analyses and tests potential uses of the PEF to reduce the environmental impact by a demonstration case-study in 3 seabream and seabass fish farms located in the Mediterranean regions: multitrophic aquaculture, new feeding systems and valorization of biowaste. This action will also demonstrate the need to include additional ecological indicators to complement Life Cycle Assessment results to obtain a better understanding of the system sustainability, as proposed by PEF recommendation

– Communication strategies: to ensure the added value and maximize the environmental and socioeconomic benefits of sustainable aquaculture products, action B4 focuses specifically in understanding consumer perceptions, raising awareness and informing consumers about the impact of their aquaculture-fish product choice with the aim of realizing a behavioral change towards more sustainable aquaculture product consumption.

Conclusion

AQUAPEF project starts in September 2018 and currently is undergoing. Final results of the tool demonstration and communication strategies are still under development. Thus, this is a presentation of the overall project concept.

Acknowledge

This project is co-funded by LIFE European Environment Programme (LIFE17 ENV/ES/000193), which is the EU's financial instrument supporting environmental, nature conservation and climate action projects throughout the EU. The implementation, updating and development of EU environmental and climate policy and legislation by co-financing projects with European added value are among its main priorities.

BROWN SEAWEEDS – A STATUS REPORT OF OFFSHORE CULTIVATION AND EXPECTED MARKET DEVELOPMENTS IN EUROPE

Diogo Raposo*, Frank Neumann, Jon Funderud

Seaweed Energy Solutions (SES)
Bynesveien 50C, 7018 Trondheim, Norway
raposo@seaweedenergysolutions.com

A resource forgotten in Europe

Globally, the cultivation of brown seaweeds takes the largest share of marine aquaculture production, mainly due to extensive farming of kelps, like *Saccharina japonica* ('Kombu') and *Undaria pinnifatida* ('Wakame') in Eastern Asia. While a highly important food commodity in Asia, in Europe seaweeds have not been part of the mainstream culture, and often only known in the context of Sushi. For both 'Wakame' and 'Kombu', there exist European species with comparable qualities for food consumption, namely *Alaria esculenta* (Atlantic Wakame) and *Saccharina latissima* (Royal Kombu), respectively. The value of seaweeds for the culinary and for our diet has increasingly caught attention of European chefs and food industry players, and the present scenario suggests a potential uptake in the European food market. Meanwhile, cultivation of these species is still in a pre-commercial phase, due to the relatively small amounts required to date.

In addition, in some areas, kelp forests have been declining in a worrying pace. For these and other reasons there cannot be expected major volumes of wild harvested seaweed in the future, which is why the more expensive, but also more sustainable path of cultivation is the only likely supply option.

A cultivation industry in its beginnings

Initial considerations of cultivating brown seaweeds in Europe were in the context of very large-scale farms for biomass-for-fuel scenarios. However this would require huge investments and levels of automation, versus a very low achievable unit price. Since a few years ago, it has been understood that the path towards cultivation for food as main product, similar to most of the actual cultivators of brown seaweed. The combination of near-term market demand expectations and possible specific sales price that can be achieved has been identified as the most promising sector to yield commercial feasibility. Seaweed Energy Solutions (SES) built a pilot cultivation farm in 2014, in which the technical feasibility of harvesting 100-150 tons per year was demonstrated. Since then, several companies in Europe, in particular in Norway, have been increasingly active and planning to upscale production with similar, relatively conventional farming techniques, and similar target volumes. After initial experiences in the (more complex) cultivation process of seaweed for food – since the raw material must be stabilised very soon after harvest, similar to fish –, the break-even for cultivation activities in a typical brown seaweed farm in Norway is expected to be in the range of 200 to 500 tons per year, depending on the sales price achieved per kilogram of raw material.

This contribution will describe the chosen farming technique and process implemented by SES in order to yield break-even cultivation within a short time frame, and without major investment requirements, allowing for a modular upscaling.

At the present stage, the market is not defined to a point that specific stabilising/processing methods are identified to be the most relevant ones for the industry. The seaweed landed on dock is mainly frozen, for the sake of availability, reasonable cost and relative flexibility for further processing options

Opportunities and threats for brown seaweed in European food market

Like for other products – as long as there is no large-scale production but significant initial investments are required – there is a need of relatively high sales prices of early production years. The food market – especially in the premium and HORECA sections – has been identified as an enabler for this phase

Brown seaweed are increasingly recognised for their health benefits and valuable compounds. They are a natural source of iodine, lack of which in the European population has been a concern for the health departments. They are also a source of more the 50 different minerals and trace elements, and omega-3 fatty acids. They are prebiotics. They are a natural texturizer and natural preservative. Containing higher amounts of glutamate, brown seaweeds give the *umami* taste and a enhancement of flavours.

(Continued on next page)

Given the varying characteristics of the raw material, as well as the high standards of the target markets it is highly important to perform frequent analyses on composition and product quality, and also to improve and consolidate knowledge about these aspects, which is the target of several research projects and initiatives, in some of which SES has participated or is participating. The present status of the discussion will be presented.

Valorization of environmental benefits

The ongoing years have been and will remain a dynamic phase for seaweed-for-food in Europe, and consequently seaweed cultivation in general. Overall, seaweed is a highly sustainable and energy-efficient food resource, as no fresh water is used, no fertilisers or chemicals applied in the sea, and no significan footprint on land is caused. Therefore, its use as a food ingredient has tremendous impact for the environment.

There are even benefits of seaweed cultivation on several levels, which may or may not soon be taken into account on a policy level. They absorb significant amounts of nutrients (N, P) and increase the CO_2 uptake capacities of the water body. As such, brown seaweed may be a prime candidate for adding sustainability to aquaculture operation, be it in IMTA approaches. The cultivation of seaweed in the sea can actually be compared to planting a temporary forest, contributing significantly to mitigate such effects as water quality and biodiversity decline. The seaweed forest is a biodiversity enhancer, e.g. through increased shelter and maternity areas for juvenile fishes, crustaceans and others. Among other initiatives, in particular the 'Seaforester' organisation aims at turning the wide recognition of these values of seaweeds into action. The concept of seaforestation, as well as the knowns and un-knowns in relation to this approach, will be briefly presented

Potential threats to sustained large-scale cultivation like e.g. genetic deterioration from breeding and diseases are being targeted in research efforts, including the ongoing GENIALG project. The findings of this and other ongoing projects like MACROSEA, KELPPRO and SEABEST will be presented, with the aim to give a global insight into the actual status and future prospects of brown seaweed cultivation.

FEEDING MANAGEMENT OF JUVENILE PIKEPERCH *Sander lucioperca* UNDER PRODUCTION CONDITIONS

Tobias Rapp*[1], Moritz Tielmann[1], Ralf Bochert[2], Marcus Stüeken[1]

Introduction

Pikeperch is a promising species for cultivation in recirculation aquaculture systems (RASs) (Wang et al. 2008). It is valued by consumers, offers a stable sales market and the attainable market prices are high (Knaus, et al., 2008). However, pikeperch production in RAS is currently still expensive and it is essential to optimize the use of resources. The use of fish feed, typically the most prominent variable cost factor (Alanärä et al., 2001), can mainly be optimized by the feeding management to reduce the amount of feed loss without compromising fish growth. Here we present a study on the effects of number, duration and period of feeding events in the feeding regime of juvenile pikeperch under production conditions.

Material and methods

The experiment was conducted in eight tanks with each 1.5m^3 water volume and water treatment systems. The feeding regimes included 1) continuous 24h/d feeding with 30min feeding intervals (C30), 2) continuous 24h/d feeding with 30min feeding intervals, whereas the feeding period was extended by 35% until the assigned amount of feed was fed (C30L), 3) continuous 24h/d feeding with 120min feeding intervals (C120), and 4) intermitted 12h/d feeding with 30min feeding intervals (I30) during daylight hours. Pellets were supplied with a drum feeder. Before the start of the experiment fish were graded by size (mean weight±SD: 104.6±3.63g; mean length±SD: 23.6±2.1cm). Each tank was stocked at a density of 16.7kg/m^3. After 42 days the study was terminated and 50 randomly chosen fish from each tank were measured for total length and weighed and biomass in each tank was assessed to calculate specific growth rate (SGR), Fulton's condition factor (K), coefficient of variation (CV), biomass gain, apparent feed conversion ratio (aFCR), apparent protein efficienc ratio (aPER), and apparent lipid efficiency ratio (aLER)

Results

Coefficient of variation showed significant differences between treatments whereas differences in SGR, K, biomass gain, aFCR, aPER, and aLER were not significant (Table 1). The CV was higher when feed was only supplied for 12h (I30) compared to when fish were fed over a 24h period (able 1).

Discussion and conclusion

The high CV for fish with an intermitted feeding regime (I30) indicates a more heterogenic growth compared to a continuous feeding. Fish with more heterogenic growth have to be graded more frequently to reduce mortality through cannibalism (Baras & Jobling, 2002) which increases working hours and expenses.

There was a trend that treatment C30L experienced highest SGR, K, biomass gain, and better feed efficiency (i.e. aFCR, aPER, aLER) although differences were statistically not significant. This could indicate a more sufficient feeding when feed is provided slower (Alanärä et al. 2001), but not too slow to support feed monopolization (Grant 1993). Thus, data of this work could provide additional support for the advantage in prolonged feeding events during a continuous 24h feeding regime. However, potential effects were not great enough to be depicted by the duplicate design due to its low power. Therefore, we encourage further studies with a specifically adjusted experimental design

(Continued on next page)

Table 1: Mean (±SE) specific growth rate (SGR), Fulton's condition factor (K), coefficient of variation (CV), biomass gain, apparent feed conversion ratio (aFCR), apparent protein efficiency ratio (aPER), and apparent lipid efficiency ratio (aLER) of four different feeding regimes. Additionally the corresponding test statistics are given. Feeding regimes include continuous 24h/d feeding with 30min feeding intervals (C30), continuous 24h/d feeding with 30min feeding intervals, whereas the feed was supplied over a period that was 35% longer compared to the C30 treatment (C30L), continuous 24h/d feeding with 120min feeding intervals (C120), and intermitted 12h/d feeding with 30min feeding intervals (I30) during daylight hours.

Variable	C30 (Mean±SE)	C30L (Mean±SE)	C120 (Mean±SE)	I30 (Mean±SE)	F-value; df; P-value

EFFECT OF FOUR DIFFERENT COMMERCIAL FEEDS ON GROWTH PERFORMANCE AND SURVIVAL OF EUROPEAN PERCH *Perca fluviatilis* I N RECIRCULATING AQUAQUALTURE SYSTEM

Ralf Bochert*[1], Frederik Buhrke[1] and Tim Gottschalk[2]

[1] Mecklenburg-Vorpommern Research Centre for Agriculture and Fisheries, Institute of Fisheries, Research Station Aquaculture, D- 18375 Born
r.bochert@lfa.mvnet.de

The aquaculture production of European perch is still limited by several bottlenecks. Predicting growth rates, feed intake and energy requirements of the farmed fish in different life stages are crucial for the viability of an enterprise. Especially the economic production of high quality and healthy meat depends essentially on the composition of artificial diets. There are different products on the feed market which may suit the production of European perch. It is known that the European perch tends to accumulate visceral fat in its cavity, which can lead to a lower filet yield and higher amount of carcasses. Taking this in consideration it is of great importance to test different commercial feeds on their performance for perch farming to optimize production costs.

We tested four different available commercial feeds (3mm), of which three were declared for percids (feeds A, B, D), in a practical approach during grow out from 100g to 200g fresh weight in a three month trial in triplicate at an initial density of about 20kg/m³ (157 fishes per treatment). The amount of crude protein ranged from 49 – 54% and crude fat ranged from 10% (feed C and D), 15% (feed A) and 20% (feed B). Further, D was floating feed in contrast to sinking feeds A, B and C.

At the end of the experiment we will compare survival, final fresh weights, specific growth rate, Fulton's condition factor (K), coefficient of variance, filet quantity and quality (fatty acid analysis), visceral somatic index and hepatosomatic index.

After 73 days of the experiment mean survival was highest with feed D (99.2%). Remarkable lower survival was overserved for feed A. At this stage of the experiment no differences between sinking (B, C) and floating feed (D), nor between feed declared for percids (B, D) and alternative feed (C) were ascertained.

The experiment is still in progress and the results are not available at time of abstract submission. The final results will be presented at the resubmitted version of this abstract and provided on the poster.

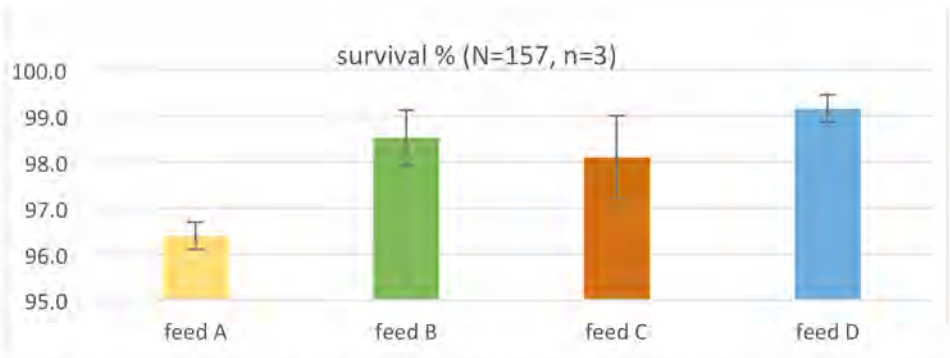

Fig. 1: Mean survival (%) of *Perca fluviatilis* after 73 days during growth out with four different commercial feeds.

GAMETE MATURATION OF THE POLYCHAETE *Nereis diversicolor*: EFFECT OF DIFFERENT TEMPERATURE AND PHOTOPERIOD CONDITIONS

D. Quintana, I. Martín, C. Lobo, I. Rasines

Instituto Español de Oceanografía. 39012 Santander (Cantabria)
E-mail: inma.rasines@ieo.es

Introduction

Nereis diversicolor is a polychaete species which is suitable for industrial aquaculture, because of its adaptability to wide environmental conditions, feed flexibility (detritivorous, carnivorous) and high growth rates under culture conditions (Batista et al., 2003). However, reproduction control (or programming) is a bottleneck for *N. diversicolor* production and further research is needed, particularly regarding gamete maturation. The present study aims to investigate specific factors (temperature and photoperiod) as well as aquaculture procedures that influence gamete maturation for both reproduction management and improving and getting successful artificial fertilization of cultured *N. diversicolor*. In particular, since a massive reproduction event was observed in our aquaculture facilities after a steep fall in water temperature, we study whether a cold treatment can influence gamete maturation (experiment 1). In difference to this observation, we hypothesize that warm temperatures can influence gamete maturation as occurs during spring-summer natural conditions (experiment 2). In relation to experiment 1, Bagarrao et al. (2013) tested short-time temperature falls to induce spawning; hence, we investigate if this kind of punctual thermal shock can also influence gamete maturation (experiment 3). In addition, since photoperiod usually interacts with temperature for maturation, we analyze this effect on gamete maturation of *N. diversicolor* (experiment 4).

Material and methods

Experiment 1 (cold treatment): 150 worms (815±228 mg of initial body weight) were distributed into six tanks (25 worms per tank) after three summer months of acclimation under natural temperature (18.4±0.9ºC) and photoperiod (L:D, 15:9) conditions. A cold temperature treatment (11.7±0.3ºCand L:D 15:9) was applied to these worms (three tanks), in comparison to control groups (three tanks) maintained like in summer conditions (19.1±1.1ºCand L:D 15:9).

Experiment 2 (warm treatment): 180 worms (1053±272mg) were spread in six tanks (30 per tank), after being in artificial conditions of temperature (12.9±0.6ºC) and photoperiod (L:D, 15:9). Three of these tanks were subjected to warm temperatures (18.8±1.2ºand L:D 15:9) and compared with the other three tanks kept like in initial conditions (11.7±0.3ºCand L:D 15:9).

Experiment 3 (punctual cold treatment): 180 worms (689±125 mg) were distributed into six tanks, after being under artificial conditions of temperature (18.8±0.8ºC) and a winter natural photoperiod (L:D, 9:15). These worms were shocked with a short cold treatment (11.7±0.3ºCand L:D, 9:15) lasting six days, and then reverted to initial conditions for the remaining experiment. Control groups were always maintained like in initial conditions (19.5±0.9ºCand L:D, 9:15).

Experiment 4 (temperature-photoperiod): 360 worms from our stock were sampled (755±173 mg) and distributed into twelve tanks, after three months in natural winter conditions of temperature (11.2-13.0º) and photoperiod (L:D, 9:15).Three groups of these worms were changed to 19.2-20.8ºC and/or L:D 15:9 (9 tanks, 3groups x 3 tanks) to study the individual effect of temperature and photoperiod, as well as their interaction.

The maturation stage of the gametes (free sperm or tetrad stage for males, and oocyte diameter>175µm for females), survival and weight of the worms were recorded at the end of the experiments. The end of each experiment coincided with the time of gamete maturation observed in similar experimental tank/s of worms which were periodically sampled, being: five weeks (experiment 1), three weeks (e2), four weeks (e3) and two weeks (e4). Data were statistically compared by a t-student test for the experiments 1, 2 and 3, and by a 2-way ANOVA for the experiment 4. Also 1-way ANOVA and Tukey post-hoc tests were used for between-group comparisons for experiment 4.

(Continued on next page)

Results

At the end of experiment 1, mature females, mature males and total mature polychaetes were not significantly (P>0.05) different in the cold group (11.7ºC) of worms as compared to the control one (19.1ºC). However, total survival and final body weight of worms were both significantly (P<0.05) higher in the cold group. On the other hand, a significantly higher number of mature females (12, almost double) were retrieved from the warm treatment (18.8ºC), compared to the control group (11.7ºC) in experiment 2.The total number of mature polychaetes (13) showed the same pattern, though barely significantly (P=0.052). Mature male number, final body weight and survival were not significantly modified. In experiment 3, the punctual 6-day cold treatment (11.7ºC) did not increase the number of total mature worms nor mature females in comparison to the control treatment (19.5º). However, the punctual cold treatment influenced a significant low reduction in the number of mature males (from 1.3 to 0), while survival and final body weight were not significantly modified. Experiment 4 showed a significant effect of temperature, irrespective of photoperiod, on the number of mature females and total matures. A significant effect of photoperiod on the number of mature females and total matures was also obtained, irrespective of temperature. In consequence, the interaction effect was not found statistically significant. Between-group comparisons found significant differences for the higher number of mature females and total matures from the group treated with high temperatures (19.2-20.8ºC) and photoperiod L:D 15:9 against the control group.

Discussion

Results indicate that changes in temperature imposed on worms that have been under summer conditions (18.4º and L:D 15:9), by using a cold water treatment of 11.7º, did not have a significant effect on maturation. On the contrary, a warm temperature treatment (18.8ºC) did have a significant effects on female gamete maturation, as well as on the total number of mature worms, that had been previously subjected to "cold" artificial conditions (11.7ºand L:D 15:9), almost doubling both values. The final body weight of worms under cold treatments was also significantly higher in experiments 1 and 2, which suggests both gamete emission by worms under warm experimental temperatures and some worm degeneration related to the high maturation observed. Survival under cold treatments was only higher in experiment 1and it was probably related with the longer experimental time used in this trial since worms always die after spawning. It is also remarkable that the "punctual cold shock" treatment (experiment 3) significantly reduced the number of mature males; this is particularly noteworthy given the low proportion of mature males. In addition, this thermal shock did not improve any other of the measured parameters such as female maturation, total maturation, survival or final body weight. Experiment 4 indicates the importance of temperature for oocyte maturation, irrespective of photoperiod, as well as the significant effect of photoperiod for oocyte maturation, irrespective of water temperature. A treatment by treatment comparison suggests that the simultaneous treatment with long photoperiods and high temperatures should be recommended to achieve gamete maturation, although an increase in only one of these factors alone promotes gamete maturation.

IMTA IN THE ATLANTIC AREA: DEFINITION, BEST-PRACTICE, STATUS AND NEEDS

Ratcliff JJ.*[1], Jacquemin B.[2]

1 Irish Seaweed Research Group, Ryan Institute, National University of Ireland, Galway, Ireland
jessica.ratcliff@nuigalway.ie
2. Centre d'Etude et de Valorisation des Algues, Presqu'île de Pen-Lan, 22610, Pleubian, France

Whilst Integrated Multi-Trophic Aquaculture (IMTA) is conceptually appealing, it has nevertheless failed to become a part of mainstream aquaculture on an industrial scale. The European Project Integrate, funded by the ERDF through the Interreg Atlantic Area Programme has looked into reasons for this lack of uptake. As part of this process each project partner from the European Atlantic Area countries UK, Ireland, France, Spain, and Portugal, held a series of thematic roundtables asking questions aiming to define what IMTA best-practice might be, and how it might be achieved. For each of 5 areas, namely, environmental; economic; social; regulatory and technical, the expert groups were asked to define IMTA best-practice, to identify challenges and bottlenecks to its achievement and to recommend priority areas for research and development. These country by country analyses have been synthesised to provide an overview of the European Atlantic Area situation, including what is common across the board, and what is unique to countries or regions.

From these roundtables a common problem emerged: although the conceptual definition of IMTA was clear, a more utilitarian definition making some of the details explicit, was necessary. It was envisaged by IMTA stakeholders and producers that by addressing this need IMTA could be better regulated and commercialised and, in addition, the development of an IMTA technical standard could be facilitated. INTEGRATE addressed this by organising an 'IMTA Definition Event', that was hosted by the Interreg Atlantic Area Programme Managing Authority in Porto, Portugal, in May 2019. The event brought together 44 international experts and the structured discussion built on information gathered previously by questionnaire. In large part, consensus around a 'Europe-appropriate' IMTA definition was achieved, although some points remain in need of further clarification

Synthesised results from the expert roundtables, the questionnaire and the preliminary conclusions from the IMTA definition event will be presented.

Acknowledgements
INTEGRATE is funded by the ERDF through the INTERREG Atlantic Area 2014-2020 Programme (project grant number EAPA_232/2016).

BUILDING KNOWLEDGE FOR A SUSTAINABLE AQUACULTURE INDUSTRY: THE DECISION-SUPPORT TOOL SEAGRID

Ravagnan E.[1*], Tassetti A.N.[2], Fabi G.[2]

[1] NORCE Environment, Norway; [2] CNR-IRBIM, Italy; [3] NORCE Society, Norway

Norwegian Research Centre (NORCE); Nygårdsgaten 112, 5008 Bergen, Norway
elisa.ravagnan@norceresearch.no

The aquaculture production in Norway has experienced an extraordinary growth in the recent years and it is expected to export more than 200 billion NOK per annum by 2030. While offshore locations are currently tested, the traditional Norwegian aquaculture industry has been mainly located in the coastal and fjord areas, thus interacting with other marine activities.

The main objective of the AquaAccept project was to explore the sustainable development of coastal area activities, with special focus on aquaculture, from an interdisciplinary perspective, drawing on expertise in biology, ecology, economics, sociology and computer science. One of the main project's goal was to develop a decision-support tool (SEAGRID) to aid stakeholders and decision-makers address conflicts and syne gies between marine activities.

The SEAGRID, a GIS-based, user-friendly tool, can be used to quantify environmental, social and economic suitability and it allows stakeholders and decision makers to make spatial choices that strike a balance between multiple ecological, economic and social objectives.

SEAGRID uses stress level and conflict score analyses to evaluate marine activities interactions, including environmental risk calculations as well as socio-economic evaluations. SEAGRID assesses conflict scores, generate matrices of interactions, environmental risk and social acceptability, plots maps, evaluates spatial and/or temporal interactions existing in a specific marine coastal area, calculates overlaps and ranks the effects of synergies and conflicts by the calculation of global stress levels.

Environmental data, available from regional and national authorities have been used to implement the environmental layers and score calculations. Socio-economic data were obtained from public databases (production costs and revenues) and from national and local surveys and interviews carried on in the AquaAccept project. The data have been synthesized, as quantitatively as possible, and managed inside the SEAGRID database. Their environmental, economic and social aspects in terms of induced stress levels and multiple layer matrices and stakeholder interactions were evaluated for the Boknafjord (Rogaland County, South-West Norway) case study.

The results from the case study analysis and the final implementation of the SEAGRID are currently being discussed with the stakeholders (local and national authorities, industries, interested commercial and private actors) to promote a bottom-up approach meeting the needs for a cross-sector and transparent management of the marine areas.

The results of the case study will be presented at the conference.

THE USE OF FULL-FAT SUPERWORM (*Zophobas morio)* MEAL IN GUPPY (*Poecilia reticulata*) NUTRITION

Introduction

The interest of pet food market in insect meals increases, and in the most cases meets more liberal law regulations that other branches of feed production (Lahteenmaki-Uutela et al. 2017). However, in opposition to aquaculture, a very few studies are done on ornamental and laboratory fish species. It creates the need of development of sustainable feeds for non-edible aquaculture species seems to be important from nutritional, environmental and marketing point of view (Vargas-Abúndez et al. 2018, Zarantoniello et al. 2018, Vargas-Abúndez et al. 2019). Moreover, the initial studies showed that superworm (*Zophobas morio*) is an attractive feed component for guppies (*Poecilia reticulata*) kept in experimental conditions (Rawski M., unpublished data).

The aim of the experiment was to assess the effects of 100% inclusion of the *Zoophobas morio* full fat-meal into the diet of guppy in comparison to commercial fish feed.

Materials and methods

The experiment lasted 60 days. A 150 juvenile (14 day old) gupies from outbreed line maintained at Poznań University of Life Sciences were used in the experiment. At day 1 The mean total body length of the fish was 8,5 mm.. The fish were randomly allocated into two treatments: control – feed with commercial feed, and experimental: feed with *Zoophobas morio* full fat meal only. The fish were allocated to 6, filtrated and aerated 20l tanks (3 replications/ treatment, 25 fish/ tank. The temperature of water was: 25-27º C, filtration flow: 160 l/h, and applied photoperiod of 12h of light and 12h of darkness.

The insect meal was obtained from HiProMine S.A (Robakowo, Poland). *Zophobas morio* larvae were feed with plant origin by-products, they were dried in 50º C for 24h. The insect meal as well as commercial feed were finely grinded and stored in fridge through the time of experiment (4º C).

The animals were feed once daily at 8.00 until visual satiation. At day 1, 30 and 60 survival rate, total body length and its gain were assessed. All obtained data were statistically analysed with the use of T-student test, with significance level of $p \leq 0.05$.

Results

The results obtained in two month long experiment showed no difference in mortality, total body length, total body length gain. The fish from control group reached 13,5 mm of total body length while *Zophobas morio* feed 13,4 mm. Survival rate in both cases was high and comparable: 90,7% in control and 85,3%.

Discussion and conclusion

According to available scientific literature, the presented study is probably the first case of the use *Zophobas* morio full-fat meal in juvenile guppy rearing. It shows the possibility of the use of insect meal as the basal diet in omnivorous ornamental fish nutrition, which may be an alternative for conventional feed resources. The results confirm the possibility of partial or total inclusion of insects to ornamental fish diet (Vargas-Abúndez et al. 2018, Vargas-Abúndez et al. 2019).

However further studies on the insect effects on physiology and reproduction of ornamental fish should be performed due to variability of observed in other species effects on fish growth, gastrointestinal physiology and microbiota (Vargas-Abúndez et al. 2018, Józefiak et al. 2019, Zarantoniello et al. 2019).

Introduction

Various forms of recirculating aquaculture systems (RAS) can be used to grow marine shrimp practically anywhere. By locating these systems in greenhouses or insulated buildings fresh, large shrimp can be produced year-round near consumer markets, opening opportunities for branding a higher-quality, sustainable, local-grown seafood product. One of the major costs associated with growing marine shrimp inland is salt, and the current standard is to use complete, brand name sea salts. The purpose of this project was to evaluate the use of an inexpensive salt mixture at various inclusion levels for the production of shrimp.

Materials and Methods

An 84 day-long experiment was conducted using 20, 1m^3 tanks. Each tank had a 15 L external biofilte , a 15 L settling chamber, and an electrical heater. Five treatments were developed (Table 1) with combinations of a least cost salt formulation (Table 2), and a standard, store-bought, full sea salt Crystal Sea® Salt – CSS).

Each treatment was randomly assigned to four tanks which were located in a climate-controlled (20°C), insulated building with household fluorescent lighting kept on constantly. Shrimp were stocked at 4.3g mean weight and fed three times per day based on estimated FCR and survival. A repeated measures (RM) ANOVA was used to analyze water quality data over time, and one-way ANOVAs were used to analyze final dissolved mineral content and shrimp production data

Results

Because the RM ANOVA considers the entire data set over time, it did detect some subtle but consistent significant differences between treatments with regard to DO, pH, and nitrite levels. However, these differences do not correspond to the proportion of either salt mixture. There was significantly more sulfate, magnesium, and strontium in the CSS than the LCS mix and that was evident from dissolved mineral data.

There were no significant differences detected in any measured shrimp production metrics, which included average weight, growth rate, FCR, biomass (kg m^{-3}), and survival (Table 3).

The cost of salt per kilogram of shrimp was significantly lower in the 50% CSS/LCS treatment than the 100% or 75% CSS, and the 75% and 100% LCS treatments were significantly lower than any of the other three treatments (Table 4). The 100% LCS treatment was less than half the cost per kilogram than the 100% CSS treatment.

Table 1. The experimental treatments.

5 Treatments
1.) 100% CSS
2.) 75% CSS – 25% LCS
3.) 50% CSS – 50% LCS
4.) 75% LCS – 25% CSS
5.) 100% LCS

Table 2. The least-cost salt formulation (LCS).

15 ppt. Salt Solution @ 1m^3	
NaCl	11,310 (g)
$MgSO_4$	1,830 (g)
$MgCl_2$	855 (g)
$CaCl_2$	376 (g)
KCl	240 (g)
$NaHCO_3$	90 (g)

(Continued on next page)

Table 3. Shrimp production results in the five treatments using combinations of a Crystal Sea Salt (CSS) and a Least Cost Salt (LCS) formulation.

	Treatment				
	100% CSS	75% CSS	50% CSS/LCS	75% LCS	100% LCS
Average Weight (g)	22.9 ± 0.8	22.2 ± 0.5	22.4 ± 0.2	22.5 ± 0.6	22.5 ± 0.4
Growth rate (%)	1.6 ± 0.1	1.5 ± 0.0	1.5 ± 0.0	1.5 ± 0.1	1.5 ± 0.0
FCR	1.8 ± 0.1	1.7 ± 0.1	1.8 ± 0.1	1.6 ± 0.1	2.1 ± 0.2
Kg/m^{-3}	3.8 ± 0.2	3.9 ± 0.2	3.8 ± 0.3	4.0 ± 0.2	3.2 ± 0.3
Survival (%)	67.2 ± 3.8	70.3 ± 3.9	68.3 ± 5.2	73.1 ± 4.2	57.2 ± 6.2

Table 4. The cost of salt per kilogram of shrimp produced in each treatment.

Cost of Salt per Kg of Shrimp	
Treatment	$USD
100% CSS	$6.66[a]
75% CSS	$5.50[a]
50% CSS/LCS	$4.57[b]
75% LCS	$3.20[c]
100% LCS	$2.87[c]

Discussion

This study demonstrates that using a simple, in-house made salt formulation can be an effective strategy to produce shrimp in intensive, indoor farming. The shrimp were grown to over 22g, which is a highly marketable size in the US, and can fetch a substantial price. Survival was lower than expected across treatments, but most notably in the 100% LCS treatment. This warrants further investigation and a follow-up project is looking at the effects of using lower levels of CSS, down to about a 5% CSS - 95% LCS blend to determine if a small amount of CSS is needed. Likewise, examining the effects of balancing some of the relatively deficient minerals in the formulation will be explored

Nonetheless, the production levels from the LCS-containing formulations are encouraging, especially when the cost per kilogram of shrimp is considered. This has potential to reduce the costs of production in intensive shrimp farming substantially. Reducing recurring costs in this manner may make this production strategy more financially feasible and allow farmers to produce shrimp close to consumer markets at inland locations.

MICROARRAY-PREDICTED MARKER GENES AND MOLECULAR PATHWAYS INDICATING COMBINED CROWDING AND THERMAL STRESS IN RAINBOW TROUT (*Oncorhynchus mykiss*)

Introduction

Stressors in aquaculture cover a broad and diverse range of abiotic and biotic factors. The co-occurrence of multiple stressors has various physiologic consequences for the farmed fish ranging from moderate alterations at the molecular level to increased disease susceptibility, behavioural disorders or even mortalities (Schulte, 2013). The objective of the present study was to identify and evaluate informative indicators for the welfare of rainbow trout *Oncorhynchus mykiss* exposed to (A) a critical water temperature of 27°C and (B) acute crowding of 100kg/m^3 combined with water temperature of 27°C. To this end, we combined a broader and complementing panel of phenotypic, plasma- and transcript-based parameters, to understand whether the concurrent occurrence of thermal and crowding stress evoke additive or synergistic or even antagonistic effects at the molecular level.

Material & methods

Rainbow trout at the age of ~10 months were randomly distributed over six experimental tanks in a recirculating aquaculture system (RAS). The experimental procedures are illustrated in Fig. 1.

Further husbandry conditions are detailed by Rebl et al. (2017). Eight days after the start of the experiment, seven rainbow trout per tank were randomly sampled. Blood, head kidney and spleen of these animals were isolated and either used for profiling of plasma parameters or cell culture or nucleic acid extraction.

Microarray-based gene-expression analysis was performed on 8×60 K AgilentSalmon Oligo Microarrays (Agilent Technologies) following the Agilent 60-mer oligo microarray processing protocol, as described by Rebl et al. (2017).

Fig.1. **Schematic representation** of the stress experiment subjected to rainbow trout. In the reference tanks, temperature (16°C) and density (30kg/m^3) were kept constant. In the 'temperature stress' tanks, water temperature was gradually increased up to 27°C (stocking density: 30kg/m^3). In the 'temperature/crowding stress' tanks, rainbow trout were exposed to stocking densities of 100kg/m^3 and gradually increased temperatures up to 27°C.

(Continued on next page)

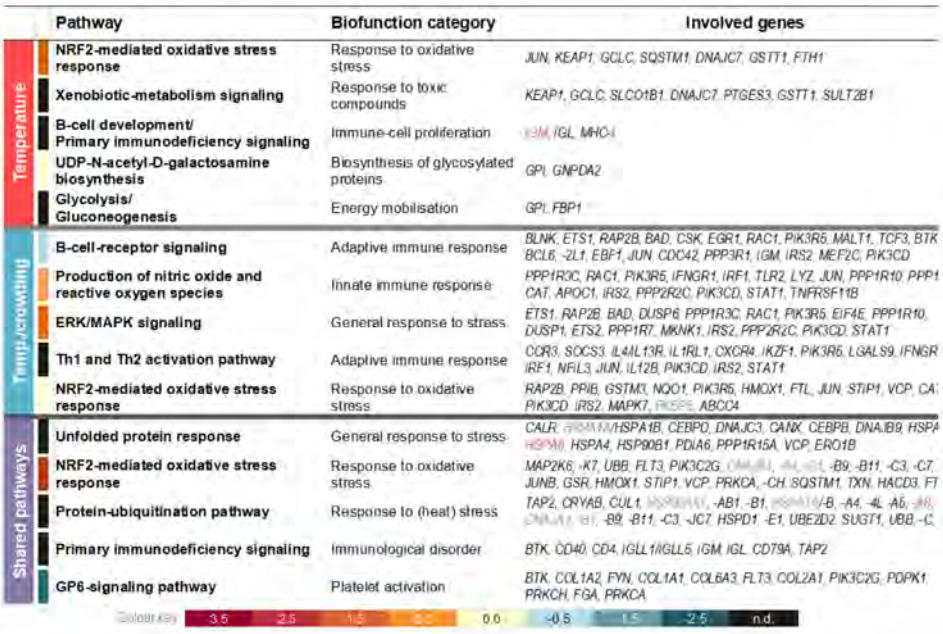

Fig.2. **Pathway analysis** of the DE gen sets exclusively affected by temperature stress alone (red label), by combined temperature/crowding stress (blue) and shared by temperature stress and combined temperature/crowding stress (purple). The 5 most strongly affected pathways are listed. Z-scores (colour code below the scheme) indicate activated or repressed pathways.

Results

We determined health index, spleen-somatic index and haematocrit and recorded, in addition, traditional plasma parameters of rainbow trout under challenging *versus* control conditions. However, each of these tests revealed non-significant differences between the two stress groups and the reference group. On the other hand, we detected a strong influence of both stress conditions on gene expression in the spleen. In total, the transcript abundance of almost 1500 genes was modulated at least 2-fold in rainbow trout stressed by temperature stress alone or combined temperature/crowding stress over the unstressed control fish. The complete microarray-data set has been deposited in the GEO database (accession #: GSE129271). Based on the sets of differentially expressed (DE) genes, we identified unique and common tissue- and stress type-specific pathways reflecting the crossroads between signal transduction, metabolic and immunologic pathways to cope with thermal and crowding stress (Fig. 2).

The immunologic aspects of the transcriptomic analyses were confirmed in primary-cell-culture experiments

Discussion and conclusion

The present study demonstrates that temperature and crowding stress share similar expression profiles. Nevertheless, we identified stress-specific pathways and thus contribute to improve the monitoring of the salmonid's welfare in aquaculture.

Introduction

The Senegalese sole (*Solea senegalensis*) is a flatfis that is distributed throughout the Mediterranean Sea and in the Atlantic areas of Africa. Its culture has a high commercial value, with sole being a good candidate for diversification of the European markets, saturated because of the overproduction of seabream and seabass. A limiting factor in Senegalese sole aquaculture is the absence of methods for controlling reproduction in captivity due to problems with sole generations born and bred in captivity. This species is characterized by a karyotype with 42 chromosomes, and a preliminary physical map, with chromosomal markers for the 21 pairs has been constructed (García-Cegarra et al., 2013; Portela-Bens et al., 2016). A possible sexual proto-chromosome in the sole (Portela-Bens et al., 2016), originated by fusion of 2 acrocentrics has also been described (Merlo et al., 2017; García-Angulo et al., 2018). Results presented here show the updated integrated map in the Senegale sole and the characterization of relevant genes for aquaculture as some involved in sexual determination, differentiation and maturation, immunology and metamorphosis. In addition a comprehensive study of repeat sequences and miRNA location in the sequenced BACs will be presented.

Material and Methods

Cytogenetic methods and protocols used for mFISH, NGS sequencing and genomic comparison have been described in Portela-Bens et al. (2016) and García-Angulo et al. (2018).

The "MISA" program (Microsatellite identification tool) was used to determine the distribution of satellite DNA in *S. senegalensis* chromosomes. The data were distributed by BACs hybridized per chromosome and they were measured as number of loci (NL) per Mb of chromosome.

A nucleotide database was created containing 2981 sequences from BAC clones of a *Solea senegalensis* BAC library and interrogated using blastn command for potentially conserved miRNAs (Arias et al., 2018). The reference transcriptome for *S. senegalensis* (v4.1) was downloaded from Solea DB (Benzecri et al., 2014) and used for target prediction using miRanda v3.3a.

Results

An integrated genetic map with 97 BACs hybridized to the chromosomes of the karyotype of *S. senegalensis* has been constructed (Fig 1). BACs were isolated from a library by selecting genes involved in important processes in the sole aquaculture: reproduction, sexual determination / differentiation, immunology and metamorphosis. BACs showed a distribution in all the chromosomes not at random but a co-localization related with its functional activity was observed. Each BAC was sequenced and its sequences used to comparative genomic studies with other species.

A total of 5330 microsatellites were identified based on BAC sequences and comprising 1.27% of the genome analyzed. In average, 595,7 loci were found per Mb of Chromosome. The NL abundance ranged between 229.9 loci per Mb in chromosome 20 and 935,4 in chromosome 17.

The BLAST analysis of 2981 contigs yielded 272 miRNA matches. These matches resulted in 124 potential miRNAs organized in 45 groups. Of the 45 groups, 19 were assigned to the Senegalese sole chromosomes using BAC-FISH data, and 34 unique mature sequences targeted 12387 sequences from an *S. senegalensis* reference transcriptome. Of the 59514 sequences, present in the reference transcriptome, 12387 were putative targets according to miRanda, with some of them appearing up to seven times.

(Continued on next page)

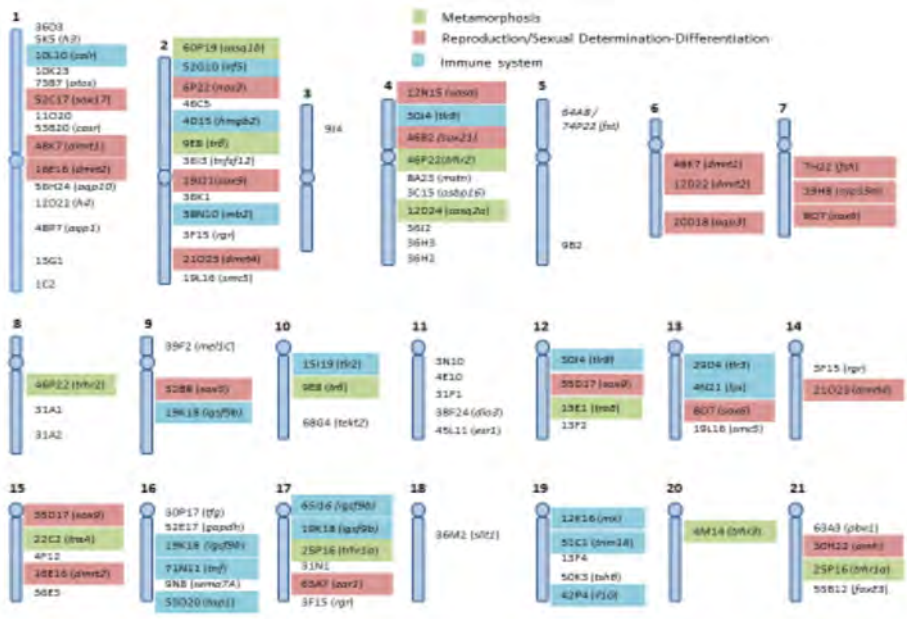

Figure 1. Integrated genetic map in *Solea senegalensis*

Discussion

The possibility of integrating the genetic and physical maps combining the linkage analysis information with the sequencing and its chromosomal location will facilitate the assembly of genome sequencing as well as obtaining very useful information for different aspects such as evolutionary studies through comparative cartography with related and model species or the identificatio and monitoring of quantitative traits loci and genes involved in sexual differentiation. Considering that Senegalese sole still lacks a useful genetic map for applications such as QTL screening and marker-assisted selection (MAS) additional genomic data are of special relevance.

SSRs contribute to the structure of DNA, the organization of chromatin, the regulation of DNA recombination, transcription and translation, gene expression and cell cycle dynamics. The abundance of SSR observed in *S. senegalensis* is similar to that found in the genome of the fugu puffer fish, *T. rubripes,* and slightly less than half in the green puffer fish, *T. nigroviridis*.

Thirty-four unique miRNA mature sequences targeted 12387 sequences from an *S. senegalensis* reference transcriptome. This suggests that miRNAs might modulate a wide range of processes in this species. These results might be helpful for understanding processes such as sexual differentiation, larval development, and disease susceptibility, which hamper the commercial utilization of this species in aquaculture.

Introduction

Two emissions are of concern in state-of-the-art recirculating aquaculture systems: nitrate and fish faeces (sludge). Nitrate emissions can be reduced using a denitrification reactor. This, however, entails additional challenges that emerge from the use of an external carbon source, such as storage, safety or fish-health (Müller-Belecke et al. 2013). Sludge disposal and the use of an external carbon source for the denitrification account for up to 4% of production costs (Tschudi, 2013). In principle, these emissions could be reduced in a single step: partially digested sludge serves as a carbon source for denitrification.

The objective of this study was to determine the feasibility of a partial anaerobic digestion reactor (pADR). In the pADR organic solids (TVS) are degraded to easily degradable substances such as volatile fatty acids (VFA) and filtered using an ultra-filtration unit, to produce a solids free carbon source for use in an MBBR denitrification reactor (**Error! Reference source not found.**).

Material and Methods

A designated pADR, consisting of two separate tanks (T1, 45 l; T2 40 l, overall HRT 8.5d), was constructed and operated in two trials (durations of 15d and 8d respectively). In the second trial, an ultra-filtration system was added to the reactor and solids free permeate was produced. In a further trial, permeate from the sludge filtration was used as carbon source in bench-scale moving-bed denitrificatio reactors (V = 15 l), operated with synthetic wastewater. Additionally, the denitrification reactors were operated using ethanol and sucrose as carbon sources, to determine reference values to the permeate.

Results and Discussion

In the pADR trials, an average VFA production per gram of TVS in the inflow of 0.07mg/mg and 0.057mg/mg respectively, was determined, corresponding to an increase in VFA concentration of 35% and 43%. Compared with other studies, the achieved VFA production is two to three times lower (Conroy and Couturier, 2010; Suhr, Pedersen, and Nielsen, 2014).

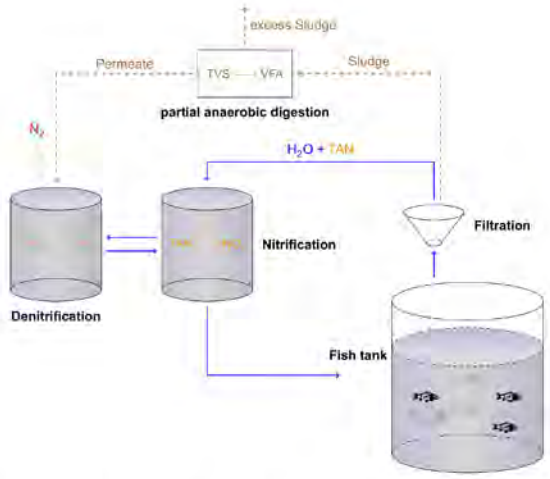

Fig. 1 RAS with an integrated partial AD process (compartments were omitted or simplicity). The supply of an external carbon source and the sludge disposal are substituted by the pADR, whereby the organic solids present in the sludge are degraded to a carbon rich, solids free permeate, which is used as carbon source for the denitrification.

(Continued on next page)

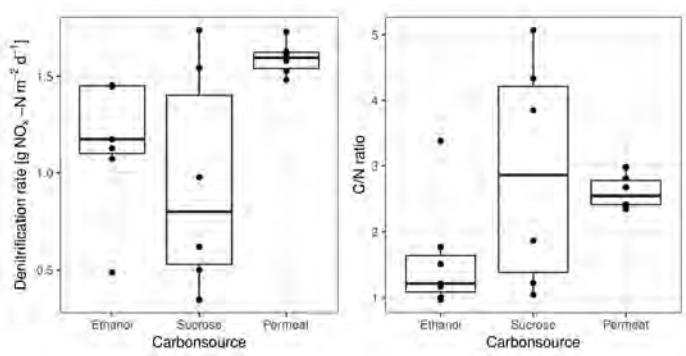

Fig. 1: Denitrification rates and C/N ratio achieved in the denitrification trials.

In the denitrific tion trials, reactors operated with permeate exhibited the highest average denitrification rate of 1.59 ± 0.09mg/m²/d, while ethanol and sucrose exhibited denitrification rates of 1.17 ± 0.34g/m²/d and 0.96±0.57g/m²/d, respectively. Utilized C/N ratios were 2.6±0.26 for permeate 1.57±0.85 for ethanol and 2.9±1.73 for sucrose (Fig. 1).

Based on a model calculation, it was determined that if using permeate as a carbon source (with an equivalent DONALD performance, achieved in this thesis), it was determined that nitrate emission could be reduced by 34.6%, water exchange by 24.2% and sludge disposal by 24%.

Conclusion

It was possible to produce a carbon-rich, solids-free carbon source from digested sludge, which additionally was a suitable carbon source for denitrification Sludge digestibility has to be improved to allow larger permeate production and therefore nitrate reduction. Nitrate emissions, water exchange and sludge disposal could be reduced substantially using the proposed technology.

Introduction and objective

University students that are today following courses dealing with aquaculture will be in the future the professionals of the sector. Understanding their perception about the sector before starting the courses is interesting as a reference of a specific social segment (age, education profile). Information about aquaculture has been provided to evaluate changes in perception among European (Altintzoglou et al., 2010) and Spanish (Claret et al., 2016) consumers. In this case, the effect of a course on aquaculture on the students' perception is assessed. The aims of the work are (1) to explore the relation between demographic data, as well as some psychographics modulators, with the perception about aquaculture, and (2) to evaluate changes on the psychographic modulators and the perception on aquaculture, after having received information about the topic.

Material and Methods

A group of 69 undergraduate students from an engineering school at the Universitat Politècnica de Catalunya were asked to answer a questionnaire including a set of beliefs summarizing the perception about aquaculture, before having received any previous information on the topic. Data about their personal profile (age, gender), objective knowledge about aquaculture and fish buying and consumption habits (frequency and attributes driving fish buying and consumption) were also gathered. A questionnaire was posed to determine their psychographic profile (involvement as a consumer, domain specific innovativeness, subjective knowledge about fish, pessimistic bias, environmental friendliness, personal welfare, social representation of food, hedonistic traits and neophobic traits) (Reinders et al., 2016). The questionnaires for psychographic profile and beliefs, were repeated at the end of the course. The demographic data and the psychographic modulators were used to segment the group and assess potential relations with the beliefs in each segment. Results were analysed by means of ANOVA, plus Tukey test, to assess the relation between personal data and psychographic profile with the beliefs ($p \leq 0.05$). A paired sample t test was applied to compare responses before and after ($p \leq 0.05$). Consensus among students for each one of the beliefs was assessed by estimating the Interquartile range (IQR) of the responses. The salience of attributes driving fish buying and consumption was estimated by a Cognitive Salience index (CSI= frequency/number of time in each position, where max value is 1).

Results

The student population analysed is 21.4 years old as a mean, 47.9% of them were women and 52.1% men. A 56.3% of them is responsible for buying food at home. Their mean objective knowledge about aquaculture, before the course, scored 6.9 out of 10. Their mean fish consumption could be considered high since 49% of them are heavy consumers (once a week or more) while 25% are regular consumers (2-3 times a month). The highest CSI, i.e. the most salient attribute, is pleasure (0.82 out of 1.0), being origin the next one (0.725 out of 1.0). The brand and the price are the least salient attributes. Gender, responsibility for buying food at home and level of fish consumption promote significant differences in the agreement with some of the beliefs. Men show more agreement with topics as human health and fish welfare. Students that are responsible for buying food are more worried about welfare and environment. The level of fish consumption segments the agreement with topics related with fish welfare, i.e. the lower the consumption, the higher the concern about welfare in farmed fish

The analysis of the psychographic modulators, before and after the course, shows that the involvement as a consumer and the subjective knowledge about food have significantly increased, while the pessimistic bias and the neophobic traits have significant y decreased. They are closely linked factors since a higher level of knowledge may reduce the fear or the uncertainty associated to food consumption.

(Continued on next page)

Half of the beliefs posed undergo a significant change in the level of agreement after the course. Among the beliefs where there is a significant difference (10 out of 20), 6 of them imply a better image of aquaculture. The most significant change refers to the quality of the fish: the students move from agreement that wild fish quality is better to disagreement with the sentence. Before the course, wild fish was considered fresher, healthier and more controlled, and it was considered that farmed fish live crowded and not in their natural habitat. The beliefs referring to the image of aquaculture in society reach the highest level of agreement. After the course, two of these sentences have significantly increased their agreement, so students agree more with the belief that the society distrust the production processes in aquaculture and tend to reject its products, which are two sentences closely related.

When the students are segmented according to the psychographic modulators (high, ambiguous, low) there is only one belief, 'aquaculture is an abuse on the part of humans on fish', that show significant differences. The higher the innovative character, the lower the agreement with the sentence. Inversely, the higher the pessimistic bias and the neophobic trait, the higher the agreement with the sentence.

Discussion and conclusions

The present study reflects a very homogeneous group in their profile and perceptions (STEM students in a narrow range of ages). A similar study relating psychographic characteristics with consumer perceptions of farmed fish in five countries, found much more diverse profiles (Reinders et al., 2016). The psychographic profile of the students shows a group including mainly involved consumers, environment friendly, with high values for hedonic and personal welfare and with an optimistic bias. Nevertheless only one belief, in the field of ethics, was significantly related to psychographic modulators. The most pessimistic and with neophobic traits students considered aquaculture an abuse on the part of humans on fish, while this was not the case for students with a higher innovative character. This and other ethical approach sentences, related to environment and welfare, were the most sensitive ones, mainly for non consumers and occasional consumers, with negative opinions about farmed fish. These are important issues when dealing with campaigns directed to young people. Among consumers with a much broader profile, providing information on aquaculture has sometimes managed to change the perception (Claret et al., 2016), with less clear results when the previous opinion was already very positive (Altintzoglou et al., 2010). In our case, perceptible changes in specific topics occur. Nevertheless, before the course the consensus in the beliefs was higher than after it. This reflects a different sensitivity towards opinion changes within the group. Defining the main drivers for these changes is an interesting issue needed to build up efficient and positive messages

IMPROVING AUTOMATIC FEEDING PROTOCOLS IN SEMI-INTENSIVE POND CULTURE OF PACIFIC WHITE SHRIMP (*Litopenaeus vannamei*)

João Reis*, Melanie Rhodes, D. Allen Davis

School of Fisheries, Aquaculture and Aquatic Sciences
Auburn University, AL, 36849
Jzt0062@auburn.edu

The continued success of shrimp farming will rely on improved feed management and reductions in labor costs. Shrimp are grazers eating many small meals with limited stomach capacity for food storage. Hence increased performance may be obtained by spreading feed through multiple meals. Previous works in similar conditions have demonstrated that moving from two feeding per day into multiple feeding systems increases growth rate and production. Further advances have been made with on-demand (satiation) feeding systems. Building on previous research, the goal of this work was to develop a standard feeding protocol (SFP) for automatic feeding systems to maximize growth rates in semi-intensive pond production of Pacific White Shrimp, *Litopenaeus vannamei*. For the first trial a 13-week trial was performed in 16, 0.1 ha outdoors ponds, stocked at a 26 shrimp/m^2, and fed a 35% protein soy-optimized feed. Four treatments including: three fixed feeding treatments of 130, 145 and 160% of a SFP (SFP130, SFP145, SFP160, respectively) were offered using automatic timer-feeders, and a fourth treatment utilized on-demand acoustic feeding system (AQ1). Results for this trial are summarized in Table1. No statistical differences were found between treatments for survival and FCR. increased feed inputs resulted in significantly higher production and higher product value. The best response was with the AQ1 acoustic feeding as animals under this treatment were offered higher feed inputs resulting in larger shrimp and consequently yields.

Following the results of the first trial, a second pond production trial with four treatments is being conducted. Including three timer feeder feeding treatments (12hr daytime, 12 hr nighttime and 24h/day), as well as a fourth treatment utilized on-demand acoustic feeding system (AQ1). Results will be reported.

Introduction

Nutritionally balanced diets are paramount for fish growth and welfare, particularly when fish are subjected to stressful conditions. To enhance fish disease resistance and general health, fish diets are often supplemented with immune-modulators such as β-glucans. These compounds are known to have beneficial effects in fish innate immune response (Guzmán-Villanueva et al., 2014). β-glucans show repeating patterns on their structure that are recognized in the gut by cell pattern recognition receptors (PRR), leading to the activation of the host´s innate immune cells enhancing its immune response (Dalmo et al., 2008). The present work aimed to evaluate the effects of both short- and long-term dietary supplementation with algae (*Phaedactylum tricornutum*) extracted β-glucans on immune related genes expression, oxidative stress biomarkers and plasma immune parameters in gilthead seabream juveniles.

Materials and methods

The trial comprised four isonitrogenous (63% crude protein) and isolipidic (17% crude fat) dietary treatments. A high quality, practical diet was used as CTRL, whereas 3 experimental diets based on CTRL were further supplemented with a constant dose of β-glucans, derived from *Saccharomyces cerevisiae* (diet C+) and different extracts of *P. tricornutum* (diets PH21 and PH37). Diets were randomly assigned to quadruplicate groups of 200 gilthead seabream (*Sparus aurata*) (initial body weight: 4.1 ± 0.1g) that were fed to satiation three times a day for 8 weeks in a pulse feeding regimen. Fish were first fed the different experimental diets intercalated with the CTRL diet every 2 weeks. After 2 and 8 weeks of feeding, 3 fish per tank were sampled. Blood was collected for haematological procedures according to Machado et al., (2015) whereas liver, gut and head-kidney samples were collected for further analyses. Immune parameters were analysed on blood plasma to evaluate fish immune status

Results

All groups showed equal feed conversion ratio (FCR) and relative growth rate (RGR) values (1.2 and 3.8%/day, respectively) and attained similar final body weight (FBW) (CTRL: 41.4 ± 1.6g;C+: 42.5 ± 0.9g; PH21: 42.1 ± 1.1g and PH37: 41.9 ± 1.9g). Regarding immune parameters, no changes were observed in plasma bactericidal and anti-protease activities and IgM levels among different dietary groups.

Discussion and conclusions

β-glucan supplementation independently from the source did not affect fish growth performance. Absence of clear effects on plasma innate immune parameters suggests that the dietary treatments did not elicit a systemic response. However, from the nature of β-glucan stimulus it is reasonable to expect a local immune activation in the gut. Further analysis on liver, gut and head-kidney samples are currently underway to obtain an overall picture of fish health status

Introduction

Cultivated microorganisms can be a sustainable aquafeed resource that can meet the future needs for lipids and the essential fatty acids EPA and DHA (Chauton et al., 2011). The production of lipids and EPA/DHA varies between photosynthetic microalgae species and cultivation conditions (Reitan et al., 1994; Brown and Robert, 2002, Wang et al., 2019). Increased nutrient stress in the cultivation process is a strategy to increase lipid content of the microalgae biomass (Chen et al., 2011; Vu et al., 2016; Wang et al., 2019). The lipid and fatty acid profiles of the microalgae are believed to be important for the utilization by the fish of these biomasses in aquafeed (Sevgili et al., 2019), as the distribution of fatty acids in the lipid classes will determine the nutritionally availability in fish feed in general (Guedes et al., 2010)

In this study, typical microalgae species used in aquaculture were grown under different cultivation conditions and analyzed for total lipid and fatty acid contents. Based on the lipid content and fatty acid profile the species could be considered as a source for use in aquafeed.

Materials and Method

Screening experiments for obtaining optimal conditions for lipid production of four selected microalgae species have been conducted: (1) *Phaeodactylum tricornutum* CCMP 2561, (2) *Isochrysis* aff. *galbana* clone T-Iso CCAP 927/14, (3) *Rhodomonas baltica* NIVA-5/91, and (4) *Nannochloropsis oceanica* CCMP1779. The microalgae were grown at different temperatures (18 °C, 20 °C, 23 °C, 25 °C and 30 °C) at light intensities (50-130 µmol photons/m²sec). As a basis F/2 medium was used. For characterizing the effect of nitrogen limitation on the lipid production, the concentration of nitrogen was reduced to 10% and phosphorous increased with 25% of the original F/2 media. On the other hand, for production of high-density biomass of *N. oceanica*. the nitrate content was increased 3.3-fold and for *P. tricornutum* the phosphate content was increased by a factor of 2.4. Lipids and fatty acids were analyzed as described in Wang et al. (2019)

Results and Discussion

The percent content of EPA and DHA varied between the microalgae species when cultured with increasing nitrogen limitation, showing decreased contents in *P. tricornutum* and *N. oceanica* with increasing nitrogen limitation, wheras the contents increased in T-ISO (Table 1). Highest EPA content was found in *P. tricornutum* while T-ISO had highest DHA content.

Table 1 - Summary of Pacific white shrimp response to different feed management protocols

Treatment	IndW (g)	Survival	Yied (kg/ha)	Total Feed Input (kg/ha)	FCR	Feed Cost ($/ha)	Shrimp Value ($/ha)	Partial Income ($/ha)

[1]PSE – Pooled Standard Error

(Continued on next page)

All four species accumulated lipids mainly in the form of TAG when cultured under nitrogen limitation (Figure 1). *N. oceanica*, accumulated 51% of the dry weight as lipid in moderate nitrogen limitation and up to 87% of the fatty acid was in TAG.

The lipid content in the microalgae produce for high biomass was higher in *N. oceanica* than in *P. tricornutum* (Table 2).On the other hand somewhat higher contents of EPA + DHA was found in the latter one. In conclusion, broth *N. oceanica* than *P. tricornutum* are regarded as potential microalgae biomass for us in aquafeed (Sevgili et al., 2019).

ENHANCING EUROPE-ASIA COOPERATION IN AQUACULTURE EDUCATION – ACHIEVEMENTS OF THE EU HORIZON2020 PROJECT - EURASTIP

M. Reuver[1*], J. Maher[1], J.C. Bostock[2], Y.Y. Sung[3]

1. AquaTT, Olympic House, Unit 3, Pleasants Street, Dublin 8, Ireland
Email: marieke@aquatt.ie
2. Institute of Aquaculture, University of Stirling, Stirling FK9 4LA, UK
3. Institute of Marine Biotechnology, Universiti Malaysia Terengganu, 21030 Kuala Terengganu, Terengganu, Malaysia

The European Union (EU) funded EURASTiP project is an initiative to reinforce international cooperation on aquaculture between Europe and countries from Southeast Asia. The project fosters the development of stakeholder platforms in Thailand, Vietnam and Bangladesh to link with the European Technology and Innovation Platform (EATiP) and its regional and national Mirror Platforms. Amongst other activities, brokerage events, industrial and research exchange visits support business and trade whilst education activities support educational links across the regions. Consolidating existing EU-Southeast Asian collaborations in the field of education and training as well as enhancing new collaboration through numerous activities is a key objective of EURASTiP.

One of the first activities carried out in relation to aquaculture training was a training survey to identify existing aquaculture education networks and their activities. The two most frequent type of collaborations were identified as receiving students and collaboration with research stakeholders. Important benefits of EU-Asia collaborations were considered as knowledge and skills sharing, along with the development of best practice and expertise across both regions. The major challenges were identified as lack of funding to support collaborations and cultural differences between actors from Europe and Asia. Further to the training survey, an alignment workshop was held to bring together the champions of major aquaculture education networks to exchange best practice in relation to aquaculture training provision between Europe and Asia; and to identify the key topics of common interest to both regions for the future of aquaculture education. Based on the selected key topics, three capacity building workshops were planned, two of which have taken place, covering the topics: 1) Promoting Innovative Teaching through Collaboration in the International Aquaculture Sector; 2) Ensuring Education is Responding to Industry Needs. The third and final capacity building workshop will take place in November 2019 alongside the International Fisheries Symposium in Kuala Lumpur (Malaysia) focusing on Enhancing Opportunities for Mobility.

In addition to the capacity building workshops, the EURASTiP project has supported an exchange programme for aquaculture educators to maximise collaboration and strategic partnerships. As part of a broader Asia-Europe exchange programme under EURASTiP, a series of thirteen Educator exchange visits have been supported. These are intended to help build collaborative partnerships between Europe and Asia and participants have shared their experiences through blogs, reports and videos. Additional education and support resources are being developed from these to further support understanding and cooperation between Asia and Europe.

Other educational and training materials for aquaculture educators have been developed as part of the project. These include example educational material, based partly on the exchange programme, being developed to support understanding of European and Asian aquaculture sectors. These are being made available as Open Educational Resources (Pounds & Bostock 2019a&b) which can be adapted and re-used for different purposes via the AQUACASE website (www.aquacase.org). The testing of these materials is also underway to help provide guidance for future development. Also, a Best Practice Case Study Report has been developed to help with overall capacity building. Examples of collaborative education and training between Asia and Europe have been written up and collated into a downloadable publication (Bostock 2019). This also includes a summary of issues that need to be considered when developing educational collaborations and student mobility, especially with respect to recognition of academic qualifications and credit

This project has received funding from the European Union's Horizon 2020 research and innovation programme under Grant Agreement no 728030 (EURASTiP). This output reflects the views of the author(s).

EVALUATING THE ENVIRONMENTAL CONDITIONS REQUIRED FOR THE DEVELOPMENT OF OFFSHORE AQUACULTURE: IMPACT ON FARMED ATLANTIC SALMON HEALTH AND WELFARE

Sonia Rey Planellas, Aimee Wilford and Bernat Morro

Behaviour and Welfare Group, Institute of Aquaculture, University of Stirling FK9 4LA, Scotland
email: sonia.reyplanellas@stir.ac.uk

Introduction

Scottish salmon is worth over £2 billion to the country's economy. It is Scotland's top food export and a particularly valuable product, at about 10% above the world price. Recently, the Scottish Government developed a plan that aims at doubling this production of salmon by 2030. However, a number of factors limit the progress of the industry in its current form, which is based primarily on sea cages in sheltered, fjordic sea lochs where water exchange is restricted. These limitations include the impact of sea lice infestations on fish health (Black 2001), the cost and environmental impact of chemical treatments against the parasite (Costello 2009, SARF 2016, Van Geest 2014), their development of resistance to these treatments (Aaen et al. 2015), planning issues (James & Davies 2010), the (regulatory) Scottish Environment Protection Agency (SEPA) biomass limit of 2500t/site, and the increasing impact of harmful algal blooms (HABs), which can be particularly acute in restricted water exchange environments (Gowen et al. 2012). Moreover, the industry also faces opposition from environmental campaigners who fear that farming in sea lochs might damage wild stocks and the ecosystem. Development of aquaculture in more dispersive "offshore" environments offers a potential solution to some of these problems. Improved, science-based evidence with direct relevance to the complex environment of the west coast of Scotland will permit planning and informed regulation of this offshore transition.

The project will address a number of the issues, specifically offshore developments, algal blooms, [sea lice/AGD] host-pathogen interactions and fish health and welfare. These will be addressed through four interconnected work packages: 1) Physical Oceanography, 2) Wave modelling and risk, 3) Hydrodynamic and sea lice/HAB modelling, and 4) Fish health and welfare implications. The latter addresses the particular issue of moving cages offshore and the impact on Atlantic Salmon health and welfare (Kirchhoff et al 2011, Ashley, 2007).

Materials and methods

Health historical data will be supplied by the partner salmon company regarding mortalities, condition, growth, health blood parameters, sea lice counts, and gross gill scores (e.g. amoebic gill disease (AGD) and proliferative gill disease (PGD)). Data on detailed morphometrics and welfare scoring indices (external appearance and fin and tissue damage) will be supplemented by 'in situ' sampling data in the same periods and at the same sites where the physical oceanography samplings take place. Environmental and physical data will also be provided by the company to complete the database from the sampling sites.

There will be 3 main sampling points per treatment (offshore vs inshore farms), at which a total of 45 fish will be sampled per site (15 fish per cage, 3 cages per site, and 2 sites). Historical and newly-collected fish heath data will be analysed, through both univariate and multivariate statistics, in relation to physical oceanographic parameters, waves, sea lice, and HAB data, as well as by elaborating model predictions.

Initial sampling was already performed in winter 2019. Fish were weighted and measured, sea lice, AGD and PGD scored and skin mucous, blood and tissue sampled and stored for posterior analysis.

The next sampling will take place in spring 2019 and at harvest (August-September 2019). By the time of the conference, more data will be available.

(Continued on next page)

Results and Discussion

Because this is an ongoing project and the current results are only preliminary, more data to support the claim of an offshore site's potential in improving welfare in Atlantic salmon is needed. However, current results indicate that offshore environments presented significantly lower incidence of parasites (AGD, *Caligus* sp. and adult male sea lice) and had better welfare indicator scores, such as fin damage and cataracts. The decreased incidence of parasites could be the result of increased water velocities, improved aeration and net cleanliness in offshore sites. This increased water velocity could also explain the lower number of sea lice due to the increased difficulty in attachment to the fish (Revie *et al.,* 2004). However, results indicate that fish were smaller in the offshore site. Later samplings will show whether this weight and length difference is maintained.

Additional work and analysis of historical data is required to confidently validate the hypothesis that high energy offshore sites improve welfare and overall health of Atlantic salmon. However, current results are promising.

USING MROSATELLITE MARKERS TO ASSESS POST-STOCKING SURVIVAL OF HATCHERY-REARED ATLANTIC TROUT (*Salmo trutta* L.) IN TRIBUTARIES OF A PREALPINE LAKE

N. Rhyner*[1], C. Pietsch[1]

[1]Fish Welfare Group, IUNR, Zurich University of Applied Sciences, P.O. Box, Campus Grüental, 8820 Wädenswil (Switzerland)
E-Mail: nicola.rhyner@zhaw.ch

Introduction

As countermeasures against ongoing declines and habitat alteration, many fish populations in Switzerland are supplemented through stocking of fish raised in captive environments. However, the success of this stock enhancement often remains unclear and hatchery-reared fish possibly are inferior to remnant wild individuals (Araki et al. 2008). Thus, the verification of the stocking success becomes more and more common and is often evaluated using genetic methodology. We conducted such a genetic success control of the stocking practice of lacustrine Atlantic trout (*Salmo trutta* L.) for the cantonal fishing office of Canton Zürich (FJV) in Switzerland

Materials and Methods

A predefined number of individuals from a broodstock were hand stripped in spring 2018 and their hatchery-reared offspring was stocked as fry in early spring 2018 in three experimental tributaries of Lake Zürich in Switzerland by the FJV. Parr in these three tributaries were caught in autumn 2018 by electrofishing and a small fin clip of each individual was taken for subsequent genetic analyses. In total we genotyped 207 parr and 48 broodstock fish (22 males & 26 females) using a set of 19 highly polymorphic microsatellite markers to assess survival of these stocked fry over the first summer past stocking using parental analysis. To further test for possible genetic differentiation between the broodstock and remnant trout populations in the three tributaries, we additionally genotyped adult fish from each of the three tributaries.

Results

Preliminary results showed that the proportion of stocked parr among the three experimental tributaries on average varied between 49% and 62%, depending on whether parentage was determined using a strict exclusion or categorical allocation approach. Analysis of genetic diversity parameters revealed poor genetic diversity and signs of bottleneck effects in the broodstock. We further observed significant genetic differentiation between the broodstock and all three groups of adult fish among the three sampling locations. Thus, although about half of all parr were positively identified as stocked fish, their long-term survival and supplementary effect on remnant populations is questionable and needs further research.

Introduction

Fish farmed for human consumption are reared in artificial environments that are very different from conditions that species experience in the wild. Consequently, the environment influences many aspects of the biology of cultured animals, including sexual phenotype through epigenetic mechanisms (Feeney et al., 2014). Disease outbreaks occur eventually in fish farms, causing economic loses. However, the epigenetic consequences that these reiterating infections can potentially cause in fish during their development and whether these can alter the reproductive system, remain unknown. Here we present a study for which two model research tools have been selected; the zebrafish as a suitable model for aquaculture research (Ribas and Piferrer, 2014) and the lipopolysaccharide (LPS) from Gram negative bacterial wall as a model to stimulate the immune system in fish (Forn-Cuní et al., 2017). The aim of this work is to develop a suitable *in vivo* system to study whether infections occurring in fish during sex differentiation are able to alter the final gonadal phenotype throughout epigenetic changes.

Materials and methods

AB zebrafish were housed following standard conditions (Ribas et al., 2014;) (Bioethical Committee code: 9977). Zebrafish juvenile at 15 days post fertilization (dpf) were stimulated with three different strains of LPS; *Escherichia coli*, *Pseudomonas aeruginosa* or *Aeromonas hydrophila*, during sex differentiation. First, and in order to find the median lethal dose (LD50), animals were exposed to different LPS concentrations and survival were recorded. Samples were taken at 3, 6, 24, 48 and 72 hours after LPS stimulations for studying the expression levels of three immune genes (*IL-1β*, *TNF-α*, *Casp9*) involved in the inflammatory response. Methylation patterns of these immune genes were studied by Methylation Bisulfite Sequencing (MBS), a candidate gene approach (Anastasiadi et al., 2018), by high throughput sequencing (Illumina, paired-end). Surviving individuals were transferred into tanks and kept until adulthood to check final sex ratios

Results

Fish survival was dependent to the dose and the LPS strain, being the *A. hydrophila* strain with the highest toxicity. Gene expression of the studied immune genes were downregulated after *P. aeruginosa* exposition but a significant upregulation was found when zebrafish were exposed to *A. hydrophila*. Methylation levels in the juvenile larvae showed significant changes in the methylation levels of specific CpGs of the three studied genes (Fig.1). Short exposition of LPS was not able to change sex ratios but a feminization tendency was observed after longer exposition to *A. hydrophila* in a dose-response and family-dependent manner.

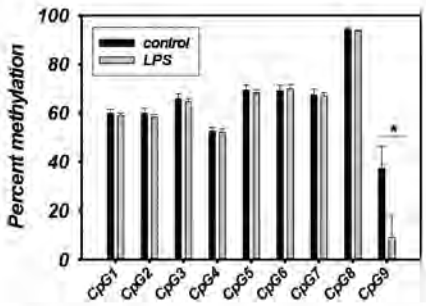

Figure 1. Methylation of immune genes (IL1β) of 15 dpf zebrafish expose during 3h to LPS of *P. aeruginosa*. Data showing as mean ± SEM. Sample size n = 6-7 zebrafish per treatment. Significant differences *($P < 0.05$) were analyzed by Student's t-test.

(Continued on next page)

Discussion and conclusions

Here we have developed an *in vivo* model to study the effects of immune stimulation during gonad differentiation that results in long-term influences in the sexual phenotype and it is able to alter methylation and gene expression patterns. We have identified the LD50 that is able to induce an activation of the immune system by reducing fish survival proving that LPS from *A. hydrophila* has a higher toxicity than the LPS of *P. aeruginosa* but less than *E. coli*, as partly shown in other studies in zebrafish (Novoa *et al.,* 2009). Zebrafish is a gonochoristic species in which all individuals starts developing as female and later, during sex differentiation, male differentiation processes appear throughout apoptotic and p53 signaling pathways that are responsible of the testes development (reviewed in Liew and Orban, 2014). Here, by stimulating zebrafish fish LPS from *A. hydrophila* we have been able to alter sex ratios by decreasing the number of males in a dose and family dependent manner. Intra-family variation of the other environmental factors (i.e., temperature and density) have been observed in zebrafish (Ribas et al., 2017a, 2017b). Previous studies in zebrafish treated with heat-killed bacteria from *E. coli* during sex differentiation showed a female bias due to the activation of NF-κB pathway that induced anti-apoptotic effects in the differentiating gonad (Pradhan *et al*., 2012). We observed that methylation and expression mechanisms were involved in the LPS stimulation in the juvenile larva and so interfered in the final sexual phenotypic fate. However, the epigenetic and transcriptomic mechanisms involved in the gonadal changes need to be further elucidated. In conclusion, our results showed interactions between immune–reproduction systems and we identified methylation differences for particular CpGs of the studied immune genes that can be worth for developing markers that can improve breeding programs (e.g., selection of high quality broodstocks).

E-mail: grigos@hcmr.gr

Introduction

The myxozoan parasite *Enteromyxum leei* is a serious pathogen of sharpsnout sea bream, *Diplodus puntazzo* causing epizootic outbreaks with severe catarrhal enteritis. There are currently no prescription medicines effective against this parasite and most attempts to control it in the field and/or in experimental trials have failed. However, empirical and experimental evidence have shown the benefits of certain feed additives against this infection in Gilthead seabream (Palenzuela et al., 2017). Therefore, the aim of the present work was to evaluate in controlled conditions a commercial blend of phytobiotics (Sanacore), and its potential to control enteromyxosis. This was accomplished during a lab-controlled challenge in which feed intake and growth, survival, immunological and parasitic measurements, were studied.

Materials and methods

Sharpsnout sea bream juveniles (~2g) were given a commercial diet until they reached a size of approximately 12g, and they were then transferred to the challenge environment and distributed in 6 identical net cages (1m^3) (300 fish/cage) arranged within a large (50m^3) inland concrete tank. In this environment, experimental fish were delivered either medicated (Sanacore 0.3% included) or control extruded diets prepared in the facilities. Four weeks after the start of the challenge with donors all surviving fish were individually weighed and the following growth parameters were calculated: FCR, SGR and FE. Samples were taken for the measurement of immunological parameters (hemoglobin concentration, respiratory burst activity, lysozyme, anti-protease activity and ceruloplasmin) and for the diagnosis and quantification of *E. leei* rDNA by qPCR.

Results & Discussion

Eventually, the cumulative mortality after challenge reached values as high as 22 & 27% in the control and the treated groups respectively, indicating insignificant differences between Sanacore-fed and control groups. Growth was greatly affected by *E. leei* infection since the calculated growth parameters seemed to be considerably impaired in comparison with normal sharpsnout sea bream growth curves. Weight increase (~10g) was low in both groups. Minor differences between the two groups were observed in (impaired) measured growth parameters (FCR: 3 vs 2.86; FE: 33.6 vs 35.6; SGR: 0.55 vs 0.58 for control- and Sanacore- fed fish, respectively). Out of the 90 experimental fish examined, 69 samples were positive for *E. leei* by qPCR (76.67% prevalence). Of these, 35 belonged to the control group (77% prevalence) and 34 to the Sanacore group (75.56%). No differences were found in the mean intensity of infection between groups or among replicate cages within each group (Figure 1). Prevalence and intensity of infection among challenged mortalities trial were 63.2%, and 13.9 ± 1.5, respectively. While these values are similar to those of donor fish, they are significantly lower than in experimental fish at the end of the trial. Concerning the immunological measurements, the parasitological challenge significantly affected fis fed both the control and the Sanacore diets as observed through the reduced hemoglobin concentration and the increased respiratory burst activity of the fresh blood, observed at the end of the experiment relative to the initial levels. A decrease in the values of anti-protease and anti-bacterial activities of the challenged fish was also observed, which was significan in the case of ceruloplasmin activity in control fish. However, this infection-induced immunosuppression observed in both groups was reduced or even totally reverted (depending on the immunological parameter concerned) in fish fed Sanacore for one month before the challenge.

In a different study, Sanacore reduced the prevalence and intensity of *E. leei* infection and improved the condition of gilthead sea bream in an experimental challenge with this parasite, although it did not clear off the infection (Palenzuela et al., 2017). Given the high pathogenicity of *E. leei* in *D. puntazzo*, it is not surprising that nutraceutical strategies could not prevent clinical enteromyxosis in this trial, in which a very high infection pressure was applied. However, the drop observed in some immune-related parameters in challenged control fish appeared reduced in Sanacore-treated fish, indicating a biological effect of the supplement.

Introduction

Aquaculture fish production first exceeded fisheries production in 2012, and is currently the fastest growing food-producing sector in the world. However, such intensified fish production is prone to disease outbreaks, of which opportunistic pathogenic bacteria are a major cause. During their early life stages, marine fish are particularly vulnerable to infections in intensified aquaculture (Vadstein et al., 2018)we explore the microbial community of fish larvae from an ecological and eco-physiological perspective, with the aim to develop the knowledge basis for microbial management. The larvae are exposed to a huge number of microbes from external and internal sources in intensive aquaculture, but their relative importance depend on the rearing technology used (especially flow-through vs. recirculating systems due to their yet undeveloped immune system and the inherent bacterial load caused by high stocking densities. This is particularly relevant for the early life stages of the European eel *Anguilla anguilla*. Bactericidal treatments may prove useful in the short term (Sørensen et al., 2014), though they also destroy benefici l bacteria and in the long term may lead to a less stable microbial community (Vadstein et al., 2018)we explore the microbial community of fish larvae from an ecological and eco-physiological perspective, with the aim to develop the knowledge basis for microbial management. The larvae are exposed to a huge number of microbes from external and internal sources in intensive aquaculture, but their relative importance depend on the rearing technology used (especially flow-through vs. recirculating systems. By optimising operational conditions such as substratum, nutrition, filtering, and water retention time, this may help to support more favorable microbial communities and hence improve the stability and rearing success in recirculating aquaculture systems (RAS). This study examines the vital processes for eel embryo survival during egg incubation and subsequent hatch and survival of larvae, coupling egg-associated bacterial colonization in different sea water environments, with pelagic bacteria levels and organic matter character.

Materials and methods

Eggs harvested from captive bred European eel were fertilized using pre-diluted milt, and activated using artificial seawater based on reverse osmosis water and reef salt (Sørensen et al., 2015). Buoyant eggs were distributed into three 60 L conical incubators connected to three different types of seawater, applied as flow-through with the water inlet at the bottom. Incubators were held at 18ºC, at low light and a constant supply of 0.2 µm filtered air. The three water masses used for incubation were treated as follows: 1) MSW - preconditioned microbial matured seawater, selected for increased microbial stability by aid of RAS retention time, and steady nutrition levels; 2) UFSW - MSW that was further treated by passing through cross flow Ultrafilter ~50kDa, removing particles smaller than bacteria and vira; and 3) UVSW - MSW which was then passed through 1 µm 20” cartridge filter and UV-treated (UVSW). Each incubator was sampled daily to estimate egg density, bacterial load, fertilization, survival, hatch, and subsequently larvae survival to day 12. Egg-associated bacteria were quantified at 0, 2, 4, 24, and 48 h post-fertilization, using the Bactiqant method (Mycometer, Hørsholm, Denmark) - a novel technique measuring enzymatic metabolic processes of bacteria. In addition to egg-associated bacteria, the bacteria in the incubation water were quantified in regards to both the in- and out-flowing water, to assess the impact of the eggs and their bacteria on water quality. The inlet and outlet water were also analysed for fluorescent dissolved organic matter (FDOM), which may have an impact on heterotrophic bacteria in the rearing medium. Furthermore, microbial growth potential in the three different water treatments was assessed to quantify microbial stability or shelter effect (Blancheton et al., 2013)”container-title”:”Aquacultural Engineering”,”page”:”30-39”,”volume”:”53”,”source”:”ScienceDirect”,”abstrac t”:”The current onshore aquaculture trend is to develop large scale production of diversified fingerlings and very large units for fish ongrowing. This requires an industrial type of approach including quality assurance and minimization of failures in addition to management of bio-technical and economic aspects. Therefore, all the key biological mechanisms involved in Recirculating Aquaculture Systems (RAS. Hatch was assessed by sampling ~100 buoyant embryos at 50 HPF from each water type, inserted into triplicate antibiotic flask containing 200ml 50 ppm rifampicin and 50 ppm ampicillin (Sørensen et al., 2014), and incubated in temperature controlled environment (18ºC) until 60 HPF, when the ratio of hatched larvae was determined. Larval survival was estimated by random selection of 3 × 20 larvae from each water type and inserting upon hatch into 200ml flasks of antibiotic similar to above. Flasks with larvae were cultured in a temperature controlled environment, and survival was quantified daily throughout the yolk sac period until day 12 DPH (Sørensen et al., 2016)

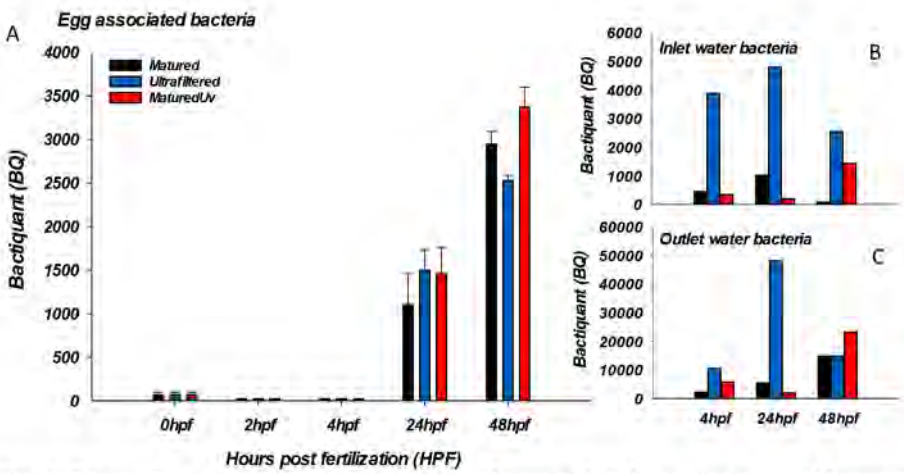

Fig. 1: Bacterial activity (Bactiquant) on incubated eggs and in the rearing water of European eel eggs reared using Matured (MSW), Ultra filtered (UFSW), and Matured UV treated water (UVSW). A: Egg-associated bacteria colonizing the egg of European eel between 0 h post fertilization (HPF) to 48 HPF. B: Bacteria levels of water inlet to the egg incubator. C: Bacteria levels of water and outlet of the egg incubator.

Results and discussion

The study showed that conditioning RAS water by microbial maturation, selecting for K-strategist, and reducing growth potential in the water effectively improved stability in the rearing environment and increasing embryonic rearing success in European eel (Fig. 1).

Bacterial colonization of eggs occurs rapidly, and various filtration techniques can improve survival, but also tend to induce instability and increase variability forming a "virgin" water mass ready for colonization by opportunistic pathogens (Vestrum et al., 2018)and that recirculating aquaculture systems (RAS. By analyzing water content and characteristics regarding fluorescent dissolved organic matter, we could differentiate between the carbon footprint of 'good' and less 'good' aquatic environments and their effect on colonization level/speed on incubated eggs.

NEW FUNCTIONAL FEED SUPPLEMENT: EFFECTS OF DIETARY YEAST AUTOLYSATE ON INTESTINAL MICROBIAL COMMUNITIES OF SEA BREAM (*Sparus aurata*)

Introduction

Fish protein hydrolysate is rich in free amino acids, bioactive compounds and water-soluble proteins that improve feed digestibility and palatability, thus promoting fish growth and feed utilization. Protein hydrolysate from yeast (*Saccharomyces cerevisiae*), is assumed to have similar beneficial effects of fish protein hydrolysate but, in addition, it contains several immune-stimulating compounds, such as β-glucans and mannan-oligosaccharides, which have positive influence on immune responses and stress tolerance of fish. However, the introduction of any new ingredient in the diet needs to be carefully evaluated since diet is one of the main factors shaping the intestinal microbiota. The gut microbial communities of fish is indicated being correlated with host metabolism, nutrition, growth, immunity, and disease resistance, in a similar way as reported for mammals.

The present study aimed to investigate the effects of a diet rich in plant proteins, supplemented with 5% of either fish protein hydrolysate or autolysed dry yeast (HiCell, Biorigin) on intestinal microbiota of gilthead sea bream.

Materials and methods

Seven hundred twenty S.aurata with an initial mean body weight of 122.18 ± 6.226 g (mean ± s.d.) were randomly distributed into nine fibreglass tanks (80 fish/tank) connected to a flow-through fish rearing system with three complete daily water changing in each tank. Experimental tanks were supplied with water with an approximately constant temperature of 24.5 ± 2.26 °C (Fronte et al. 2019).

Three dietary formulations (A, B and C) were produced by Naturalleva VMR S.r.l. (Italy). The diet based on commercial fishmeal (FM)/vegetable meal containing 46% crude protein and 16% fat) was used as the control diet (A). The other two diets were characterized by FM replacement with fish hydrolysate (diet B) and with the commercial additive HiCell (diet C). Fish were fed with the experimental diets in triplicate (3 tanks/diet) for 90 days.

At the end of the trial 15 fish/dietary group five fish/tank were sampled. The intestine was aseptically removed from each fish and squeezed to collect the fecal matter. For microbiome analysis, bacterial DNA was extracted from each faecal sample. The high-throughput sequencing of 16S rRNA gene was applied to analyse and characterize the gut microbial communities of rainbow trout as described in Rimoldi et al. (2019). The obtained sequencing raw data were analyzed using the QIIME software. A Two-way ANOVA was applied to test for differences in mean values of bacterial taxa between the experimental groups using STATISTICA software (StatSoft, Inc.). A $p\text{-}value<0.05$ was considered significant.

Results and Discussion

Totally 102 operational taxonomic units (OTUs) of bacteria were identified from the 2,327,049 sequences obtained by Illumina MiSeq 16S rRNA gene sequencing. Interestingly, our data revealed that inclusion of autolysed dry yeast was associated with an increased bacterial diversity compared to fish protein hydrolysed supplemented diet. Indeed, although most of the bacterial taxa were common between dietary groups, fish receiving autolysed yeast showed higher abundance of *Bacillus* and *Shewanella* genera, besides to be characterized by specific bacterial genera, such as *Megasphera*, potentially beneficial for host (able 1).

In conclusion, autolysed dry yeast could be a valid alternative protein source for aquafeed production, since it positively affects the intestinal microbial communities of sea bream by increasing the number of indigestible carbohydrate degrading and short chain fatty acid producing bacteria.

Introduction

In the history of the Baltic Sea, mussel farming was a negligible element of fisher , but recently it has become a topic of great interest. Results already indicate that commercial farming of mussels can be viable and has the potential to offer environmental as well as socio-economic benefits (Lindahl et al. 2005). Especially the cultivation of *Mytilus* spp. seems to be a sustainable method to produce a high valuable feed stock and simultaneously function as a promising nutrient retention measure to relieve coastal waters of surplus nutrients.

Regardless of the cultivation candidate and strategy, a successful production of bivalve shellfish always starts with collecting mussel seeds or the direct settlement of planktonic mussel larvae originating from permanent mussel beds. Even tough, *Mytilus* spp. dominates the animal biomass on hard substrate habitats within the range of its salinity tolerance (Kautsky 1981) some areas in the Baltic Sea are characterized by sandy or muddy grounds providing only a limited amount of hard substrate as well as lacking a steady blue mussel population. Nonetheless, affected areas can still fulfill other key criteria important for site selection (e.g. sheltered positions, good logistical connections, sufficient phytoplankton concentrations). The Bay of Greifswald (GWB), for example, offers promising mussel farm sites, but due to its little amount of hard substrate, only a limited permanent mussel population as well as high fluctuations of larvae supply are presumed. Before establishing cultivation sites at GWB, it is necessary to proof if external larval transport into the target area is sufficient enough to provide an adequate mussel larvae concentration for cultivation purposes. In order to evaluate the larvae supply in GWB and the south western Baltic Sea, a mussel larvae distribution model approach is tested as well as settlement success at two test sites.

Material and methods

To trace larvae drift ways, the hydrodynamic 3d General Estuarian Transport Model (GETM) is combined with an Lagrangian particle tracking approach. Study area is GWB as well as the coastal waters of the south western Baltic Sea. The hydrodynamic model describes the years from 2016 until 2018 and has a spatial resolution of 50m (GWB) and 200m (south western Baltic Sea). Release points of particles (1 particle resembling 1000 larvae) are known mussel beds inside and outside of GWB as well as areas with a high likelihood of mussel population based on seabed habitat documentation. Particles are released on a daily basis and as soon as water temperature at mussel bed sites reach 15 °C and on a daily basis. The spawning period is set to 90 days. A drifting period of 450 degree days (temperature in °C * time in days), and a mortality were applied according to existing literature data (Stuckas et al. 2017, Kautsky, 1982). To verify the model approach and evaluate settlement success, two strategies are applied, consisting of direct larvae sampling in the water column and via observation of settlement. Settlement was recorded at two small scale test farms located in GWB and in the Bay of Wiek as well as on different sea signs in the target area.

Results

A preliminary first model approach with particles released within GWB already shows high inter-annual variations in spatial distribution. Similar results concerning spatial distribution are shown by the navigation sign monitoring. A comparison of modelled water temperature at different spawning sites, indicates that temperature induced spawning in GWB could start earlier compared to external spawning grounds. Supporting those results, bivalve larvae abundance in the central part of GWB shows concentration peaks at the end of May while sampling stations outside record highest peaks later in June or even July.

Discussion

First results of this study already indicate, that areas within in GWB most probably depend on larvae entering from the outside GWB to ensure reliable amount of larvae for production purpose. Ongoing studies will show if a sufficient amount of larvae is entering GWB and how they will complement the larvae distribution within. Modelling the larvae drift paths over the time span of three years will also give an inside look of how different environmental factors (salinity, temperature) effect temporal and spatial distribution. Therefore, final results could provide information about farm sites most suitable for mussel production in GWB as well as similar areas with a limited amount of hard substrate.

Introduction

Pancreas disease (PD) caused by salmonid alphaviruses (SAV) leads to severe economic losses in Atlantic salmon aquaculture. Outbreaks of PD lasting 3-4 months regularly occur in Norway, but as there are often no obvious external signs of infection [1, 2], and as an estimated one-third of SAV infected populations in Norway do not develop clinical PD [3], monitoring and control is difficult. Heritability of survival to PD challenge is high (~0.4 in post-smolts, ~0.5 in fry) [4, 5], and quantitative trait loci affecting resistance have been detected [6], suggesting that resistance to this disease could be increased with selective breeding. Viral load may be a more appropriate phenotype than survival for assessing resistance and tolerance to PD as mortalities to PD in the field can often be negligible even though populations of animals are carrying and shedding the virus into the environment.

Our analysis of the gene expression response to infection comparing fish ranked with high- or low-genomic estimated breeding values for PD resistance suggest that better protection of salmon against PD might be associated with earlier mobilization of acquired immunity, which accelerates clearance of the pathogen and resolution of the disease (unpublished results). Expression quantitative trait loci (eQTL) might explain the differential expression observed for some genes in response to PD challenge in fish with high- versus low-genomic breeding values. The aim of this study was to characterize QTL and eQTL associated with SAV3 viral load post-challenge in a Norwegian Atlantic salmon population.

Materials and Methods

Survival data and samples from a PD experimental disease challenge test (10 full-sib families, ~110 unvaccinated salmon parr per family, challenged by intraperitoneal injection or cohabitant infection) were obtained from SalmoBreed (Benchmark Holdings PLC UK). All challenge testing procedures were performed by VESO Vikan in a secure containment facility in Namsos Norway using standard operating procedures as approved by the Norwegian Animal Research Authority. Half of the 10 families chosen had high estimated genomic breeding values (h-gEBV), and half had low estimated genomic breeding values (l-gEBV), for PD days survival after intraperitoneal injection (Fig. 1).

Relative viral load was assessed using real-time reverse transcription PCR threshold cycle (*Ct*) value analysis on samples taken ~3.5 and 7 weeks (days 25 and 49) post-infection. Survival status (dead/alive, P_{DA}) was assessed 7 weeks post-infection. DNA was extracted from tail fin samples and genotyped using a ~55K Axiom Affymetrix SNP Genotyping Array (NOFSAL03). Heritability and genetic correlations for P_{DA} and $C_{t.}$ were assessed using a genomic relationship matrix (GRM), and a genome-wide association study (GWAS) fitting the GRM was performed to detect putative QTL. Differential gene expression between h-gEBV and l-gEBV familes was assessed using mRNAseq on heart samples taken at 0-, 4- and 10-weeks post-infection to search for eQTL.

Results

Genomic heritability for P_{DA} and C_t ranged from 0.40 to 0.74 and from 0.15 to 0.21 respectively (dependent on challenge test type, cohabitant challenge having the highest heritability). The genetic correlation between P_{DA} and C_t was high (0.91 to 0.98). The correlation of Ct values between IP and CH challenge tests was 0.73. A single genome wide viral load (*Ct*) QTL was detected on Ssa03 (Fig. 2), in the same region of the genome as a previously identified QTL for PD survival [6]. Several genes mapping to the region of the QTL were differentially expressed, and candidate eQTL were detected, including one trans-eQTL associated with several differentially expressed genes with putative immune function.

(Continued on next page)

Discussion and Conclusion

SAV3 viral load (C_t) is highly correlated with challenge survival P_{DA} and could provide a more efficient means for assessing resistance to PD under some circumstances in the field. But the C_t trait has lower heritability than P_{DA}, so that genetic gain in resistance from genomic selection would be expected to be lower for C_t. Clues about possible genes and causative mutations affecting PD resistance on Ssa03 from QTL and eQTL analyses will be discussed.

As the demand for seafood increases in the future due to rising human population growth, production of seafood products will have to increase to meet new and existing consumption. While fisheries will continue to provide seafood for the markets, an increasingly larger percentage will be coming from farming. To meet this demand, more sophisticated approaches to culture will be required that will involve new species, integrated culture practices like IMTA, lower trophic levels, intensification of production and more sophisticated monitoring. Regarding monitoring, recent advances in genetic technology, primarily in human health, has shown the microbiome of an organism (the microbes that live on and in an organism) is directly related to the overall health of the animal. Our team has begun to extend this genetic approach to invertebrate species in aquaculture using next-generation, high throughput eDNA sequencing technology (Illumina MiSeq). Samples were taken from 3 different species in culture, the giant scallop *Placopecten magellanicus*, the green sea urchin *Strongylocentrotus droebachiensis* and the northern sea cucumber *Cucumaria frondosa* from different body parts of the animals. In total, 1559 species of identified bacteria were found associated with these invertebrates. There were significant differences found between the 3 invertebrate species in taxonomic groups ranging from species to class. There were significant differences between body parts. Some of the dominant classes of bacteria found were Flavobacteriia, Gammaproteobacteria, Chlamydiia, Deltaproteobacteria and Epsilonproteobacteria. It is anticipated the results of this work will begin to develop a baseline for the microbiome of cultured marine invertebrates and develop into a tool that can be used to study organisms in relation to culture stress and environmental changes in marine ecosystems.

COCKLES HARVESTING, TRANSPORT AND PACKAGING: HOW TO IMPROVE THE QUALITY OF PRODUCT IN CONSUMERS TABLE

Rocha R.J.M.[1*], Pires S.F.S.[1], Martins D.[1], Rodrigues A.C.M.[1], Ofoegbu P.U.[1], Pereira V.[1], Pacheco M.[1], Costa A. P. L.[1], Soares A.M.V.M.[1]

Introduction

In Portugal, harvesting of cockles (*Cerastoderma edule*) is still carried out using artisanal techniques, which consist in the use of hand-raking or dredges operated by small vessels. In most cases, this process starts at ebb tide and cockles remain in net bags outside water or in the boat until the harvesting is concluded, which can take a few hours. Therefore, these techniques can induce stress in bivalves, especially during summer time, as they are exposed to air and temperature fluctuations, from harvesting to arrival at depuration and expedition centers (Alfaro et al. 2019)"ISSN":"00448486","abstract":"Temperature fluctuations during the live storage and transport of bivalves are known to be one of the most important stressors for these markets. However, the biological mechanisms that induce these stresses and the immunological responses to stressors are not currently understood. In this study, a gas chromatography–mass spectrometry (GC–MS based. Temperature fluctuations can induce physiological and metabolic alterations, thermal and oxidative stress and, ultimately, oxidative degradation of lipids (lipid peroxidation – LPO) and cellular damage. The level of stress and damage in bivalves can influence the energy budget and induce mortality during the depuration and commercialization processes, reducing the quality and shelf life of the product. Besides that, lipid peroxidation is usually associated with quality losses and organoleptic alterations (Ferreira et al. 2010), which may depreciate the product and cause consumer reluctance in future acquisitions. However, if care is taken during the harvesting process, in particular by using isothermal containers to maintain the temperature, some damage can be avoided. This study was developed to compare two methodologies: *i*) bivalve harvesting by conventional methods with exposure to air and temperature variations, and *ii*) bivalve harvesting to refrigerated containers, to evaluate its effect on the quality and shelf life of the product. Additionally, we also aimed to evaluate the packaging methods after depuration, comparing the conventional net plastic bags with burlap bags, which can maintain a humid atmosphere during more time.

Material and Methods

Cockles were harvested in Ria Formosa, Algarve, South Portugal, with bivalve dredges and divided in two groups: group 1 – cockles were maintained in the boat exposed to air and temperature alterations during approximately 3 hours, group 2 – cockles were harvested and immediately conditioned in isothermal boxes with cold packs (6±1 ºC). Animals from the two groups were sampled after arriving at the expedition center in Ria Formosa (3h after harvesting). Posteriorly, the two groups of bivalves were transported in a cooled environment (6±1 ºC) to the experimental depuration center in Aveiro University (7h) and sampled at arrival. After, bivalves were depurated during 24h in recirculated 250L tanks at 15 ºC and posteriorly sampled. Finally, bivalves of the two groups were packaged into two different types of bags (n=5): traditional net bags and burlap bags. After packaging, cockles were stored for 6 days at 5±1 ºC, to simulate the conditions during commercialization period. In each sampling, edible tissue samples were immediately frozen in liquid nitrogen and kept at -80 ºC until biochemical determinations. Lipid peroxidation and cellular energy allocation (ratio between energy reserves and energy consumption) were measured. Comet assay was performed in fresh samples to evaluate the DNA damage.

Results

Cockles transported in a cooler environment presented lower levels of DNA damage after both transport and shelf life period (Fig. 1 a). Results of sampling after arriving experimental depuration center revealed that energy consumption in bivalves transported in a cooler environment after harvesting was lower when compared to the values obtained in bivalves transported at ambient temperature. Higher values of energy reserves were measured in the cooled group comparing to ambient temperature group after the transport (Fig. 1 c). Regarding the energy budget, it is possible to observe a significant increase during the ice cooled transport comparing to the ambient temperature. Additionally, the transport in cooler conditions seemed to increase the quality of cockles until 6 days of shelf life, as lipid peroxidation (LPO) was lower in these group of *C. edule*, especially for animals stored in traditional net bags (Fig. 1 b).

(Continued on next page)

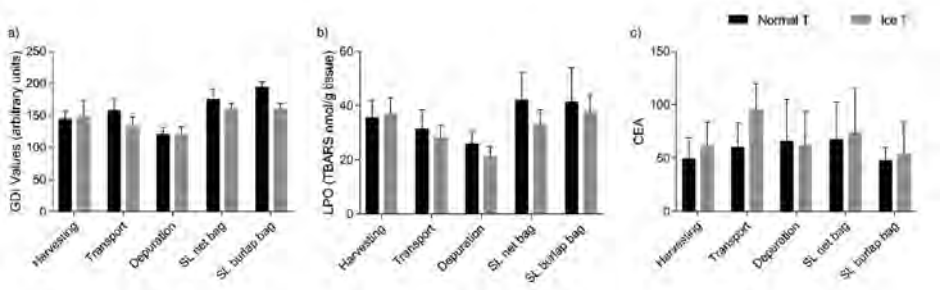

Fig. 1 Values of *Cerastoderma edule* harvested and transport in normal conditions (Normal T) *vs* transport in isothermal boxes with cold packs (Ice T) at the different points of handling until 6 days of shelf life period (SL): a) DNA damage (GDI values, as arbitrary units); b) lipid peroxidation (LPO – nmol TBARS/ g tissue); and c) cellular energy allocation (CEA). Values are presented as mean ± SD.

Discussion and conclusions

The transport of harvested *C. edule* in a cooled environment seems to be an effective measure to minimize all the stress associated with handling procedures and assure the better quality of the final product. Traditional net bags seemed to be more appropriate for the storage of cockles during the shelf life period, probably due to their bigger pore when compared to burlap bags, that allows for better rates of gas exchanges. So, our study emphasizes the importance that simple and low-cost changes in the harvesting procedure can have to improve food quality. Further work testing different times of shelf life and considering other materials for the bags may be performed and give new insights to bivalve market.

Introduction

The pullet carpet shell *Venerupis corrugata* (Gmelin, 1791) is a clam species traditionally harvested at the Southwestern and Mediterranean Europe, mainly in Portugal, Spain, France and Italy. Poor management and pathogen-induced mortality determined natural stocks' reduction, forcing aquaculture production in order to respond to a high market demand. With an actual high market value (wholesale price over $20USD per kg) when compared to most shellfish species, intensification of *V. corrugata* aquaculture production is very likely. It may also support stocks' recovery under high consumption and increased mortality due to disease outbreaks and extreme climatic events, predictably more frequent under future environmental reality in a changing climate. This includes several undergoing global phenomena such as ocean acidification (OA) and warming (W), known to alter seawater chemistry impacting marine calcifiers such as clams. In this work we assess the performance of *V. corrugata* larval culture, from the first planktonic larval phase to settlement, under OA-W projected scenarios, aiming at foreseeing the resilience of the earliest, most fragile, life stages of the species to the expected future climate conditions.

Material and methods

Broodstock from the Ria de Aveiro (NW Portugal) was induced to spawn by thermal stimulation. Fertilized eggs were incubated to hatch in 1-µm filtered, UV-sterilized artificial saltwater under control conditions: unmanipulated pH (~8.2) and 18ºC. The D-larvae retained in a 60µm-sieve 48 hours post fertilization (48h pf) were exposed in triplicate to nine OA-W scenarios (Figure 1) resultant from a factorial experimental design of three pH levels at three different temperatures. Mortality and development stage were assessed every 3 to 4 days until settlement was complete in all experimental treatments (after 28 days of exposure, at T28). Shell length (SL) was measured at T0, T14 and T28, and growth rates calculated per treatment. The effects of temperature, pH and the potential interaction between these factors on the assessed endpoints were tested through permutational multivariate analysis of variance (PERMANOVA, *Primer v7 software*).

Results

Apart from an initial increased survival under acidity, potentially due to changes in the microbiome, there was an apparent lack of effect of the experimental treatments on mortality after 28 days of exposure (Figure 2). Still, the factors under study interact significantly (T14: *Pseudo-F*=7.5939, *P*=0.0001; T28: *Pseudo-F*=6.7797, *P* =0.0001) affecting larval development, which was notably accelerated by warming, despite the relatively delayed growth under acidity, an effect attenuated by the simultaneous increase in temperature (Figure 3).

Discussion and conclusion

Our results reveal the improved performance of *V. corrugata* larval culture under some of the tested OA-W scenarios, specifically the warmer (22ºC) at control (8.2) and intermediate (7.9) pH levels, suggesting that warming is likely to favor larval development and, to some extent, counteract growth impairment under acidity. As early life stages are generally more prone to the tested stressors (Przeslawski et al., 2015), this work points to the resilience of this bivalve to the expected OA-W and to its high productive potential under the future climate.

Introduction

Fish feed accounts for around 50% of intensive fish farming costs, and fish feed production and consumption have a strong environmental impact. Using breeding programs to improve feed efficiency could highly increase aquaculture sustainability. Still, it is likely that individual feed intake (FI), body weight gain (BWG) and their interrelation could change substantially depending on the genetic background and on the rearing temperature. Genetics by environment interactions were already demonstrated on the growth of European sea bass (Vandeputte et al, 2014). Here, we studied three European sea bass populations: Atlantic Ocean (AT), West Mediterranean sea (WM) and East Mediterranean sea (EM) at two temperatures (18 and 24°C) in order to 1) assess the differences in the relationship between FI and BWG for each population, temperature and population by temperature interaction and 2) determine the variations of such traits at individual level.

Material and methods

We used 200 European sea bass from the three sea bass populations (62 AT, 66 WM, 72 EM). At the beginning of the experiment, fish were seven-months old and weighing 21.4 ± 8.3 g. These fish were reared in individual aquaria in order to permit individual FI measurement, as described by Besson et al (2019). Among these 200 fish, 100 were reared at 18°C and 100 were reared at 24°C. We firstly identified the ad libitum (ADL) feeding rate of each fish (100% ADL) by adjusting rations weekly over a four-weeks period. Each fish was then fed to 100 % ADL for 22 days, and then 80%, 60%, 40%, 20% and 0% ADL for 10-11 days at each level. Individual FI and BWG were measured at each level and FI and BWG relative to metabolic body weight were calculated ($MBW=(Wi \times Wf)^{0.4}$, with Wi and Wf initial and final weights, Saravanan et al, 2012).

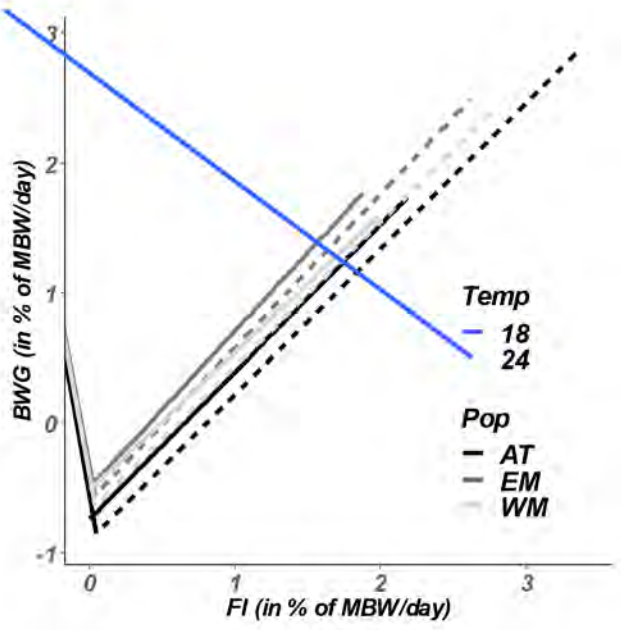

Figure 1 BWG evolution in function of FI

(Continued on next page)

We first studied the intercept and slope of the linear relationship between BWG and FI with an analysis of covariance. To assess individual variations within each interaction, parameters of the linear relationship between BWG and FI were then calculated for each individual and compared. Finally, residuals of the linear relationship between BWG and FI were calculated using the whole dataset and corrected for population and temperature effects. The Pearson's correlation between residuals ad libitum (res100%ADL) and during fasting (res0%ADL) was estimated. All the analyses were performed using R software.

Results

There was no significant difference in slope in the relationship between BWG and FI (Figure 1) between populations, temperatures, and population by temperature interactions. A significant difference in intercept was found between populations ($P < 0.001$) and between temperatures ($P < 0.001$), but interaction was not significant (> 0.05)

EM fish had a significantly higher intercept than WM ($P < 0.01$) which had a significantly higher intercept than AT ($P < 0.001$). Fish reared at 18°C had a significantly higher intercept (< 0.001) than those reared at 24°C.

At individual level, within each population by temperature interaction, coefficients of variation of intercept and slope were ranged between 15% and 25% and between 15% and 29% respectively.

Finally, Pearson's correlation between res100%ADL and res0%ADL was not significantly di ferent from 0 ($r = -0.08$).

Discussion and conclusions

Given the observed homogeneity of slope between populations, temperatures and interactions, it can be considered that a given increase in FI will lead to a similar increase in BWG, whatever the population or the rearing temperature. Moreover, intercept was higher at 18°C than at 24°C: we can make the hypothesis that maintenance costs are lower at 18°C. Similarly, intercept differences between populations may be explained by different maintenance costs. Actually, several phenotypic traits were already demonstrated as significantly different between these populations (Vandeputte et al, 2014). No genetics by environment interaction seemed to be involved in the relationship.

Furthermore, as measuring FI is complex in fish, we tried to find an easier trait (loss of weight during fasting, expressed by res0%ADL) to select for in a breeding program. As the correlation between res100%ADL and res0%ADL was not significant, weight loss during fasting cannot be used to predict which individual fish would have the best growth performance at its ad libitum FI. However, the present experiment was done using really specific rearing conditions: fish were juveniles and isolated (which induces stress). Correlation estimates may be biased by the time lapse existing between measurements done at different feeding levels.

Nevertheless, this study generated key information for breeding programs. A broad individual variability was existing in the relationship between BWG and FI, suggesting opportunities for selective breeding, if this variability is of genetic origin.

Introduction

Food security relies on depuration of mollusc bivalves and these good practices are regulated among the European countries (EU 2004). So far, physiological requirements of the diverse commercialized species, as optimum temperature range, are not considered in the purificati n process, which can compromise animal metabolism, welfare and quality of the final product. Further, bivalves harvested in class C areas are usually avoided by stakeholders due to economic constraints, as they must be transposed to relaying areas for a minimum of two months prior to depuration, before being commercialized for human consumption. Thus, our objectives were to evaluate: 1) if bivalves harvested from class C areas are able to depurate to class A values in 24 h; 2) if there are differences in purification capability due to water temperature; and 3) if water temperature will affect the biochemical responses of depurated bivalves.

Material and Methods

Clams (*Ruditapes decussatus*) and razor clams (*Solen marginatus*) were selected as the model bivalve species, as they have a broad distribution and high economic value in Europe. Bivalves were harvested in class C areas in Algarve, south Portugal, and transported to Aveiro University facilities in less than 24 h. Animals were depurated during 24 h in 250 L modular depuration systems equipped with a filtration system and a UV-c unit (25W UV-c, 6.000 μW.s/cm^2), testing 4 temperatures (10, 15, 20 and 25 ºC). Bivalves were sampled for microbiological and biochemical analyses at 0 (arrival) and 24 h (depuration period). Microbiological load (most probable number – MPN – of *E. coli per* 100g of tissue and intravalvular liquid), antioxidant defences (catalase, glutathione S- transferases, and total glutathione), oxidative damage (lipid peroxidation and DNA damage) and cellular energy allocation were evaluated.

Results

R. decussatus and *S. marginatus* individuals were able to depurate their microbiological load to class A values in 24 h at all tested temperatures. However, *R. decussatus* presented the lower microbiological load at 20 ºC (<18 *E. coli*/100g) and *S. marginatus* between 10 and 15 ºC (mean values of 69 and 62 *E. coli*/100g, respectively). No changes were observed on clams antioxidant defenses, but for razor clams tGSH levels were impaired with increasing temperatures (Fig. 1 a). Clams seemed to have a higher range of temperature tolerance, with DNA damage increasing only at 25 ºC, whereas for razor clams temperatures above 20 ºC caused an increase in DNA strain breaks. Regarding energy consumption, clams presented a higher activity of electron transport system than razor clams, although no significant changes in energy consumption were observed due to water temperature (Fig. 1 d).

Discussion and conclusions

This study shows that bivalves from class C areas can depurate their microbiological load to values of class A areas in 24h if optimized condition of depuration systems are available. Further, we observed that the efficacy of purification of each species was influenced by water temperature with *R. decussatus* individuals more tolerant to water temperature changes than *S. marginatus*. These differences are in accordance with the ecological niche of each species, since clams usually stay at the surface of the sediments, thus more exposed to environmental changes (thermal/desiccation fluctuations) than razor clams that live buried in the sediments (Monaco et al. 2019). Thus, it is highlighted the relevance of considering species-specific requirements to improve purification and welfare of live bivalves during the commercialization chain. In sum, strength might be given towards a rethinking of the possibility for direct depuration of animals from class C areas and the adjustment of the depuration process to fulfill species-specific requirements of cultured bivalves

Introduction

Coral reefs represent one of the most diverse ecosystems in the world, with critical importance for various organisms. People also depend heavily on this marine ecosystem in ecological, economic and cultural terms (Laurans et al., 2013; Spalding et al., 2017). However, coral reefs are declining due to various natural and anthropogenic factors such as global warming, pollution or illegal fishing with destructive gears (McClanahan et al., 2014). In addition, the capture of wild scleractinian corals is an activity practiced in several tropical and subtropical regions, mainly for the aquarium industry (Wijgerde et al., 2012). Coral aquaculture (*in situ* or *ex situ*) is, therefore, a possible solution to minimize the capture of wild organisms, allowing the production of these organisms for various purposes, such as reef restoration, artificial reef building, or commercialization for educational and ornamental purposes. However, the need to optimize zootechnical procedures persists in order to maximize the rate of survival and growth. The main objective of this work was to study the effect of light (intensity and spectra) on survival, growth, photobiology, energy allocation and energy consumption of *Montipora digitata* fragments obtained from mother colonies acclimated to different light scenarios (mimetizing different sea depths).

Material and methods

Eight colonies of *M. digitata* (with the same genetic origin) were acclimated for two months in experimental systems with artificial light (full spectrum) under two photosynthetic active radiation (PAR) intensities: 4 colonies in high light (HL, 130 ± 20 µmol quanta.m^{-2} .s^{-1}) and 4 colonies in low light (LL, 70 ± 10 µmol quanta.m^{-2}.s^{-1}) conditions. Afterward, colonies were fragmented in ~ 2 cm length fragments, originating a total of 56 fragments (28 from HL and 28 from LL acclimated colonies), which were cultured in two 235L glass tanks connected to the same filtration system, as described by (Rocha et al., 2015). Four light treatments were tested, using two light spectra (red and blue) and two photosynthetic active radiation (PAR) intensities (130 ± 20 and 70 ± 10 µmol quanta.m^{-2}.s^{-1}). Fragments originated from HL and LL acclimated colonies were identified and cultured during four months in the described light treatments (n=7). Survival, growth rate, maximum photosynthetic efficiency of dark-adapted PSII (fv/fm, *in vivo*), and energy allocation were evaluated.

Results

No mortality occurred during the experiment. An effect of mother colony origin was observed, with fragments from LL acclimated colonies presenting a higher growth rate when compared to fragments from HL acclimated colonies. Light spectra also significantly affected the growth rate of corals, with fragments reared under red light low intensity (PAR 70 ± 10 µmol quanta.m^{-2}.s^{-1}) showing a higher growth rate (Fig. 1). In terms of fv/fm, it was observed that fragments from HL acclimated colonies, reared in red light low intensity, increases the photosynthetic efficiency from T0 to T1. The mother colonies also influenced the energy reserves in the fragments exposed to different light conditions. It was observed a higher protein content in fragments from LL acclimated colonies in all treatments. Regarding lipid content, an interaction was observed with fragments from HL acclimated colonies having higher lipid levels at low light treatments and fragments from LL acclimated colonies having higher lipid content when reared in high light conditions.

Discussion and conclusions

The results suggest that mother colonies acclimated to low light conditions will originate fragments that can present better growth performance. Additionally, red light spectra with low intensity can be more appropriate to culture *M. digitata ex situ*, with organisms presenting better growth rate and photosynthetic activity. In this study, it was observed that the high light intensity provokes photo-inhibition and consequently low photosynthetic efficienc , as previously reported by Barton et al. (2017). Interestingly, the high light conditions seem to promote higher content of proteins, probably fluorescent

(Continued on next page)

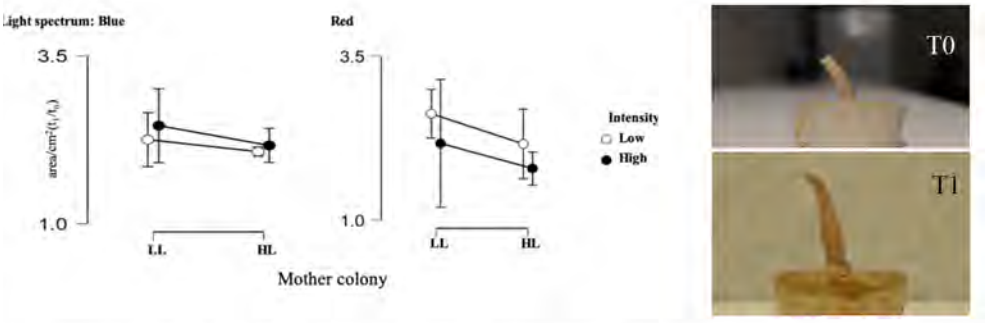

Figure 1. Growth rate of *M. digitata* fragments originated from colonies acclimated to low and high light conditions (LL and HL, respectively), cultured during 4 months in different light spectra (red and blue) and photosynthetic active radiation (PAR) intensities (130 ± 20 and 70 ± 10 µmol quanta.$m^{-2}.s^{-1}$).

proteins, that can be used for protection to high intensity exposure (Roth, 2014)creating habitat for these diverse and productive ecosystems. Light is thus a key regulating factor shaping the productivity, physiology, and ecology of the coral holobiont. Similar to all oxygenic photoautotrophs, Symbiodinium must safely harvest sunlight for photosynthesis and dissipate excess energy to prevent oxidative stress. Oxidative stress is caused by environmental stressors such as those associated with global climate change, and ultimately leads to breakdown of the coral-algal symbiosis known as coral bleaching. Recently, large-scale coral bleaching events have become pervasive and frequent threatening and endangering coral reefs. Because the coral-algal symbiosis is the biological engine producing the reef, the future of coral reef ecosystems depends on the ecophysiology of the symbiosis. This review examines the photobiology of the coral-algal symbiosis with particular focus on the photophysiological responses and timescales of corals and Symbiodinium. Additionally, this review summarizes the light environment and its dynamics, the vulnerability of the symbiosis to oxidative stress, the abiotic and biotic factors influencing photosynthesis, the diversity of the coral-algal symbiosis, and recent advances in the field. Studies integrating physiology with the developing \"omics\" fields will provide new insights into the coral-algal symbiosis. Greater physiological and ecological understanding of the coral-algal symbiosis is needed for protection and conservation of coral reefs.","author":[{"dropping-particle":"","family":"Roth","given":"Melissa S.","non-dropping-particle":"","parse-names":false,"suffix":""}],"containe -title":"Frontiers in Microbiology","id":"ITEM-1","issue":"AUG","issued":{"date-parts":[["2014","8","22"]]},"publisher":"Frontiers Media S.A.","title":"The engine of the reef: photobiology of the coral-algal symbiosis","type":"article-journal","volume":"5"},"uris":["http://www.mendeley.com/documents/?uuid=894fd674-5cb7-3a57-beb9-00ad15f16d62"]}],"mendeley":{"formattedCitation":"(Roth, 2014. This study emphasizes that several factors must be considered to a successful coral aquaculture, including the type of light (intensity and spectrum). However, the origin of mother colonies, namely PAR acclimation conditions (e.g., different depths or shadow conditions), can have a preponderant role in the optimization of coral aquaculture to maximize biomass production.

EXPERIMENTS OF WRECKFISH (*Polyprion americanus*) LARVAL CULTURE IN GALICIA (SPAIN)

J.L. Rodríguez[1*], A. Araujo, N. Fuentes, B. Alvarez-Blázquez, E. Pérez, A. Vilar and F. Linares

*Instituto Galego de Formación en Acuicultura (IGaFA). Niño do Corvo s/n 36626 Illa de Arousa (Spain)
e-mail: xose.luis.rodriguez.villanueva@xunta.es

Introduction

The wreckfish, *Polyprion americanus*, is a very interesting species for diversification in aquaculture in the European Atlantic zone because of its rapid growth, good adaptation to captivity (Machias *et al.*,2003, Papandrolakis *et al*,.2004; Rodriguez *et al*., 2014), late maturation (Sedberry *et al*., 1999), onset, high market price and very limited catches. In recent years, the Diversify project (UE) has made important progress in reproduction,, broodstock nutrition and incubation. However, larval culture is still the main bottleneck in wreckfish aquaculture. In this work, some experiments of larval culture that led to the first juveniles of wreckfish are show

Materials and Methods

The rearing trials were carried out at the Galician Institute of Aquaculture (IGAFA) in Galicia, using two batches of 5,000 larvae each, from the broodstocks of the IEO (Vigo) and the Aquarium Finisterrae (A Coruña). The larvae were released in two 400 L concave cylindrical tanks at a density of 12.5 larvae/L. The culture was carried out using a recirculation system (RAS), operating at 16-17 ºC, salinity 36 %, oxygen 7.2-8.4 mg/L, with natural photoperiod. Levels of ammonium, nitrites, nitrates and pH were monitored and recorded daily. The opening of the mouth of the larvae occurred at 6 dph (days post hatching) and feeding was initiated at 8 dph. From 8 dph to 19 dph, larvae were fed with rotifers enriched with products specifically developed for this species by the University of Las Palmas de Gran Canaria (FCPCT). From 15 to 23 dph, *Artemia* nauplii (A_0) was also given. Between days 18-48 dph, the larvae were fed with metanupliu (A_1) enriched with special products developed by the FCPCT. From day 40 to 48 dph, commercial dry food was supplied; and weaning finished at 48 dph. Samples of larvae were regularly taken for their measurement, taking photos and observing the stomach content.

Results

The newly hatched larvae had a size of 4.70 ± 0.27 mm. Before opening their mouth (8 dph) the growth was very slow, but then the growth rate increased progressively. After 65 dph, the larvae were on average 12.77 mm (Fig.1). The survival rate of the larvae was: 0.18 % (9 individuals) for the batch from IEO and 0.32% (16 individuals) for the batch from Aquarium Finisterrae. Some individuals exhibited swimming difficulties, aprobably due to dysfunction of the swim bladde

Discussion and Conclusion

Despite the low survival rates, these results represent an important first step towards the development of a larval protocol for wreckfish aquaculture. It is noteworthy that the behaviour of wreckfish larvae is quite different from the other marine species that are currently being cultivated; and therefore, a special zootechnics is needed for this species. More research is needed to identify the factors influencing the quality of the spawning as many larvae had jaw joint problems during the first days of life, which caused difficulties to capture the food and they ended up dying when the nutrients from endogenous reserves were finished

Introduction

In the last years, several of the serious incidents involving acute fish mortalities in recirculating aquaculture systems (RAS) for Atlantic salmon (*Salmo salar*), have been caused by hydrogen sulphide (H_2S). These incidents have mainly occurred in seawater systems, e.g. post-smolt production. H_2S is formed by sulphate-reducing bacteria which uses sulphate (SO_4^{2-}) and organic material under anaerobic conditions (Muyzer and Stam, 2008). Seawater contains 1000 times more SO_4^{2-} than freshwater (Gerardi, 2006), increasing the potential risk for H_2S production. However, using seawater is pivotal to avoid desmoltification and preparing salmon for seawater transfer (Mortensen and Damsgård, 1998). Therefore, the idea of removing sulphate from seawater through membrane filtration have been proposed as a measure for reducing fish mortalities caused by H_2S. The aim of the following study was to: 1) understand what microbial environments in RAS have the highest potential risk for H_2S-formation, 2) test the hypothesis that sulphate-removal in seawater reduces the risk of H_2S formation, and 3) to gain a better understanding of the dynamic between organic material and sulphate concentration for H_2S formation in RAS-water.

Materials and Methods

Three main environmental sources where H_2S could potentially form in a commercial RAS were selected: sludge, biofilter elements and RAS-water. A small-scale batch experiment was conducted where each of these three potential sources were exposed to seawater, freshwater, brackish water and treated water (freshwater + filtered seawater). The filtered seawater was provided by a membrane filtration technology developed during the same project that this study is a part of. The H_2S kinetics and production rate was measured for each test. The organic material was also measured in form of COD (chemical oxygen demand). To gain insight on the microbial environment, bacterial activity, number and community was also investigated.

Results

The results of this experiment are still under development and analysis and will therefore be presented at the European Aquaculture Society conference.

MICROALGAE CULTIVATION FOR BIOREMEDIATION OF NUTRIENTS UNDER AQUAPONIC CONDITIONS

Robert C. Röllig

Chair of Aquaculture and Sea-Ranching, Rostock University
Email: robert.roellig@uni-rostock.de

Introduction

Microalgae are considered an important group of organisms, ecologically and for numerous applications – these include production of pharmaceutical ingredients and chemical raw materials, food and dietary supplements, (aqua)feed, biofertilizers and bioactive compounds, biofuels and bioplastics, biosensors as well as biomass production and bioengineering, e.g. CO_2-fixation and waste water treatment (Chapman et al., 2013; Harun et al., 2010)

Modern RAS production facilities create considerable amounts of nutrient rich waste water. To prevent eutrophication and recycle valuable nutrients terrestrial plants can be grown in soilless cultivation systems, a principle widely known as aquaponics.

Another approach doing so is the cultivation of microalgae, with waste waters serving as the culture medium. Nutrients contained in waste water are hereby recovered while the water is biologically remediated (Chiu et al., 2015; Queiroz et al., 2013; Sriram et Seenivasan, 2012).

In this study we aimed to assess the potential of green microalgae to develop biomass suitable for possible further applications grown in waste water deriving from a production site of African catfish (*Clarias gariepinus*) under controlled and pilot scale conditions.

Materials and methods

For this study, stocks of a limnic green algae polyculture dominated by *Scenedesmus* sp. were maintained in cell culture flasks with ventilation caps utilizing F/2 medium. To create pre-cultures used for actual cultivation stock cultures were transferred to aerated 2L glass chemostats and added to fish aquaculture waste water which had been filtered threefol

Pre-cultures were kept in a fed-batch cultivation process with artificial illumination set at a 16/8h light/dark rhythm until reaching an OD665-value (optical density obtained at a wavelength of 665nm as proxy for concentration of algal cells) of approximately 1.0.

Actual cultivation took place in a greenhouse aided by artificial illumination set at a 16/8h light/dark rhythm. To run a cultivation cycle, 7L (i.e. 5% of total volume) of pre-culture were transferred and inoculated in a 140L tubular photobioreactor (PBR) containing double filtered fish aquaculture waste water from the same source

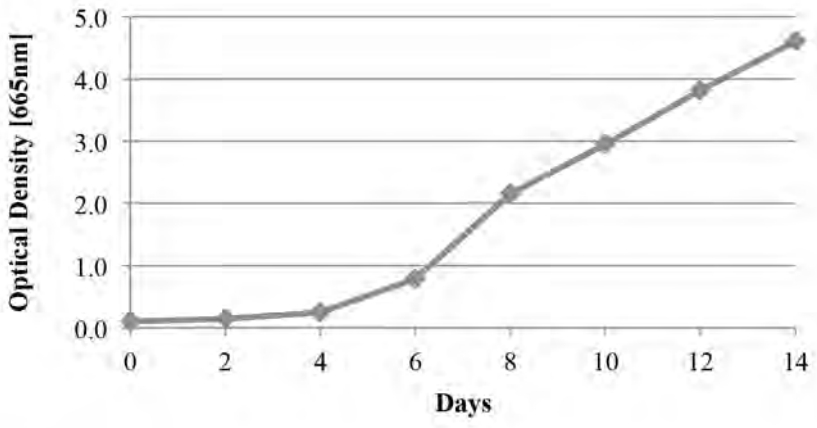

Fig. 1: Development of optical density over time measured at a wavelength of 665nm of a green algae polyculture in waste water deriving from a production site of African catfish (*Clarias gariepinus*).

(Continued on next page)

Several growth and nutrient parameters including OD665, cell densities, chlorophyll contents, dissolved organic and inorganic as well as particulate organic nutrient contents (nitrogen=N, phosphorus=P) were assessed over the course of 14 days. Additionally, the fatty acid profile of the obtained algal biomass was analyzed. To verify results a total of four cultivation cycles had been conducted.

Results

OD665-values as a preliminary result had increased from approximately 0.1 at day zero (D0) to more than 4.6 at the final D14 and hence, multiplied numerous times which indicated that under the given conditions the green algae polyculture had grown strongly, (figure 1). Further results from this study will be presented

Discussion and Conclusion

Members of the genus *Scenedesmus* have shown to efficiently remove nutrients including N and P from artificial and real waster waters alike (Voltolina et al., 1999; Martinez et al., 2000; Ruiz-Marin et al., 2010; Ji et al., 2013).

Growth curves of these algae had an appearance similar to the ones in our study indicating that the utilized polyculture was able to thrive and develop quantities of biomass suitable for further applications (Xin et al., 2010).

RAINBOW TROUT (*Oncorhynchus mykiss*) GROWING TRIAL USING DIETS WITH DIFFERENT DOSAGES OF THE SAME ADDITIVE

Roncarati A., Meligrana M.C.T., Magi G.E., Mariotti F.

School of Biosciences and Veterinary Medicine, Camerino University, Matelica, Italy

Introduction

In animal nutrition, the phospholipids are considered to play an important role in the digestion of fat. In larvae and early juveniles, dietary phospholipids improved growth and increased survival rates and decreased incidence of malformation in larvae (Kanazawa, 1993; Fontagnè et al., 1998). A specific class of phospholipids, the lysophospholipids, induces a better absorption of nutrients than other phospholipids due to their hydrophilic nature; in particular, they help in fatty acid absorption by the formation of micelle structures as shown in different animal species (Gheisar et al., 2015; Kim et al, 2018). Limited data are reported for the lysophospholipids in fish during growing

In order to investigate the effects of an emulsifie , based on lysophospholipids (LEX), on rainbow trout during the growing phase, a trial was performed evaluating the growth performances and feed conversion rate. For the aim, the (LEX) was supplemented to diet at two different doses.

Materials and Methods

For the trial, we employed 6 000 rainbow trout, averagely weighing 47.8±3g, which came from the pre-growing sector where they were reared. The fish were stocked in 12 tanks (3 tanks per diet group) at 4.93kg/m^3. The test additive (LEX) was supplied by the company in a ready-to-use powder form. For 90 days, 4 groups, with 3 replicates each, were considered: 1) Positive Control (normal energetic level); 2) Negative Control (Positive Control without a fraction of energy added); 3) Negative Control plus additive at 500ppm; 4) Negative Control plus additive at 750ppm. The Diet 1) was formulated in accordance with the person in charge of the nutrition line of the commercial feed employed for rainbow trout juveniles submitted to pre-growing phase. The diets were administered by hand twice a day, 6 days per week, and the quantity of the daily ratio was recorded.

At the end of the trial, all the fish were weighed whereas the mean final length was sampled in 20 fish. The main zootechnical performances were determined and submitted to statistical analysis. To investigate potential differences in the intestinal structure among the groups, standard histological techniques were performed by means of light microscopy (Nikon Phase Contrast 0.90 Dry, Japan). Tissue morphology was evaluated according to a grading system (absent, light and high damage) in order to assess possible changes in cell morphology. Quality traits of the fillet were examined in six fish/group at the end of the trial; a portion of dorsal muscle, deprived of skin and subcutaneous adipose panicle, was collected, homogenised and submitted to the following analysis: dry matter (determined at 105°C for 24h); total nitrogen (Kjeldahl, conversion factor of N to protein 6.25); total lipids extracted with chloroform/methanol (2:1 v/v) (Folch et al., 1957) and converted to fatty acid methyl esters following Sukhija and Palmquist (1988).
Data collected every sampling were submitted to analysis of variance using General Linear Model (PROC GLM) of SPSS 25 (IBM Corp., 2017). The differences among the means were verified by Test of Pairwise. Effect was considered significant when $P<0.05$

Results and discussion

The final mean body weight showed significant differences among the four groups: the fish fed on Diet 3 were the heaviest (166g), followed by those of Diet 4 (154g), and finally those fed on Diet 1 (133g) and Diet 2 (127g) respectively, which weighed far less. On the other hand, no significant differences were observed with respect to either the final mean body length (21-22.5cm) or the survival rate among the groups.

The two diets containing the emulsifier allowed for a significant y greater weight gain (106-118g) and specific growth rate (1.30-1.38%day^{-1}) with respect to the Positive (85g; 1.14%day^{-1}) and Negative (80g; 1.09%day^{-1}) Control diets. The Diet 3 and Diet 4 groups showed a significantly lower and, therefore, more favorable feed conversion ratio (1.14-1.15) than the other two Control groups (1.23-1.29). As far as the somatic indices are concerned, no significant differences were noted among the four groups in the VSI, PFI, and HIS, while the KI was significantly higher in the fish fed on two diets containing the emulsifie . A good general morphological condition was noted in the fish fed on Diet 3 and 4: the architecture of the intestinal wall was generally normal in terms of thickness and development of the villi whereas the Diet 1 and Diet 2 groups frequently presented an alteration in the structure of the intestinal wall.

(Continued on next page)

Concerning quality traits, protein content ranged between 19.5% in fillet of trout fed Diet 3 and 20.1% in group receiving Diet 4. Lipid fraction varied from 0.7% (Diet 4) to 1.1 in Diet 1. The highest n-3 PUFAs was detected in fish fed Diet 4 (0.227g $100g^{-1}$ fillet) compared to the others (Diet 3: 0.193g 100^{-1}; Diet 1: 0.119 g $100g^{-1}$; Diet 2: 0.069g $100g^{-1}$ fillet)

MYCOTOXINS – A WORLDWIDE THREAT FOR THE BLUE REVOLUTION?

Introduction

Mycotoxins are toxic secondary metabolites produced by various species of filamentous fungi, contaminating a wide variety of mostly plant origin agricultural commodities, animal feeds and human foods.

Reports of mycotoxins-related pathologies in aquatic species have been the driving force for research in this field since the 1960's.

As their chemical structures vary considerably, mycotoxins cannot be classified as one group according to their mode of action, toxicology or metabolism. (Gonçalves, et al., 2019); Additionally, specific biological classification is limited due to the species variability in the arbitrary group of aquatic organisms cultivated for aquaculture. Nevertheless, a common characteristic of mycotoxicoses in all species is the early pathogenesis and route of intoxication. Toxic molecules carried by food or water are internalized or topically come in contact with the organism's mucosal tissue, where first pathological processes can usually be detected, this is followed in most cases by the host circulation carrying the toxins and toxic metabolites, further altering the homeostasis of cells, tissues organs and systems. These changes are often clinically manifested in productivity, pathogen susceptibility, genetic and immune changes and more.

In recent years a shift towards increase use of plant origin materials and reduction of the animal component in aquatic feeds created a 'more-than-ever' risk of mycotoxicoses in aquaculture systems, which is now a globally growing and fast developing industry.

In the near future, Human societies will face an enormous challenge of feeding and caring for a global population of over 9 billion people, in what seem like, a determinative period of time for addressing impacts of climate change and environmental degradation of the resources base. (FAO, 2018).

Global sustainable aquaculture, as agreed by many, could be one of the major factors comprising the answer for this challenge, creating an equal, clean and available source of food and income for populations around the world.

Modern aquaculture needs to address many complex issues, from preservation of fisheries, water resources and the aquatic environment, through animal and human welfare, to reduction in the use of antibiotic substances in an effort to fight the problem of antibiotic resistant pathogens, which are all interconnected to the threats posed by mycotoxins. Research efforts and increased awareness for prevention, together with development of novel mycotoxins mitigation strategies, could play a major role in future aquaculture as the solution for feeding a healthy and sustainable world in upcoming years.

While currently over 350 compounds are considered to be mycotoxins, the most influential ones are Aflatoxins (AF), Ochratoxins (OTA), *Fusarium* spp. toxins such as Fumonisins (FUM) and Zearalenone (ZEN), Trichothecenes such as Deoxynivalenol (DON) ,T-2 toxin and their derivates and a growing group of emerging mycotoxins that includes sub-groups such as the Enniatins and Beauvercins (Pietsch, 2019).

These toxins are currently in the spot light of research as their impacts in aquaculture and other feed, food and health are complex and manifest themselves often with reduced, productivity, increase in disease and economical losses estimated to billions of US dollars every year (Anater, et al., 2016)

(Continued on next page)

Materials and methods

Over a period of five years (2014-2019) 114 samples of globally distributed finished aquatic feeds were analysed for mycotoxin contamination within the scope of the BIOMIN Mycotoxin Survey Program. These samples were analyzed using Liquid Chromatography-Mass Spectrometry/Mass Spectrometry (LC-MS/MS, Spectrum 380®) screening for more than 700 mycotoxins and other secondary metabolites.

Results

All samples showed co-contamination by > 1 compound with a maximum count of 78 different toxins contaminating single aquatic feed sample. From the group of major mycotoxins, ZEN was the most commonly present, detected in 73% of all samples at a mean concentration of 59ppb and maximum concentration of 615ppb for positive samples. DON and FUM B1 were detected both in 48% of samples (means of 249, 100ppb and maximums of 2486 and 2087ppb both respectively). AF B_1 and OTA occurrence is often related to storage conditions but also grain damage in the field. Both were present in 8% of all samples. Global toxin distribution was observed with foci of higher levels in Mediterranean, north European and south east Asian countries.

FRESH-WATER-PRODUCING SEAWATER-AQUAPONICS AS A SOLUTION FOR THE DRAUGHT NOT ONLY IN THE NORTHEAST OF BRAZIL

A. Rossbach

GLOASIS GmbH, Ulmenweg 7b, D-15711 Königs Wusterhausen (Germany)
Email: mail@gloasis.com

Introduction

The Northeast of Brazil was the countries' biggest Tilapia producer five years ago. Due to climate change today about 95 % of the productive water bodies have disappeared, as well as the Tilapia industry did.

As sustainable response, seawater aquaculture with a combined desalination process is to be established.

Project Description

The consortium of the Brazilian Piscis Industry Trade Ltda and the German Gloasis GmbH have developed an Aquaponics System for the annual production of: 175 tons of Tilapia, 63 tons of Shrimp, 250 tons of tomato and 238,000 heads of lettuce on 1.4 hectares of barren land.

The novelty of this project is that also up to 244 m³ of condensed water are produced daily as shown in Figure 1 below:

Process Description Example Lettuce Module

In November, the hottest month of the year, the Lettuce Module faces a cooling demand of 484.9 kW, already regarding the shading installations.

The plants itself contribute a part of the needed cooling energy by evapo-transpiration of 2.5 $kg_{H2O}m^{-2}$ per day. Further evaporation-cooling energy is supplied by Evaporation Cooling Units (No. 1 in Figure 1). In one of these, 25.52 g of seawater from the aquaculture is evaporated for the cooling of the greenhouse modules per second.

One advantage of this cooling is that the cold air also contains high CO_2-levels from the aquaculture and therefore realizes a CO_2-Fertilization of the plants.

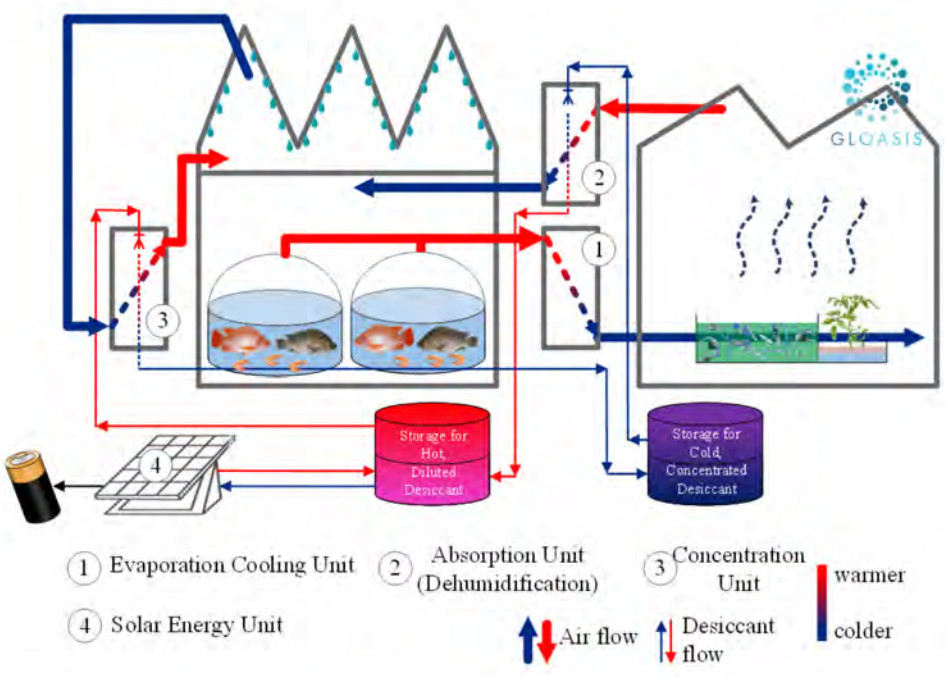

Figure 1: Cooling, Desalination and CO_2-Fertilization based on Seawater Aquaculture

(Continued on next page)

A further advantage is that the water from the aquaculture is also saturated with oxygen in this process. The peak demand of 1,060.0 $g_{O2}h^{-1}$ per tank requires a water flow rate of 135.5 ls^{-1} with an 80 % saturation efficiency in the cooling towers and a minimum level of 4 $g_{O2}m^{-3}$ water in the tanks. Thus, mayor saving in energy costs for aeration are supposed to be proven.

In the Absorption Unit (No. 2 in Figure 1), 216.7 g of water (humidity) will be absorbed by a liquid desiccant per second.

In the Concentration Unit (No. 3 in Figure 1), these 216.7 g of water will be desorbed from the liquid desiccant to the air and condensed in two adequately designed condensers.

The concentration of the desiccant requires thermal energy, which is taken from a cooling cycle of PV panels. The cooling of the PV panels automatically increases their efficienc .

Conclusion

The seawater aquaponics system with desalination is regarded to be an answer to the fresh water scarcity, lack of fertile land and climate change. In controlled greenhouse environments it is possible to maintain the perfect growing conditions for plants and animals. A key element for the success is the additional to the water treatment implemented, the use of the evaporation-condensation cycle.

The project creates closed greenhouse environments, which should therefore even be applicable in space, where all the transpired and evaporated water can be cleaned and used for aquaculture and horticulture and thus for the survival of humanity.

ANTIOXIDANT EFFECT OF THYMOL AND SORBIC ACID IN FISH HEPATOCYTES *IN VITRO*

Introduction

Aquaculture has grown consistently over the last decade and aqua species production will continue to increase, as a result of growing demand for seafood (Huntington and Hasan, 2009). However, aquaculture has to face important challenges in terms of health management and environmental impact like intensive fish farming, increase in water temperature due to global warming, world sea metal pollution, and pathogen infections (Cochrane et al., 2009). All these challenges induce oxidative stress in fish that could depress growth performance and impact the anti-oxidative ability (Slaninova et al., 2009). There is a growing intertest in use bioactive compounds of plant extracts and organic acids as feed additives, because of their antimicrobial power as well as their potential positive effect on immune defense mechanisms, but little is known about their potential against oxidative stress. The aim of this study was to assess the effect of thymol and sorbic acid on PHLC-1 hepatocytes cell line during a H_2O_2-induced oxidative stress. The PLHC-1 (*Poeciliopsis lucida* hepatocellular carcinoma) cell line was used in this study since it is a recognized *in vitro* model to study the hepatic metabolism in fish

Materials & methods

PLHC-1 were seeded at a density of 400 000 cells/ml in Eagle's Minimum Essential Medium (EMEM). Once adhered, PLHC-1 cells were incubated with 3 different concentrations of each active principle tested: thymol (0 M, CTR-T; 10 M, T10; 25 M, T25; 50 M, T50) or sorbic acid (0 M, CTR-S; 100 M, S100; 250 M, S250; 500 M, S500). PLHC-1 were cultured for 48 hours and viability was measured by MTT test, by incubating cells with MTT 1mg/ml for 4 h, and subsequently adding DMSO to dissolve formazan, before analyzing samples in a plate reader. In parallel, PLHC-1 cells were incubated with the same concentrations of thymol and sorbic acid listed before and after 24h or 48h, 0.01% H_2O_2 was added in order to induce an oxidative stress. At both time points, it was measured reactive oxygen species ROS production, by adding dihydrorhodamine123 (DHR123) 10μM for 30min at 30ºC then reading fluorescence by flow cytometry, and mRNA expression of peroxisome proliferator-activated receptor alpha (PPARα). Data were analyzed with one-way ANOVA.

Results

Cell viability was not affected by thymol at any dosage after 48h. Sorbic acid significantly increased viability of PLHC-1 cells at all the dosages tested, compared to control *($P<0.01$)*. Sorbic acid did not show any effect on ROS production. T25 showed a significant decrease in ROS production after 48h and T50 significantly decreased ROS both at 24h and at 48h (*$P<0.05$*). PPARα mRNA expression was significantly decr ased by T25 and T50 at 24h, and after 48h all the thymol dosages tested significantly decreased PPARα expression (*$P<0.01$*). On the opposite, sorbic acid significantly increased PPARα, in a dose-response manner, after 48h of incubation (*$P<0.05$*).

Discussion

Our findings indicate that sorbic acid was able to increase viability of PLHC-1 hepatocytes, as well as increase PPARα mRNA expression. PPARα has a central role in inflammat ry responses and oxidative stress, and its activation stimulates antioxidant enzymes (Toyama et al., 2004). The positive modulation on cell viability, mediated by sorbic acid during the oxidative challenge, could be related to its ability to increase PPARα expression by modulating ROS scavenging, even if it was not possible to detect significant results about ROS production. On the opposite, thymol showed a significant decrease in ROS production, along with a reduction in PPARα expression. Considering that PPARα agonists are able to decrease ROS formation, the decrease in ROS production mediated by thymol could be related to an increased activation of PPARα receptors. This would indicate a negative feedback mechanism of regulation of gene expression: the lower the level of ROS, the higher the PPARα protein amount and the less transcription of new PPARα mRNA was required.

Conclusions

(Continued on next page)

The present data represent a preliminary study where an oxidative challenge protocol was optimized and where the effect of thymol and sorbic acid on fish hepatocytes during this challenge was studied. The research was aimed to evaluate their positive modulation on oxidative responses with the aim to prevent oxidative stress, since during stressful condition the balance of ROS production is disturbed. Both thymol and sorbic acid seem to exert a positive modulation by acting on different ways, scavenging ROS production or increasing viability and PPARα expression. Further analysis will be aimed to increase the panel of biomarkers aimed to define this mode of action, like oxidative enzymes and other markers involved in the inflammatory response

ENVIRONMENTAL SUSTAINABILITY INDICATORS APPLIED IN SMALL SCALE FAMILY FISH FARM AT THE ATLANTIC FOREST IN SOUTH AMERICA

E.M. Godoy, G.W. Bueno*, N.S. Fialho, M.R. Brande, F.C.M. Godoi, R. Roubach and F.S. David

São Paulo State University (Unesp), Aquaculture Center of Unesp (Caunesp), R. Quirino de Andrade 215, 9º andar, Centro 01049-010 - São Paulo - SP – Brazil
E-mail: guilherme.wolff@unesp.br

Fish farming practiced on small farms is an important economic and social alternative for local populations. However, the peculiarities of each production system adopted, the lack of standardization of the zootechnical management and the potential environmental impact of the fish production compromise the permanence of the producer in this activity. In this context, the present study aims to evaluate environmental sustainability through the application of indicators in family fish farms producing Nile tilapia (*Oreochromis niloticus*) in semi-intensive ponds in the Ribeira Valley region of Atlantic Forest, Sao Paulo state, Brazil.

The family farms were selected because they met the following criteria: i) produce Nile tilapia (*Oreochromis niloticus*) in earth ponds in a monoculture system; (ii) production for commercial purposes; iii) use of extruded feeds; iv) only use family labor. During a production cycle (8 months), three ponds (sample units) monitored in each fish farm, totaling six sample units evaluated. In fish culture A, production was carried out in a single-phase system: Phase I - fish weighing 1 g distributed in three ponds until reaching a minimum slaughter weight of 600g. In fish culture B, production was carried out in a two-phase system: Phase I - fish weighing 1g to 80g distributed in three ponds; Phase II - all fish (> 80g) were transferred to a single pond until reaching a minimum slaughter weight of 600g. The zootechnical, environmental variables and environmental sustainability indicators (ESI) based on four aspects: use of natural resources, efficiency in the use of resources, release and accumulation of pollutants and conservation of genetic diversity, according to the proposal by Valenti et al. (2018).

These data then used for the determination of the ESI of aquaculture enterprises and elaboration of performance scale diagrams (Figure 1). The fish farm A presented sub-index of 1.00 in relation to efficiency in the use of energy (E), nitrogen (N), phosphorus (P) and carbon (C), showing to be greater in 46%, 2%, 27% e 18% in relation to fish farm B, for E, N, P and C, respectively.

The environmental sustainability index for fish farms A and B were 0.95 and 0.75, respectively and influenced by the high generation of pollutants in fish farms. Thus, it is evident the importance of the use of tools that help in the correct definitions and limits to help the planning and direction of fish production in tropical waters, in order to minimize the impacts of aquaculture on the aquatic ecosystem. The results shown that this methodology is an efficient tool to help aquaculture managers and producers in the planning and organization of the activity in a sustainable way.

REVIEW ON SEX DETERMINATION PROCESS, ALL-FEMALE PRODUCTION AND GROWTH PERFORMANCES IN EURASIAN PERCH, *Perca fluviatilis*

Carole ROUGEOT

Aquaculture Research and Education Center (CEFRA), Liège University, 10 Chemin de la Justice, 4500 Tihange, Belgium
Email: C.Rougeot@ulg.ac.be

Introduction

The sex determination process in Eurasian perch (*Perca fluviatilis*), that display a sexual growth dimorphism towards females, is mainly under the control of genetic factors, govern by the sex chromosomes system XX/XY, with a probable autosomal influence as proven by sex reversal experiment, gynogenesis and hybridization. Beside this chromosomal control, sex steroids, mainly E2/11KT ratio, are strongly involved in the control of the development of the phenotypic sex, as important sex steroids levels are measured during all the embryonic period, from fertilization (maternal transmission) until the onset of histological differentiation of the gonad. Although the lability of sexual development was clearly established, no effect of temperature on sex differentiation process was described up to now for this species. This lability of the sexual development could be used to control the sex ratio and produce all-female population, that allow the improvement of the productivity under controlled conditions. This paper will review the bases of the sex determination process in E. perch, as well as the different methods of sex control, from hormonally sex reversal treatment to chromosomes set manipulation (triploïdisation and gynogenesis).

Sex determination process

Sex determination process in E. Perch is mainly under the control of sex chromosomes, with female XX and male XY chromosomic system with a probable implication of autosomes. The 11KT to E2 ratio plays a major role in the sex differentiation process in E. perch. No effect of temperature was reported under experimental conditions (Rougeot, 2019).

Sex control and all-female production

In E.perch, hormonal sex control and all-female production could be achieved within 2 generations by naturally or artificially crossing hormonally sex-reversed XX males breeders with normal XX females. The optimal treatment to obtain functional XX male is 5 to 10 mg MT per kg of food applied at 70 mg mean body weight during 30 days. The production of all-female population will allow to improve the productivity about 30% (fig.1)

Chromosomes set manipulation

The induction of 90 to 100% of triploid E. perch is obtained using a heat shock of 30°C, applied 5-7 minutes post-fertilization for 10 to 25 minutes with 45% of survival rate.

COMPACT PHOTOBIOREACTORS FOR LIVE MICROALGAE PRODUCTION IN AQUACULTURE HATCHERIES AND NURSERIES

A. Roulston*, S. Glover, J. Long, R. Roulston

Industrial Plankton Inc., 3378 Burns Avenue, V8Z 3P2, Victoria BC, Canada
Email: ashley@industrialplankton.com

Photobioreactors in Aquaculture

Availability of high quality microalgae is a bottleneck in aquaculture hatcheries and nurseries. Numerous species of nutritious microalgae are used to feed bivalve and crustacean larvae. In marine finfis hatcheries algae is used to tint water to enhance larval survival, or to nutritionally enhance zooplankton fed to larvae. In any facility, algae contaminated with pathogens (i.e. *Vibrio* spp.) can result in high larval mortality and lower growth rates. Traditional methods of microalgal production are unreliable and labour intensive, while substitutes such as concentrates and dried algae can degrade water quality as they decompose, increasing the organic load in the system and creating a substrate for pathogenic bacteria. Automated photobioreactors offer a compact and easier method of producing live algae onsite compared to traditional methods (e.g. figure 1). They are often more cost effective than substitutes and contribute less to the organic load in the water. Closed photobioreactors provide a biosecure culture environment and reduce the chance of culture contamination. This control over the microbial environment is of paramount importance since pathogenic or probiotic organisms introduced into algae cultures will be transferred downstream to livestock, impacting survivability and ultimately profits

Introduction

The land-locked central European countries rely heavily on common carp aquaculture in fishponds (e.g. Czech Republic, Poland, Hungary). There has been some debate between environmentalists and carp farmers concerning eutrophication of water bodies; often clandestine (Roy *et al.* 2019, unpublished). Over the years, share of fish meal in carp feeds has come down and use of alternative plant protein sources have intensified, generally rich in anti-tryptic factors or phytate-bound phosphorus. We undertook a systematic analysis of information from six-decades of literature data, focussing on common carp's dietary nitrogen (N) and phosphorus (P) supply and their footprints (faecal, metabolic losses) from artificial feedstuffs and natural prey or combined.

Materials and Methods

Data from 70 research articles on *Cyprinus carpio* digestibility published between 1973–2017 were analysed with additional data from 34 *C. carpio* growth trials to ascertain ecologically relevant dietary N, P levels under semi-intensive rearing conditions. Statistical analyses of numerical data (inter-quartile range (IR)), tests (ANCOVA, multiple regression) and modelling (GAM, LOESS) were done in R. All ranges are expressed in IR, except thermal growth coefficient (TGC; expressed in semi-upper IR to demarcate 'good' growth). All data are presented on dry matter (DM) basis.

Estimated N, P digestibility of cereals from metadata were validated through digestibility trials in our laboratory (Guelph system; 30% diet replacement method; 1% yttrium oxide as marker; 150-475 g carps). Apparent digestibility of N and P in commonly used cereals in Czech fishponds (wheat, corn, triticale) and carp's natural prey (daphnia, chironomid larvae, cyclops) were determined. Both literature data and our experimental results were applied to budget the faecal and metabolic footprints of dietary N, P of common carp in Czech fishponds, at national level

Results

Global metadata

Inter-quartile range (IR) of nitrogen (N) and phosphorus (P) content in feedstuffs were 5–8% and 0.7–1.2% of dry matter respectively with digestible N:P 7.2:1–44.1:1. N-digestibility IR (79–99%) was high, whereas IR of P-digestibility (27–47%) was rather poor. Dietary energy digestibility (gross energy and non-protein energy) was >76%. Higher P in feedstuffs caused signific nt negative interferences for N-digestibility. IR of nutrient content in carp faeces were estimated at 0.5–1.7% N and 0.4–0.9% P, with a 'eutrophic' N:P ratio (0.6:1 to 4.7:1). Considering the metabolic losses (16.9–30.7% of N intake), the N:P ratio of carp excreta seems 1.53:1–6.83:1, which is still 'eutrophic'.

Table 1: Nutrient footprint (faecal and metabolic losses) from supplementary feeding

Cereals	Natural food
Avg. N: 2.62% and P: 0.58%	Avg. N: 9.57% and P: 1.19% (DM basis)
24.1–44.9 kg N ton carp produced^{-1}	9.9–18.2 kg N ton carp produced^{-1}
8.7–11.6 kg P ton carp produced^{-1}	0.7–0.9 kg P ton carp produced^{-1}
N:P ~3:1–4:1	N:P ~14:1–20:1
Diffused footprint	
17–31.5 kg N and 4.7–6.2 kg P ton carp produced^{-1}	
Diffused N:P stoichiometry: ~ 9:1–12:1 (non-eutrophic)	

(Continued on next page)

Under semi-intensive system, digestible 'supplementary' nutrients (N: 3.3–4.9%, P: 0.2–0.5%; even lower) can support at least 0.6–1.2 thermal growth coefficient (reasonable growth) and be ecologically relevant. Eutrophication potential of faeces of carps seems linked to P-digestibility. While brewery wastes, microbial protein and natural prey offer high P digestibility (75–90%), knowledge gaps still exist in P digestibility of ingredients.

Application of global metadata and digestibility trial results

Production of 18460 tons common carp year^{-1} (CZ-Ryby 2019) by the Czech Republic (largest producer in EU) is supported by cereals (~2–2.5 FCR; 36920–46150 tons) and carp's natural prey (~0.3–0.4 FCR; 5538–7384 tons DM basis). Carp's excretory N, P footprints from both compartments (cereals and natural prey) and the diffused footprint is given in Table 1. Collating these values with 41080 ha of Czech fishponds (CZ-Ryby 2019), a spatial footprint of 7.6–14.2 kg N and 2.1–2.8 kg P ha^{-1} was apparent. Land-based agriculture in the Czech Republic has approximately 2–3 times the N (up to 32 kg ha^{-1}; Rosendore *et al.* 2016) or P (up to 5-6 kg ha^{-1}; Csatho *et al.* 2007, Kronvang *et al.* 2007) footprints. The N and P retentions in carp were ~28–36% and 39–50%, respectively.

Considering the complex dilution, assimilation and re-generation processes of nutrients occurring within the system (fishponds), we have adopted the principle of diffused footprint rather than cumulative footprint (Csatho *et al.* 2007). Afterall, it is not practical to assume that all excreted nutrients by carp are the actual residues; furthermore, digestive and metabolic losses with varying nutrient concentrations does not 'simply' add-up. Keeping the solution chemistry in mind, can explain the contradictions from studies accusing semi-intensive carp farming for eutrophication vs. studies not corroborating such allegations (Roy *et al.* 2019). Our preliminary estimates show that it is naïve to blame supplementary feeding (or present culture practices *per se*) in Czech fishponds for causing eutrophication. Rather, ways to improve N and P retention in carps should be the priority.

Disease outbreaks have been considered as a major problem for sustainable shrimp aquaculture. Amongst all, Vibriosis, caused by bacteria from Vibrionaceae family, is of major concern in farmed shrimps. In recent years, acute hepatopancreatic necrosis disease (AHPND), caused by toxic strains of *Vibrio parahaemolyticus* has severely damaged the global shrimp industry causing mortality up to 100% resulting in huge economic losses. In addition, other *Vibrio* species like *V. harveyi*, continue to cause significant mortality, especially at larval and post-larvae stages of farmed shrimps. Previously, antibiotics were used to prevent or cure bacterial diseases. However, due to the emergence of concern for antibiotic resistance, their uses have been restricted. Therefore, the development of alternative (preventive) strategies against disease in these commercially important animals is of major importance. Shrimp has only innate immune system lacking both specificity and memory. But, in contrast recently there are increasing number of evidences in invertebrates which suggests that phenotypic responses to environmental factors or any insults related to fitness which exposed to the animals persist across generations. In the present study, using brine shrimp as a model organism, we verified the possibility or impossibility for development of a disease resistance phenotype after application of the immunostimulatory plant-derived phenolic compound. Exposure of phenolic compound to the brine shrimp parental population induced and transmitted the resistance phenotype in 3 subsequent unexposed generations against pathogenic *Vibrios* and epigenetic reprogramming is most likely to play a pivotal role in the underlie mechanism.

IMPLEMENTING PRECISION FISH FARMING ON A RAINBOW TROUT FARM: A DATA ASSIMILATION APPROACH

Introduction

Innovations and decrease in costs of sensors are making it possible to apply to aquaculture the concept of "Precision Livestock Farming", introduced in the agrifood sector in early 2000. The implementation of the "Precision Fish Farming" (PFF) framework (Fore et. al., 2018) is likely to revolutionize the aquaculture industry, leading to a new generation of softwares and decision support tools, based on dynamic data and process driven models. At present, however, a few examples of PFF implementation can be found, concerning only the more mature industry, i.e. salmon farming. In this paper, a process based dynamic model of a "virtual" rainbow trout farm is presented, which includes a data assimilation algorithm, thus representing a first attempt of applying PFF to this aquaculture typology. This study was developed in the framework of the EU H2020 project GAIN Green Aquaculture INtensification in Europe (Grant Agreement 77330).

Methodology

Data Assimilation (DA) algorithms are being currently used in many scientific fields, e.g. mechanics, oceanography, meteorology, as they allow one to combine model output and field data as long as they are collected. The purpose of DA is two-fold: i) to correct the prediction of output variables, based on the information provided by any new datum; ii) to improve the estimation of the remaining state variables, which may include also some key model parameters. Key to that is the assumption that the state variables are regarded as stochastic ones: the dynamic of their expected values is driven by a set of governing differential equations but their fluctuation are driven by the differences between model output and observations. The core of the virtual farm model is a dynamic individual bioenergetic model of rainbow trout, which was identified on the basis of the literature and calibrated using a set of data collected at a trout farm in Preore, Northern Italy. The model equations (Brigolin et al., 2014) allows one to predict fish weight/length, on the basis of feed quantity and composition, as well as fish oxygen demand and ammonia excretion. This module was coupled with one simulating the dynamic of dissolved oxygen and water temperature, in relation to the oxygen level and temperature of the input. Two key parameters, i.e. the feed assimilation efficiency and the respiration rate, were included in the state vector and, therefore, treated as stochastic variables. The model was forced with hourly values of dissolved oxygen and temperature of the input water. DO and Oxygen data in the raceway system were collected every 15 minutes and processed in real time. Fish average size was determined weekly using the Vaki Biomass Daily System, purposely calibrated.

Results and discussion

Preliminary results show that the model allows one to accurately predict short term variation of DO, thus providing relevant information for managing the oxygenation system, in order to avoid hypoxic conditions and maximizing fish appetite. Furthermore, the model provides an accurate estimation of the feed ration, based on reliable short term predictions of fish average weight and of the feed assimilation efficienc , which is recursively estimated using the DA algorithm. Those findings will be further tested across a range of fish size and temperature/oxygen conditions. Subsequently, a population model will be developed, based on MonteCarlo methodology, in order to simulate the evolution of the whole weight distribution. Furthermore, the model will be used for assessing the local impact of the fish farm, in terms of release of Dissolved Inorganic Nitrogen in wastewater.

Introduction

In the past 20 years, aquaculture has been the fastest growing food production sector (FAO. 2014). The intensification of fish farming expose fish to stressful conditions and bacterial infections (Pulkkinen et al., 2009). One of the challenging diseases in the fresh water fish farms is columnaris disease, caused by *Flavobacterium columnare*, which can cause rapidly spreading epidemics and high in fish (Suomalainen et al., 2005). Antibiotic treatment is necessary and it is common that the farms are using several treatments in one season, increasing the risk of antibiotic resistance strains spread (Pulkkinen et al., 2009). A potential alternative for antibiotic treatments are bacteriophages (i.e. phages), viruses that infect bacteria. *F. columnare* phages are host specific and possible to isolate from the environment (Laanto et al., 2011). In this study, we screened the diversity of *F. columnare* and its phages in 10 different fish farms from Finland and Sweden. We were able to isolate phages that can infect virulent *F. columnare* strains. The large collection of well characterized phages and hosts allow us to study the potential for using phage therapy against columnaris disease.

Materials and Methods

Bacterial strains and phages were isolated from 10 different fish farms from Finland and Sweden using culture-based methods. Bacteria were genetically characterized using previously established methods (Suomalainen et al., 2006, Laanto et al., 2011, Kunttu et al., 2012, Almeida et al., 2019). The virulence of selected 34 strains was tested with rainbow trout fry. Host range of all new phage isolates was tested with 229 bacterial strains, and a subset of 15 phages isolates, infecting different host genotypes, were further characterized for their morphology using transmission electron microscopy (TEM).

Results

The 126 new *F. columnare* strains were clustered into genotype groups C (73), E (24), A (16) or G (8). Genotype could not be confirmed for some of the strains. Based on 16S rDNA, all strains from Finland belong to genomovar group I. Strains from Sweden belong to genomovar group I or I/II. In virulence experiment, the most virulent genotype groups were E and C, which caused 100% mortality within 15 hours post infection. 64 new *F. columnare* phages were isolated of which most infected the virulent C genotype host, the rest infecting genotype G and A hosts. Only from one fish farm were phages isolated that infected all three different kind of host genotypes. Based on the host range, most of the phages were host specific infecting same genotype group as the isolating hosts. Some phages had broader host range and were able to infect strains from two or three different genotype groups (including genotype E). TEM analysis indicated all phages belong to the *Myoviridae* family, and have icosahedral head and a stiff, unbending tail, (Figure 1).

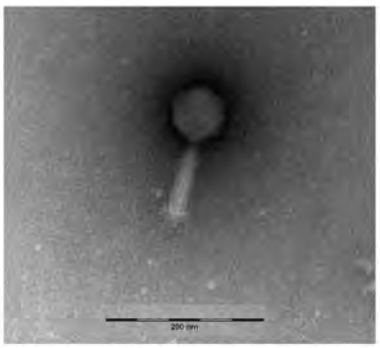

Figure 1. Negatively stained *Myoviridae* FCOV-F2, *F. columnare* bacteriophage. Icosahedral head and stiff, unbending tail. Imaged with TEM, 80 kV. Scale bar 200 nm.

(Continued on next page)

Discussion & conclusion

We isolated new *F. columnare* strains and their phages from Finnish and Swedish fish farms, and characterized the isolates. Our results support the previous findings of high variability in virulence among *F. columnare* genotypes (Suomalainen et al., 2006). Phages infecting both, highly virulent and less virulent *F. columnare* strains, can be isolated from the fish farms during columnaris outbreaks like mentioned before (Laanto et al., 2011). Our host range study indicate the isolated phages are able to infect and inhibit more than 90% of 229 bacterial strains in our collection. With these collections, we can start to plan and implement phage therapy against *F. columnare*. Combination of phages infecting different hosts could be used as part of phage cocktail to prevent or treat columnaris infections in fish

Introduction

Diet, among other factors, has substantial effects on stress tolerance and health, and therefore, fish must be fed an adequate diet that meets all their nutrient requirements for proper growth and resistance to stress and disease problems. In other words, feeding fish with an inadequate nutritional diet not only affects growth and feed efficiency but also increase susceptibility to disease and induces the appearance of deficiency signs, including altered behavioral and pathological changes (Oliva-Teles, 2012). Currently, some considerable effort is addressing the replacement fish meal and fish oil with other protein and lipid sources such as the plant-based (Lazzarotto et al., 2015).

Some researchers have shown that skin colour is highly dependent on the carotenoids present in the diet (Ho et al., 2013); therefore, skin colour can provide useful information for regulating proper feeding. Despite the importance of fish skin colour, very few studies have investigated the effects of different diets on fish skin.

Hyperspectral imagery (HSI) is an emerging technology that integrates both spectroscopy and imaging in a single system; is enabling simultaneous acquisition of spatial and spectral information from an object. Hyperspectral Imaging (HSI) has been used to quantify many fish and fish products features (Saberioon et al., 2017), However, to the best of our knowledge, the feasibility of HSI to determine the impact of diet changes in live aquatic organisms has not been studied. Therefore, the main aim of this study was to investigate the suitability of using the HSI system in Vis and NIR range (400-1000 nm) to evaluate the influence of two di ferent diets on live fish skin

Materials and method

The rainbow trouts were produced at INRA-PEIMA (Sizun, France). Experiments were designed in a split-block design with three replications for each diet; therefore, 80 fish were fed a commercial based diet (3 tanks) and 80 were fed a 100% plant-based diet (3 tanks). After three weeks, all fish were mildly anaesthetised and used for hyperspectral image acquisition in the wavelength range of 393-1009 nm. Diets were manufactured at the INRA NUMEA facility of Donzacq (France). The acquired hyperspectral images were corrected. Afterwards, the reflectance spectrum from the region of interest (ROI) was computed by averaging the spectral value of all pixels in the ROI for each sample. Finally, After spectra pre-processed, Support vector machine (SVM) as a classifier was employed to develop the classification models for discriminating two different diets.

Results

The Vis/NIR hyperspectral imaging for the two diets were similar but had differences in reflectance intensity in the range from 450- 750 nm and 900-1000 nm (Figure 1). It can be seen that the mean reflectance values of PBD are higher than CBD in most of the visible bands (450 – 750 nm), but the mean reflectance values of CBD are higher than PBD in NIR bands (900 -1000 nm). This implied that different diets had induced significant alterations to fish skin in a way that can be detected by spectral information. The differences between spectra might be mainly associated with how the different types of lipids, influence the absorption and deposition of carotenoids. In short, oils contain varying amounts of stanol and sterols which interfere with the uptake of carotenoids (Kalinowski et al., 2007).

The SVM classifier showed significant accuracy for classifying fish based on their diets (CCR = 0.83, Kappa = 0.6

(Continued on next page)

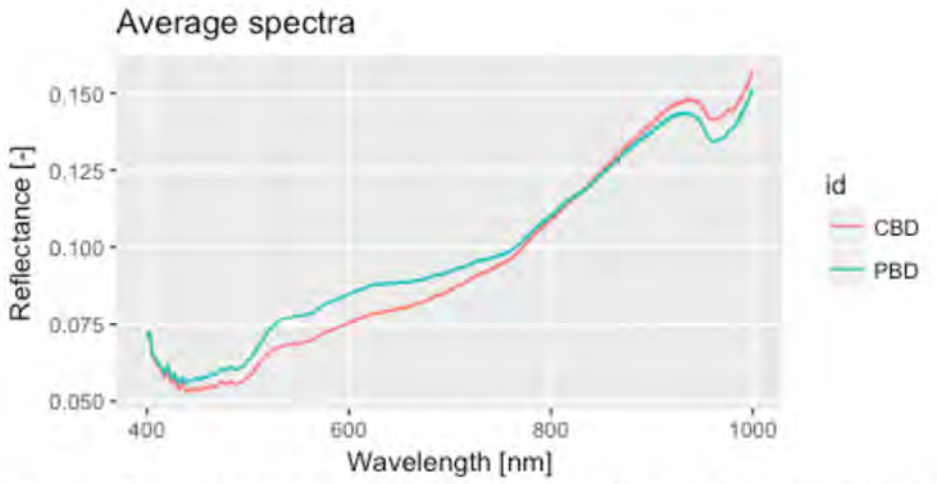

Figure1: The mean Vis/NIR spectral reflectance of rainbow trout skin for commercial based diet (CBD) and plant-based diet (PBD)

Discussion and Conclusion

The overall results indicate that Vis/NIR hyperspectral imaging combined with machine learning algorithms has the potential to be used as a rapid, accurate and non-destructive method to discriminate of fish based on their diet received during the cultivation. The skin pigmentation in farmed rainbow trout has commercial value because the high visual impact on the consumers and affects marketing prospects; therefore, the presented system in this study can provide more objective, accurate, fast tools in determining the effects of different diets on the external appearance of rainbow trout. Additionally, it will pave the way for a better understanding of the precision fish farming concept in aquaculture by controlling and monitoring of feeding impacts on fish skin during cultivation. Furthermore, it can be used in the better implementation of European Union regulation (EC 178/2002) on traceability of food and feed, food and feed producing animals, and substances intended to be incorporated into food and feed by providing diet information based on fish skin

ASSESSMENT OF THE EFFECTS OF *Nannochloropsis gaditana* ENZYME HYDROLYSATES ADDED INTO AQUAFEEDS ON GROWTH, MUSCLE COMPOSITION, PIGMENTATION AND OXIDATIVE CONDITION OF SEA BREAM (*Sparus aurata*) JUVENILES

M.I. Sáez*, A.J. Vizcaíno, A. Galafat, R. Cerri, I. Ruíz-Jarabo, S.T. Tapia, M.D. Suárez, T.F., Martínez, F.J. Alarcón

Introduction

The existence of a recalcitrant, cellulose-rich cell wall in *Nannochloropsis* sp. could limit the *in vivo* bioavailability of the intracellular components, so that the theoretical feeding potential of the microalgae might not be reflected on the animals, neither in terms of fish growth or physiological condition parameters (Cerezuela *et al.,* 2013). In order to cope with such limitations, some strategies aimed at disrupting cell walls prior to the inclusion of microalgae in aquafeeds have been proposed in the literature (Tibbetts *et al.,* 2017). Unfortunately, none of them can be considered as feasible in terms of practical application, due to a numerous list of constraints. Consequently, simple, economical, and cost-effective cell-wall disruption protocols are still needed, aimed at easing industrial up-scaling. In this regard, this study evaluate the use of hydrolytic enzymes capable of weakening *N. gaditana* cell walls, namely cellulases, prior to its incorporation into feeds. Cellulase enzymes have a wide range of industrial applications, so that they are available for feed-processing industry at affordable price, and consequently, any bioprocess that includes them could be easily scalable at industrial level. The overall objective of this *in vivo* study was the assessment of possible improvement in protein bioavailability, as well as on the occurrence of potential effects of microalgae as functional additive on growth, muscle composition, oxidative status, and pigmentation of seabream juveniles.

Materials and methods

N. gaditana biomass was obtained from Estación Experimental "Las Palmerillas" (Fundación Cajamar, Almería). Two formats of algal biomass were used: raw wet algal biomass (**RAB-C**) (about 20% DM); and freeze-dried algal biomass (**FAB-C**). A batch of both formats was subjected to cellulase enzyme hydrolysis (**RAB-H** and **FAB-H**, respectively). The enzymatic treatment was standardized in order to obtain a hydrolysate directly utilizable in feed processing at low inclusion rate (5% DM). Four isonitrogenous and isolipid (47% and 17% DM, respectively) experimental diets were elaborated at the CEIA3-University of Almería facilities (Service of Experimental Diets). A microalgae-free diet was used as control (**CT**). Gilthead sea bream juveniles were randomly distributed in 15 tanks (15 fish per tank) of 400 L tank. Animals were fed at 2% of the biomass .. Fish were sampled after 90 days, and biometric and morphometric analysis were carried out. Muscle proximate analysis (AOAC, 2000) and lipid oxidation (Buege and Aust, 1978) by thiobarbituric acid reactive substances (TBARS), were determined. Instrumental colour was measured on skin side of fillets by CIE (1986) L*, a*, and b* system. The parameters lightness (L*), redness (a*), and yellowness (b*) were recorded.

Table 1. Growth performance, nutrient utilization, skin colour (L*, a*, b*) parameters and TBARS muscle content of *S. aurata* juveniles.

Values are expressed as mean ± SD, (n=3). Values in the same column with different lowercase letter indicate significant difference ($p<0.05$).

(Continued on next page)

Results and discussion

Overall growth performance and nutrient utilization data are shown in Table 1. Fish fed with 5% of *N.gaditana* biomass diets showed figures similar to control group, although control fish showed significantly higher protein efficiency ratio than **FAB-C** specimens. Besides higher protein content (75.68 and 75.26 % DM respectively, p= 0.0030), in fish fed with diets including microalgae hydrolysates (**RAB-H** and **FAB-H**,), compared to control fish, no differences were found in proximate analysis.

Microalgae have the potential to synthesize low concentrations of biomolecules such as astaxanthin, lutein, carotene, among other nutraceutical compounds. Many of these microalgae-derived compounds can influence tissue pigmentation, and are recognized as health-promoting substances, mostly due to antioxidant activities (Nakagawa *et al.,* 2012). In this sense, taken as a whole, *N. gaditana* inclusion in diets affected a* and b* parameters (p=0.020 and 0.009, respectively). In general, the skin of microalgae supplemented fish, compared to control batch, were greenish (a*) and yellowish (b*), mostly due to differences b* observed for raw biomass hydrolysate. In addition, *N. gaditana* at low inclusion rate (5%) in diets caused a greater muscle antioxidant response (p<0.001). Similarly, this effect is more evident when microalgae biomass in diets was pre-treated with cellulase enzymes (**RAB-H** and **FAB-H**, p< 0.001).

Conclusions

The results obtained indicated that *N. gaditana* biomass at low inclusion rates (5%) in aquafeeds could have an impact on different aspects related to protein utilization, antioxidant activity and skin pigmentation of sea bream. In addition, a prior enzymatic treatment by celullases can increase the bioavailability of metabolites with potentially bioactive and functional effects. However, further research assessing the potential effects on digestive physiology, metabolism and fish immune response are needed.

FEED PELLETS CONTAINING pDNA AS ON-FARM STRATEGY FOR ORAL IMMUNIZATION OF AQUACULTURED FISH

M.I. Sáez*, A.J. Vizcaíno, T.F., Martínez, F.J. Alarcón

E mail: msc880@ual.es

Introduction

The need to control emerging fish diseases, mostly linked to intensive rearing, that constraint the aquaculture sector has driven different promising initiatives aimed at designing effective immunization strategies. In this context, research efforts have been focussed on the development of innovative vaccines, such as DNA-based, established on gene transfer for transient gene expression of immunogenic proteins. Compared to direct administration of antigenic proteins, which stimulate almost exclusively humoral immunity, DNA vaccines are able to stimulate both humoral and cellular responses, this fact ending up in efficient immune response (Tonheim *et al*., 2008). Nevertheless, commercial plasmid DNA (pDNA) vaccines are intended exclusively for parenteral administration, owing to the degradation of pDNA taking place during its transit through the digestive tract. On the other hand, oral administration is considered the ideal route for mass administration of bioactive substances in aquacultured fish, and besides being a simple delivery strategy, research has revealed growing evidence of the key role of the intestinal mucosa as part of the immune system of fish (Xue *et al*., 2013). However, stomach acidity and digestive nucleases cause together quick, extensive hydrolysis of orally delivered pDNA that ends up in loss of biological activity. In this sense, the protection provided by encapsulation in inert biopolymers might enable substances with interest in fish immunization to resist the gastrointestinal transit (Kim *et al*., 2014). In this regard, research aimed at carrying pDNA-nanoparticles at precise dosage in practical commercial feeds particles for farmed fish still remains a major challenge. The aim of this study was the assessment of preloaded feed pellets as a delivery system for pDNA, with the purpose of evaluating the potential administration of DNA vaccines orally in aquacultured fish. Pellets were made up by usual feed ingredients, which were mixed with chitosan nanoparticles entrapping a model plasmid (pCMVβ) expressible in eukaryotic cells, before being elaborated.

Materials and methods

The plasmid pCMVβ, integrating lacZ reporter gene encoding for *E. coli* β-galactosidase was chosen for this study as eukaryotic expression vector. The preparation of chitosan-nanocapsules was based on the protocol described in Sáez *et al*. (2017). An experimental feed was elaborated (**NANO-FEED**) adding chitosan-pDNA nanoparticle suspensions to the feed ingredients during the mixing step, prior to the granulation process. The diet was elaborated by LifeBioencapsulation S.L. (Almería, Spain). Two hundred and forty juveniles (16 ± 2 g) of gilthead sea bream were used in the assays. Oral administration (**NANO-FEED)** was conducted by pellets loaded with pDNA-chitosan nanoparticles in order to guarantee the ingestion of a total amount of 40 μg pDNA per fish during 1 day. Intramuscular (i.m.) injection of equal amounts of plasmid (**IM-pDNA**) and commercial β-galactosidase antigen (**IM-β-gal**, 10 μg) were also carried out with the purpose of comparing oral and i.m. administration. A **CONTROL** group with animals that did not receive any substance completed the experimental design. All the experimental groups were fed on control diet (without pDNA) throughout the experimental

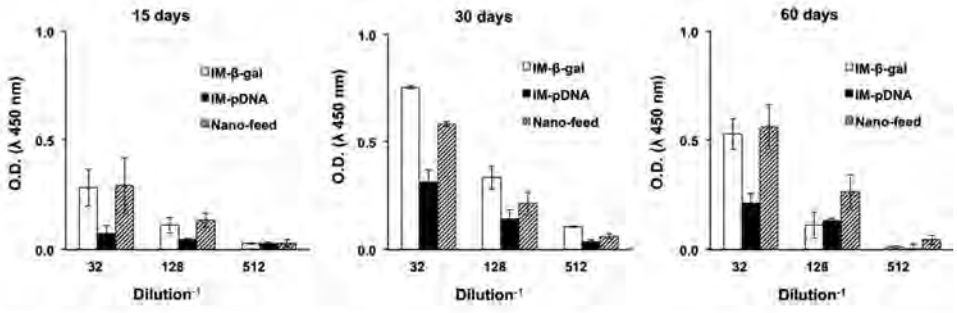

Figure 1. ELISA titration of anti-β-galactosidase IgM in fish sera. Animals were immunized by three different procedures: i) intramuscular administration of β-galactosidase enzyme (IM-β-gal); ii) intramuscular administration of pCMVβ plasmid (IM-pDNA), and iii) oral administration of chitosan-pCMVβ nanoparticles in feed pellets (nano-feed).

(Continued on next page)

period, except for the one-day oral administration of pDNA in NANO-FEED group. The possible *in vivo* expression of the exogenous gene was measured in different fish tissues during 60-d by two different procedures. On the one hand, the activity of the enzyme β-gal was detected and quantified in muscle, liver and intestine (An *et al*., 1982 and S-gal staining) on the other, specific IgM against β-gal antigen was titrated in blood samples by indirect ELISA..

Results and discussion

The expression of the reporter gene was detected in fish tissues following both oral and i.m. administration of pDNA up to 60 days. This period of sustained expression is, roughly, within the range described in other studies broaching oral delivery of pDNA (Rivas-Aravena *et al.,* 2013). However, organ distribution of the gene expression was more evident after oral (β-gal activity measured in gut, liver and muscle) than after parenteral administration (restricted to adjacent muscle tissues). In agreement, specific IgM titration indicated that humoral immune response was more intense and sustained throughout the experimental period after oral than after i.m. delivery of equal amounts of pDNA (Fig.1).

Conclusions

These results suggest that feed pellets containing chitosan nanoparticles might enable efficient oral delivery of pDNA, a fact that might imply valuable applications in terms of on-farm mass immunization purposes, especially with regard to DNA-based vaccines and small size fish, in which i.m. administration remains unfeasible. Moreover, it is also important to remark that the feed proposed here can be formulated according to the specific size of the target fish. In this regard, by adapting the feed particle size, fry could be orally vaccinated through feed loaded with pDNA entrapped in suitable nanoparticles.

Introduction

The interest in microalgae has come up strongly in the last years, given that they stand valuable, and yet mostly untapped, potential for reducing the dependence on unsustainable conventional raw ingredients used in aquafeeds. However, the existence of a cellulosic-rich cell wall in genus as *Nannochloropsis* joined to the unappreciable digestive cellulose activity in the gut of carnivorous/omnivorous marine fish (including gilthead seabream) could limit their digestibility and the further bioavailability of the intracellular nutrients. In this sense, a pre-treatment of the algal biomass seems to be needed in order to breaking these walls for improving the nutrient bioavailability of microalgae. Some strategies using mechanical pre-treatment have been proposed (Tibbetts *et al*., 2017) however, these processes can significantly increase the price of microalgae, which is already very high, which would probably make it impossible to scale up industrially. A cost-effective alternative can be the breakage by hydrolysis using cellulolytic enzymes. The use of these industrial enzymes could solve the problem and try to increase the bioavailability of the nutrients of the microalgae biomass. With this purpose, this work aims to assess the effectiveness of using a commercial cellulase from *Aspergillus niger* for cell wall disruption in the microalgae *Nannochloropsis gaditana.*

Materials and methods

Raw wet (RAB-H) (about 15% DM) and freeze-dried biomass (FAB-H) of *N. gaditana* provided by Estación Experimental "Las Palmerillas" (Fundación Cajamar, Almería, Spain) were used. Enzymatic hydrolysis was carried out using an *in vitro* model. For each assay, a known amount of each microalgal biomass, providing a final concentration of 15mg dry weight mL^{-1}, was suspended in 100mM sodium citrate buffer solution (pH 5.0) and incubated at 50ºC under continuous agitation for 4h in presence of a commercial cellulase. Samples were withdrawn at different times and immediately immersed in a hot water bath (100ºC) for 5 min for stopping the enzymatic reaction. To understand the degree of the hydrolysis process, the evolution of total reducing sugars released from microalgae were evaluated using the dinitrosalicylic acid (DNS) method according to Miller (1959). In addition, total amino acid released was also quantified (Church *et al*., 1983).

Results and discussion.

The results obtained after the glucose equivalent and free amino acids quantification revealed the efficacy of the enzymatic pre-treatment. Quantification of reducing sugars showed a significant increase in glucose concentration over the enzymatic reaction in raw wet and freeze-dried biomass of *N. gaditana*, reaching the highest values at the end of the treatment (Figure 1). Results evidenced a significantly higher breakdown of the microalgae cell wall in RAB-H compared with FAB-H, reaching values above 15g free glucose equivalent per 100 g of microalgae biomass. Similarly, the quantification of the free α-amino groups at the end of the enzymatic procedures revealed a remarkable increase of these when the algal biomass was enzymatically treated. The final concentration of free amino acids was significantly higher in RAB-H, reaching values greater than 18g free amino acids 100g of $protein^{-1}$, compared to those obtained in FAB-H (9.6g free amino acids 100g of $protein^{-1}$)(Figure 2).

Conclusions

Results obtained evidenced effectiveness of an enzymatic pre-treatment with cellulase represents for weakening microalgae cell wall as a promising tool for increasing the nutritional value by improving the bioavailability of intracellular components, especially in raw wet algal biomass. In this regard, a previous step for cell wall disruption/hydrolysis is recommended before including microalgae biomass in aquafeeds.

Introduction

The use of microalgae as functional additive at low dietary inclusion level has been considered as a promising strategy for improving the growth and the condition status of fish. Howeve , there are studies reporting that theoretical potential of microalgae is not necessarily reflected in a significant improvement on growth rates, or in other parameters indicative of general status of fish (Cardinaletti *et a*l., 2018). Indeed, the existence of the cell wall limits the digestion of microalgae and the further bioavailability of the intracellular nutrients (Wu *et al*., 2017). Therefore, pre-treatment performed on crude algal biomass may represent a useful tool for weakening the recalcitrant microalgae cell wall before inclusion in aquafeeds in order to facilitate the action of fish digestive enzymes for increasing nutrient bioavailability. In this regard, we hypothesize that low dietary inclusion level of enzymatically-hydrolysed microalgae might improve the digestive functionality of fish. With this purpose, the overall objective of this study is focused specifically on the assessment of potential effect of using microalgae hydrolysates as functional additive in practical diets for gilthead seabream juveniles.

Materials and methods

A feeding trial was carried out at the "Planta de Cultivos Marinos" of University of Cádiz (Puerto Real, Cádiz, Spain). 225 gilthead seabream juveniles were randomly distributed in 15 tanks of 400 L capacity at a density of 15 individuals per tank and fed at 2% of the biomass with five isonitrogenous and isolipidic (47% and 17% DM, respectively) experimental diets supplemented with 5% of *Nannochloropsis gaditana* in four different formats: i) wet crude biomass (**RAB-C**), ii) freeze-dried crude biomass (**FAB-C**), iii) enzymatically-hydrolysed wet biomass (**RAB-H**) and iv) enzymatically-hydrolysed freeze-dried biomass (**FAB-H**). In addition, a microalgae-free diet was used as control (**CT**). All experimental diets were tested in triplicate. At the end of the feeding trial (90 days), fish were euthanized by spine severing, and biological samples were obtained for determination of digestive enzymatic activities and study the intestinal mucosa by scanning electron microscopy (SEM). For enzymatic activity analysis, intestines from eight fish per tank were randomly pooled to obtain four enzymatic extracts from each experimental tank in order to determine leucine aminopeptidase (Pfleidere , 1970), alkaline phosphatase (Bergmeyer, 1974), trypsin (Erlanger et al., 1961) chymotrypsin (Del Mar *et al*., 1979) and total alkaline protease (Alarcón *et al*., 1998) activities. For ultrastructural analysis, SEM visualization fields were recorded, and digital images were analysed using UTHSCA ImageTool software to obtain several measurements of enterocyte apical area.

Results and discussion

The use of *N. gaditana* at 5% inclusion level did not affect negatively none of the digestive enzyme activities measured (Table 1). Fish fed on RAB-H, FAB-C, FAB-H showed significantly higher trypsin, leucine aminopeptidase and alkaline phosphatase activity levels ($p<0.05$) than fish fed on control diet. This fact might be related to an improvement in the efficiency of the digestive processes and the intestinal absorptive capacity. Brush border enzymes such as alkaline phosphatase and leucine aminopeptidase play a fundamental role in the final stages of digestion, allowing the absorption and transport of nutrients through the enterocytes, and they are used as indicators of the intestinal integrity or as a general marker of nutrient absorption. In addition, intestine mucosa plays a key role in digestion and absorption processes, and as protective barrier. The analysis of intestinal mucosa using SEM images confirmed the absence of damage or inflammation on the intestinal microvilli. Fish fed on microalgae hydrolysate-supplemented diets (RAB-H and FAB-H) showed a significant increase in the enterocyte apical area compared with control groups (Figure 2). The results obtained indicate that the use of microalgae induced a significant e fect on the morphology of the intestinal mucosa.

Conclusions

The results obtained showed that the use of *Nannochloropsis* as feed additive for feeding *S. aurata* juveniles increases the level of activity in several digestive enzymes. In the case of fish fed on microalgae hydrolysates it was found as additional effect a significant increase in the apical area of enterocytes which might reflect a higher mucosal absorptive surface in those specimens. More studies are now in progress for determining the effects of microalgae hydrolysates on fish growth and metabolism, fish immune response, antioxidant activity and skin pigmentation

ENDOCRINE AND METABOLIC EFFECTS OF PHE-ENRICHMENT DIETS FOR ATTENUATING STRESS IN FISH

Introduction

Stress is the most studied physiological process to assess the welfare state in farmed fish. For this reason some experiments have aimed at reducing the stress response through the use of food additives, such as essential amino acids (Herrera et al., 2017). It seems that phenylalanine (Phe) has mitigating effects on the stress system, probably due to its participation in the formation of the catecholamine hormones (adrenaline and noradrenaline) which are involved in the stress response (Saavedra et al., 2010; Herrera et al., 2017). Therefore the objective of this work is to study the physiological effects of Phe-enriched diets on two fish species, focusing on the stress system at both endocrine and metabolic levels

Material and methods

Seabreams with an average weight of 65.00±1.38g (mean±SE) and meagres with an average weight of 138.67±27.07g (mean±SE) were stocked at 20 fish/tank in 250 and 500 tanks, respectively.

Each fish species was fed two experimental fish feeds: control and control+5% Phe for seven days. At the end of the experiment, blood and brain samples were taken from 10 basal specimens and 10 specimens previously submitted to air exposure stress (3 min). The samples were analyzed using commercial kits and GC-MS; and plasma adrenaline, noradrenaline, triiodothyronine (T3) and thyroxine (T4), and brain Phe concentration were measured.

The concentration of brain Phe in meagre was higher in those specimens fed the enriched diet, however, in seabream there was only an increase in brain Phe in those fed the enriched diet and subjected to stress (Figure 2 A).

Phe-enrichment diet did not affect the T4 values in meagre, however, the T4 (Figure 2 C) concentration increased significantly in stressed seabreams. In meagre, the enriched diet led to an increase in the concentration of T3 in those specimens subjected to stress although no similar effect was observed in seabream (Figure 2 B).

Discussion

In gilthead seabream, the lack of plasma hormonal variations may be due to the fact that Phe concentration was too low for detecting effects, according to Herrera et al. (2017), who reported that only high concentrations of Phe produced endocrine effects in cod (*Gadus morhua*).

The accumulation of Phe in brain has not been previously described in fish and this first approach could indicate a quick response (accumulation) of this amino acid in seabreams after stress, although the effects on meagres could be more dependent on the feed type.

According to Peter (2011) an increase in adrenaline produces an increase in plasma T4 levels, this occurs in our results since for both species an increase in plasma adrenaline is associated with an increase in T4. The levels of T3 are lower since, as adrenaline precursor, favors the synthesis of this against the cortisol and therefore does not produce the conversion of T4 to T3.

Introduction

Egypt considered the 11th world inland capture fisheries, produced 231 959 tons and the 6th world aquaculture producer, produced 1. 371 million tons (1.7% of the world aquaculture production) (**FAO, 2018**). Egypt is also the 1st Mediterranean Sea, Arab and African aquaculture producer (**FAO, 2018**). Egyptian aquaculture development production has increased from 61.6 to 1370.66 thousand tons representing 20.5 and 80.3% of the total production in the years 1991 and 2016, respectively (**FAO, 2002, 2004; GAFRD, 2010; 2016**). Egypt aquaculture production divided to 68.60% tilapia, 11.21% mullets, 14.65% carps, 0.56% catfishes, 1.78% European seabass, 1.94% sea bream and 1.17% meager (**GAFRD, 2016**). Egypt European seabass total production in 2016 was 25681 tons divided to 1183 tons (4.61%) from capture fisheries and 24498 tons (95.39%) from aquaculture (**GAFRD, 2016**). Although Egypt has 9 legal marine hatcheries (3 governmental and 6 privet sector marine hatcheries) produced 44.224 million fry, only 5.686 million were European seabass fry production (**GAFRD, 2016**), Egyptian marine aquaculture still depending on fry collected from natural resources. Egypt total wild fry collection in 2016 were 51 million fry, most of the fry were mullets, shrimp and eels., while at the same time 0.900 million fry were European seabass and sea bream fry (**GAFRD, 2016**). European seabass are a gonochoristic species and gonads are undifferentiated during the first year of life (**Gorshkov** *et al*. **2004**). **Carvalho** *et al*. **(2014)** reported that sex control in fish is one of the most promising strategies in aquaculture. The European seabass females, which show 30 to 50% higher growth rates than males (**Gorshkov** *et al*. **2004**). The estradiol-17β (E2) hormone may change the morphology of gonads, negatively affects survival and impairs growth in addition to changing the sex ratio (**Piferrer, 2001**). **Wang** *et al*. **(2008)** studied effects of E2 on growth performance of bluegill sunfish and found that the fish in the E2 treated groups grew significantly slower than the control fish. This research work aims to study impacts of Estradiol (E2) sex reversing hormone and Marine Synbiotic enriched microdiets on the European seabass larval early weaning and physiology.

Materials and Methods

European seabass larvae four treatments were control greenwater (Inve O.Range® microdiet without treatment) (G), marine synbiotic (*Bacillus subtilis* HS1 probiotic bacteria 1x 10^7 CFU + 1 mg chitosan gm-1) treated Inve O.Range® microdiet (MS), estradiol sex reversing hormone treated Inve O.Range® microdiet (150 mg g-1) (E2) and marine synbiotic and estradiol sex reversing hormone treated Inve O.Range® microdiet (MSE2) treated Inve O.Range® microdiet (E2) stocked in 30 L^3 glass aquariums triplicates in the Fish Reproduction and Spawning lab. Marine hatchery. The marine synbiotic used in this experiment developed through by Dr. Hassan A. Ibrahim and Dr. Ahmed Md. Salem according to (**Salem, 2016; Salem and Ibrahim, 2015; 2017**). Larvae samples were randomly collected from treatments tanks for body length and some fish physiology parameters to statistically determine the length growth and physiology performances

Results

The larvae weaned in marine synbiotic treated microdiet achieved the best significant ($P < 0.05$) final total length, final standard length, total length gain, total length average daily gain, total length specific growth rate and total length gain% between 35dph and 50dph. The marine synbiotic treated achieved the best significant ($P < 0.05$) final total length condition factor, final standard length condition factor and survival rate %. The larval weaning using greenwater control non treated, achieved the highest significant ($P < 0.05$) aspartate aminotransferase U/l and alanine aminotransferase U/l. The larval weaning using synbiotic treated achieved the highest significant ($P < 0.05$) alkaline phosphatase U/l. The highest significant ($P < 0.05$) in acid phosphatase U/l achieved by marine synbiotic and estradiol E2 treatements. The larval weaning tanks using greenwater control nontreated, achieved the highest significant ($P < 0.05$) Albumin g/l. The marine synbiotic treated microdiets larvae achieved the highest significant ($P < 0.05$) body supernates total protein in g/l and globulin in g/l. The highest significant ($P < 0.05$) Glucose in g/l achieved by marine synbiotic and estradiol E2 treatment. The larvae fed estradiol E2 treated microdiet showed the highest significant ($P < 0.05$) body supernates triglycerides in mmol/l. The European seabass (*D. labrax*) larvae weaned in marine synbiotic and Estradiol treated microdiet decreased the negative impacts of the Estradiol on the larval length, weight growth, condition factors, survival rate % and immunity and liver function parameters.

A DIRECT AND STRAIGHTFORWARD METHOD FOR MEASUREMENT REAL MAXIMUM FISH STOMACH VOLUME TO IMPROVE AQUACULTURE FEEDING RESEARCH

Andrés Salgado-Ismodes, Ítalo Salgado-Leu and Iván Valdebenito

Escuela de Acuicultura, Universidad Católica de Temuco, Temuco, Chile
Email: asalgadoismodes@gmail.com

Introduction

A common method for investigating the diet of fish is the analysis of stomach measurement (Adeyemi & Akombo, 2012; Abdul et al., 2016). Various methods have been used to measure the maximum stomach volume in fish (Kariya et al., 1968; Kimball & Helm, 1971; Jobling et al., 1977; Burley & Vigg, 1989), but the most commonly used method has been the measurement of volume under 50 cm pressure head, described by Jobling et al. (1977). The main aim of the present study is to validate a simple and direct measurement method based on Archimedes' principle, which provides real value for maximum stomach volume in fish. Likewise, Archimedes' principle is commonly used in fisheries and fishing biology since several years ago (Yañez-Arancibia, 1975). The purpose of this study results is to apply this method to aquaculture fish feeding

Materials and methods

The experiment was carried out with thirty rainbow trout Oncorhynchus mykiss (Walbaum, 1792) juveniles. Before sampling, fish were starved for four days and then fed until satiation with commercial food, once per day. Fish weight and standard length were measured. Body cavity was opened, and the stomach was removed for the measurement of stomach volume under Jobling and Archimedes' principle methods. Also, the stomach and stomach contents were weighed to determine ratio stomach volume/stomach weight.

Results

Constants, potential models and determination coefficients according to relationships and methods are presented (Fig. 1). A good positive correlation between stomach volume and fish weight was observed in both the Archimedes' principle and Jobling methods, with the R^2 values of 0.68 and 0.56, respectively (Fig. 1a). The same tendency was found in the correlation between stomach volume and stomach content, with the Archimedes' principle method being higher than the Jobling's method (R^2 values of 0.95 and 0.68, respectively; Fig. 1b). Likewise, a good correlation was obtained between stomach volume and stomach weight, where the R^2 values in the Jobling's method were slightly higher than those of the Archimedes' principle method (Fig. 1c). The behaviour of the curves created by plotting the points (X, Y) of the various relationships is as follows: with the Jobling's method, the intersection of the curve with the Y-axis (0.0499, 4.3092 and 3.7867 in Figures 1a-1c, respectively) is higher in each case than the Archimedes' principle method (0.0007, 1.4467 and 1.6138 in Figures 1a-1c, respectively). The slope values obtained with the Jobling's method (1.059, 0.6439 and 0.7575 in Figures 1a-1c, respectively) were lower than with the Archimedes' principle method (1.829, 1.827 and 1.1143 in Figures 1a-1c, respectively), in each case producing a lower curve position within the coordinate planes.

Discussion and conclusion

According to the present experiment, the Archimedes' principle method is more effective and provides greater data precision in the measurement of real maximum stomach volume in fish, based on higher R^2 (means best curve adjustment) compared to results obtained by Jobling method. The following aspects demonstrate the method's superiority: 1) it yields the maximum real value of stomach expansion in a situation where a fish wants to ingest as much as it can, 2) the measurement process is simple and quick, and 3) relationships with stomach volume observed when using the Archimedes' principle method present values that are optimally adjusted and have greater certainty than values obtained using the Jobling' method. The higher stomach volume values obtained using the Jobling's method can be attributed to the forced expansion of the stomach, owing to the constant hydraulic pressure head of a 50 cm column of water applied by liquid entering the stomach and resulting in a higher curve position corresponding higher values of stomach volume (depending variable) for each independent variables (fish weight, stomach content, stomach weight) which is not the case with the Archimedes' principle method.

(Continued on next page)

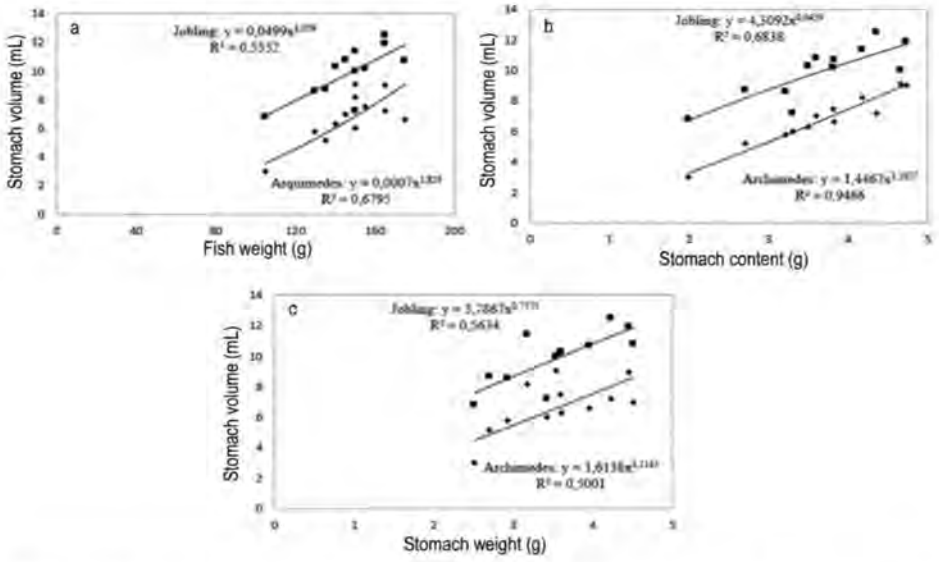

Figure 1. Relationship between stomach volume and a) fish weight, b) stomach content and c) stomach weight rainbow trout (*Oncorhynchus mykiss*) fed until satiation and following two assay methods. Each point represents an individual fish. Jobling method (▪, n = 12), and Archimedes method (♦, n = 12).

Thus, the same explanation can be applied to the ratio of volume to weight: if the same weight of the stomach divides both measured volumes, the Jobling's method will yield a higher value. According to the relationship between stomach volume and stomach content, the Archimedes' principle method presented a higher coefficient of determination than the Jobling's method; this could be because the first method considers the real maximum volume of the stomach, while the second considers the maximum forced expanded stomach volume. Because of this study, Archimedes' principle method is recommended to be applied in Aquaculture fish feeding research, due to its simplicity nature and accurately, which make more accessible the labor and time.

Introduction

Understanding the stress responses of organisms is of importance in the performance and welfare of farmed animals, including fish. Especially fish in aquaculture commonly face stressors, and better knowledge of their responses may assist in better husbandry and selection of breeding stocks. In this respect, European sea bass (*Dicentrarchus labrax*), a species with high cortisol concentrations in blood, is of major importance.

The main objectives of the present study were to integrate results from various experiments and different populations on individual divergent cortisol responsiveness in European sea bass. Special attention was given to the repeatability and consistency of cortisol stress response, the identification of individuals showing a consistent low (LR) or high (HR) cortisol response, and the physiological mechanisms regulating these responses.

Materials and Methods

European sea bass samples from a selective breeding program were studied. The analysis used both families (full- and half-sib) and individuals as factors. Three experiments were performed using 72 fish in Experiment 1 (6 families of 12 individuals), 960 fish in Experiment 2 (96 families of 10 individuals), and 400 fish in Experiment 3 (20 families of 20 individuals).

For the identification of consistent divergent cortisol responses a standardized acute stress protocol was performed. Specificall , fish in each tank were stressed once per month for 4 (Exp. 1) and 3 (Exp. 2 & 3) consecutive months by lowering the water of the tank (confinement) and then chasing them with a net for 5 minutes. Fish were left confined for 30 minutes, and then carefully netted, immediately anaesthetized in ethylene glycol monophenyl ether (300 ppm; Merck; 807291; USA) and blood was immediately collected from the caudal vessel via heparanized syringes and centrifuged (2,000 g; 10 min). The resulting plasma was stored at -20°C until analyzed for cortisol, corticosterone and adrenocorticotropic hormone (ACTH) using commercially available ELISA assays.

For the calculation of repeatability and the characterization of LR and HR individuals the Z-score of cortisol values was used instead of the raw data. This method was employed in order to control for variations in the cortisol data between the samplings and avoid the "noise" of such variation in the analysis to obtain repeatability estimates.

Table 1. Cortisol repeatability in the three experiments.

	Exp. 1	Exp. 2	Exp. 3
Repeatability	0.389	0.293	0.441

LR and HR fish were identified in all experiments. These fish were shown to differ in their free cortisol concentration, as well as in unstressed cortisol levels either before any stress sampling or one month after the last stress sampling. Moreover, these differences were stable 1.5 years after their characterization. These fish showed no difference in their post-stress and unstressed levels of ACTH. However, there were differences in the circulating levels of cortisone, and especially the ratio between cortisone to cortisol.

(Continued on next page)

The repeatability of the post-stress cortisol levels was assessed using the repeatability statistic, *r*. The consistency of the response within an individual across all samplings was tested by a nested ANOVA, with the factor Individual being nested in the factor Family. The null hypothesis was that individual Z-scores were inconsistent within individuals and hence the variable was not repeatable.

For the identific tion of LR and HR individuals, the sum of the Z-scores of all samplings was calculated for each individual fish and ranked. Fish belonging to the upper quartile of the distribution of Z-scores were identified as HR, and those belonging to the lower quartile as LR fish

Head kidney tissues of selected LR and HR individuals were superfused through an *in- vitro* superfusion system and stimulated with the same amount of ACTH to assess their cortisol biosynthetic capacity. Moreover, the expression of important genes in cortisol regulation was assessed.

Results

In all experiments a moderate to high repeatability coefficient was estimated, showing that cortisol responsiveness is an individually consistent and repeatable trait (Table 1).

LR and HR fish were identified in all experiments. These fish were shown to differ in their free cortisol concentration, as well as in unstressed cortisol levels either before any stress sampling or one month after the last stress sampling. Moreover, these differences were stable 1.5 years after their characterization. These fish showed no difference in their post-stress and unstressed levels of ACTH. However, there were differences in the circulating levels of cortisone, and especially the ratio between cortisone to cortisol.

Analysis of head kidney capacity to produce cortisol using the superfusion technique showed that HR fish were capable to produce more cortisol and for longer time when simulated with the same amount of ACTH. Furthermore, significant differences in the expression of genes involved in the signaling of ACTH in the head kidney (*mc-2r*) and the catabolism of cortisol (*hsd11b2*) were observed between these phenotypes.

Discussion

All the above underline the genetic component of the trait, which has been estimated at 0.34-0.36 (Chatziplis et al., submitted; Vandeputte et al., 2016), while quantitative trait loci (QTL) linked to this trait have been found (Chatziplis et al., submitted; Massault et al., 2009). Therefore, cortisol responsiveness could become a suitable candidate for use in selective breeding programs as a new selection criterion. Research regarding the genetic basis of this trait using SNP based GWAS is in progress aiming additionally at providing an in-depth study of the relation between cortisol responsiveness and resistance in three common diseases that infect European sea bass in aquaculture.

Introduction

Peroxiredoxins (Prxs) belong to the family of cysteine dependent peroxidases which is able to detoxify hydrogen peroxide, peroxynitrite and organic hydroperoxides (Abbas et al., 2005)cytokines, integrins and many other gene families playing key roles in the immune response are highly represented. IRIS also includes proteins of unknown function and expressed sequence tags that may not represent genes. The predicted cellular localization of IRIS proteins is evenly distributed between cell surface and intracellular compartments, indicating that immune specificity is important at many points in the signaling pathways of the immune response. IRIS provides a resource for further investigation into the function of the immune system and immune diseases.","author":[{"dropping-particle":"","family":"Abbas","given":"A R","non-dropping-particle":"","parse-names":false,"suffix":""},{"dropping-particle":"","family":"Baldwin","given":"D","non-dropping-particle":"","parse-names":false,"suffix":""},{"dropping-particle":"","family":"Ma","given":"Y","non-dropping-particle":"","parse-names":false,"suffix":""},{"dropping-particle":"","family":"Ouyang","given":"W","non-dropping-particle":"","parse-names":false,"suffix":""},{"dropping-particle":"","family":"Gurney","given":"A","non-dropping-particle":"","parse-names":false,"suffix":""},{"dropping-particle":"","family":"Martin","given":"F","non-dropping-particle":"","parse-names":false,"suffix":""},{"dropping-particle":"","family":"Fong","given":"S","non-dropping-particle":"","parse-names":false,"suffix":""},{"dropping-particle":"","family":"Lookeren Campagne","given":"M","non-dropping-particle":"van","parse-names":false,"suffix":""},{"dropping-particle":"","family":"Godowski","given":"P","non-dropping-particle":"","parse-names":false,"suffix":""},{"dropping-particle":"","family":"Williams","given":"P M","non-dropping-particle":"","parse-names":false,"suffix":""},{"dropping-particle":"","family":"Chan","given":"A C","non-dropping-particle":"","parse-names":false,"suffix":""},{"dropping-particle":"","family":"Clark","given":"H F","non-dropping-particle":"","parse-names":false,"suffix":""}],"container-title":"Genes and immunity","id":"ITEM-1","issue":"4","issued":{"date-parts":[["2005","6"]]},"language":"eng","page":"319-331","publisher-place":"England","title":"Immune response in silico (IRIS. Moreover, Prxs involve in cellular homeostasis, apoptosis, immune response, signaling pathways and cell growth. Peroxiredoxin 4 (Prx4) classified under the typical 2-Cys Prx class, based on their catalytic mechanism and position of cysteine (Cys) residues (Wood et al., 2003). Prx4 considered as effective H2O2 scavenger for Endoplasmic reticulum generated H2O2 (Tavender and Bulleid, 2010) and as a consequence, generates hydrogen peroxide. The production of hydrogen peroxide is thought to lead to oxidative stress that ultimately results in apoptosis. Here, we show that mammalian peroxiredoxin IV (PrxIV. Here we identified the HaPrx4 gene from the big belly seahorse transcriptome library, characterize biochemical properties and determine its innate immune responses following challenge experiment.

Materials and methods

Big belly seahorses were acclimatized at laboratory conditions (18 ± 2°C temperature and 34 ± 0.6‰ salinity) and spatial distribution of *HaPrx4* was analyzed in six healthy seahorse using qPCR. The immune challenge experiment was done for the four immune stimulants such as lipopolysaccharide (LPS), polyinosinic:polycytidylic acid, *Edwardsiella tarda*, and *Streptococcus iniae*. The mRNA expression level of *HaPrx4* in liver was explored by qPCR. The recombinant protein (rHaPrx4) was expressed and purified using the pMAL Protein Fusion and Purification System and insulin disulfide reduction assay was performed to determine the antioxidant activity.

Results

The open reading frame of *HaPrx4* is 777 bp which encodes for 258 amino-acids long protein with 28.81 kDa molecular weight. The theoretical pI is 6.36. Pairwise sequence alignment showed the highest similarity (93.5%) and identity (88.1%) with the *Miichthys miiuy* (Chinese drum) and multiple sequence alignment contained conserved 2-cys Prx motif 1(FYPLDFTFVCPTEI) and motif 2 (GEVCPA), including peroxidatic and resolving cysteines. Highest expression for the *HaPrx4* was observed in ovaries among fourteen tissues. The mRNA level of *HaPrx4* was significantly upregulated after the immune challenge experiment in the seahorse liver tissues. Insulin reduction assay showed the precipitation of insulin increased with the incubation time when increasing the rHaPrx4 concentration.

(Continued on next page)

Discussion and conclusion

Prx are thiol specific antioxidants which plays crucial role in homeostasis. The Prx motif 1 and motif 2 were highly conserved among other organisms Prx sequences, suggesting that catalytic function of HaPrx4 is conserved among different species. Also, phylogenetic analysis revealed HaPrx4 was evolutionary related to the teleost. The highest mRNA expression of *HaPrx4* showed in ovaries as a result of high ROS level in the ovaries when producing high energy for the reproduction activities (Faron et al., 2015). The prominent transcript level elevation exhibited in liver tissue to mediate the redox status during pathogenic infection. The results of insulin reduction assay showed the oxidoreductase activity of HaPrx4. Altogether, we characterized the molecular and functional levels of *HaPrx4* of big belly seahorse. Transcription levels of *Haprx4* were studied in wide range of tissues and prominently in ovaries. Moreover, immune challenge experiment revealed that HaPrx4 plays an important role in the innate immunity of seahorse against bacterial and viral pathogenic attack.

BREWERS' SPENT YEAST AND GRAIN AS ALTERNATIVE INGREDIENTS FOR AQUACULTURE FEED

D. San Martin*, B. Iñarra, M. Orive, A. Estévez, J. Nazzaro, R. Fenollosa, J.M. Martinez, A.M. De Smet, J. Zufía

AZTI, Parque Tecnológico de Bizkaia, Astondo Bidea, Edificio 609, E-48160 Derio (Spain
E-mail: dsanmartin@azti.es

Introduction

Aqua-feeds are formulated to contain all the essential nutrients that farmed fishes need to keep healthy and to maintain the benefits of seafood consumption. Currently, they are highly dependent on fish meal (FM) and fish oils (FO). Approximately, the 65 % and 83 % of FM and FO goes to aquaculture production, Tacon and Metian (2008). Samuel-Fitwi et al. (2013) have demonstrated that replacing FM by alternative ingredients, such as soybean or rapeseed, involves less environmental impact. The FM standard trout feed has an impact of 1,797 kg CO_2 equivalent per ton while the soybean and rapeseed meal based aqua-feeds has 1,019.65 and 1,037.13 kg CO_2, respectively.

Within this framework, alternative ingredients which successfully replace these marine components are required to result in sustainable and economical feeds. However, the suitability of these new ingredients will depend on improving feed efficiencies

Brewing industry produces large quantities of by-products in processing raw materials to beer: about 6 and 1 million tons of brewers´ spent grain (BSG) and yeast (BY). BY is often mixed with wastewater, while 70 % of BSG is used in fresh for feed, 10 % for biogas and 20 % landfilled, which implies the loss of a valuable product. However, the use of BSG as a direct supply for feed without any treatment can limit their feasibility. BSG and BY are characterized by their high protein content: about 20 % in BSG and 40 % in BY Therefore, brewers´ by-products stand as a potential alternative for replacing fish meal in aquaculture feed, due to their availability in Europe and their nutritional characteristics

Material and methods

The Brewery project aims to demonstrate the feasibility of the utilisation of Brewers' Yeast and Spent Grains in Senegalese sole, Sea bream and Trout feeding in the north-east region of Spain by carrying out five actions

1. Pre-Industrial optimization of processes for obtaining brewers´ by-products-based meal & aquafeed prototypes: An optimized drying process at semi-industrial scale will be developed obtaining 2 meal prototypes. Experimental aqua-feed diets including developed 2 meals will be formulated till optimum level of inclusion.

2. Design of a valorisation scheme for brewers' by-products including all stages of the value chain: The valorisation scheme will address the technical and administrative actions for each stage. It will be contrasted with Stakeholders.

3. Demonstration trial of the valorisation scheme applied to the case study: north-east region of Spain. A demonstration trial at a semi-industrial scale and in real operational conditions will be carried out. By-products will be taken from the most important breweries of Spain. They will be adapted and stabilized by an optimized drying process. Fish growth trial with developed aqua-feed will be carried out. Finally, the sensory quality of produced fish will be assessed

4. Feasibility assessment of the implementation of the valorisation scheme in an industrial reference scenario: The valorisation scheme will be assessed from the technical, economic, social and environmental points of view, as well as the eco-design of the valorisation plant at full scale.

5. Replicability and transferability of the valorisation scheme at European Level: The valorisation scheme will be replicated and transferred to EU. A comprehensive analysis of the replicability to 2 European areas will be carried out. A replicability and transferability plan will be performed in each of them.

(Continued on next page)

Results

The production of alternative ingredients for aquaculture feed based on brewers´ by-products has been validated from the technical, environmental and economic point of view. Four ingredient prototypes have been obtained through the combination of hydrolysis and drying process. The enzymatic hydrolysis as pre-processing prior to dehydration has been studied with the aim of assessing the increasing of the digestibility of ingredients. Then, an innovative and efficient drying process has been validated to stabilize by-products over time and to ensure their applicability in aqua feeds. Drying process consists of two steps: a low energy demanding dewatering process and, once the moisture has been reduced till 55 %, a highly efficient thermal drying process to achieve a moisture content of less than 10 %

The obtained four ingredient prototypes have been formulated and tested in digestibility tests with two fish species in RAS aquaculture systems: Sea bream (*Sparus aurata*), as a model of a Mediterranean aquaculture specie, and Rainbow trout (*Oncorhynchus mykiss*), as a model of a freshwater specie. Obtained results have shown acceptable digestibility results between 53,97 % to 93, 81 %. Hydrolysed prototypes have shown higher digestibility than non-hydrolysed.

Discussion and conclusion

Brewers´ by-products stand as a potential alternative for replacing FM in aquaculture feed, due to their availability in Europe, their nutritional characteristics and the obtained results in the digestibility trials with fishes.

All this involves an increase of the sustainability of aquaculture by providing new sustainable and economically advantageous protein sources that could replace fish meal. Their availability will contribute to reduce the environmental impact related to fish meal based aqua-feed. In addition, the reduction of aquaculture production costs will contribute to achieve the objectives established by the new European Common Fisheries Policy and the replacement of marine origin ingredients (fishmeal) will contribute to reduce significantly wild catches, contributing to achieve the goals defined in the Marine Strategy Framework Directive

Introduction

Production of bivalve molluscs spat in the hatchery encounters difficulties mainly associated with the conditioning of broodstock, and the settlement and metamorphosis of larvae. To settle and metamorphose larvae must be competent to respond to morphogenetic cues (Fitt et al. 1990; Morse, 1992). However little is known about the molecular mechanisms that take the larvae to metamorphose except for various chemical inducers that have been identified in different molluscan larvae. The γ-aminobutyric acid (GABA) has been shown to be an effective inducer in *Haliotis* sp., several clam species, oysters and mussels (Morse, 1992; García-Lavandeira et al. 2005;, Alfaro et al. 2011; Mesías-Gansbiller et al. 2008, 2013). IBMX was active inducing metamorphosis in gastropods but had not effect on the black scallop *Chamys varia* (Degnan and Morse 1995; Mesías-Gansbiller et al. 2008). The catecholamine epinephrine was effective in mussels and *Crassostrea* sp. (Coon et al. 1985; García-Lavandeira et al. 2005; Alfaro et al. 2011). L-DOPA potentiated metamorphosis in oysters and the mussel *Mytilus edulis* (Cooper 1982; Coon et al. 1985, 1986; Dobretsov and Qian, 2003; Mesías-Gansbiller et al. 2013). However, no inducers have been identified in the carpet shell clam *Ruditapes decussatus* (Linnaeus, 1758) so far. The aim of this work is the identification of inducers of the metamorphosis of *R. decussatus* larvae.

Materials and methods

One experiment of induction of the metamorphosis has been developed following the specifications described in García-Lavandeira et al. (2005) and Mesías-Gansbiller et al. (2013). Competent larvae of the clam *Ruditapes decussatus*, were supplied by the CIMA of Ribadeo and subsequently treated with several neuroactive compounds: GABA, epinephrine and norepinephrine, L-DOPA, serotonin, acetylcholine and IBMX. Three different concentrations of the possible inductor were used: 10^{-4}M, 10^{-5}M and 10^{-6}M and the exposure time to the inducers was 48 hours. Experiments were performed in triplicate in Petri dishes of 90 mm, for each one of the inducer concentrations and at a density of 4 larvae/ml. Each experiment included a control without potential inductor. Metamorphosis has been monitored with a Nikon SMZ-2T microscope. The percentage of metamorphosis was calculated as 100 (total number of larvae metamorphosed/total number larvae). A larva undergoes metamorphosis when has lost its velum and was using its foot to crawl.

Results were analysed by the SPSS 20.0 program. Percentages of metamorphosis and mortality were analysed by ANOVA. The results were considered to be significantly di ferent when $p<0.05$.

Results and discussion

GABA, epinephrine, norepinephrine, L-DOPA and IBMX did not increase the percentages of metamorphosis in *R. decussatus* larvae after a 48-hour exposure comparing to the control larvae. Maximum percentages of settlement were induced by acetylcholine and serotonin. Exposure to 10^{-4}M and 10^{-5}M acetylcholine induced significant levels of metamorphosis in *R. decussatus* with percentages of 76% and 75%, respectively, comparing to the control larvae ($p<0.05$). Exposure to 10^{-4}M and 10^{-5} M serotonin induced similar levels of metamorphosis, with percentages of 74% and 75% ($p<0.05$), respectively. The presence of acetylcholine, serotonin and other inducers did not affect the mortality of *R. decussatus* larvae comparing to the control larvae. However, it is important to point out that larval mortality ranged between 30-40%.

To our knowledge there are not previous studies of the induction of metamorphosis in *R. decussatus*. However, several authors have reported the role of GABA, epinephrine, serotonin and acetylcholine as active inducers of metamorphosis in the clam species clams *V. pullastra* and *R. philippinarum* (Urrutia et al. 2004; García-Lavandeira et al. 2005).

Introduction

Lectins are a class of proteins with special carbohydrate recognition domains. These proteins are able to identify carbohydrates and their conjugates by non-reversible covalent binding, forming cell aggregations (Yang et al., 2016).On the basis of their primary structure of their carbohydrate recognition domains (CRDs), structural folding, and cation requirements, animal lectins can be classified into several families, including C-, F-, P-, and I-type lectins, galectin, pentraxin, and others (Chen et al., 2011). C-type lectins are carbohydrate-binding proteins that depend on Ca^{2+} participation to recognize carbohydrates and glycoproteins and contain one or more carbohydrate-recognition domains. F-type lectin contain unique fucose- and calcium-binding sequence motifs and have been proposed to mediate molecular recognition in innate immunity (Anju et al., 2013)superoxide dismutase (SOD.

Materials and methods

Red lip mullets with an average body weight of 100 g were selected and acclimatized to the laboratory conditions. Five healthy fish were selected and blood and 11 other types of tissues were collected including the head kidney, spleen, liver, muscle, gills, intestine, kidneys, brain, skin, heart, and stomach by dissection. Another set of mullets was divided into four groups with 100 g average body weight and was subjected to an immune challenge experiment using Lipopolysaccharide (LPS), *Escherichia coli*, poly I:C and *Lactococcus garvieae*. After the challenge, tissues from the spleen & head kidney were collected from five individuals at 0, 6, 24, 48, or 72 h post injection (p.i.). After that the isolated tissues were subjected to RNA extraction and CDNA synthesis process. Finally, their molecular and transcriptional features were analyzed using bio informatics analysis and qRT-PCR.

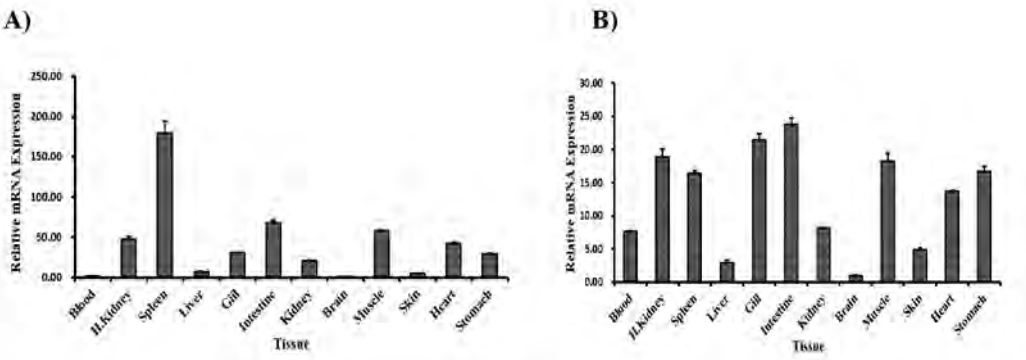

Fig. 1 A) & B) Tissue-specific transcriptional profiles of C-lectin A and F-type lectin in red lip mullets. The calculations were performed by the Livak method. Data are presented as mean ± standard deviation (n = 3).

(Continued on next page)

Results

C-lectin A consists with 462 amino acids with 52.76 kDa of predicted molecular mass. The theoretical pI calculated as 7.5. F-type lectin consists with 310 amino acids and 34.3 kDa of predicted molecular mass with 5.32 theoretical pI. In analysis of tissue-specific expression, the highest expression of C-lectin A was observed in the spleen, whereas F-type lectin was highly expressed in the intestine. Of note, we found that the transcription of C-lectin A and F-type lectin were significantl upregulated when the fish were stimulated with Lipopolysaccharide (LPS), *Escherichia coli*, poly I:C and *Lactococcus garvieae* suggesting that such immune responses.

Discussion and conclusion

This study provides an experimental insight into the molecular and transcriptional characteristics of C-lectin A and F-type lectin genes in the red lip mullet. Transcriptional analysis of C-lectin A and F-type lectin revealed their different distribution patterns in different tissues of red lip mullets. The mRNA expression levels of C-lectin A and F-type lectin were determined at different time points after the fish were challenged with bacterial or viral components. The significant changes in their expression allow us to propose possible functions of C-lectin A and F-type lectin in the innate immune system of red lip mullets. Overall, this study provides the experimental insight into the characteristics and immune-system relevance of C-lectin A and F-type lectin genes in red lip mullets.

erik.sandblom@bioenv.gu.se

Introduction

Carbon dioxide (CO_2) is still widely used to stun fish prior to slaughter in aquaculture, but the method has been criticized for resulting in poor welfare. Alternative methods such as electrical stunning, or means of alleviating the negative effects of CO_2, have therefore also been developed. Yet, knowledge gaps exist with regards to physiological stress responses and details on the mechanism of action of the various methods. This constrains further development of ethically acceptable stunning techniques for fish.

Materials and methods

In a series of lab studies on Arctic char (*Salvelinus alpinus*), an important cold-water aquaculture species in Sweden, cardioventilatory responses, blood physiological indicators of stress and behaviours were recorded during electrical field exposure (Sandblom et al. 2012), as well as during stunning with CO_2 exposure alone and in combination with excessive supply of oxygen (hyperoxia; Sandblom et al. 2013) or chilling (hypothermia; Seth et al. 2013), which have been suggested to alleviate the adverse effects of CO_2. The lab-based studies were further complemented with an on-site study where behaviours and blood samples for cortisol analysis were assessed in Arctic char prior to slaughter in a commercial facility using both CO_2 and electrical stunning in parallel (Gräns et al. 2016).

Results

Ten minute exposure to CO_2-saturated water at 10°C triggered aversive escape responses. These were accompanied by gradually reduced heart and ventilation rates, reduced blood pressure and moderately increased plasma cortisol levels before equilibrium was irrecoverably lost after ~3 minutes. Chilling to 0.25°C did not markedly affect behavior, cardioventilatory responses or the time until loss of equilibrium during CO_2 exposure, but the increase in plasma cortisol was significantly exacerbated. Ten minute exposure to 10°C water saturated with combinations of CO_2 and pure oxygen resulted in similar behavioral responses and plasma cortisol increase compared with exposure to pure CO_2. However, the hyperoxic CO_2 exposure resulted in a more variable cardioventilatory response, and fish recovered quickly when returned to water with normal oxygen levels (normoxia), which fish exposed to pure C_2 did not.

Electrical stunning (4V/cm, 125 Hz) for 5 and 30 s rendered the fish immediately motionless and was associated with a brief (~5 s) four-fold arterial blood pressure spike. Cardioventilatory arrest followed the 5 s exposure, but in ten out of eleven fish the cardiac activity recovered within 18-97s and ventilatory activity recovered within 38-733s after stunning. Nevertheless, signs of a systemic stress response were evident after the electrical exposure, which included elevated blood pressure, ventilation amplitude and plasma cortisol. After the 30 s exposure, cardiac activity initially recovered, but subsequently declined as ventilation never recovered.

In the on-site study, CO_2 exposure triggered aversive struggling and escape responses for 5-10 min before the fish became motionless. Fish exposed to an electric current became instantly motionless. On average, fish recovered from the electrical stunning within 5 min, whereas fish stunned with CO_2 did not recover. Electrically stunned fish had more than twice as high levels of plasma cortisol compared to fish stunned with CO_2. This result was surprising considering that the behavioural reactions were much more pronounced with CO_2 exposure.

Discussion and conclusion

Collectively, these data show that neither hypothermia nor additional oxygen reduce behavioral or physiological stress

(Continued on next page)

responses during CO_2 exposure in Arctic char. Moreover, additional oxygen results in quicker recovery if the fish is transferred to normoxic water following CO_2 stunning. While electrical field exposure rendered the fish instantly motionless, it appears that circulatory failure due to cardiac ischemia resulting from ventilatory failure is a principal cause of subsequent death. Thus, the relationship and timing of ventilatory failure and loss of consciousness following electrical stunning needs further study. For example, studies combining measurements of cardiac and brain electrical activities (*i.e.,* electrocardiogram and electroencephalogram, respectively) could be instrumental to evaluate consciousness and the welfare implications of this important finding. Moreover, the dramatic arterial blood pressure increase observed in char may partly explain hemorrhages and ruptured blood vessels that are frequently observed in electrically stunned fish of some species.

Introduction

Aquaculture is still growing. In order to keep this process going there is the need to find additional feed ingredients to increase the amount of available feed for aquaculture. Incorporating plant material in feeds for carnivorous fish imposes certain problems, such as anti-nutritional components, which are limiting the widespread and complete substitution of fishmeal and fish oil by plant materials. In general, aquaculture organisms only convert a fraction of the supplied feed into harvestable biomass. Simultaneously, dissolved and particulate nutrients are excreted into the waters. Applying the Integrated Multitrophic Aquaculture concept and thereby converting the excessive excreted nutrients with organisms of low trophic levels, such as polychaetes, is an opportunity to produce the required valuable biomass for the additionally required feed.

This study was performed to evaluate the potential of particulate matter originating from the culture of African catfish (*Clarias gariepinus*) to cultivate the polychaete *Hediste diversicolor* as a secondary organism. Furthermore, we investigated the effect of temperature on growth and fatty acid composition of *H. diversicolor*.

Materials and Methods

Three separated culture systems were applied. These systems were subdivided into three replicate tanks and a reservoir, which combined the aerobic biofilter and the pump sump for the re-distribution of the culture water. Each reservoir was equipped with an air pump and a submerged water pump and for each tank the same water exchange rate was adjusted.

Two of the systems were additionally equipped with cooling units, to set up the three systems with different culture temperatures (12°C, 16°C and 20°C).

Hediste diversicolor were stocked in a 10 cm sediment layer (average grain size 0.5 – 2.0mm), fed with particulate matter from a Recirculated Aquaculture System (RAS) used for the commercial production of African catfish. The intended daily energy content per individual worm was set to 1 kJ. The stocking density of the worms was approximately 830 individuals per m², which resulted in about 200 individual worms stocked in an average space of 0.24m² per tank.

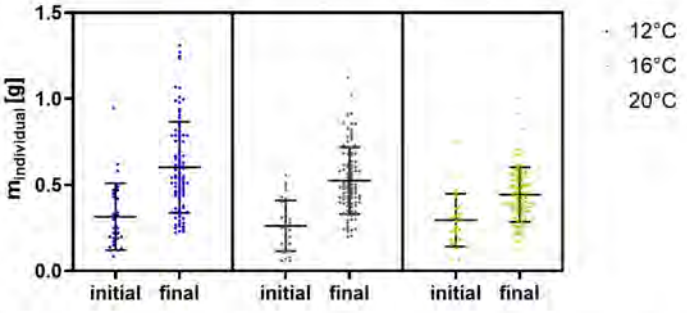

Fig. 1: Individual worm biomass recorded for the three different temperature treatments (left: 12°C; middle: 16°C; right: 20°C).

(Continued on next page)

The feeding experiment lasted for 28 days and during the feeding experiment temperature, salinity, oxygen saturation and oxygen content as well as pH were daily measured by a handheld measuring device. Furthermore, the dissolved nutrient concentrations (ammonium, nitrite, nitrate and orthophosphate) were analyzed to assure the required water quality for the worms. After stocking the worms to the tanks and an acclimatization of about 14 days, sub-samples of worms were collected from each tank and the average bodyweight at the start of the feeding experiment was calculated. This procedure was repeated at the end of the feeding experiment and the weight difference was used for calculating the Specific Growth Rate (SGR) of the differently treated worms. Further sub-samples were analyzed for their fatty acid composition.

Results

Water parameters were in the expected range and appropriate for the successful cultivation of *H. diversicolor*. Salinity, oxygen saturation and oxygen content as well as pH showed no differences, but the temperature differed significantly ($p<0.001$), resulting at 12.2 ± 0.2°C for system I, 15.8 ± 0.8°C for system II and 19.9 ± 0.8°C for system III. The dissolved concentrations of the analyzed nutrients were below the levels recommended for the culture of *H. diversicolor* (Bischoff 2007).

All groups showed a positive biomass gain but growth varied with the different temperatures (Fig. 1). The SGR decreased with increasing temperatures and was 2.47 ± 0.22%*d^{-1} for system I, 2.37 ± 0.24%*d^{-1} for system II and 1.45 ± 0.16%*d^{-1} for system III.

The analyzes of the fatty acid composition of the worms revealed significant spearman correlation between temperature and changes in fatty acid proportion for Oleic Acid (18:1cis-Δ9; ρ=-0.839), Linoleic acid (18:2cis,cis-Δ9,Δ12; ρ=-0.373) Arachidic acid (20:0; ρ=-0.588) Myristic Acid 14:0 (ρ=0.302), Palmitic Acid (16:0; ρ=0.291).

Discussion and Conclusions

Applying the particulate matter originating from the culture of African catfish under freshwater conditions to the polychaete *Hediste diversicolor* under brackish or seawater conditions is possible and leads to positive growth. These growth rates were comparable to literature under similar conditions (Bischoff 2007, Nesto et al. 2012, Wang et al. 2018) but lower compared to Santos et al. (2016). Nevertheless, the worms by Santos et al. (2018) where fed either commercial fish feed or non-proceeded makerell's filets, which were higher in protein, fat and ene gy content.

The correlation analyses revealed that the fatty acid proportions of *Hediste diversicolor* only correlated between the changes of ω−6 fatty acids and the temperature.

Introduction

RAS proteins are a family of GTP-binding proteins, which are involved in regulating the immune system, majorly NF-kappa-B-dependent pathways. The first evidence of that was found by Julian Downward who detected an RAS-dependent activation of T-lymphocytes (Wuebbles et al., 1990).

Mutation of these RAS proteins have disastrous consequences for the respective signal transduction pathways, including a misdirected signal transfer or cancer (GOODSELL, 1999). Therefore, RAS proteins were first identified as oncogene

KB-RAS is a small but potent RAS protein subfamily, whose members act as inhibitors of NF-kappa-B is (Chen, Wu, & Ghosh, 2003). KB-RAS proteins are encoded by the NKIRAS genes. The full length sequences of both KB-RAS orthologs (NKIRAS1 and NKIRAS2) were identified in rainbow trout, showing an incredible level of sequence conservation among different phyla. To date, little is known about the NKIRAS gene family in rainbow trout *Oncorhynchus mykiss*.

Here, we characterized the gene and protein structures of the NKIRAS gene family in *O. mykiss* and functional aspects of the members NKIRAS1 and -2. We also suggest a novel function for the KB-RAS2 isoform X4, which is absent in mammals.

Material and methods

Healthy rainbow trout (*Oncorhynchus mykiss*) weighing 80–100 g was purchased from a local rainbow trout breeding farm (LFA-MV Born [Germany]) for gene isolation.

RNA was isolated from the gills, head kidney, liver, and spleen of rainbow trout using TRIzol (Invitrogen/Life Technologies) and subsequently purified with the RNeasy Mini Kit (Qiagen). Total RNA was reverse-transcribed with SuperScript II Reverse Transcriptase (Life Technologies) after priming with oligo-d(T) and random hexonucleotides. We amplified and subcloned the open read frame (ORF) and inserted it in frame to v280- Mammalian Expression Vector previously double-digested with the same restriction enzymes. The final clones were utilized for functional analyses.

CHSE-214 cells were transfected, respectively, with vectors expressing pPLUM tagged with NKIRAS1 and GFP tagged with NKIRAS2 to monitor transfection efficacy and localize the proteins in the cell

CHSE-214 cells were co-transfected with increasing quantities (100-1000ng) of the plasmids expressing either NKIRAS1 or -2 and 50 ng of the ELAM- driven NF-kB reporter vector (ELAM-1-luc (Schindler & Baichwal, 1994)). Cells were stimulated either with $3x10^5$ CFU/ml heat-killed *Pseudomonas aeruginosa* or with 100 ng/ml, FSL-ST (Invivogen) for 24 h.

Luciferase activity of cell lysates was measured with the Dual-Luciferase Reporter Assay System (Promega).

Results

Preliminary results show that NKIRAS1 protein is acting as inhibitor of activated NF-kappa-B, but not NKIRAS2.

In contrast to mammals, NKIRAS2 seems to enhance the expression of immune-related genes. Fig. 1

Confocal microscopy confirmed the same sub-localization of the protein as seen in mammals previously. Both NKIRAS1 and NKIRAS2 are expressed in nuclei and cytoplasm (Fig. 2).

(Continued on next page)

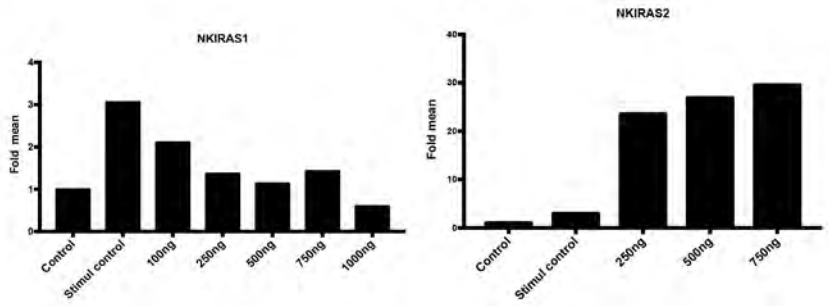

Fig.1: CHSE-214 cells were transfected with increasing quantity of plasmid containing, respectively, NKIRAS1 and NKIRAS2. Cells are stimulated for 24h with Flagellin or with heat killed *Pseudomonas aeruginosa*.

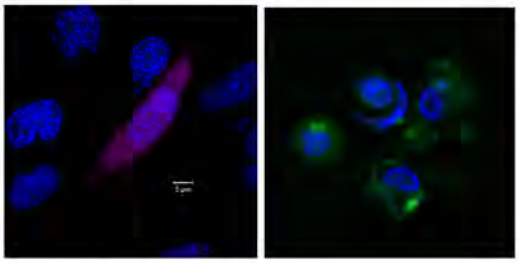

Fig. 2: CHSE-cells were transfected with 1000ng of vector expressing pmPLUM (NKIRAS1) and GFP (NKIRAS2). Cells nuclei were stained with Hoechst 33343dye and fixed with 4 Roti-Histofix 4%.

Discussion and Conclusions

NKIRAS1 and NKIRAS2 are described in literature as two inhibitors of NF-kappa-B (Fenwick, 2000). However, our results suggest that NKIRAS2 might have an additional function in rainbow trout. We observed that NKIRAS2 acts in a different direction than in a mammalian system. Our alignment of the amino acid sequence of NKIRAS2 isoforms highlighted a different N-terminus that could be responsible of the immune enhancing effect on trout. NKIRAS1 conserved its inhibiting function, as we found that it might silence the NF-kappa-B-dependent immune response with increasing quantity. The conserved structure of NKIRAS1 and NKIRAS2 suggests a well-preserved function during the evolution. Due to the whole-genome duplication in teleost fishes (Glasauer & Neuhauss, 2014), the presence of several and structurally different isoforms of NKIRAS2 must be taken in consideration for further studies.

Introduction

Feed industry contributes vital role in aquaculture. In that, fish meal is a major ingredient used to develop the fish and shrimp feed. Protein content of the feed has been decided a quality and price of the feed. Generally the fish unable to synthesizes fatty acids directly like linolenic, linoleic and arachidonic acid and whilst, decrease the production of fish meal we can move to the unconventional feed ingredients to replace fish meal. A disease free healthy stock can be achieved by feeding appropriate live feeds. Artificial feeds are not match to live feed organisms in terms of acceptance and nutritional factors. Live feeds have rich protein and essential fatty acid content (unsaturated fatty acids, HUFA) for better growth, efficient breeding, survival, sexual maturation and reproductive performance of cultivable organisms. Apart, live feed has organic acids, carbohydrates, vitamins, and minerals and hence they are commonly known as “living capsules of nutrition”. Polychaete worms have superior qualities than other live foods, so we can use polychaete worms as a live food for aquatic organisms.

Importance of Polychaetes in Aqua Feed industry:

Polychaete worms live in every type of habitat in the sea they can be found in the sands of any beach, all the way down to the deepest depths of the oceans. However, a few species live in freshwater and also abundant in seagrass beds and mangrove areas. Polychaetes worms could decay most of the organic matter present in the sediment or mud. Majority of them are filter feeders. Polychaetes are recently used as an ingredient in formulating feeds for fish, crustaceans and other organisms. It is used as feed in aquaculture either live, in blast frozen form, or as a constituent of formulated feeds. They are used as a maturation diet for shrimp broodstock (Olive, 1999). In commercial shrimp hatcheries, broodstock fed with live polychaetes, which promotes higher fecundity due to the high polyunsaturated fatty acids, especially arachidonic acid, eicosapentaenoic acid and docosahexaenoic acid in the polychaetes. Polychaetes used for improvement of diets in hatcheries and larval rearing units for both finfis and Crustacean. Whilst, polychaete worms are rich in carotenoids so incorporation of polychaetes in the diet of ornamental fishes may increase the colour pattern

The use of polychaete worms could ensures adequate nutrition for brood stock of crustaceans & fishes. They are rich in essential amino acids like Cystine, Proline, Leucine, Lysine, Aspartic acid, Threonine, Glutamic acid, Asparagine, Phenyl alanine, Histidine, Valine, Isoleucine, Glycine, Serine, Tryptophan, Alannine, Arginine, Tyrosine and Essential Fatty acids like Alphalinolenic acid, Linolenic acid, Oleic acid, Stearic acid, Palmitic acid, Moroctic acid.

Polychaete worms have a wide applications in aquafeed industry, live bait industry, toxicity testing and prevent coral bleeching because of its nutrient profile. Development of easy and economically viable culture techniques recommended to fulfil the polychaetes demand

Save polychaetes!!!
Save ecosystem!!!

GENERATION OF THEMATIC MAP OF MACROPHYTE AND INTERPRETING ITS EFFECT ON ICHTYOFAUNA IN BHIMTAL AND NAUKUCHIATAL LAKE

Sagar Kuveskar and Amita Saxena*

GBPUA&T, Pantnagar, Uttarakhand
Email-sagar.kuveskar14@gmail.com

Naukuchiatal is the deepest lake with an area of around 44.5 ha in Nainital, Uttarakhand. It houses a unique biodiversity. Along with Sattal and Bhimtal, this lake is being used traditionally as primary source of drinking and irrigation water. The thematic map was created showing the quality wise distribution of macrophyte in both the Lakes. Icthyofauna regarding species distribution in the lake was collected. Macrophyte analysis was done on site and the result were interpolated to see the effect of macrophyte on icthyofauna and result obtained were Naukuchiatal Lake has obtained more transparency then Bhimtal Lake which shows that there is a low concentration of suspended sediments in the Lake indicating that there is medium to dense population of macrophyte this will help to increase prey-predator interaction. Major species avalaible in both the Lakes are omnivores but *Puntius spp, Rainbow trout, Botia spp, Garra gotyla, Glyptothorx Cyprinus carpio, Tor spp, Ctenopharyngodon idella*, *Barilius bendelisis* are macrophyte eaters.

Introduction

India has many impoundments such as tanks, ponds, reservoirs, and lakes. Lakes and reservoirs are larger in size as compared to ponds and tanks. Lakes are large inland water bodies which are surrounded by land. They are also connected to streams or rivers. In India, there is no specific definition of the lake has been given. They are loosely described as different types such as natural, man-made and ephemeral consisting wetlands **(Reddy and Char, 2006).** Bhimtal and Naukuchiatal Lake are situated in the lesser Himalayan region of Uttarakhand in India. Naukuchiatal is mesotrophic with intermediate levels of nutrients **(Sharma *et al.*, 1985; Pant *et al.*, 1985; Raina and Petre, 1999; Chauhan *et al.*, 2009)**. But in winter it has found that the lake turns into eutrophic and causing fish kills (**Pant and Sharma, 1985).** Macrophytes are directly related to the ageing of the Lakes. The colonization of macrophytes especially rooted plants enrich the water with nutrients above normal resuspension of nutrients. This colonization stimulates production in pelagic water and sedimentation to produce more area for macrophyte colonization. Littoral vegetation with the basin morphometric determines the rate of Lake Succession **(Carpenter, 1981).** Fluctuations in submerged macrophytes are experienced not only in natural but also in managed ecosystems which as there plants affects the physical and chemical environment and thereby biota. The effect on aquatic biota including epiphytes, grazers, detritivores and fishes is visible due to the variation in macrophytes abundance and diversity **(Carpenter and Lodge, 1986).** Lakes such as Loktak Lake, Bhopal Lakes, Pong Dam Lake, Kanji Lake are infested by the Water hyacinth (*Eichhornia spp*.) causing endemic diseases by providing the optimum conditions for the breeding of aquatic vectors **(Reddy and Char, 2006)**. The fisheries resources are left untapped in the majority of the upland water resources. As they are the inland water resources, there is a lack of documentation and databases of water and fisheries resources for fisheries management of these areas. As compared to other inland resources, the manual data collection and analysis of upland resources including Lakes is more tedious and they are considered in inland fisheries. Upland Lakes and aquatic organism are getting disturbed by various anthropogenic activities, tourism, nutrient runoff, and macrophyte infestation, immediate mitigation and research should be carried out to analyze some factors affecting the Lake. As the upland Lakes such as Bhimtal and Naukuchiatal selected as study area of interest are less studied as compared to other inland water bodies. Remote sensing data has become a common and essential tool in GIS analysis. Many studies have demonstrated the effectiveness of using remotely sensed data as a powerful technology tool which has considerable potential in the monitoring of coastal resources such as mangroves, estuaries and other landforms. Remote sensing can give various indices by ecosystem status which includes a compact system of the surface ecosystem at a particular time and place **(Platt and Sathyendrath, 2008)**.

Material and method

Lake was divided into five grids. In each grid variety of macrophyte were noted. Location of macrophyte was note down with the help of GPS. Data was added in the excel sheet. X and Y data was feed in software. Shape file of the area was added in ArcGIS software. X and Y data was feed in software by mentioning X as longitude and Y as latitude. Project coordinate system was set as WGS_1984_UTM_Zone_44N. In Arctool Box, Geostatistical analytical was clicked in which IDW (Inverse Distance Weightage) method was used to create a layer. The thematic map was created showing the quality wise distribution of macrophyte. Icthyofauna regarding species distribution in the lake was collected and identified morphologically (Days 1889). Macrophyte analysis was done on site and the result were interpolated to see the effect of macrophyte on icthyofauna.

(Continued on next page)

Result

In Bhimtal Lake macrophyte were more concentrated in 79↑ 33' 15 " E longitude and 29↑ 20' 58" N latitude and in Naukuchiatal Lake macrophyte were more concentrated in 79↑ 35' 10 " E longitude and 29↑ 19' 14" N latitude.

Literatures were cited and sampling survey was done on Bhimtal and Naukuchiatal Lake shows that the lake has the moderate influence of macrophyte. Table 4.8 shows the name of macrophyte in both Lakes.

Some literature were cited and some of the parameters was taken into consideration for obtaining the effect of macrophyte on fishes and the result shows that macrophyte may have positive as well as a negative effect which can be directly or indirectly on fishes. Aquatic macrophyte are needed to keep the healthy fish stock in natural water but there over dominance may harm the aquatic icthyofauna present in water. Naukuchiatal Lake has obtained more transparency then Bhimtal Lake which shows that there is a low concentration of suspended sediments in the Lake indicating that there is medium to the dense population of macrophyte this will help to increase prey-predator interaction. Major species avalaible in both the Lakes are omnivores but *Puntius, Cyprinus carpio, Tor spp, Ctenopharyngodon idella* are macrophyte eaters. Macrophyte helps as food, spawning and shelter for fishes *Cyprinus carpio* needs Hydrilla for laying their eggs which acts as a substrate for attachment of egg and their survival and also eat some macrophyte, both the Lake have Hydrilla which will have a positive effect on fish. Grass carp are considered to eat 170 different species of macrophyte which shows it has feeding relation with macrophyte showing a positive effect**. Schuytema (1977)** suggested grass carp can be used as biological control of aquatic plants but pointed out at a number of negative impacts. As *Tor spp* prefereable food is *Myriophyllum, Chara* etc which shows that macrophyte is a part of the food chain showing a positive effect on icthyofauna. **Pathani (1980)** observed that *Tor tor* and *Tor putitora* feed on the submerged aquatic plants such as *Ceratophyllum spp, Hydrilla spp, Myriophyllum spp* and *Vallisnaria spp.* Both the Lakes are abundant with submerging macrophyte which will not affect the *Tor spp*. For *Puntius sp* macrophyte helps in shelter and feeding. Puntius favourite food is Hydrilla and Vallisneria. **Devaraj *et al.* (1977)** have tried to control aquatic vegetation such as by using the ornamental fishes such as *Puntius spp* and found that the fingerlings can feed on *Lemna spp* and *Hydrilla spp* at a rate of more than fifty percentage of their bodyweight. For all other species, macrophyte acts as sheltering ground during higher temperatures. A large amount of floating macrophyte may eventually decrease the light penetration leading to a decrease in dissolved oxygen level which may hamper the fishes, But both the Lakes have the least abundance of floating macrophyte and also the average dissolved oxygen in Bhimtal Lake was 9.0 mg/l and Naukuchiatal Lake was found to be 8.65 mg/l which shows that floating macrophyte is not affecting the icthyofauna. There is a negative relationship between abundance of submersed macrophyte and planktonic algae biomass **Canfield *et al*. (1984)**. Both the lake have more infestation of submerged macrophyte as they eventually uptake more nutrients which will lead to a decline in nutrient cycling that may lower the productivity of plankton. Fish that feed directly on plankton could be negatively affected. Biodiversity in Bhimtal Lake was found to be more than Naukuchiatal Lake. Macrophyte were found to be more in Bhimtal Lake like *Lemna, Azolla, Eichhornia, Polygonum.*

MONOCULTURE OF PIKEPERCH (*Sander lucioperca*) IN INTENSIVE SYSTEM OF IRAN

Mohammad Sayyad Bourani[1], Pourkazemi, M. Mortezaei, S.R, Valipour, A

mohammadborani@yahoo.com

Iranian Fisheries Science Research Institute, Inland waters Aquaculture Research Center,Agricultural Research Education and Extension Organization(AREEO), Anzali, Iran

Sander lucioperca (Pikeperch) is one of the economies known for its high quality meat, reduced natural resources, high prices and popularity among consumers as an ideal choice for commercial production. Intensive culture for Sander production are in the early stages of development in Europe and Asia. The habit of artificial feeding fish is gradual (the best temperature for rearing fish that has the best conversion factor, growth rate, protein efficienc , and instantaneous growth rate is at 22-23 ° C. The appropriate light period for breeding was 16 hours of darkness and 8 hours of light. 1718 intensively reared juveniles and stocked into four ponds for 240-day long culture in pond culture.

SGR was 0.762±0.441%.d-1, FCR = 1.8±1.2, FC = 0.72±0.09 and survival rate was 76.8% at the end of the 270-day rearing period. The fish density was observed about 15 kg per cubic meter. No difficulties were observed in adaptation of intensively cultured juveniles to pond conditions. During the study, it was obtained a high survival rate and excellent ability of pikeperch juveniles to consume dry feed after their re-adaptation to aquaculture system.

IMPACT OF HYPOXIA STRESS ON THE IMMUNE STATUS OF FARMED PIKEPERCH (*Sander lucioperca* L., 1758)

N. Schäfer[1]*, M. Verleih[1], T. Korytář[2], A. Rebl[1], J. Matoušek[2], J.Chabera[2], V.Stejskal[2], M. Stüeken[3], R. M. Brunner[1], J. A. Nguinkal[1], L. de los Ríos-Pérez[4], T. Goldammer[1]

Introduction

Pikeperch (*Sander lucioperca* L., 1758) is native to the northern hemisphere and increasingly important for the European aquaculture. It is susceptible to typical stress parameters in aquaculture like husbandry procedures and changing water conditions (Baekelandt et al. 2018). Low dissolved oxygen (DO) levels can have severe effects on the health of aquatic animals (Eissa and Wang 2016). Oxygen saturation is therefore an important parameter for the welfare status of farmed fish. Saturations below 40% are regarded as unfavourable for aquaculture facilities (Bregnballe 2015). In detail, hypoxia can be caused by high water temperatures, insufficient water circulation or high stocking densities, increasing the oxygen demand. Effects on the immune response of cultured fish due to adverse husbandry have been shown, amongst others, by Korytář et al. (2016). They demonstrated that high stocking densities induce specific immune pathways in kidney and liver of maraena whitefish (*Coregonus maraena* B., 1779). Until now only few details about the stress physiology of pikeperch have been evaluated (Milla et al. 2015). A comprehensive analysis of acute and chronic hypoxia stress affecting its immune system is fundamental for successful rearing practices and welfare maintenance in aquaculture. This work of the Campus bioFISH M-V was financed by the European Maritime and Fisheries Fund (EMFF) and the Ministry of Agriculture and the Environment Mecklenburg-Western Pomerania, Germany (Grant #: MV-II.1-RM-001). Furthermore it is part of the AQUAEXCEL[2020] project (TNA Identification Code AE080004).

Material and Methods

Pikeperch (mean weight 208g) were reared at 23°C for up to 28 days in recirculating aquaculture systems. The control group (n = 40) was kept under normoxic conditions (100% DO). The experimental group (n = 40) was kept under hypoxic conditions (40% DO). At day 1, 7, 14, 21 and 28 samples of peripheral blood, liver, head kidney, HK leukocytes, gills, spleen and skin were collected (Fig 1). Following analyses included the determination of blood parameters, cell compositions and transcript levels of possible biomarker genes.

Results

Preliminary data show that blood parameters like glucose, lactate and cortisol do not significantly correlate with stressed or unstressed fish. Furthermore, cytometry analyses indicate a change of immune cell composition within peripheral blood and head kidney leukocytes in stressed fish. Transcript level analysis of possible biomarker genes in liver and head kidney tissue suggests that hypoxic conditions activate stress-relevant signaling and immune-system pathways. Network analyses confirm the interaction of the investigated factors within the hypoxia-stress response

Discussion and Conclusions

The present study investigates the influence of oxygen deficienc on the immune status of farmed pikeperch. We conclude that acute hypoxia stress induces molecular mechanisms stimulating immune responses, especially the innate immunity. Chronic hypoxia stress, on the other hand, finally suppresses the immune system impairing the response to pathogens. With this work, we contribute to the knowledge on the stress-immune crosstalk in the novel aquaculture species *Sander lucioperca* and support regional farmers with identification of specific markers for a diagnostic tool assessing the health status in farmed pikeperch.

ASSESSING THE POTENTIAL OF THE COLD WATER SEA CUCUMBER SPECIES *Parastichopus Tremulus* FOR USE IN CIRCULAR AQUACULTURE

E. Schagerström*, K. Bladin, K. Sundell

Department of Biological & Environmental Sciences, University of Gothenburg, SE405 30 Gothenburg, Sweden
ellen.schagerstrom@bioenv.gu.se

Aquaculture in Sweden and Norway, although existing for several decades, have mainly focused on salmonids in monoculture. The recently formed research collaboration centre SWEMARC at Gothenburg University focuses on implementing new species and technology into local aquaculture, such as RAS and IMTA.

The CIRCULAR project evaluates the use of the aspidochirotide red sea cucumber *Parastichopus tremulus* as detritivorous component, eating the waste from e.g. fish, in an integrated marine aquaculture system consisting of cold-water species. *Parastichopus tremulus* is a species on which relatively few scientific studies have been made (e.g. Jespersen & Lützen 1971, Hauksson 1979, Holland 1981). It is mainly found on deep soft bottoms (35- >100m) in Scandinavia, and is occasionally caught as by-catch in trawl nets and lobster pots. They spawn during the summer months; reports show gonad ripeness between May-July (. Age of reproduction is unknown, as is growth rate.

We aim to develop a breeding protocol for *P. tremulus,* with studies on e.g. spawning induction, development time, effects of feed quantity and -quality for the auricularia and pentactula larvae on growth and survival. In order to determine the potential of this species in an IMTA, we have already performed studies on adult feeding efficiency and stress tolerances. Once the juveniles have developed, they will undergo these same studies in order for us to further assess the suitability of *P. tremulus* for farming in an IMTA.

Introduction

Due to the growth of the human population and the growing demand for seafood aquaculture is an increasingly important and fast-growing industry. In order to perform salmon fish farming in a sustainable, non-harmful and environmentally friendly way it is important to gather accurate information about fis welfare along with productivity indicators as this can serve as basis for optimal operation decisions. New enabling technologies i.e. advances in machine learning and underwater camera technology allow now for an individual based characterisation of farmed salmon. In line with the recently published Precision Fish Farming (PFF) concept [1] the continuous and automatic analysis of individual salmon based on high quality video recordings is a prerequisite for measuring the current state of the fish population with highest accuracy in a cost effectively way. In this work we present recent progress of the automatic characterisation of individual salmon seen in video-streams from full scale industrial fish-cages.

Material and Methods

One objective within the INDISAL project [2] is the automatic computer vision and machine learning based characterisation of salmon in fish-cages. In a first step we find and track the best visible heads of the salmon in a underwater fish-cage video stream and analyse the relative motion of the fish mouth. We exploit a recent deep learning based approach [3] for the detection of the salmon head and/or other fish-parts. In particular we introduced the classes “fish”, “eye”, “head”, “mouth” among others like “tail” and “topfin” which are useful for an automatic analysis of typical underwater recordings in fish-cages. The deep neural network was then trained with labeled data representing a large variety of scenes in order to work robustly in many different lighting conditions. After the training-phase real time video-streams or recordings can be analysed and clearly detected fish heads (where also the mouth and eye are found) are tracked and a subsequent computer vision based analysis of the relative motion of the mouth allows us to determine the “mouth opening frequency”.

Results

The developed approach robustly finds and tracks the most suitable salmon heads that are visible in underwater video-streams from a full scale industrial fish-cage. Initial results confirm that within an additional step we are able to classify a mouth as “open” or “closed”, thereby getting information about the “mouth opening frequency”.

Discussions and Conclusion

Within the presented approach we have the focus to determinate salmon status variables that can be objectively measured. In future work we intend to relate these objective measurements also to fish welfare indicators [4]. Additional fish-status variables one may consider to extract include appearance and behaviour based variables like size, shape, physical damages/ wounds, amount of lice, swimming speed, feeding activity, stress and possibly other welfare indicators.

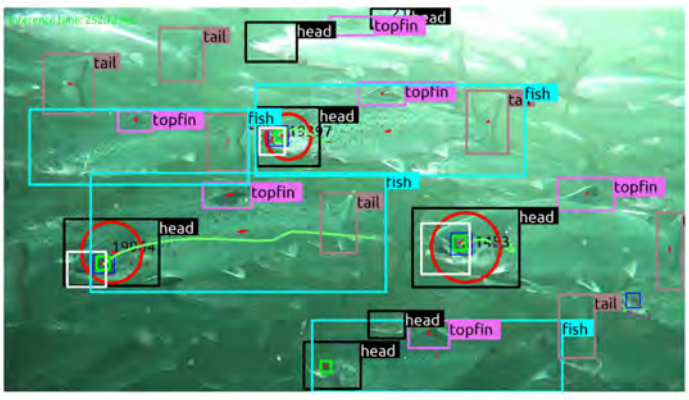

Fig. 1: The automatic recognition of salmon and fish-parts allows for example for a more detailed analysis of the mouth motion in the head region.

CLIMATE CHANGE IMPACTS ON THE EUROPEAN ISLANDS' AQUACULTURE SECTOR

Kyra Hoevenaars*, Tamás Bardócz, and Lena Schenke

*AquaBioTech Ltd, Central complex, Naggar street,Targa Gap, Mosta, Malta
Email: kyh@aquabt.com

According to the fifth Assessment Report of the Intergovernmental Panel on Climate Change, the warming of the climate system is unequivocal and continued emission of greenhouse gases will cause further warming and long-lasting changes in all components of the climate system, increasing the likelihood of severe and irreversible environmental impacts, which can induce large socio-economic damage. New policies on mitigation and adaptation are needed. In the field of Climate Change adaptation, policy makers must have detailed and accurate information about likely impact chains and about the costs and benefits of possible resilience strategies corresponding to the potential decarbonisation pathways. EU islands are particularly vulnerable to Climate Change consequences.

The SOCLIMPACT project aims at modelling and assessing downscaled Climate Change impacts and low carbon transition pathways in European islands and archipelagos for 2030-2100, complementing current available projections for Europe, and nourishing actual economic models with non-market assessment. The project is developing a thorough understanding on how Climate Change will impact the EU islands located in different regions and focuses on the Blue growth sector.

One of the fast-growing Blue Growth sectors is aquaculture. Aquaculture accounts for 20% of the fish production in Europe. Climate change impacts and risks for the sector were identified based on climate hazards, vulnerability factors and exposure.

The main risks for marine cage aquaculture recognised are:

- Change in production due to changes in seawater characteristics and temperature
- Increased fragility of the aquaculture activity due to extreme events
- Increased environmental pollution from aquaculture sites due to changes in coastal hydrodynamics

Impact chains for these risks have been developed and operationalised to identify the major risks and enable comparison between risks and islands.

ZEBRA-MUSSEL (*Dreissena*) CULTIVATION IN BALTIC COASTAL WATERS – AN OPTION FOR BLUE GROWTH AND WATER POLICY IMPLEMENTATION?

Gerald Schernewski*[a,b], Rene Friedland[c]

1. Introduction

Blue and zebra mussels (*Dreissena*) are naturally occuring the the Baltic Sea and its coastal waters. Both species are generally suitable for suspended cultivation in mussel farms. Despite that, commercial mussel farms are an exception in the Baltic Sea. Reduced salinity and the associated slower growth hardly allows a cost-covering blue mussel production for human consumption. Zebra mussels, who prefer low salinities, are too small for direct human consumption. However, both species are suitable for the production of mussel meal, which could serve as feed in fish aquaculture, replacing fish mea

The European Commission Regulation (EC 710/2009) provides detailed rules on organic aquaculture animal and seaweed production. Feeds for carnivorous aquaculture animals, for example, need to be organic and preferably of local origin. A sustainable mussel farm could provide organic feed meal and could favor organic fish aquaculture, which is hampered by limited feed availability, quality and/or high feed costs.

The Blue Growth Strategy is the European long-term attempt to support sustainable growth in the marine and maritime sectors. The European Commission intends to boost the aquaculture sector and EU countries were asked to set up multiannual plans to promote aquaculture. However, with respect to mussel farming the production trend in Europe is decreasing since the beginning of the century, whereas it is still increasing fast in other parts of the world. The same is true for the production of organic fish in German , which decreased by 35% since 2013 (EUMOFA 2017, www.eumofa.eu).

Mussel farms not only provide food and protein-rich feed. Blue and zebra mussels are efficient filter feeders, which reduce phytoplankton concentrations and bind the nutrients nitrogen and phosphorus. According to HELCOM (www.helcom.fi), eutrophication is still one of the main threats to the Baltic Sea and is caused by excessive inputs of nutrients to the marine environment. When farmed mussels are harvested, the nutrients are removed and this process counteracts eutrophication. Additionally, mussels increase water transparency. Within the EU Water Framework Directive, blue mussel farms are already discussed and tested as a measure to combat eutrophication in coastal waters.

With focus on zebra mussels (*Dreissena*) in selected Baltic coastal waters, we address the questions: Is it realistic to produce mussels as fresh feed and meal on a commercial basis and support Blue Growth? Can zebra mussel farming play a role as measure in the Water Framework Directive (WFD) by removing nutrients and combating eutrophication? Can it play a role for improving water transparency and enabling macrophyte restoration? Is it possible to use mussel cultivation to improve transparency and attractiveness of bathing waters at beaches? This presentation summarizes most recent findings by Schernewski et al. (2018) and Friedland et al. (2019a, 2019b).

2. Methods

For this study we improved an ecological model added an economic model, collected a wide range of data and carried out field and feeding experiments as well as surveys among tourists and local inhabitants. The ecological model consist of a coupled 3d-hydrographical-biogeochemical model (GETM-ERGOM) linked to a mussel module. We present the results for several spatially explicit and realistic scenarios of mussel farming.

(Continued on next page)

3. Results

Zebra mussel farming seems to be a suitable measure for removing nutrients, raising water transparency and improving ecosystem quality, but its quantitative potential in our case study site, the large, shallow Oder Lagoon, is limited. In smaller water bodies with less external nutrient loads, zebra mussel cultivation may be a suitable water quality management option.

In the Oder Lagoon, mussel cultivation could be implemented for concrete local purposes, like small scale feed production, improving water transparency at beaches or as environmental measure to enable macrophyte recovery. Zebra mussel cultivation in the lagoon would not be profitable as a business, because the market for fresh feed mussels is limited (animal parks, aquaculture) and mussel meal production would require a large production. Zebra mussel farms would produce feed of high quality that could serve as replacement for fishmeal. It would meet the standard for organic certified production and could support organic fish aquaculture (Naturland, https://www.naturland.de). The demand and price for such a product may increase in future and may make a commercial production realistic. Our model simulations suggest that as soon as a compensation for nutrient removal is considered, all mussel farm scenarios could cover the costs. Further, our experiments confirm that the conditions for an environmental friendly farming approach in the lagoon are suitable

From a practical point of view, the positive effects of mussel farms on water transparency are, at the moment, most important. Even to establish mussel farms in the surrounding of beaches to improve bathing water transparency, was perceived as a worth considering option by our local and regional stakeholders. However, the potential water transparency improvement (Secchi depth) seems limited to about 20 cm. A higher mussel biomass may cause negative impacts on the environment and increase the risk of hypoxia.

Most promising in our stakeholders' view are mobile mussel farms, which increase water transparency in shallow areas (water depth below 2 m) and initiate a recovery of submerse macrophytes, without disturbing already established submerse macrophytes. These mussel farms could potentially be moved to other places once the macrophytes are re-established. A temporary installation was perceived as a major advantage, because it limits potential local negative effects of mussel farms on sediments and the re-use in a different place would reduce costs. However, this has not been tested so far and additional field experiments are necessary to confirm the suitability of such an approac

DEVELOPMENT OF A NOVEL, LAND-BASED AQUACULTURE PROCESS FOR THE PRODUCTION OF MARINE SPONGE *Chondrosia reniformis* AND THE PHARMACOLOGICAL USE OF SPONGE COLLAGEN

K. Schiefenhövel*, M. Schiffer-Harms and J. Henjes

Alfred-Wegener-Institute, Knowledge and Technology Transfer, Aquaculture Research, Am Handelshafen 12, 27570 Bremerhaven, Germany
*Email: karin.schiefenhoevel@awi.de

Introduction

Marine sponges are one of the most important sources of bioactive compounds used in medicine, industry and as nutraceuticals. As sessile organisms, sponges have developed chemical defense mechanisms to avoid the covering of algae, bacteria and infectious microorganisms (Chanas et al., 1996; Thoms et al., 2006). Regarding the development of nutraceuticals *Chondrosia reniformis*, a sponge species from the Mediterranean, is of special interest due to their high amount of collagen (Swatschek et al., 2002). To gain a high yield of collagen, plenty of sponge biomass is needed. Avoiding exploitation of natural resources, special culture techniques need to be developed. Experiments showed, that mariculture is not an adequate technique for a mass reproduction of *C. reniformis* (pretrials by KliniPharm, 2004). A land-based cultivation and high mass production of *C. reniformis* and the associated collagen could not be realized yet, because the animals are very sensitive to transportation and make high demands on culture conditions (Nickel and Brümmer, 2003; own experience, 2018 and 2019).

The project AkPhaKol will address the detection of convenient recirculating aquaculture system conditions for *C. reniformis* fragments to build up a sustainable source for sponge biomass accompanied by a maximized collagen production. Reduction and loss of microorganism associated with the sponge species as well as nutrient content in the culture water shall be minimized by an optimized design of culture tank and water treatment. In addition a specific adapted food for this species shall be developed, which is not available on the market yet. The project partner KliniPharm GmbH will be provided with the extracted collagen from sponges. It will be used for the manufacturing of coatings for solid pharmaceuticals relating to the application of colon-targeting.

Materials and methods

Evaluation of adequate rearing conditions related to amount and content of collagen of *C. reniformis*, tests on culture methods, holding structures, abiotic factors and nutrition are conducted at the Alfred-Wegener-Institute. *C. reniformis* were obtained from the sampling area located in the Mediterranean Sea around the Island Kalymnos, Greece and subsequently raised in a recirculation aquaculture system at the Centre for Aquaculture Research, Bremerhaven. Despite sponge specimen collection, substrate structure, abiotic factors and composition of nutrient matter of the native marine water of *C. reniformis* are collected and identified in laboratories. Data are used for the developing of a special tank design, evaluation of the optimal rearing conditions and the detection of adequate food composition.

After cutting of sponge specimen, sponge fragments were glued to an artificial substrate and abiotic factors like temperature, light and current are tested and the effects on survival, growth and collagen content are examined. In a further experiment, feeding trials like feeding strategies and different food types are tested on sponge fragments: a self-developed food, commercial available liquid food for filter feeders and the detritus from fish or shrimp culture. Fragments growth, survival rate and collagen content are measured in specific intervals

Results

Running-in of culture tanks with water retreatment processes was successful; the values of abiotic factors adjusted to native conditions like temperature, light, current and nutrient content remain stable. Efficient transportation conditions as high water volume and cooling were essentials for survival of sponge specimen. One week after arrival, survival rate of sponge specimens was high with 90% and they attached to the bottom of the culture tank.

Started with the first experiment, sponge specimen were cut into fragments and glued to artificial substrate, they remain attached and after a week began to encrust the substrate. During this experiment, sponge fragments were fed with a mixture of commercial available liquid food and a deep-frozen floating feed consisting of different microalgae. Results on growth and collagen content will be measured in a further step. Design and development of a special adapted feed for *C. reniformis* is in progress, which will be applied in a further experiment.

(Continued on next page)

Discussion and conclusion

To avoid sudden death of sponge specimen short after arrival, the running-in of the aquaculture system have to provide stable values of abiotic factors (similar to natural habitat) and parameters in the biological water treatment.

One of the important parameters for a successful land-based aquaculture is an optimal food supply, the development of a special feed, which needs to have the correct size for filtering and meets the needs of the species *C. reniformis*. Additionally the amount and the regularity of feeding intervals is crucial; high loads of food will lead to blockage of the ostia and too low food supply in staving of sponge fragments.

Concluding, ideal transportations condition, an aquaculture system without fluctuation in abiotic factors and the development of an optimal feed adapted to this species is essential for survival, growth, amount of symbionts and of collagen content.

INVESTIGATIONS ON NATURE AND LEVEL OF RESIDUES IN FARMED FISH AS PART OF THE EUROPEAN PESTICIDE REGULATION

C. Schlechtriem

Fraunhofer Institute for Molecular Biology and Applied Ecology IME, Auf dem Aberg 1, 57392 Schmallenberg, Germany
E-mail: christian.schlechtriem@ime.fraunhofer.de

Introduction

The declining availability of pelagic forage/trash fisheries products and the increasing demand for these resources for aquafeed production is causing the price on international markets to rise as well as stimulating the search for alternatives. Plant-derived commodities are the only realistic alternative to replace fish meal and fish oil in rising demand in aquafeeds. With an increasing amount of plant material in aquaculture diets, there is an increasing risk for pesticide residues in aquaculture diets and their transfer into aquaculture products. Therefore, the EU has published data requirements for fish as part of the approval process for pesticides (EU-Commisson, 2013a). A working document on the nature of pesticide residues in fish was published to provide guidance on the performance of fish metabolism studies (EU-Commission, 2013b). Important inland aquaculture species reared for human consumption such as rainbow trout (*Oncorhynchus mykiss*) or common carp (*Cyprinus carpio*) are the recommended test species. Metabolism studies on fish are required when a pesticide of moderate to high lipophilicity (>logP 3) is used on crops and may lead to significant residues in fish feed, generally considered to be ≥0.1 mg kg^{-1} of the total diet. Fish dietary burden calculation is therefore an important prerequisite to decide on further experimental testing as part of the consumer risk assessment. Metabolism studies using radiolabelled test material are difficult to apply under aquatic conditions. Large volumes of contaminated water may result from metabolism studies and need to be treated using powerful filter technology. In addition to that fish metabolism studies reflecting oral ingestion of contaminated feed need to be carried out with animals of marketable size. This is to provide sufficient tissue for the quantitation of residues in the fish product (fillet, liver), and to enable identification of radiolabelled metabolites. The availability of an in vitro approach to provide information on metabolism of pesticides in farmed fish would be thus advantageous.

Material and Methods

The software *DietaryBurdenCalculator* was developed that allows the determination of the worst case feed composition made of plant derived feedstuffs. This is the composition leading to the maximum dietary burden of pesticide residues. Calculations are based on the simplex algorithm which allows solving large-scale linear programming problems quickly. The calculator allows estimating the specific dietary burden for common carp and rainbow trout, offers the possibility to consider maximum inclusion rates, and enables optimised residue estimation by adding non-contaminated substitutes as a source of protein, carbohydrates or fat (Klein et al. 2015).

Fish metabolism studies in both rainbow trout and common carp were carried out, following the working document on the nature of pesticide residues in fish using ^{14}C-labelled pesticide to assess the practicality of conducting metabolism studies in fish for regulatory purposes (Schlechtriem et al. 2015)

In order to evaluate the potential of in vitro fish hepatocyte assays to provide information on in vivo metabolite patterns of pesticides in farmed fish, in vitro incubations using suspensions of freshly isolated or cryopreserved primary hepatocytes obtained from common carp and rainbow trout were performed. In vitro and in vivo metabolite patterns were compared (Bischof et al. 2016).

Results & Discussion

Due to the increased amount of plant-derived materials in aquaculture diets, fish might increasingly become exposed to pesticide residues through their diets. Reasonable worst case estimates of the fish dietary burden are therefore important to decide on further testing such as fish metabolism or feeding studies, The software *DietaryBurdenCalculator* follows a realistic dietary optimisation scenario and allows the determination of the worst case feed composition made of plant derived feedstuffs leading to the maximum dietary burden of pesticide residues (Klein et al. 2015).

(Continued on next page)

Results of the metabolism studies with comon carp and rainbow trout (Schlechtriem et al. 2015) show that metabolism studies for regulatory purposes can be carried out with both fish species under laboratory conditions. The experimental design reported in the working document on the nature of pesticide residues in fish is suitable for quantifying the transfer of residues to edible tissues and enables characterisation of the chemical nature of residues. Based on the findings of the fish metabolism study and the estimated maximum residues which may occur in fish feed (maximum dietary burden), a feeding study may be required for fish, where residues at levels above 0.01mg kg^{-1} fresh matter may be reasonably expected in edible tissues. Feeding studies are required to determine the magnitude of residues in products of fish origin in order to assess possible consumer risks arising from ingestion of these products and to establish MRLs for edible fish commodities which still need to be defined. An official test protocol for feeding studies is being developed. Dietary burden calculation as outlined by the EU working document (EU-Commisson, 2013b) is currently limited to the two recommended test species trout and carp which are considered as representatives of the full range of fish species raised for human consumption. However, the dietary burden of fish species raised in aquaculture is likely to be much more diverse. Along with the development of guidance on fish feeding studies it would therefore be desirable to develop a wider range of fish feeding tables including salt water species to derive the realistic worst case dietary burden. Testing based on this dietary burden could still be conducted with the selected representative species.

The results from the in vitro/in vivo study (Bischof et al. 2016) confirm the presence of relevant differences in the metabolism of xenobiotics/pesticides between fish species. They further provide evidence that in vitro assays based on primary fish hepatocytes well reflect the in vivo metabolite patterns of xenobiotics/pesticides, in particular they reflect the in vivo species differences of metabolite patterns. Finally, the results of the in vitro study indicate that cryopreserved hepatocytes produce comparable metabolite patterns to freshly isolated cells. The in vitro hepatocyte assay could thus serve as a valuable tool to support in vivo metabolism studies on fish carried out as part of the approval process for pesticides according to the EU regulation 1107 (EU, 2009).

COMBINATIONS OF BROWN SEAWEEDS AS FEED ADDITIVES IMPROVED THERMAL SHOCK RESISTANCE OF PACIFIC WHITE SHRIMP POST-LARVAE REARED IN BIOFLOC SYSTEM

D.D. Schleder*, P.C. Rezende and F.N. Vieira.

Instituto Federal Catarinense - Campus Araquari, 280 road, Colégio Agrícola
89245-000, Araquari, Santa Catarina, Brazil
E-mail: delano.schleder@ifc.edu.br

Introduction

Brown seaweeds have important nutritional and functional properties. These seaweeds show higher antioxidant activity than red and green seaweeds, and have a diverse content of bioactive compounds, such as polysaccharides, terpenes, phenols and polyphenols, minerals, polyunsaturated fatty acids, vitamins, and carotenoids (Balboa et al., 2013; Gómez-Gil et al., 2000). The present work aimed to assess the effect of different combinations of the brown seaweeds *Sargassum filipendula* and *Undaria pinnatifida* as feed additives on growth parameters and thermal shock resistance of Pacific white shrimp post-larvae reared in biofloc system, during nursery phase.

Materials and methods

The experiment was performed at the Marine Shrimp Laboratory (LCM, *Laboratório de Camarões Marinhos*), of the Federal University of Santa Catarina (UFSC, *Universidade Federal de Santa Catarina*, Brazil), using *Litopenaeus vannamei* post-larvae at the stage of 20 days post-hatchery (PL20, ± 0.006 g). PLs20 were stocked in 400 L tanks at 1500 PLs m^{-3}, and the rearing was managed as a superintensive biofloc system for seven weeks (until they reach 1 g), under four treatments: PLs fed diets containing different ratios 0.5%:2%, 0.5%:4%, 1%:2% and 1%:4% of the dry biomass of *S. filipendula* (S):*U. pinnatifida* (U), respectively, and control diet (without addition), all in triplicate. During the experiment, animals were fed six times day^{-1} and the water quality parameters were monitored (temperature, pH and dissolved daily, and total ammonia, nitrite and nitrate once a week). Following the feeding trial, we determined the growth parameters, and subjected the PLs to thermal shock (28.6 °C to 13.5 °C for 1h, and then back to 28 °C).

Results

The water quality parameters remained at acceptable levels for shrimp nursery, as suggested by Van Wyk and Scarpa (1999), and did not differ among the treatments. Growth parameters also did not show any significant differences among the treatments.

On the other hand, PLs fed diets containing the 1S:2U ratio showed higher survival after thermal shock (Table 1.).

Discussion and conclusion

Many studies have shown that brown seaweeds can affect the resistance of different organisms to thermal stress (Kandasamy et al., 2011, 2014; Schleder et al., 2016). In previous reports, shrimp fed *S. filipendula* did show higher survival after thermal shock (around 97% compared to 43% in the control group), while increasing levels of *U. pinnatifida* had negative effects on thermal shock resistance, with the higher level (4%) causing 100% mortality. The combination of both brown seaweeds in the diets (0.5S:1U, 0.5S:2U and 0.5S:4U) avoided the negative effect of *U. pinnatifida* on the resistance of shrimp juveniles to thermal shock, but the survival remained similar to the control group (around 30%) (Schleder et al., 2016, 2017). Interestingly, in the present work, the combination 1S:2U improved significantly the resistance of shrimp post-larvae to thermal shock.

In conclusion, the combination of *S. filipendula* and *U. pinnatifida* in the diet can improve PLs resistance to acute thermal stress without affecting their growth performance. These results are particularly important for shrimp industry, since after nursery phase shrimp are transferred to grow-out tanks in the shrimp farms, where they face several environmental stresses, such as thermal stress.

(Continued on next page)

Table 1. Survival rate (%) of *Litopenaeus vannamei* post-larvae fed diets containing 0.5%:2%, 0.5%:4%, 1%:2% and 1%:4% of the dry biomass of *S. filipendula* (S):*U. pinnatifida* (U), and the control diet with no supplementation, after 24 hours post-thermal shock .

Treatments	Survival rate (%)
Control	50.0[a*]
0.5S:2U	44.5[a]
0.5S:4U	46.7[a]
1S:2U	73.3[b]
1S:4U	55.6[a]

Introduction

Shrimp farming has experienced strong growth in recent decades. In nature, shrimp feed mainly on plankton and microorganisms. In commercial aquaculture, shrimp are fed with pellets basically made of fish meal and fish oil (Tacon & Barg, 1998). Even when optimally prepared feed supports the best growth, extensive shrimp aquaculture has a high impact on the environment, and feeding is a cost-intensive component of shrimp breeding. Biofloc technology is an alternative system to maintain water quality and provide shrimp with an additional source of high protein and low fat nutrients (Ebeling et al, 2006). Depending on which bacteria are used, biofloc systems with different characteristics will develop. In the present study, different systems with chemoautotrophic and heterotrophic bacteria as well as a bacterial mix (mature biofloc) were compared in terms of biofloc nutritional value (assessed via proximate analysis) and their influence on shrimp growth.

Material and methods

The experiment consisted of three treatments (chemoautotrophic, heterotrophic and mature biofloc) each with four replicates (tanks) all randomly distributed. In each tank, 105 individuals of *L. vannamei* with an average weight of 3.46±0.01g were placed. The animals were kept in tanks for five weeks and fed four times a day with pelleted shrimp feed (Guabi Potimar "oti Mirim QS 1.6mm", -35% crude protein, made at Guabi Nutrição e Saúde Animal S.A. in Brazil). Consumption was controlled each 90min after feeding by weighting pellet´s rest. New feeding settings were adjusted based on previous consumption. Growth rate and survival were assessed after 35 days based on weekly weight of 30 shrimps per tank. Biofloc samples from each tank were collected lyophilized and homogenized for proximate analysis (including ash, crude lipids, carbohydrates, and crude proteins) as well as energy and fatty acids contents. For the proximate analysis the ash content, crude lipids, carbohydrates and crude proteins were determined. In addition, the energy and fatty acid content were measured in the different biofloc types

Results

There was no significant difference in crude lipid content among treatments (mature: 1.22±0.37%, heterotrophic: 0.86±0.81%, chemoautotrophic: 0.75±0.37%). In all three treatments saturated fatty acids had the highest proportion of total fat (mature: 70.70±3.91%, heterotrophic: 64.53±6.00% and chemoautotrophic: 60.25±11.27%). Ash content was higher in the heterotrophic tanks (58.22±1.01%) than in the mature (53.77±1.96%) and chemoautotrophic (47.45±1.79%). The protein content was in the heterotrophic treatments (30.03±0.47%) significant higher than in the mature (23.15±1.89%) and chemoautotrophic (22.63±1.41%). Carbohydrate content of all treatments were significantly different. The chemoautotrophic system had the highest quantity of carbohydrates with 29.2±3.11%, followed by the mature tanks (21.88±3.32%) and the heterotrophic treatments (10.89±1.55%). The chemoautotrophic (8.26±0.27%) and heterotrophic (8.33±0.62%) treatments significantly di fered on energy content from the mature (10.93±0.09%) treatment.

There was no significant difference between all three treatments in terms of shrimp growth (Fig. 1) or survival rate (mature: 93.33±2.23%, chemoautotrophic: 91.67±3.11% and heterotrophic 91.00±5.41%).

Discussion

The use of particulate organic material, such as microorganisms contained in floc-based products, has been proposed as a potential food source for aquatic animals (Emerenciano, 2011). Biofloc systems in this experiment showed low levels of crude lipids with a high proportion of saturated fatty acids and low content of unsaturated fatty acids, which is not optimal for feeding *L. vannamei*. Alday-Sanz (2010) suggested optimal lipid content between 6-8% for shrimps. Crude protein in the heterotrophic biofloc treatment was relatively high and comparable to commercial shrimp feed. The present results suggest that these different bioflocs might be partially used as feed by the shrimps. High and comparable survival rates and good growth rates indicate that the animals have grown very fast in the different biofloc systems. When shrimp is mainly fed with commercial feeds, the type of biofloc has no influence on growth and survival. Other parameters such as temperature and nutrients accumulation or even extension of the cultivation period may drive shrimps performance in systems using the tested bioflocs while the kind of bacterial groups developed within the tanks may just complement the culture conditions.

Introduction

The adhesion of microorganisms on surfaces and the consequent biofilm formation is of major concern in the aquaculture sector, since biofilms are difficult to remove and may act as a reservoir for potentially pathogenic bacteria (Bourne et al., 2006). Recently the potential of using submersed sensors is increasing in aquaculture tanks or cages for water monitoring purposes. The biofilm formation can affect the function of these sensors that may lead to misinterpretation of the acquired measurements. Water monitoring sensors have parts made of stainless steel and once introduced into the water, they serve as a new niche for microbial colonization. The PCR-DGGE method is useful tool as a first approach for studying microbial communities, as it allows a quick screening of the microbial succession among temporal samples. The aim of this study was to evaluate qualitative as well as quantitative the formation of biofilms on stainless steel surfaces under seawater conditions.

Methods

Sterilized stainless steel coupons were placed in an aquarium tank, part of an experimental marine Recirculated Aquaculture System (RAS). Two fish species were reared in the RAS, *Dicentrarchus labrax* and *Sparus aurata*. Fish were fed a commercial pellet diet three times per week. Physicochemical parameters (T, salinity, pH, O_2, NO_2^- and total TAN) of the water were monitored with sensors or spectroscopic methods.

Sampling for microbiological analysis was conducted at 24h, 48h, 72h and every three days thereafter until the 30th day. Tank water and coupons (in triplicate) were sampled. Biofilm cells on coupons were sampled according to protocol by Kostaki et al. (2012).

The bacterial community composition of the tank water as well as the biofilms and their temporal changes were assessed by denaturing gradient gel electrophoresis (DGGE) based on the 16S rRNA gene. Tank water samples (100ml) and samples from the bacterial solution of the detached cells of each coupon were centrifuged at 5.000g for 5min. Then the cell pellets were lysed using a lysozyme based protocol to extract bacterial DNA. PCR amplification, using the primers 341 F (with GC clamp) and 907 R, targeted the V3-V5 region of the gene. The amplification products (~580bp) were examined by electrophoresis on 1.2% agarose gels.

DGGE was performed with the DCode Universal Mutation Detection System (Biorad). Samples were loaded on 6% (w/v) polyacrylamide gels with the denaturing gradient ranging from 20% to 60% (100% contains 7M urea and 40% formamide) and gels were run in 1x TAE electrophoresis buffer at 60^{o}C and electrophoresed at 200V for 4h. Gels were stained with ethidium bromide, visualized and photographed with a Gel-Doc imaging system (Biorad).

Results and Discussion

Sea water physicochemical parameters were stable during the experimental period, within values that ensured optimal rearing conditions. Mean values and their standard deviation are as follows: Temperature 23.5 ± 0.4 ^{o}C, salinity 35.3 ± 0.5psu, pH 7.06 ± 0.11, oxygen saturation 100.6 ± 0.6%, nitrite 0.14 ± 0.08ppm, TAN 0.07 ± 0.03ppm.
The microbiological analysis of the tank water revealed that the water microbial load ranged from 3.8 to 5.4logCFU ml^{-1} (Fig.1). The observed fluctuati n followed the feeding regime. This in line with the reports where, bacterial activity and abundance in RAS, found to be affected by the changes in feed loading (Rojas-Tirado et al., 2018).
The DGGE profiles revealed that the microbial association of the tank water remained unchanged during the experimental period. Similar results have been reported by Attramadal et al. (2012, 2014), who found that the tank water of the RAS is characterized by stable carrying capacity and microbial community composition.

(Continued on next page)

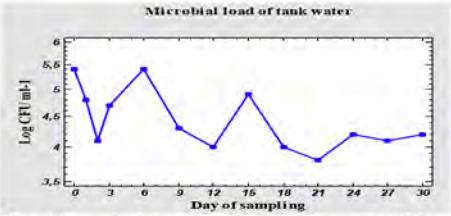

Fig. 1 Population of the marine heterotrophic bacteria of the RAS water (logCFU ml^{-1})

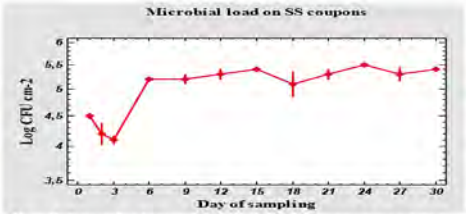

Fig. 2 Population of the marine heterotrophic bacteria forming biofilm (logCFU cm^{-2})

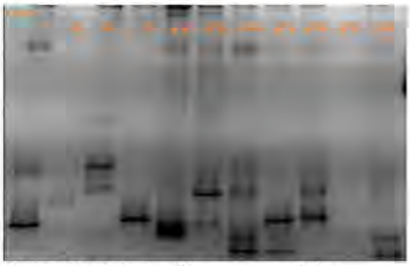

Fig. 3 DGGE profile pattern of the microbial community forming biofilm on the SS coupons during 30 days.

Within 24h the biofilm cells on the coupons reached a population of 4.5±0.05logCFU cm^{-2}. The maximum microbial load of biofilm was achieved within the 6th day, remaining stable until the 30th day (Fig.2). On the other hand, DGGE bacterial profiling revealed a constant change of microbial species during the biofilm development (Fig.3). The dynamic succession of microbial species during biofilm development on fibe glass surfaces has been also previously shown by using DGGE profiling of bacterial 16S rRN genes (Bourne et al., 2006).

Conventional microbiological analysis combined with molecular techniques demonstrated the dynamics of the biofilm development on stainless steel surfaces in a Mediterranean RAS. This work highlights the importance of conducting studies *in situ* for prolonged time periods, as an approach for better assessment of the biofilm formation on test surface materials

RAINBOW TROUT WELFARE INDEX MODEL 1.0

Mark Schumann[a]*,Cornelius Becke[a], Andreas Müller-Belecke[b], Roland Rösch[a]

[b]Fisheries Research Station of Baden-Württemberg, Argenweg 50/1, 88085 Langenargen, Germany

Introduction

Animal welfare is becoming an increasingly important factor in aquaculture (Ashley, 2007; Browman et al. 2018) as environmentally literate consumers pressing for more species-appropriate methods of food production worldwide. Based on the Salmon Welfare Index Model (SWIM) developed by Stien *et al.* (2013), a semantic welfare index model was designed for rainbow trout (*Oncorhynchus mykiss*) and verified for flow-through as well as recirculating aquaculture systems. The aim of this research project was to provide an applied basis for the assessment of rainbow trout welfare in aquaculture systems which can be further developed and adjusted at any time due to its modular design. The focus was set to develop a tool which can be used by fish farmers as well as governmental authorities

Materials and methods

In a first step, potential welfare indicators for rainbow trout were compiled based on literature references. These welfare indicators were then discussed and adjusted in an expert meeting of scientists, practitioners and veterinaries. Afterwards, the welfare indicators were grouped based on their application in the sections "environment", "stock" and "individual" (**Figure 1**) and weighted on their importance. Furthermore, each indicator was subdivided in practice-oriented levels to allow a gradual assessment of fish welfare. An overall index value of 1.0 represent optimal welfare conditions, whereas 0.0 stands for maximum violations of animal welfare.

Results

The applicability of the rainbow trout welfare index models for flow-through as well as recirculating aquaculture systems were finally verified in surveys of rainbow trout production systems in Germany and an experimental RAS facility. During on-site visits of the commercial fish farms, operators were informed about the background of the project and the intended procedure within half an hour. When data collection and management was in accordance with the good technical practice, information needed to evaluate the section „environment", using environmental parameter mean values from the last month of production could be obtained within about one hour. Evaluation for the section „stock" by observation of three separate rearing units and for the section "individual", examining 10 randomly selected individuals could be conducted within one hour. Final adjustments of the welfare index model were made following the on-site visits.

Overall, the example surveys proved the applicability of the welfare index model for rainbow trout reared in flow-through as well as recirculating aquaculture systems.

The study was founded by the German Federal Ministry of Food and Agriculture (support code 2817900215).

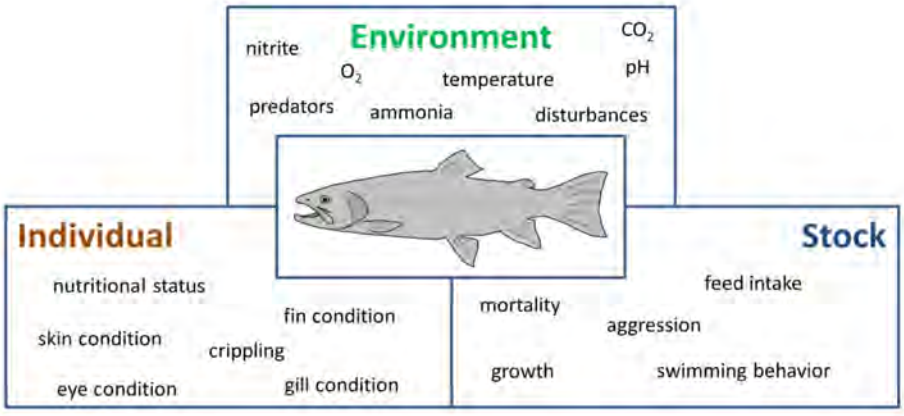

Figure 1: Welfare indicators of the rainbow trout welfare index model grouped into the three sections environment, stock and individual.

MULTI-USE POTENTIAL OF MARINE AQUACULTURE WITHIN OFFSHORE WIND FARMS IN THE GERMAN BIGHT: A SWOT ANALYSIS

M. F. Schupp [1, 2 *], G. Krause [1], V. Onyango [2], B. H. Buck [1, 3]

[1] Alfred Wegener Institute, Helmholtz Centre for Polar and Marine Research, Bremerhaven, Germany

Introduction
The European Union's Integrated Maritime Policy as well as its Framework for Maritime Spatial Planning highlight the sustainable and efficient development of ocean space as a core objective. Towards this end, users, researchers and planners alike are adopting the idea of multi-use, i.e. the combination of two or more uses in the same (ocean) space. A salient example of multi-use would be Offshore Wind Farms (OWFs) as potential locations for marine aquaculture. This combination has been widely researched and is often viewed as a sustainable and efficient way to enhance regional aquaculture production through the utilisation of synergies between sectors, however, this multi-use combination has yet to reach market readiness.

Materials & Methods
In order to better understand the external and internal factors affecting particular combinations of sectors, we applied a strategic SWOT (Strength, Weakness, Opportunities, Threat) analysis to a case study within Germany's North Sea Exclusive Economic Zone (EEZ), located within the German Bight. Case study results and factors were verified by key stakeholders from industry, research and regulatory agencies. To arrive at clear, accessible guidelines for future development, factors were analysed within the context of the following relevant dimensions: socio-economic, technological, legal and environmental.

Results
Using a SWOT approach, combined with the typology on ocean multi-use presented in Schupp et al. (2019), yields a large number of factors and exposes a large variability in the specific composition of each multi-use combination. Due to the operational differences between types of marine aquaculture, a number of possible sub-combinations can be identified, each carrying different implications for the involved actors, regulators and stakeholders.

Discussion & Conclusion
Discussions of the multi-use of OWFs and marine aquaculture have long since focused on biological and technological practicality as well as the economic feasibility and stakeholder perceptions (Buck and Langan, 2017). Nevertheless, not strictly characterizing and distinguishing the various possible types of sub-combinations could quickly lead to dismissal of the entire multi-use concept. The application of SWOT analysis, a tool more commonly used for strategic planning, to the combinations of OWFs and marine aquaculture yields a systematic overview of factors influencing their continued development. This study represents a first as it showcases all possible sub-combinations, while also taking a full account of the factors influencing their development, using the SWOT framework. It aims to serve as a fundament for pertinent marine multi-use combinations as strategic marine spatial planning continues to expand and evolve.

THE EFFECT OF TWO DIFFERENT FEEDS ON GROWTH, SURVIVIAL AND CARAPACE COLOR IN WHITELEG SHRIMP *Penaeus vannamei*

A. Segelken-Voigt*, R. Bochert

Mecklenburg-Vorpommern Research Centre for Agriculture and Fisheries
Institute of Fisheries
18375 Born (Germany)
a.segelken-voigt@lfa.mvnet.de

The whiteleg shrimp *Penaeus vannamei* Boone, 1931 is one of the most important commercial species in shrimp aquaculture and the dietary requirements of this species are a key factor during production.

The purpose of the present study was to determine the effect of two commercial feeds containing different amounts of protein on the weight gain and the survival of *P. vannamei*. Also, the pigmentation was measured with a colorimeter as the ability to market shrimps usually depends on the level of their pigmentation which is associated with freshness and quality of the product (Boonyaratpalin et al. 2001).

Two trials with commercial feeds containing 37% (Group A) and 48% protein (Group B) were undertaken with *P. vannamei* of a mean initial weight of 14.5 ± 2.1 g. In each setup, a total of 165 shrimps were held in triplicates (55 shrimps/tank) at 29°C for 100 days.

Survival in Group A was 80.6% compared to 57.6% in Group B. Also, significantly higher weight gain was recorded for Group A (F= 92.821; p= 0.0001; see Fig. 1).
Furthermore shrimps of Group A were darker compared to Group B before and after cooking (see Fig. 2).

Our findings will be complemented by further analysis of biochemistry (e.g. fatty acid-, amino acid profile) as well as astaxanthin content of *P. vannamei* and the commercial feeds.

The final results of these measurements are still in progress and not available at time of abstract submission. They will be presented at the resubmitted version of this abstract.

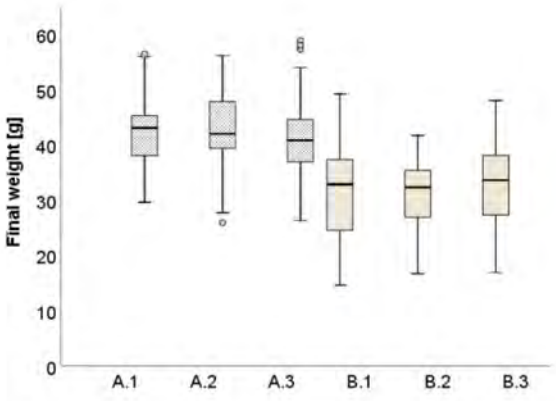

Fig. 1. Average final weight of *P. vannamei* after 100 days fed with two different commercial feeds with 37% (A) and 48% (B) protein content, respectively.

Fig. 2: Visual appearance of *P. vannamei* before (top) and after cooking (bottom), fed with two different commercial feeds with 37% (A) and 48% (B) protein content, respectively.

GROWTH PERFORMANCE AND SURVIVAL OF WHITELEG SHRIMP *Penaeus vannamei* UNDER VARYING STOCKING DENSITIES

A. Segelken-Voigt* and R. Bochert

Mecklenburg-Vorpommern Research Centre for Agriculture and Fisheries
Institute of Fisheries
18375 Born (Germany)
a.segelken-voigt@lfa.mvnet.de

The whiteleg shrimp, *Penaeus vannamei* Boone, 1931 is one of the most farmed crustaceans globally (FAO 2018). The production of animals does not only occur in open ponds but also in indoor clearwater recirculating aquaculture systems (RAS). In this regard, management factors such as water quality and stocking density are crucial for an economic production of cultivated shrimp.

The production performance of whiteleg shrimp reared with different stocking densities was evaluated for postlarvae (PL 12) and juveniles (Ø weight 2.5g) for 2 and 4 weeks, respectively. Individuals were cultivated in triplicates under controlled experimental conditions in a recirculation system of 100 l aquaria with a salinity of 20 ppt. Postlarvae were held at densities of 6, 35 and 70 shrimps/l and juveniles at 300, 600, 900 and 1200 shrimps/m². Length-weight ratio and survival were compared between treatments at the end of the experiment.

Postlarvae showed higher survival of more than 50% when held at densities of 6 and 35 shrimps/l in contrast to a density of 70 shrimps/l with only 30% survival. The specific growth rates (SGR) were 3.5 %/day for 6 shrimps/l and 2.8 %/day for 35 shrimps/l and 70 shrimps/l.

In juveniles, also the two groups held at lower densities revealed higher survival of 90% compared to the two higher densities with 70% survival. The results also indicated a higher SGR for the lower stocking densities with 3.3 %/day (300 and 600 shrimps/m²) compared to 2.5% (900 and 1200 shrimps/m²).

FEEDING STRESS DUE TO SOY BEAN MEAL AS A MODEL FOR THE DEVELOPMENT OF MOLECULAR IMMUNE MARKERS IN RAINBOW TROUT

H. Seibel[1]*, A.Rebl[2], C. Schulz[1]

[1]Gesellschaft für Marine Aquakultur mbH, Hafentörn 3, 25761 Büsum (Germany)
[2] Leibniz Institute for Farm Animal Biology, Institute of Genom Biology, Fish Genetics Unit, Wilhelm-Stahl-Allee 2, 18196 Dummerstorf (Germany)

E-Mail: seibel@gma-buesum.de

Introduction
The increasing intensification of aquaculture practices has led to public debate about the welfare status of cultured fish

In order to verify the immune status of trout in context of husbandry stress and to investigate the relationship between chronic stress, immunosuppression, husbandry and feeding we established molecular stress markers using a feeding stress experiment with soybean meal. The welfare status of trout was verified by investigation of mRNA expression of different potential stress regulated genes in whole blood to establish a minimal invasive method.

Materials and methods
A 56-day feeding experiment was carried out. The triplicate fish groups were fed isoenergetic and isonitrogenic feed mixtures in which the fish meal (50 % of the total diet) was replaced by 0 %, 33 %, 66 % and 100 % soybean meal. EDTA blood was collected from the caudal vein of immobilized trout. In total 88 different genes were tested for their suitability in stress detection using a Fluidigm Biomark HD and a Light Cycler System. Specific primers were designed. Regulated genes belonging to the superior signal transduction pathways such as SERPIN G superfamily, intracellular PI3K/actin, Toll-like receptor, NF-κB, MAP kinase and JAK-STAT signal transduction or intracellular pathogen recognition receptors were tested. The mRNA expression of blood cells was tested for different pro- and anti-inflammatory cytokines, chemokines, substances involved in the acute phase reaction, complement cascade or inflammatory reactions, and heat shock proteins. Finally, different marker genes for specific cell populations were investigated. The housekeeping genes β-Actin, EF1 and RPS5 served as internal standards.

Results and Discussion
Different genes (e.g. SAA, MPO, NOS2, UCP2) emerged as suitable stress and immune markers and therefore as welfare indicators on a molecular level, while some genes (e.g. IL10, IFN, HSP47) revealed no correlation to feeding stress.

The results represent an important basis for a better assessment of animal welfare in trout farming. They are an important first step towards making well-founded, early assessments of chronic feeding stress of trout in the future, which are minimally invasive. So far, the parameters have often been based on observations such as behavior, color changes and such aspects that are difficult to standardize. These results provide a basis for the development of practical detection systems - comparable to a diabetes test.

EFFECTS OF FERMENTED AND UNFERMENTED DUCKWEED AS FEED ADDITIVE ON GROWTH PERFORMANCE OF COMMON CARP (*Cyprinus carpio*)

A. Seitz*[1], C. Pietsch[1]

[1]Fish Welfare Group, IUNR, Zurich University of Applied Sciences, P.O. Box, Campus Grüental, 8820 Wädenswil (Switzerland)
E-Mail: andreas.seitz@zhaw.ch

Introduction

As a favoured ingredient, fishmeal is still a major part of most aquacultural diets (Lim and Webster, 2006). Since fishmeal and fish oil resources are decreasing, the replacement of these typical feed ingredients with more sustainable dietary components is desired. Therefore, duckweed with its high protein content and enormous growth rate is a promising substitute for the animal-based components in aquacultural diets.

Both fermented and unfermented duckweed have already been fed to fish. Best growth performance was achieved with fermented duckweed, whereas the fermentation process also improved other nutritional properties, e.g. it reduced the fibre content and the concentrations of antinutritional factors (Bairagi et al. 2002).

To develop more sustainable diets for Switzerland's aquaculture, the effects of either fermented or unfermented duckweed (*Spirodela polyrhiza*) were investigated in a feeding trial using common carp (*Cyprinus carpio*).

Materials and Methods

The best starter culture for the fermentation of duckweed was investigated in small-batch trials, whereby four different cultures of single strain or multi strain cultures of fermentation bacteria or fungi were tested. The large-scale fermentation was carried out with a combination of *Pediococcus pentosaceus* and a commercial mixture of bacteria and yeast (EM 1, EM Schweiz AG, Switzerland). The fermented duckweed and freshly harvested duckweed were dried, grinded and used for diet formulation. An animal protein-based control diet and the two duckweed-containing diets were extruded to contain 30% unfermented or fermented duckweed powder, respectively.

For assessing the growth performance of common carp fed the experimental diets, a subsequent feeding experiment was conducted at the Zurich University of Applied Sciences. Therefore, 630 fish with an initial weight of 60g were reared in three identical and independent recirculating aquaculture systems. Each diet was fed in triplicates to groups of 70 fish for 94 days. Three samplings were carried out to evaluate the effects of the experimental diets by measuring the length and weight of fish, calculating organosomatic indices and their specific growth rate. In addition, sensory tests were conducted and the filet quality was investigated

Results

The small-scale fermentation tests revealed that the fermentation of duckweed with *P. pentosaceus* and EM 1 had positive effects on the content of anti-oxidative substances, whereas the protein content was only slightly reduced. The fermentation process also affected the content of anti-nutritive substances. First estimations of the effects of all experimental diets on the growth performance of carps will be available for the second submission date in July whereas the results of the entire feeding experiment will be ready for presentation at the conference.

GENOMIC CHARACTERIZATION AND EXPRESSION LEVEL ANALYSIS OF MALECTIN FROM BIG BELLY SEAHORSE *Hippocampus abdominalis*

Sarithaa Sellaththurai*, K.A.S.N Shanaka, Thanthrige Thiunuwan Priyathilaka, Jehee Lee

Department of Marine Life Sciences & Fish Vaccine Research Center, Jeju National University, Jeju Self-Governing Province 63243, Republic of Korea
E. mail: sarithaasellaththurai@gmail.com

Introduction

Malectin is a novel carbohydrate-binding lectin type ER resident protein, with unique selectivity for the Glc_2-N-glycan. It was first identified in *Xenopus laevis* as an intracellular lectin involving in glycoprotein quality control. Structure determination by nuclear magnetic resonance showed the luminal part of malectin is a carbohydrate binding domain that recognizes glucose oligomers. Carbohydrate microarray analyses revealed a uniquely selective binding to a Glc2-*N*-glycan probe (Chen et al., 2011; Schallus et al., 2008)nine mannoses, and two N-acetylglucosamines (Glc(3. Most of endoplasmic reticulum (ER) synthesized proteins are glycoprotein in nature. The N-linked oligosaccharide moieties in glycoprotein is the modificatio which employed for highly diverse function. They serve as a ligand for multiple recognition process and stabilize proteins from denaturation and proteolysis, increase solubility, immune response modulation, facilitate protein orientation to relative membrane, regulation of protein turn over, fine-tune the charge and isoelectic point of protein, and pathogen interaction (Helenius and Aebi, 2004). In the present study we identified and molecularly characterized the malectin from big-belly seahorse *Hippocampus abdominalis* (*HaMLEC*). The immune response was evaluated using challenge experiment.

Methodology

Seahorse transcriptome library was constructed and the cDNA sequence of *HaMLEC* was identified. In-silico study was performed using different bioinformatic tools as follows; Unipro UGENE software, SMART, ExPASy Prosite, ExPASy ProtParam tool, EMBOSS Needle Pairwise Sequence Alignment Tool, ClustalW 2.0 program, and MEGA version 7.0.26 software. Tissue specific mRNA expression and mRNA expression at time post challenge (*Edwardasiella tarda*, *Streptococcus iniae,* polyinosinic: polycytidylic, and lipopolysaccharide) in blood tissue was analysed by qPCR using respective cDNA sample.

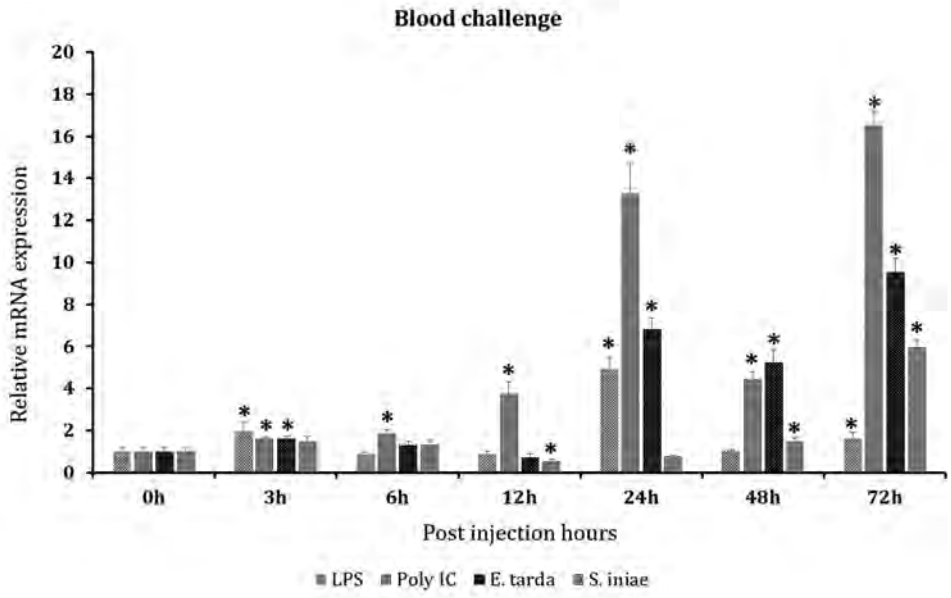

Fig. 1. Temporal mRNA expression level of *HaMELC* in blood following LPS, poly I:C, *E. tarda,* and *S. iniae* stimulation. The relative *HaMELC* transcript levels were determined using the Livak method. Each bar represents the standard error (SE) of triplicate (n=3).

Results

The *HaMELC* cDNA sequence was identified with an ORF of 864 bp, encoding 288 amino acids with the predicted molecular weight of 31.99kDa and estimated pI of 5.17. Protein domain database "SMART" revealed Malectin super family (39 - 199), N-terminal signal peptide (1 – 26) and C-terminal transmembrane region (267 -286) from the amino acid sequence of HaMELC. The deduced amino acid sequence of HaMELC showed 88.5%, 87.2%, 74.4%, 71.9%, 61.6%, and 37.3% identity with that of *Cynoglossus semilaevis, Oryzias melastigma*, *Bos taurus*, *Homo sapiens*, and *Nanorana parkeri, and Drosophila serrata* respectively. In the phylogenetic analysis HaMELC was main clustered into vertebrate and subclustered into fishes with *Cynoglossus semilaevis* and *Oryzias melastigma*. The *HaMELC* mRNA expression was observed in all tested tissues by real-time PCR (blood, brain, gill, heart, intestine, liver, kidney, muscle, ovary, pouch, skin, spleen, stomach and testis) with highest expression in ovary followed by brain. The *HaMELC* mRNA expression in blood showed significant upregulations during the experimental period except the down regulation at 12 hour post challenge with *S. iniae*. Significant upregulation was observed at 72 hour post immune challenge with all four stimulants (Figure 1)

Discussion and conclusion

According to the in-silico analysis, the typical MELC super family was obtained with signal peptide and transmembrane region from the identified *HaMELC* cDNA sequence. The sequence homology of HaMELC with MELC sequences from other species was further confirmed by phylogenetic analysis, pairwise sequence alignment and multiple sequence alignment. The observed significant upregulations following the immune challenge suggested that HaMELC might have a significant role in host immune response

HOW AQUAPONICS CAN HELP URBAN AGRICULTURE

Maryam Shafahi

*Associate Professor, Mechanical Engineering Department, California State Polytechnic University Pomona, CA 91768
Email: mshafahi@cpp.edu

Aquaponics is an environmentally friendly method of food production benefiting from the integrated cycle of aquaculture and hydroponics. It uses a closed-loop water cycle with little run-off to the environment and minimum requirement for plant fertilizer. Considering the water scarcity around the globe and all of the problems agriculture industry is facing concerning water, more water efficient practices in the field such as aquaponics are becoming the wave of the future. Aquaponics might be a candidate solution for urban agriculture specificall . This is a study on the water efficiency of an outdoor semi-commercial aquaponics system growing lettuce and tilapia located in California State Polytechnic University at Pomona. The annual water consumption of a raft bed system with the growth capacity of 250 plants per cycle was measured. The results were compared to the published data for the conventional soil farming in California and the world. Our finding shows that the outdoor aquaponics system can produce crop with 25% water efficiency enhancement in Southern California climate.

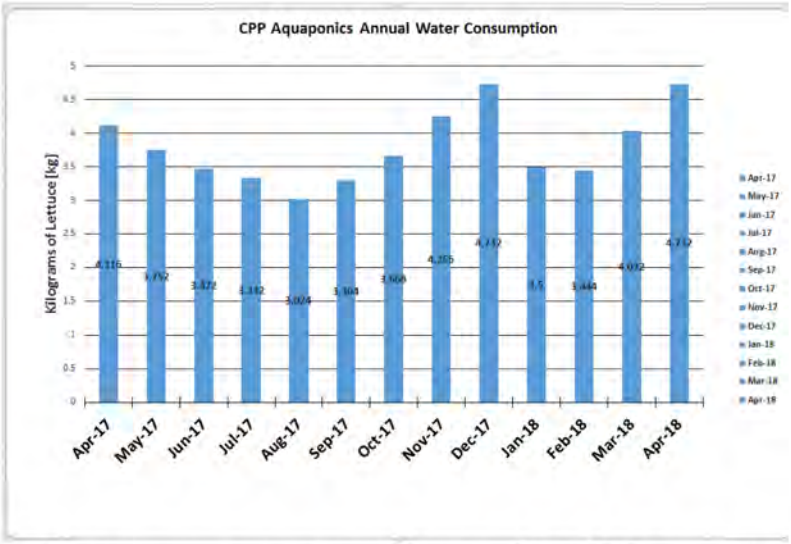

Figure 1- The annual water consumption per crop yield measured in Cal Poly aquaponics outdoor system.

CFD MODELING OF SEMI-CLOSED CONTAINMENT FLOATING SYSTEM WITH FLEXIBLE WALLS: EFFECT OF INLET ORIENTATION ANGLE ON THE FLOW FIELD HYDRODYNAMICS

Introduction

Aquaculture industry is progressively interested in producing and utilizing larger semi-closed containment systems (SCCS) to accomplish high production goals and economy-of-scale. Consequently, the large-scale systems lie in a category of high Reynolds number, which makes the flow in SCCS fully turbulent. The overall hydrodynamic performance of the system is influenced by inflow characteristics, [4] i.e. turbulence produced by inlet orientations [5]. An actual experimental study on such a high flow condition that involve velocity, uniformity, vorticity and swirl number changes is not feasible. Therefore, computational fluid dynamics modeling (CFD) is considered as a most appropriate tool to investigate the hydrodynamics of large systems. The main object of this study was to investigate the effect of inlet orientation angle on the hydrodynamics of SCCS with flexible walls and establish the optimal inlet orientation set-up for use during Atlantic salmon production in this system.

Materials and Methods

The cone shaped floating bag with flexible walls and total volume of 10 000 m^3 received water from four inlet pipes. The water was discharged through 14 sidewall outlets located at depth up to 15.5 m and bottom central drain located at 21 m depth. In order to determine the most optimal pipe orientation set-up for the system total of six cases were developed in CFD (Table 1) and compared with the empirical data collected from floating bag. Grid convergence tests was used to verify CFD model and Acoustic Doppler velocimetry (ADV) was used for velocity measurements. The hydrodynamics of the system was evaluated using different flow field indicators, such as flow velocity, distribution of vortices, turbulence in the system and vorticity.

Naiver Stokes equation for incompressible fluids was solved with SIMPLE algorithm, which is Semi Implicit Method for Pressure Linked Equations. Where initially pressure and velocity values are estimated by algorithm and later pressure-correction equation $\nabla^2 p\uparrow = 1/\Delta t\ (\nabla \cdot V)$, is solved to obtain a corrected value of pressure and velocity field and at the solution convergence is checked [3]. A k-omega SST turbulence model with first order accuracy in space and time is used to solve Turbulence Kinetic Energy (k) and Specific Dissipation Rate (ω) [1,2]. In present study, one assumption in selection of boundary conditions is that no external force factors are included in the system (sea waves effect).

Results

In all 6 cases empirical data show relatively higher velocity by a factor of 3 (at 2 and 7.5-meter depth) and 14 (at 15.5-meter depth) as compare to CFD simulations. However, both empirical and CFD data show similar velocity pattern and mixing across the whole system. Out of 6 analyzed cases, the best hydrodynamics in the system (Figure 1a and 1b) was achieved by case 2 set-up (Table I) while the large variation in hydrodynamics was observed between cases. Observed differences in velocities between CFD models and empirical measurements were further investigated.

Discussion and conclusion

To investigate the hydrodynamics of large systems, we adopted two methods (Empirical and Computational) and compared them, respectively. The understanding of flow patterns could be performed more efficiently and relatively cheaper with the help of CFD modeling and simulations. In order to achieve a good qualitive and more reliable results, it is very important to develop a Solid CFD bench model. In this study, initially we developed a reliable CFD bench model and then examined the complete flow patterns for 6 cases with different inlet orientation angles (Table I). Large difference between the flow patterns are observed among various cases, based on their inlet orientation angle change. This factor has large impact on mixing and velocity factor across the system, which in turn effect water quality for optimal fish growth/welfare, health performance and particle removal. This study shows that further optimization of the system set-up is achievable with the help of CFD modeling.

Table (I). Different inlet orientations setup

CASE	Inlet 1 Angle	Inlet 2 Angle	Inlet 3 Angle	Inlet 4 Angle
1	36.55°	36.55°	36.55°	36.55°
2	36.55°	90°	36.55°	90°
3	5°	90°	5°	90°
4	5°	5°	5°	5°
5	36.55°	36.55°	36.55°	90°
6	45°	45°	45°	45°

Introduction

It is well documented that dietary fatty acids such as arachidonic (ARA, 20:4n-6), eicosapentaenoic (EPA, 20:5n-3) and docosahexaenoic (DHA, 22:6n-3) acids are important for ensuring egg and larval quality and they significantly improve fecundity, fertilization, viability, hatching and larval survival rates in marine fish (Fernandez-Palacios *et al*., 1995; Izquierdo *et al*., 2001). Gilthead sea bream is a major marine fish farmed in Europe and is also subject to selective breeding programmes to improve growth performance, disease resistance and carcass quality (Afonso *et al.,* 2012). So far, no study has dealt with the influence of genetic selection for growth trait on the improvement of reproductive performance of gilthead sea bream. Recent work has also shown that potential of broodstock selection improved the spawning quality and the subsequent nutritional programming had a positive effect on the utilisation of low fish meal (FM) and fish oil (FO) diets by the progeny (Izquierdo *et al*., 2015; Turkmen *et al*., 2017). The present study was undertaken with gilthead sea bream broodstock to determine the effects of selection for high (HG) or low (LG) growth and dietary fatty acid source, fish oil (FO) or rapeseed and linseed oil (VO) and its interaction on reproductive performance of gilthead sea bream.

Materials and methods

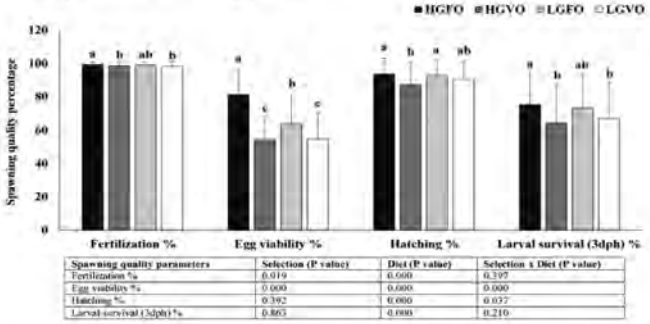
Experimental broodstock

Gilthead sea bream broodstock were used from third generation of selection under the PROGENSA (Spanish National Breeding Program) project (Afonso *et al.,* 2012). Two broodstock groups expressing either high growth (HG), or low growth (LG) were selected for the assessment of reproductive performance. HG and LG trait broodstock were kept separately for mass spawning in four tanks at the facilities of ECOAQUA institute (Marine Science & Technology Park, ULPGC, Canary Islands, Spain).

Dietary treatments

The broodstock feeds were formulated to be iso-proteic and iso-lipidic with either fish oil (FO) or rapeseed and linseed oil (VO) as the lipid source and were produced by Skretting ARC, Stavanger, Norway. Broodstock were fed with the respective diets at the rate of 1% body weight in twice a day meals for over 3 months.

Figure 1. Reproductive performance (% spawning quality) of gilthead seabream broodstock selected for high (HG) or low (LG) growth fed with either FO or VO diet during three months of experimental feeding period.



Spawning quality parameters	Selection (P value)	Diet (P value)	Selection x Diet (P value)
Fertilization %	0.019	0.000	0.395
Egg viability %	0.000	0.000	0.000
Hatching %	0.392	0.000	0.037
Larval survival (3dph) %	0.863	0.080	0.210

Means bearing different superscript letters differ significantly (P<0.05 by One-way ANOVA, Tukey Post-Hoc).

(Continued on next page)

Analysis of sperm quality

Sperm quality parameters such as sperm cell concentration (10^9 ml^{-1}), sperm viability (%) and sperm motility (%) were analyzed immediately after the semen collection.

Evaluation of broodstock spawning quality

The floating eggs were collected six days per week at 09:00 h from each mass spawning tank and egg number was counted under light microscope to estimate total fecundity, number of fertilised, unfertilised, viable and dead eggs. The viable eggs of each group were used to calculate hatching and larval survival (3 days post hatch, dph) rates.

Results

Broodstock selected for high growth fed with either FO or VO significantly (P<0.05) increased the sperm cell concentration (Table 1). In same way, HG broodstock fish significantly (P<0.05) improved the motility percentage irrespective of the dietary group. All the male broodstock exhibited same quality of sperm viability percentage (Table 1). In case of spawning quality, broodstock fish selected for high growth fed with fish oil (HGFO) based diet significantly (P<0.05) improved the egg viability percentage (Fig 1). The high or low growth selected broodstock fish fed with FO based diet shown the significantly (P<0.05) higher hatching and larval (3 dph) survival rate. Whereas, both HG or LG broodstock fed with VO based diet group exhibited significantly (P>0.05) lower level of egg and larval quality (Fig 1). The two-way analysis result revealed that both genetic selection for HG or LG and high n-3 LC PUFA (FO) diet fed broodstock group significantly improved the fertilization and egg viability percentage. Whereas, hatching and larval (3 dph) survival rate were only significantly improved by the high n-3 LC PU A (FO) diet broodstock group.

Conclusion

This study emphasizes the strong positive effect of broodstock (HG) selected for high growth improved the sperm concentration and motility percent and HG broodstock fed with high n-3 LC PUFA (FO) diet improved the egg viability percent. Further studies will address the effects of broodstock selection and dietary fatty acid level on progeny growth performance and their utilization of low FM/FO diets and assess the possible epigenetic changes in the offspring as affected by the nutritional history of broodstock.

Insects have received a great attention for their potentials as a protein resource in aqua-feeds. There is limited information on the insects for shrimp feeds. This study was conducted to replace partial fish meal (FM) with two insect meals for Pacific white shrimp. In a feeding trial, we used mealworm (MW) and black soldier fly (BSF) as the FM replacement. Tuna meal was used as the main protein source in a control diet and its 20, 40 and 60% was replaced with MW or BSF. Shrimp (body weight: 0.09g) were randomly stocked into twenty-eight experimental tanks with 4 replicates and fed the diets for 65 days. At the end of feeding trial, body weight was significantly higher in shrimp fed BSF 40 and 60% than that of shrimp fed the FM control diet. The lowest body weight or feed intake was observed in shrimp fed MW60%. There were no significant differences in composition of shrimp whole-body. This study indicates that BSF and MW can replace FM by 60% and 40%, respectively, in diets for Pacific white shrimp

Table 1. Growth performance of Pacific white shrimp *Litopenaeus vannamei* fed the experimental diets for 65 days (initial body weight: 0.09g)

THE GENETIC ANALYSIS OF TWO STERLET POPULATIONS AND THEIR INTER-POPULATION HYBRIDS

Sahana Shivaramu*, Ievgen Lebeda, Vojtěch Kašpar and Martin Flajšhans

University of South Bohemia in České Budějovice, Faculty of Fisheries and Protection of Waters, South Bohemian Research Center for Aquaculture and Biodiversity of Hydrocenoses, Zátiší 728/II, 389 25 Vodňany, Czech Republic
Email: sshivaramu@frov.jcu.cz

Introduction

The sterlet (*Acipenser ruthenus*) is a Eurasian rheophile freshwater species which is relatively small in size among the Acipenserids. Although this species is less important for caviar production, it is threatened according to the IUCN Red List (2013). Restocking activities are being undertaken along the stretches of Danube in Romania and Hungary. Genetic variability considered as a key element for adaptability against the drastic climate change and anthropogenic pressures. Investigation of genetic patterns within and between populations is considered as a prerequisite for a successful recovery program (Reinartz et al., 2011; Friedrich, 2018). As such the question of the proper source for recovery, stocking is becoming an urgent question for the initial phase of the recovery programs (Boscari et al., 2014). One likely option for restocking could be the mixing fish from different isolated populations to increase the genetic diversity and allow future selection based upon the natural pressures in the natural waters (Friedrich, 2018). The fitness of intra-specific hybrid can be higher (heterosis) or lower (outbreeding depression) than that of their parental populations. Besides, heterosis or neutral outcomes are not considered detrimental to conservation efforts, henceforth the focus of selecting candidate populations should be on the prevention of outbreeding depression. Here, we performed the genetic analysis of hatchery stocks originated from Volga and Danube sterlets using a set of microsatellite loci and, selected the best candidate parents for production of intraspecific hybrids. Also, we compared the genetic diversity among the produced purebreds and hybrids in order to find any hybridization incurred genetic incompatibilities and the genetic fate of F1 hybrids.

Materials and Methods

The tissue sample (fin clip) from 100 fishes were collected from hatchery stocks originated from Danube (Rybnikarstvi, Pohořelice) and Volga (Genetic Fisheries Center, Vodňany) respectively and stored in 96% ethanol. Six microsatellite markers viz., AciG 35, AfuG 135, Aox 45, Spl 101, Spl 163 and Spl 173 were used for amplification. The PCR amplification was carried out according to the procedure described by Havelka et al. (2013). The mean number of effective alleles (N_A), allele diversities of each locus, the fixation index (F), pairwise population differentiation (G_{ST}), DA genetic distance, expected (H_e) and observed (H_o) heterozygosities between Danube and Volga populations were calculated using GeneAlex software. The male and female candidates which expressed more number of discriminatory alleles in both populations were chosen for production of hybrids (also reciprocal hybrids) and purebreds. The level of polymorphism among produced hybrids and purebreds was assessed as described above.

Results

The allele diversity was found to be highest in Danube population for locus Aox45 (0.882). The overall allele diversity among all the loci was high in Danube population when compared to Volga population. The observed heterozygosity followed by expected heterozygosity was found highest in Danube population. The pairwise G_{ST} and D_A matrix value between Danube and Volga populations were 0.136 and 0.549 respectively. These significant values showed that the Danube and Volga stocks are moderately genetically differentiated. Likewise, the mean number of alleles was significantly higher in Danube × Volga hybrid, whereas Volga purebred displayed least mean number of alleles. The observed (0.6962±0.0498) and expected (0.7589±0.0685) heterozygosities was high in the Danube × Volga hybrid.

Discussion

Our experiment revealed that the Danube and Volga stocks are moderately genetically differentiated. It is highly essential to track the genetic condition of the broodstock constantly. The selection of broodstock containing spawning individuals characterized by high genetic variation is done when the genetic diversity values reaches critical level. In such instances, selection of spawning pairs based on genetic profiles is highly required (Kaczmarczyk and Fopp-Bayat, 2013). The mean number of alleles and, expected and observed heterozygosities were significantly high in one of the hybrid. Inheritance of genetic material from one population to another by hybridization serves as a source of adaptive genetic variation (Grant and Grant 1994). Our results shows that these hybrids can be used to exploit the heterosis over purebreds for aquaculture purposes. We also suggest to avoid use of these hybrids for restocking purposes since our results revealed the selected Danube and Volga broodstocks has moderate genetic divergence which eventually can possibly give rise to outbreeding depression in successive generations and can be detrimental to the wild stocks.

EFFECTS OF SALINITY ON CA^{2+} TRANSPORTERS IN THE MANTLE TISSUE OF *Crassostrea gigas*

J.K. Sillanpää* and K. Sundell

Fish Endocrinology Laboratory, Department of Biology and Environmental Sciences, University of Gothenburg, PO Box 463, S-405 30, Gothenburg, Sweden
kirsikka.sillanpaa@bioenv.gu.se

Introduction

The bivalve shell is composed of 95-99 % calcium carbonate ($CaCO_3$) while the rest is made of organic matrix consisting mainly of proteins and polysaccharides which are thought to control the crystallization of $CaCO_3$ (Marin et al., 2012). To build and maintain the shell, calcium needs to be taken up from the environment and transported to the area of shell growth through the mantle tissue which separates the shell from the rest of the animal body. The final layer of transport is the outer mantle epithelium (OME) facing directly the shell growth area.

In theory, calcium could be transported across in the OME either as free ionic Ca^{2+} either intra- or paracellularly, bound to organic or inorganic ligands, bound to proteins and/or within vesicles or hemolymph cells (Marin et al., 2012). Ionic Ca^{2+} transport across the OME has been shown to consist of both passive paracellular and active transcellular transfer. Ca^{2+} enters the OME through voltage-gated Ca channels across the basal cell membrane and transported further to the shell growth area via plasma-membrane Ca^{2+} ATPase (PMCA) and Na^+/Ca^{2+} exchanger (NCX) (Sillanpää et al., 2018).

Global increases in temperature will intensify the Earth's water cycle, creating increased evaporation which in turn will result in storms with increased precipitation in certain areas but also contribute to drying over some land areas. It will also result in increased melting of the sea ice and the ice sheets of both the Arctic and Antarctic areas. This increase in fresh water output to the oceans does not only create rising sea levels but will potentially also affect the salinity of the waters (IPCC 2014). Lowering seawater salinity and thus ion concentration could potentially affect calcifying organisms which dependent on the supply of Ca^{2+} and CO_3^{2-} ions from the environment.

In this study, the expression of potential Ca channels and transporters was measured in the mantle tissue of *C. gigas* exposed to different salinities. Additionally, ion transfer across the OME was assessed using the Ussing chamber methodology.

Materials and methods

Pacific oysters (*Crassosotrea gigas*) were exposed for two salinities, 16 ppt and 32 ppt for the duration of 14 days. After the exposure, tissue samples from mantles were sampled and frozen in liquid nitrogen. The gene expression of Na^+/K^+ ATPase, PMCA, sarcoplasmic/endoplasmic reticulum Ca^{2+} ATPase (SERCA), NCX, L-type Ca channel and T-type Ca channel were measured using qPCR.

Additionally, to study the ion transport across the outer mantle epithelium, the OME of ten *C. gigas* from both salinities was dissected from the ventral side of the animal. Inner mantle epithelium and connective tissue were carefully removed and the remaining OME was placed on an Ussing chamber. The transepithelial resistance (TER), transepithelial potential (TEP) and short circuit current (SCC) were measured during the whole experiment (150 minutes). On the left half chamber (the inner side of the OME) radiolabelled ^{45}Ca as well as ^{3}H-Mannitol were applied. Samples were taken from the "cold" side at 10, 15, 20, 60, 80, 85 and 90 minutes from sampling. Concentration of transported calcium was calculated from the slope of appeared radioactivity against time.

Results

The expression of NKA and SERCA as well as Ca^{2+} transfer and total ion transport (measured as SCC) across the OME were higher in the salinity of 32 ppt compared to 16 ppt. The expression of T-type Ca channel as well as paracellular permeability (measured as TER) were higher in 16 ppt compared 32 ppt.

(Continued on next page)

Discussion and conclusions

The electrophysiological parameters, TER, TEP and SCC revealed that the salinity affected ion transport. The net ion transport (measured as TEP) remained the same despite the salinity. Active transport (SCC) was higher in 32 ppt compared to 16 ppt, most likely due to the higher sodium content of the oysters' environment. This could also been seen from the higher NKA expression compared to the lower salinity as NKA is directly affected by the external sodium concentration (Meng et al. 2013). On the other hand, the TER was higher in 16ppt compared to the 32 ppt, which indicated lower paracellular permeability. Together these results show that the overall ion transport, both passive and active is decreased in 16 ppt compared to 32 ppt.

Although the active Ca^{2+} output (PMCA and NCX) did not seem to be affected by salinity, the expression of Ca channels, especially the T-type Ca channel increased when salinity was decreased to 16ppt. Meng et al. (2013) found a similar increase in Ca-channel expression in low salinities (10 and 15 ppt compared to 20 – 30) in the gills of *C. gigas*. They suggested this to be due the fact that the increased Ca^{2+} current in low salinity would induce the activity of calcium-gated K^+ -channel partly responsible for maintaining the ionic balance inside the mantle cells.

From the perspective of calcifi ation, the increase in the expression of Ca channels in low salinity could aim to keep the Ca balance stable. Similarly the decrease in the expression of SERCA would indicate this, as less Ca is sequestered inside the mantle cells. However, Ca^{2+} transfer did decrease in 16 ppt as was seen from the Ussing chamber measurements. An alternative explanation is offered by the theory that OME cells produce vesicles containing amorphous $CaCO_3$ (ACC) which are then transported to the shell growth area (Li et al., 2016a). To be able to precipitate ACC, OME cells would need to take up calcium but the deposition would be executed by exocytosis instead of using active transport. This would explain the increase in ionic Ca^{2+} transfer into the cytosol without similar increase in the expression of active Ca^{2+} transporters.

Ca^{2+} uptake into the cells might also be related to Ca-dependent signaling pathways (Zhao et al. 2012; Zhang et al. 2016). The animal might try to maintan Ca homeostasis despite the low environmental salinity, ie. to keep the intracellular Ca^{2+} concentration stable

Introduction

The growing demand for corals as ornamentals (Wabnitz et al., 2003)worth an estimated US$200-330 million annually, and oper- ating throughout the tropics. Ornamental marine species (corals, other invertebrates and fish, potential organisms for bioprospection (Leal et al., 2012), or good biological models (Watanabe et al., 2007) support a rather new sector for aquaculture. Coral cultures are a potentially sustainable, and constant biomass supply, with reduced impact on the ecosystem. A decisive next step is to overlap the gap of knowledge on culture protocols for key coral species that can meet the industry demands. *Sinularia flexibilis* (subclass Octocorallia, order Alcyonacea) is an exploited soft coral commonly found in Indo-Pacific reefs (Ofwegen, 2000) with suitable features for husbandry (*e.g.* bioactive compounds production). Photosynthetic corals rely on unicellular dinoflagellates (zooxanthellae) for photosynthesis. As mixotrophs, photosynthesis plays a decisive role on this organism energy budget (Falkowski et al., 1984). Therefore, understanding *S. flexibilis* response to light is crucial for a better husbandry. In this study we observed the energy allocation and photosynthetic response to light intensity and spectra variations.

Materials and methods

Coral specimens were collected in Indonesia and acclimated during two months in 100 -120 μmol.m^{-2}.s^{-}1 with total spectrum artificial light (12 hours photoperiod) in a standardized modular system (Rocha et al., 2015)biotechnological applications, and to supply the marine aquarium trade has prompted researchers to optimize coral culture protocols, with emphasis on ex situ production. However, the diversity of experimental systems employed to investigate ex situ coral production may be a bottleneck to the advance of the state of the art, as it impairs reliable comparisons between experiments, as well as the replication and optimization of culture protocols. This study presents a versatile modular culture system for experimental coral production ex situ, assembled using materials and equipments available from suppliers all over the world and thus allowing researchers worldwide to truly replicate experimental setups. The validation of the modular culture system was performed using the soft coral, Sarcophyton cf. glaucum, as a model organism. The validation experiment tested the effect of different light spectra on the photosynthetic performance, symbiont density, chlorophyll and carotenoid pigments concentration, survival, and growth of coral fragments. The validation experiment confirmed the potential of this modular culture system, which ultimately enables researchers to perform direct comparisons among experiments, and more efficientl contribute to advance ex situ coral aquaculture.”,”author”:[{“dropping-particle”:””,”family”:”Rocha”,” given”:”Rui J.M.”,”non-dropping-particle”:””,”parse-names”:false,”suffix”:””},{“dropping-particle”:””,”family”:”Bont s”,”given”:”Bogdan”,”non-dropping-particle”:””,”parse-names”:false,”suffi ”:””},{“dropping-particle”:””,”family”:”Ca rtaxana”,”given”:”Paulo”,”non-dropping-particle”:””,”parse-names”:false,”suffix”:””},{“dropping-particle”:””,”family” ”Leal”,”given”:”Miguel C.”,”non-dropping-particle”:””,”parse-names”:false,”suffix”:””},{“dropping-particle”:””,”fami y”:”Ferreira”,”given”:”José M.”,”non-dropping-particle”:””,”parse-names”:false,”suffix”:””},{“dropping-particle”:””,”f mily”:”Rosa”,”given”:”Rui”,”non-dropping-particle”:””,”parse-names”:false,”suffi ”:””},{“dropping-particle”:””,”fami ly”:”Serôdio”,”given”:”João”,”non-dropping-particle”:””,”parse-names”:false,”suffix”:””},{“dropping-particle”:””,”fa ily”:”Calado”,”given”:”Ricardo”,”non-dropping-particle”:””,”parse-names”:false,”suffix”:””}],”containe -title”:”Journal of the World Aquaculture Society”,”id”:”ITEM-1”,”issue”:”3”,”issued”:{“date-parts”:[[“2015”]]},”page”:”235-251”,”title”:”Development of a Standardized Modular System for Experimental Coral Culture”,”type”:”article-journal”,”v olume”:”46”},”uris”:[“http://www.mendeley.com/documents/?uuid=685fb87c-913a-40f9-98e8-b9ed8b4c9834”]}],”mend eley”:{“formattedCitation”:”(Rocha et al., 2015. After acclimation, one mother colony was fragmented into 28 fragments and randomly assigned for the different treatments (n=7). Red and blue spectra were used along with 120 ± 10 μmol.m^{-2}.s^{-1} (high) and 70 ± 10 μmol.m^{-2}.s^{-1} (low) photosynthetic active radiation for each spectrum. After four months photosynthetic performance (Rapid Light Curves) and energy allocation were assessed. Data was analyzed in R (2018) and a two-way ANOVA was performed.

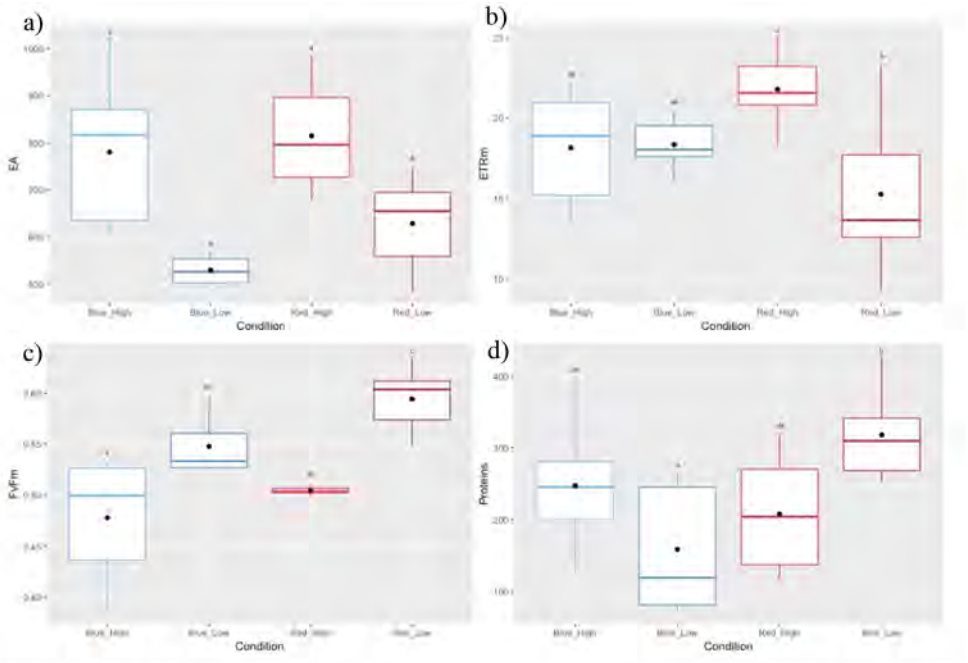

Figure 1- Boxplots for a two-way ANOVA significant differences for each condition (color and light intensity). a) Energy available significantly different for light intensity (p=0.001); b) Maximum electron transport rate significantly different for light intensity (p=0.033) and interaction between light intensity and color (p=0.024); c) Maximum photosynthetic potential significantly different for color (p=0.007) and light intensity (p<0.001); Total protein significantly different for interaction between light intensity and color (p=0.005).

Results

Red spectrum with low light intensity displayed more total protein (=309.35), better photosynthetic response (α) (=0.12), and improved maximum photochemical efficiency of photosystem II in a dark adapted state (Fv/Fm) (=0.60). On the other hand, the same condition showed lower tolerance to high light intensity, specificall , Ek (=110.61) and ETRmax (=13.63), and scarce energy available (=654.78). Blue spectrum with high light intensity showed significantly more energy available (=816.79) and better tolerance to high light intensity, namely high Ek (=211.06) and ETRmax (=18.88), but also lower total protein (=245.50), lower maximum photosynthetic potential (=0.50) and worse photosynthetic response (=0.09).

Discussion

Our data suggest that red spectrum with low light intensity incites *S. flexibilis* to allocate energy on protein assimilation (e.g. growth) while being photosynthetically efficient, which are better characteristics for husbandry under stable and controlled conditions. Alternatively, blue spectrum with high light intensity seems to be a better condition to prepare for less stable conditions (e.g. restocking), suggesting higher resistance to environmental variation, but lower fit to husbandry.

Introduction

Aquaponics is a novel and developing industry in which the combined production of aquatic organisms and plants is carried out. Aquaponics faces multiple challenges since it is a relatively new activity (Yep and Zheng, 2019). According to Goddek et al. (2015), more quantitative research is needed to develop the economic feasibility of aquaponics systems. Technical issues like optimum pH (Zou et al., 2016), nutrient balance (Nhan et al., 2019) and pest and disease issues (Mori and Smith, 2019) among others have been studied. The economic feasibility of aquaponics also has been the subject of research; however, there are not consensus about it (Greenfeld et al., 2018). Also, research has been carried out that aims to characterize the participants of aquaponics activities through surveys; in these works, the economic sustainability of the production system and the necessity of more training related to fish diseases and plant pest were identified as challenges (Love et al., 2015; Villarroel et al., 2016). In order to propose research for the improvement of aquaponics systems and management it is necessary to know the manner in which the production is being carried out and to understand the current problems faced by the participants. The aim of this work was to identify the difficulties that the Brazilians in aquaponics are facing, with the intention of elaborating research avenues specific to improving the industry in the countr .

Material e Methods

From July to September of 2018 a questionnaire for the identification and characterization of aquaponics participants in Brazil was made available in Google Forms. This was promoted and shared through social media, schools, research and extension institutions, professional platforms and discussion groups related to aquaponics. In addition to identifying the participants, the questionnaire covered other topics such as their production purpose and their problems. The problems considered were: System implantation (SI), control of climate conditions (CC), lack of technical knowledge (LTK), lack of specific supplies (LSS), diseases in the aquatic component (DA), diseases in the plant component (DP), aquatic production performance (APP), plant production performance (PPP), aquatic production commercialization (APC), plant production commercialization (PPC), organic certification (OC). The respondents were asked to assign to each one, in ascending order, a score from 1 to 4 according to the level of difficulty (being 4 the highest) or they had the option to inform if that problem does not apply in their enterprise, which would receive the score 0. A general average value was calculated for each problem using the obtained data. Also, the average score of each issue was calculated and a cluster analysis was performed for each one of the production purposes groups.

Results

A total of 39 aquaponics participants from all the regions of Brazil responded to the online questionnaire and were classified into 8 groups according with their production purpose. The issues with the highest scores were LSS, CC and SI with an average score of 2.26 ± 1.23, 2.13 ± 1.22 and 2.00 ± 1.21 respectively. The lowest score was for APC with a value of 1.03 ± 1.29 (Figure 1).

The average score for the production purpose group showed that the highest score is different for some groups. For example, the highest score for “Commercial” and “Graduate and undergraduate” groups was obtained in OC with a value of 2.91 ± 1.87 and 4. And, in the case of the “Hobby” group the highest score was in the CC issue. The lowest score is also variable for the different production purpose groups. For “Hobby”, “Others” and “Subsistence” groups the score of OC was 0 (Figure 2).

The production purpose groups can be clustered in four sets according to the main problems identified. From these, the “Others” and the “Graduate and undergraduate” groups are alone in the first and second clusters respectively, the “Subsistence”, “Subsistence and surplus sale” and the “Commercial” groups belong to the third one and the “Hobby”, “Highschool” and “Scientific” groups belong to the fourth.

(Continued on next page)

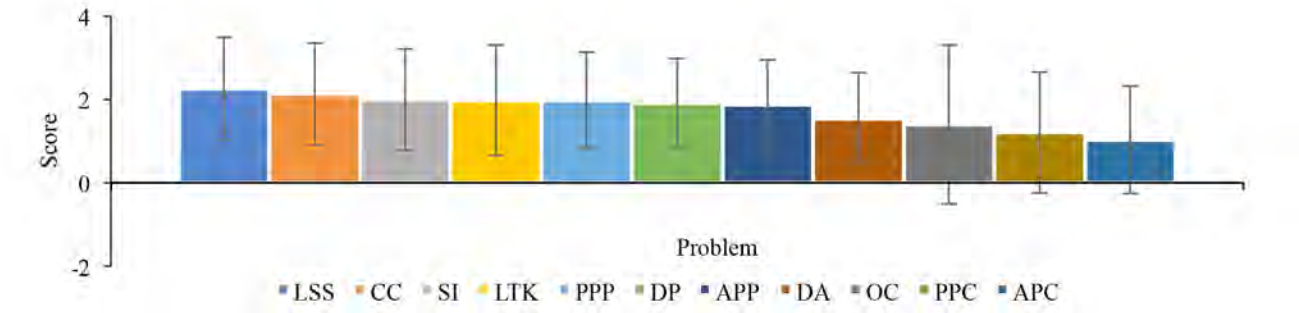

Figure 1. Average scores for each issue

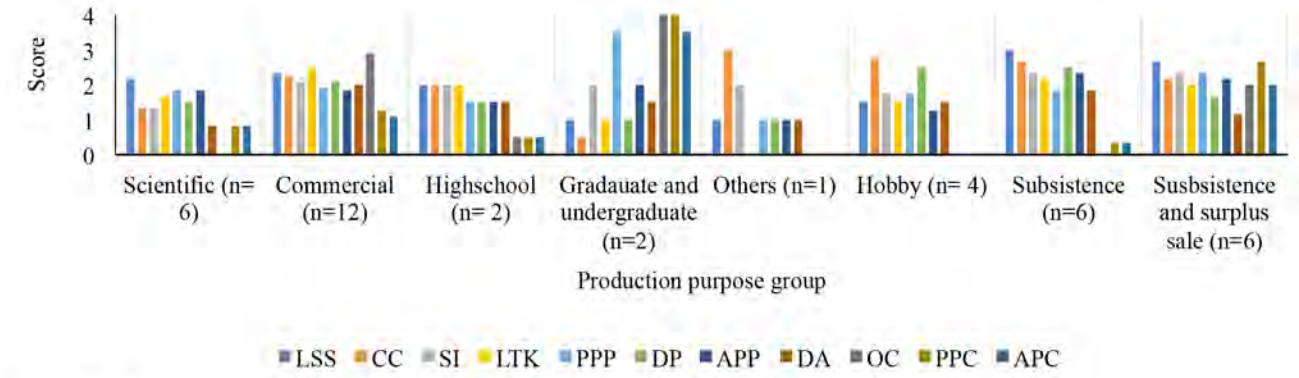

Figure 2. Average score obtained for each issue in the purpose groups.

Discussion and Conclusion

Depending on the target production group, the problems to be solved are variable. Besides the research interest of the scientists, efforts should focus on solving the problems of the target group. For the development of commercial aquaponics, research that covers the requirements of organic production should be carried out since this subject may improve the economic feasibility of the enterprise (Tokunaga et al., 2015).The research for subsistence aquaponics should be directed to systems designed with less specialized infrastructure, adapted to the climate conditions of the region and disease plant control.

MICROALGAE BIOTECHNOLOGY AS A POTENTIAL NUTRITIONAL SOLUTION FOR FISH FEED

Margarida Costa, Hugo Pereira, Pedro Quelhas, Nádia Correia, Inês Guerra, Júlio Abelho, Joana Silva*

Allmicroalgae, Research and Development Department - Fábrica Cibra Pataias, 2445-411 Pataias, Portugal
Email: joana.g.silva@allmicroalgae.com

Introduction

Aquaculture sector is growing faster than any other food-producing sector (FAO, 2018) and to meet this demand, different nutritional sources for the aquacultured animals have been discussed. Fishmeal is currently the preferred protein ingredient of feed in aquaculture industry; however, its complete or partial substitution by alternative sources is needed. Microalgae have been commonly used worldwide as an alternate protein source replacing fishmeal

Fishmeal substitution by microalgae is considered to be environmentally sustainable, as it reduces dependency on finite marine resources and surpasses the issue rased by the extensive use of land when using plant-based ingredients. However, the nutritional requirements of certain aquatic species may limit the fishmeal substitution due to unbalanced nutrient rates (Huntington and Hasan, 2009).

Microalgal biotechnology has emerged in recent decades based on their extensive different applications, such as nutraceutical research, renewable energy source, production of bioactive and health-beneficial biomolecules like β-carotene, astaxanthin, PUFA, bio-colorant production, wastewater treatment, bioremediation, human food and animal feed (Daphne *et al.*, 2015). Besides used since early, biotechnology focused in microalgae is a relatively recent field and these organisms´ growth conditions and nutritional information still need clarification

In this context, the aim of this work was to access the potential of microalgae to be used as aquafeed, concerning their industrial production.

Material and methods

Different microalgae were addressed during the present study, namely *Chlorella vulgaris*, *Nannochloropsis oceanica*, *Tetraselmis* sp. *Chlorococcum* sp., *Scenedesmus obliquus*, *Phaeodactylum* sp.. All experiments were performed at the industrial production facilities of CMP/AlgaFarm/Allmicroalgae, Pataias, Portugal. A five step scale-up was approached, with cultures starting at 5 L up and being scaled-up until reaching the 2.5 m^3 pilot-scale photobioreactor (PBR) in appropriate culture medium. After growing experiment, cells were filtered and spray dried. Spray dried microalgae samples were used for analytical quantifications: protein, ashes, starch and fiber content, as well as the digestibility rate.

Results

Preliminary results indicate that, among the studied microalgae, *Chlorella vulgaris* was the one with higher productivity, reaching 0.22 g/L/day which were immediately followed by *Scenedesmus obliquus* (0.19 g/L/day). *Chlorococcum* sp. presented the lower productivity rate, growing at 0.10 g/L/day.

Chlorella vulgaris presented the higher protein content (59%), followed by *Scenedesmus obliquus* (53%). *Tetraselmis* sp. was the species with the lowest protein values, however with the higher digestibility rate, 89%. In accordance, this microalga presented a low rate of indigestible fibers. *Tetraselmis* sp. had also the higher starch content, 14%, while the other strains showed values between 1 and 4%. Together with *Nannochloropsis oceanica*, *Tetraselmis* sp. showed the highest level of ashes, 28%, when compared with the other analyzed microalgae.

Scenedesmus obliquus presented the lowest ash content, 8%, when compared with the other five studied microalgae, followed by the *Chlorella vulgaris* with 9%. *Scenedesmus obliquus*, *Nannochloropsis oceanica*, *Chlorococcum* sp. and *Phaeodactylum* sp. have minimum levels of starch, which vary from 1 to 2%.

(Continued on next page)

Discussion and conclusions

Chlorella vulgaris industrially grown at the ALGAFARM facilities seem to meet the nutritional characteristics for a good fishmeal substitute. Fish feed are mostly characterized by their protein content which is primarily needed for muscle tissues (Delgado and Reyes-Jaquez, 2017). *Chlorella vulgaris* observed protein levels are within the range of other aquaculture composition formulations (Rodríguez-Miranda, 2014). The amount of carbohydrates in fish feed is usually low since fish have a low capacity to digest carbohydrates (Delgado and Reyes-Jaquez, 2017). *Chlorella vulgaris* presents relatively low starch content; however, starch makes it also more suitable for the extrusion process (Delgado and Reyes-Jaquez, 2017). Besides, *Chlorella vulgaris* shows also to be the most productive algae, when compared to the others tested, in what concerns to biomass.

The present study shows that microalgae, particularly *Chlorella vulgaris*, can represent a nutritional sustainable source for aquaculture feed. However, further complementary studies are needed in order to evaluate other nutritional parameters such as the lipid content, the amount of vitamins present in the microalgae, as well as *in vivo* feed experiments with aquacultured fish

CHALLENGES OF CONSUMER ORIENTED COMMUNICATION ABOUT SCIENTIFICALLY BASED SUSTAINABILITY STANDARDS FOR AQUACULTURE

J. Simons[1*], C. Vierboom[2], M. Ley[2], and S. Johnigk[3]

[1] Department for Agrcicultural and Food Market research, University of Bonn,
Nussallee 21, D-53115 Bonn;

E-mail: johannes.simons@ilr.uni-bonn.de

Problem and research questions:
Research demonstrates that consumers' knowledge about fishery and aquaculture is low. Their ideas are not so much based on facts but more on competing schemata. Requirements for sustainable fishery and aquaculture are vague and very general. Aquaculture should be "natural", "space allowance", "no drugs". Moreover fishes should live in fish friendly environment. (Verbeke et al, 2007a; Verbeke et al. 2007b, Feucht and Zander, 2015).

According to surveys sustainability aspects as well as ethical issues are relevant for a large share of consumers. However in purchase decisions these aspects play a minor role (Verbeke et al, 2007b; Feucht and Zander, 2015). But the relevance of sustainability activities in Germany increased during the last years especially fuelled by activities of retailers. In order to be able to communicate efficiently to consumers and valorise the benefits of higher production and processing standards it is necessary to get a deeper insight into the way that consumers perceive and process information on fisher .

Method:
To better understand the discussion about fishery and the psychological relevance of fish in consumers' everyday life we conducted interviews and group discussions during which the interviewees describe their everyday life with respect to fish and aquaculture. In line with the narrative paradigm (Fisher, 1984), we acted on the assumption that the experienced reality of human beings is organized and interpreted in stories and that interviewees reveal unconscious contexts based on detailed descriptions.

The interviews were analysed in the team of psychologists together with an expert in food markets and food value chains and one in fishery and aquaculture. This reduces individual biases and integrates knowledge on markets, value chains and sustainable fishery into the research process

30 in-depth interviews and six group discussions with eight to ten participants each were carried out in two waves, between November 2017 and May 2019.

Results:
Our analysis confirms previous results regarding the low level of knowledge about fisher . Moreover, ignorance of aspects that reduce the pleasure in food is a well-established way to reduce the complexity of everyday life and to enjoy food. It turns out that participants want to know, but that they feel overstrained to learn details about the systems and to bring them into a consistent concept.

However, a lot of ideas, images observations, and reflections came up during the interviews and group discussions. The mental representation of fish in general and aquaculture in particular is characterised by competing, contrasting, and ill-matching imageries. It is like pieces of a puzzle that do not result in a uniform picture.

Wild fish can trigger imageries of holidays. As a creature living in another element wild fish is a material symbol for a transition into another world. But even though wild fish evokes romantic narratives it is susceptible regarding images and ideas about polluted fish environment, contamination of fishes, exploitation of the oceans, and fishing methods that are neither fish-friendly nor environmental sound

"Aquaculture" mainly evokes schemata comparable with mass production. These schemata are very close to mass animal husbandry and characterised by an unworthy treatment of animals (cp. Simons et al., 2017). The use of antibiotics often is regarded as necessary in an environment supposed to be far away from natural. Compared to wild fish romantic and emotionally positive aspects are of minor relevance. A few emotional narratives came up, e.g. in the context of direct marketing of trout.

(Continued on next page)

The relevance of animal welfare issues with respect to fish seems to be lower than in the context farm animals. Still it is supposed that production and processing systems which are not close to nature and require the use of antibiotics negatively impact the food quality and safety. As a consequence fish welfare and fish friendly production is indirectly an important issue for consumers linked by perceived quality.

"Naturalness" is one of the dominant categories in the context of assessing food: as natural as possible is at the same time as good as possible. As aquaculture is supposed to be not natural, it has a disadvantage compared to "natural" wild fish. But wild fish has its dark sides, too. It faces a lot of image problems that can easily be activated and reduce the pleasure in eating. Against this background, farmed fish is a good but not perfect alternative in which the environment for fishes can be controlled

Conclusion:
Given the low level of consumers' knowledge there is a need for a scientifically based standard that takes into account consumers concerns and translates them into process requirements. Moreover, credible controlling and mediating institutions are necessary so that consumers can make the right purchase decision without exactly knowing why.

As consumers will hardly understand a scientific discussion and assess management practices based on their own knowledge, communication about the standard should be embedded into the narratives of consumers in order to bridge the gap between scientific arguments and consumers' perception. An example: Transferring fishes from one basin or pond to another through tubes and by help pumps may cause immediate stress to consumers as the idea of being helpless in a water stream arouses claustrophobic fears. In order to communicate that this is a fish friendly procedure it may be necessary to highlight that fishes are in their element and therefore do not fear to suffocate. Thus uncomfortable feelings that may arise unconsciously can be prevented.

Problem and research questions:
In a systematic literature review on purchase behaviour for fish and seafood products in developed countries Carlucci et al. (2015) identified sensory perception, health believes, fish eating habits, convenience perception, self-efficacy in the fish preparation process, price perception, and fish availability as main factors analysed and explain the quantity of fish consumption. Product attributes as country of origin, production method, preserving method, product innovation, packaging and eco-label influence the choice with respect to different product offerings. Besides purchase behaviour a lot of papers address the willingness to pay (WTP) for sustainability attributes in general and/or of fish welfare in particular; e.g. Zander and Feucht (2018) provide a comparison between different European countries with respect to the WTP for sustainable seafood.

To the knowledge of the authors no publicly available research explicitly focusses on the opportunities of fish and fish products for satisfying specific psychological needs. A basic study on the relevance of fish in every-day life of consumers provides a deeper insight in fish consumption and in opportunities to position fish products in their competitive environment as well as a better understanding of the impact of communication on fish

Method:
The study is based on the theoretical framework of Morphological Psychology that focuses on "impacts", which are specific for a product. Pursuant to that, the method is product-oriented and identifies the ability of products to satisfy psychological needs or motives. Insights into the impact on products are collected in qualitative interviews and group discussions in which participants describe the meaning of the product in their every-day live (Melchers and Ziems 2001). As qualitative methods are interpretative and therefore susceptible for biases, research was carried out by a team of specifically trained psychologists to improve the validity of results. Moreover market data provided additional insights and help to reduce biased interpretation.

10 in-depth interviews and three group discussions with eight to ten participants each were carried out in November and December 2017 in Germany. Given that the psychological impact of products is dependent on the cultural environment, results cannot be simply transferred to other countries.

Results:
Fish has fascinating and threatening aspects at the same time. Fishes stand for agility as well as for fluent, sudden and apparently weightless movements in any directions. They live in a submarine world that is perceived as fascinating but difficult to access for humans. Moreover fish can easily be associated with memories of holidays and of adventures. Agility, imaginations of holidays, adventures and a fascinating world support the ability of fish to enact time-outs from rigid and restrictive daily routines. The specific psychological characteristic of fish and fish products is enhanced by a low level of consumption in Germany, which amounts to about 14 kg/head/year compared to about 90 kg/head/year of meat and meat products (FIZ 2019).

The "bright" side of fish is contrasted by a "dark" side. Ideas about spoiled and awfully stinking fish and the danger of poisoning can ruin the fascinating imageries and the appetite for fish. The same holds for ideas about a polluted environment in which fishes may grow and which have negative impacts on the perception of fish as valuable food. Fish bones are a further issue that may require care in preparation and caution in eating. Stories of nearly suffocated fish eaters appeared in several interviews.

The bright side of fish in combination with its dark sides provides opportunities to demonstrate knowledge about fish, specific skills in handling fish, and to present oneself as a connoisseur and gourmet. In this respect fish can be used as a mean for impression management. Some participants told that they usually eat fresh fish in restaurants so that they are not dependent on their own skills and indulge in a time-out by being served in a particular surrounding with fish

(Continued on next page)

The results especially hold for fresh fish even though it amounts for only about 10% of the overall fish consumption in Germany (FIZ 2019). Apparently fresh fish has a dominant role regarding narratives about fish. Preserves, frozen or smoked fish do not influence spontaneous perception to the same extent

The strength of fresh fish is a barrier at the same time. The high market share of prepared fish reveals a need for consuming fish without great effort. Respective products are easy to prepare and easy to eat. They fit into everyday routines and enrich the diet in a less spectacular way.

Conclusion:

The different preparations of fish with fresh fish on the one side and prepared food like fish sticks on ready to eat products on the other address the need of enriching the daily routine in specific ways. But against the background of the "dark" sides of fish, appetite for fish and its ability to address psychological needs is not stable. Fish scandals as well as negative communication about fish can easily trigger, activate and arouse fears and spoil appetite. As a consequence the image of fish can be severely harmed with an influence market performance of the products.

DIGESTIBILITY OF FILAMENTOUS FUNGI IN RAINBOW TROUT (*Oncorhynchus mykiss*)

Aprajita Singh*, Sajjad Karimi, Aleksandar Vidakovic, Markus Langeland, Johan Dicksved, Kartik Baruah, Anders Kiessling and Torbjörn Lundh

Department of Animal Nutrition and Management, Faculty of Veterinary Medicine and Animal Sciences, Swedish University of Agricultural Sciences, 750 07 Uppsala, Sweden
Email: aprajita.singh@slu.se

Introduction

Microbial proteins including filamentous fungal biomass contain noticeable levels of protein, fatty acids and other nutritious components (Karimi et al., 2018). Also fungi cell wall contains chitin and chitosan and other polysaccharides as their bioactive components (Mario et. al., 2008). These bioactive compounds possess immunomodulatory and antimicrobial properties (Kumar et. al., 2009, Esteban et. al., 2001). Thus, fungi may play a role in improving the health of farmed fish. At the same time, it is essential to understand how digestibility of fungi is affected by sustained feeding. *Neurospora intermedia* is an edible filame tous fungi with high protein content (57.3%). In this study, a 30-day feeding trial was conducted to examine the digestibility of diets supplemented with filamentous fungi *N. intermedia* in *Oncorhynchus mykiss*.

Materials and methods

Reference diet (Ref) was prepared with fish meal as the main protein source, whereas diets NPC (non-preconditioned) and PC (preconditioned; 95^{o}C for 5 min) were prepared by mixing the reference diet mash and the dried *N. intermedia* in the ratio of 70:30. Titanium dioxide (TiO2) was used as an inert marker. Twenty fish were distributed randomly in each experimental tank (mean weight: 127± 4 g) and were acclimated for 9 days on commercial diet. Fish were fed to satiation. Faecal samples for digestibility were collected daily for 30 days and were separated at 10 day intervals for assessment of ADC per period.

Results

Significant differences between diets in apparent digestibility coefficients (ADC) were observed for dry matter (77.25-80%), crude protein (91.68- 93.34%) and gross energy (81.63- 85.35%) ($p<0.05$). There were no significant differences for interaction between diets and time intervals of fecal sampling for either test diets and test ingredients ($p>005$). Diet and interval of fecal sampling had significant effect on respective ADCs but no significant effect of diets on ADC of CP was seen at end of the feeding trial. Also, no significant difference in the ADCs for test ingredients were observed after 30 days ($p>0.05$). Furthermore, there were no significant di ferences in weight gain between the dietary treatments (>0.05).

Discussion and conclusion

Based on the above results, it can be suggested that the ADC of DM, CP and GE
depends on diet and time interval. Although no positive effect on digestibility was observed due to heat processing in this experiment, positive effect has been previously documented for extrusion cooking in diet of rainbow trout (Barrow et. al., 2007). Overall, diets with *N. intermedia* had lower mean ADCs of DM, CP and GE than fish meal diet at the end of experiment. Similar results were obtained when Arctic charr was fed with another filamentous fungi, *Rhizopus oryzae* (Vidakovic et. al., 2016). In this experiment digestibility for diets did not change at 10th and 20th day of fecal sampling. Although, apparent digestibility increased with time interval of fecal sampling and since there were no significant difference in the final weight gain of fish henc prolonged feeding trial and further investigation is recommended.

A LONG-TERM STUDY OF DOMESTICATED AND WILD ATLANTIC SALMON IN THE RIVER GUDDALSELVA

Øystein Skaala*, Besnier F., Borgstrøm R., Barlaup B., Sørvik A.G., Normann E., Østebø B.I., Hansen M.M. & Glover, K.A.

Institute of Marine Research, Nordnesgaten 50, 5218, Bergen, Norway
oystein.skaala@hi.no

Farmed Atlantic salmon are domesticated, and where significant interbreeding with wild conspecifics occurs, this may lead to changes in fitness traits, and ultimately, less productive wild populations (Reviewed by Glover *et al.* 2017). However, thus far, only a handful of studies have compared the fitness of domesticated and wild Atlantic salmon in the natural environment. Here, we present highlights from the most recent and extensive of these studies (Skaala *et al.* 2019).

250 000 eggs from 75 families of domesticated, F1-hybrid, and wild salmon were planted into Guddalselva, a river containing up- and downstream traps. In addition, >40 000 hatchery-produced smolts from the same pedigrees were released. Over eight years, 6669 out-migrating smolts and 356 returning adults were recaptured and identified to their families of origin with DNA.

In comparison with wild salmon, domesticated fish had substantially lower egg to smolt survival (1.8% vs 3.8% across cohorts), they migrated earlier in the year (11.8 days earlier across years), but they only displayed marginally larger smolt sizes and marginally lower smolt ages. Upon return to freshwater, domesticated salmon were substantially larger at age than wild salmon, but displayed substantially lower released-smolt to adult survival. Overall, egg to returning adult survival ratios were 1:0.76:0.30 and 1:0.44:0.21 for wild:F1-hybrid:domesticated salmon respectively (using two different types of data).

We conclude that spawning and hybridization of domesticated escapees can lead to i) reduced wild smolt output and therefore wild adult abundance, through resource competition in freshwater, ii) reduced total adult abundance due to freshwater resource competition and reduced marine survival of domesticated salmon, and iii) maladaptive changes in phenotypic traits.

Introduction

Aquaculture experienced a huge development during the last decades and is now expected to further increase. Indeed, the United Nation Food and Agriculture Organization (FAO) rely upon aquaculture production to provide sufficient animal proteins to more than 9 billion of people at the horizon 2050. However, to meet this challenge, aquaculture has to overcome bottlenecks with respect to fish nutrition. As the demand in fishmeal and fish oil for aquafeed production is going to exceed the offer soon, the sustainable development of aquaculture production implies the total replacement of fishmeal by affordable and suitable protein sources in fish feeds. Even fish feeds now include a large proportion of plant ingredients, the total replacement of fishmeal and fish oil by plant feedstuffs has not been successfully reached as it worsens growth performance and flesh quality, especially in carnivorous fish like rainbow trout[1]. At a nutrition level, much research is now being directed into novel feedstuffs including insect meal and yeast products as alternative protein sources or microalgae as n-3 long chain polyunsaturated fatty acids supplier to replace fish oil[2–4]. However, genetic selection of fish also appears as another key enabler for improving growth performance[5] when fed a plant-based diet. Therefore, in the present project, we decided to evaluate the benefits of combining selection of rainbow trout for better growth on plant-based diet and supplementation of plant-based diet with new ingredients including insect derived product, single cell protein (yeast) and processed animal protein on growth performances.

Materials and methods

In order to evaluate the impact of plant-based diets supplemented with new ingredients on growth performances of two lines of rainbow trout, we implemented a trial at the INRA fish farm facilities of PEIMA (Pisciculture Expérimentale INRA des Monts d'Arrée, France), using a rainbow trout line selected for better survival and growth on a 100% plant-based diet and trout from the initial unselected population. Rainbow trout (50g initial body weight) were fed twice a day until apparent satiation during 12 weeks, with one of the following diets: a commercial-like diet containing fishmeal and fish oil, a totally plant-based diet containing µalgae for DHA supply, the same plant-based diet supplemented with insect-derived product yeast proteins or a diet similar to the previous one but further supplemented with processed animal proteins. The total biomass of each tank and the quantity of feed distributed per tank were recorded every 3 weeks to determine the impact of the diets on feed intake, weight gain, specific growth rate (SGR) and feed efficienc . Whole fish were used for analysis of body composition (dry matter, protein, lipid and energy content). Blood, liver and muscle samples were also collected for plasma metabolite level determination (glucose, triglycerides, cholesterol and total amino acids) and gene expression RT-PCR analyses.

Results

Evolution of body weight gain and specific growth rate indicated that compared to a commercial-like diet containing fishmeal and fish oil, plant-based diet significantly reduced growth with a more important impact on the unselected line. Supplementation of plant-based diet with insect-derived and yeast protein products significantly improved growth performance but did not reach performances observed with the commercial-like diet. Daily feed intake decreased in unselected trout and in fish fed plant-based diet but it was partially restored by addition of alternative ingredients to plant-based diets. Compared to the commercial-like diet, all diets devoid of fishmeal and fish oil exhibited lower feed efficiency and this was significantly more pronounced in the selected line. Analyses of nutrient and energy gain and retention revealed that plant-based diet reduced nitrogen, lipid and energy gain. All were partially restored by dietary supplementation with insect, yeast protein and animal processed protein products. As regard retention, only lipid and energy retention were negatively affected by plant-based diets and partially restored by supplementation of these vegetable diets. Analyses of plasma metabolites indicated that plant-based diets reduced triglycerides, cholesterol and total amino acids.

(Continued on next page)

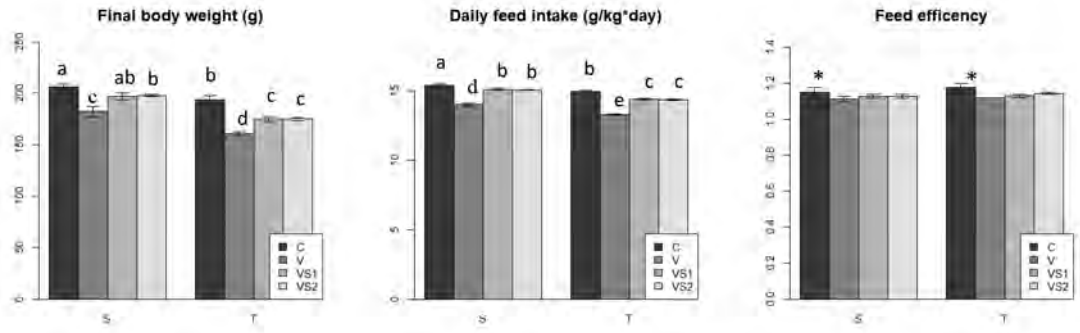

Figure: Growth parameters measured after 12 weeks of feeding trial. C: Commercial-like diet, V: Plant-based diet, VS1: Plant-based diet supplemented with insect-derived and yeast protein products, VS2: Plant-based diet supplemented with insect-derived and yeast products and processed animal protein, S: selected line, T: unselected line

Discussion and conclusion

The present study confirms the efficiency of the selection, with a global better growth of the selected line compared to the control unselected population, especially when fed a plant-based diet. When looking at the impact of the diets, the best growth occurs with the commercial-like diet that contains fishmeal and fish oil while PB diet still reduces growth performances because of lower feed intake and lower feed efficiency resulting in reduced nutrient gain. Whatever the fish line, substitution of part of the plant ingredients by a mix of insect derived product and yeast proteins increases growth without totally reaching the performance obtained with fishmeal and fish oil diets. However, interestingly, the selected line fed plant-based diet supplemented with insect-derived product and yeast proteins reaches the same growth as the control line fed the commercial-like diet, suggesting that combining genetic and new alternative diets could be a promising solution to totally suppress marine ingredients from aquafeeds dedicated to carnivorous species.

This study also highlights the leading role of feed intake in the better growth of the selected line. Enhanced feed intake also appears as a key element of the improvement of growth in trout fed supplemented plant-based diets. On the contrary, feed efficiency remains as a major bottleneck, because neither selection nor diets used in the present study were able to improve it. Therefore, in order to better understand the mechanisms underlying this negative impact of plant-based diets on feed efficienc , investigations at the level of metabolic pathways are ongoing.

MARINE RESOURCES IN CIRCULAR CLIMATE SMART FOOD SYSTEMS: A CASE STUDY OF SEAWEED CULTIVATION IN THE NORTH SEA

Maggie Skirtun, Sander van den Burg, Trond Selnes

Wageningen Economic and Research, Prinses Beatrixlaan 582 – 528
2595BM Den Haag, Netherlands
E-mail: maggie.skirtun@wur.nl

Introduction
Growth in global population will lead to an unprecedented increase in the global demand for food, and thus societies will face the challenge to increase sustainable food production. This has to be achieved in the context of a growing set of climate change-related risks, competition, scarcity of resources and the need to preserve the world's ecosystems. Hence, there is a need to make the transition from traditional towards circular and climate smart food systems. Marine resources have an important role to play in circular and climate smart food systems, for multiple reasons.

Not only can marine resources help meet future food demand – locally and abroad – they can also play an important role in stimulating food production on land and at sea, and contribute to ecosystem services. On land, marine resources can assist with improving soil quality and terrestrial production system efficienc , for both crops and livestock. At sea, marine resources can increase nursery habitats and provide valuable ecosystem services such as CO2 and mineral fixation, nutrient recycling, and long term carbon storage.

In the North Sea, development of aquaculture is becoming increasingly prominent. In particular seaweed cultivation is often considered a sustainable form of protein production. This is partly because seaweed cultivation provides ecosystem services, for example, stimulating biodiversity, improving water quality or capturing nitrogen and carbon. Seaweed cultivation can contribute to a circular economy in which nutrients that are washed away from the country by the rivers are then re-established in marine biomass. However, in large-scale cultivation, negative impacts can also occur. Large-scale seaweed cultivation demand a wide range of nutrients and the competition for these nutrients from the surrounding ecosystem can have an impact on the environment.

Objective
This study identifies the relevant ecosystem services provided by seaweed cultivation, and the positive and/or negative impacts associated with the services. It surveys the methods that can be used to estimate the economic and/or non-market values for ecosystem services from seaweed cultivation, and attempts to calculate the net benefit generated from seaweed cultivation in the North Sea.

Methodology
The study is carried out via a multidisciplinary research programme "Towards a circular and climate positive society: Marine Resources". From the economic perspective, the first phase involves a systematic review of literature on economic valuation of ecosystem services to characterise the methods that can be used to monetarise the ecosystem services, and the advantages and limitations with each method. In the second phase, primary valuation is calculated based on method(s) selected from the literature review and applied to information outputted from marine scientists regarding the types and volumes of ecosystem services produced by seaweed cultivation. Finally the results will be compared to a benchmark evaluation conducted using estimates from value-transfer of previous literature on economic valuations of ecosystem services produced by seaweed cultivation.

Intended output
The results from the study will support development of business application possibilities for low trophic species (e.g. shellfish, seaweed, worms, crustaceans) in animal production chains, carbon emission initiatives and blue growth domain. It will also be used to inform policy decisions in meeting goals set out under EU strategy to Sustainable development for climate smart food systems and circular economy.

EFFECTS OF NUTRIENT EMISSIONS FROM AN EXPOSED FISH FARM ON THE UPPER WATER COLUMN

Tale Skrove* and Yngvar Olsen

Norwegian University of Science and Technology, Høgskoleringen 1, 7491 Trondheim (Norway)
E-mail: Tale.Skrove@ntnu.no

Introduction

Input of inorganic nutrients to surface waters has the potential to affect primary production in the pelagic zone (Cloern, 2001; Olsen et al., 2014). Atlantic salmon (*Salmo salar*) aquaculture represents a source of nutrient loading to coastal waters of Norway (Wang et al., 2012). With the intended future increase of aquaculture in Norway, it is likely that large fish farms get located at more exposed sites than today. This study aimed to identify potential impacts following nutrient loading from Ocean Farm 1, a large-scale exposed fish farm, on the surrounding waters during its first summer season of production.

Material and methods

Integrated water samples (1 – 10 meters) were collected in Frohavet (N63.942 E009.134), Norway, every other week from June to September (n = 9) from a potential affected station 3000 meters downstream of Ocean Farm 1 (Affected) and from a nearby control station not affected (Control). The water was filtered through a 200 µm net at the stations and later analyzed for ammonium (NH_4), nitrate (NO_3), phosphate (PO_4), chlorophyll *a* (chl *a*) and particulate organic nitrogen (PON), phosphorous (POP) and carbon (POC).

Results

Results showed no statistical significant difference between the Affected and the Control station of the measured variables, except phosphate, which showed lower concentrations at the Affected station than at the Control station (Table I). The elemental C:N:P-ratio (weight) of particulate organic matter on the downstream station was 74:11:1 whereas it was 71:10:1 in the Control station. The differences between the stations was not significant ($p > 0.05$).

Discussion and conclusion

Ammonia is released from fish farms to surrounding waters whereas nitrate is supplied from deep water. The total concentrations of chlorophyll *a,* and dissolved inorganic nitrogen (ammonia plus nitrate) and phosphorous in this study were well within normal concentrations, according to the Norwegian Water Management Regulations and the OSPAR Commission (OSPAR, 2005; Vannforskriften, 2006), indicating a healthy pelagic ecosystem. The nutrients are quickly taken up by the phytoplankton and can be traced through changes in the C:N:P ratio reflecting phytoplankton biomass. Inorganic nitrogen and phosphorous emissions from aquaculture are characterized by a higher N:P ratio than natural supply from deep water and an enhanced N:P ratio of particulate suspended matter may reflect an influence of aquaculture of surface waters (Wang et al., 2013). In this study, the ratios suggested a weak phosphorous limitation of the water masses, which could be driven by emissions from aquaculture. However, no difference in particulate N:P ratios was found between the Affected and the Control station, and the results could be because of natural high N:P loading, perhaps in combination with total aquaculture emissions in the region. As aquaculture is growing, it is important to keep monitoring the effect that fish farms may have on the environment, both at well-established sites and at new, more exposed locations, in order to monitor the influence on the marine ecosystem.

CULTURAL SERVICES OF MARINE BIVALVE AQUACULTURE

Aad C. Smaal

HZ University of Applied Sciences, Edisonweg 4, 4382 NW Vlissingen. Aquaculture and Fisheries Dept, Wageningen University and Research
aad.smaal@wur.nl

Introduction

Marine bivalves have been a resource for human nutrition since pre-historic times. Their easy access and high nutritional quality have favoured their use throughout human history. Bivalve aquaculture and wild catch have shown a steady increase from 5 to 17 million tons per year over the period 1995 - 2015. Bivalve aquaculture nowadays dominates over wild catch almost 9-fold and this figure still increases. In addition to aquaculture for production, both wild and cultivated bivalves have a suite of functions in the ecosystem. These functions are defined as goods and services (Smaal et al., 2019). Examples of regulating services are water filtration that improves water quality by turbidity control and nutrient regeneration, and nutrient uptake and accumulation for eutrophication control. They also contribute to coastal defence as reef building eco-engineers and to nature quality by providing habitats that are biodiversity hotspots.

Cultural services are defined as the nonmaterial benefits people obtain from ecosystems, such as cultural diversity, spiritual and religious values, knowledge systems, educational values, inspiration, aesthetic values, social relations, sense of place, cultural heritage values, recreation and ecotourism (Millennium Assessment, 2005) . For marine bivalves many examples exist of cultural services. Shells are well-known collector items. Collecting seashore shells is worldwide spread leisure activity, and an organised profession as well, in the framework of the scientific discipline of malacology. This links to marine bivalves as a source of knowledge. Shells as fossil records have information for evolutionary studies, and their mineral content can reflect past climatological events as long-term archives. Shells are widely used for decoration and in art. Educational programs and community involvement exist in bivalve restoration programs. Sea gardening of marine bivalves is an upcoming leisure activity. Hence cultural services link directly to social structures that provide the framework for the appreciation of these services. Nonmaterial services may be more difficult to quantify than the other services, yet the benefits for people go far beyond the material benefits, as it concerns the core of human life that is able to reflect on all different services of – in this case - the marine bivalves (Harari, 2018; Daniel et al., 2012). In this presentation some examples of cultural services are reviewed

Introduction

A critical process when planning Integrated Multi-Trophic Aquaculture (IMTA) systems, and that drives the success of their implementation, is the estimation of nutrient fluxes among the different trophic-levels to be farmed and consequent production volumes. Often-used approaches in this process are: (i) the upscaling of small-scale experiments, carried out under similar conditions of those observed at the farm site (Abreu et al., 2011)”container-title”:”Aquaculture”,”page”:”77-87”,”volume”:”312”,”issue”:”1”,”source”:”ScienceDirect”,”abstract”:”The use of ecological engineering tools for the development of a more sustainable aquaculture is crucial. In this context, seaweed based Integrated Multi-Trophic Aquaculture (IMTA; and (ii) heuristic assessments based on simple mass-balance models (Nobre et al., 2010)”container-title”:”Aquaculture”,”page”:”116-126”,”volume”:”306”,”issue”:”1”,”source”:”ScienceDirect”,”abstract”:”Integrat ed multi-trophic aquaculture (IMTA. However, such approaches can be time consuming, require historical data, cannot provide long-term predictions neither simulate changes in production conditions, for instance different feed compositions and retentions efficiencies for the IMTA fed component. This is a relevant aspect for IMTA systems that couple organisms with a long production cycle (e.g. fish) with organisms with a shorter production cycle (e.g. green seaweed). In the context of the ValorMar project (www.valormar.pt), the nutrient contribution of the fed component of a land-based commercial IMTA system, integrating finfis (*Dicentrarchus labrax*) and seaweed (*Ulva spp.*) was simulated by means of a detailed model that can simulate fish ammonia excretion with a resolution of hours for an entire production cycle (~3 years). The main objective was to provide insights for the seaweed production considering business as usual and an expansion scenario.

Methods

Total ammonia (TAN) production by the seabass culture over its production cycle (~2 years), was predicted using the dynamic nutrient-based model FEEDNETICS (Soares and Silva, 2018), calibrated for seabass (D*icentrarchus labrax*). This application was carried out by simulating the seabass production following the planned feeding regime, under the expected environmental conditions, and for two different expected mortality rates (i.e. 15% and 20%).

In order to provide insights for the seaweed production, the ammonia contribution (TAN, kg N.day^{-1}) was compared with the Ulva requirements, estimated using a static model (Nobre et al., 2017)to assess water renewal rates and nitrogen limitation in commercial seaweed farms”,”container-title”:”Journal of Applied Phycology”,”page”:”3039-3055”,”volume”:”29”,”iss ue”:”6”,”source”:”Springer Link”,”abstract”:”Key factors affecting the economic sustainability of any aquaculture industry and in particular the seaweed industry are its ecological interactions and impacts. Understanding these issues requires an extended production analysis and simulation, given the natural variability and dynamics of external factors that affect those interdependencies. As such, making sense of production data is required for suitable planning and resource optimization in a seaweed farm. The present work calculates the required water renewal rates for seaweed flow-through production units, using a novel simple user-friendly nitrogen budget model. The user interface is straightforward and the model parameter inputs and outputs are minimal, whereby the target users are commercial seaweed farmers. The model was parameterized for production kinetics of Ulva spp. based on an extensive literature survey, and was evaluated with published data on seaweed-growing experiments. Results for the estimated number of volume renewals per day are in agreement with the experimental data. The outputs indicate that this application can be used to estimate the envelope, i.e. average lower and upper ranges for water renewal rates for a given production in a given site. This model and corresponding parameterization for Ulva spp. are available to be used by farmers, managers and researchers in the form of a spreadsheet file (available as Supplementary Material, for two production scenarios: business as usual and an expansion scenario, representing the latter an increase by 6 fold in production (Nobre et al., 2018).

(Continued on next page)

Results

Figure 1 shows model results, indicating that the ammonia produced by the seabass can contribute as the nitrogen source of the current Ulva requirements. However, if considering the scenario of production expansion, the ammonia produced by the seabass culture seems to be insufficient to contribute significantly as the main source during the entire production cycle.

Discussion and conclusion

The use of a nutrient-based model for the estimation of seabass ammonia production provides reliable detailed outputs over the entire production cycle (~2 years), while the simple Ulva nutrient budget model provides threshold for the TAN requirements of a much shorter production cycle. This approach provided valuable insights about the finfis culture potential as the main nutrient source of the seaweed production, which can be used for production planning for the current production volume and for the 6-fold expansion scenario. This work is a preliminary approach to an overall assessment of nutrient sources and requirements within the IMTA system boundaries. Further work must be developed in order to account for water renewal rates, and nutrient mass fluxes among compartments (i.e. finfis earth-pond and seaweed tank) and from water inlets that supply the system.

Each year, tens of thousands of domesticated Atlantic salmon, *Salmo salar* L., escape from Norwegian sea cages and into the wild. Most of the escapees disappear into the wild without ever being observed again, but some survive and return to freshwater as sexually mature adults. Escaped domesticated salmon have lower spawning success than wild salmon, but successful spawning and introgression of domesticated salmon have been documented in several Norwegian rivers. Offspring of domesticated salmon also have lower survival than offspring of wild salmon in the wild, which may reduce productivity in wild populations following introgression. Why offspring of domesticated salmon display increased mortality in the wild is not known, but one possible explanation is that domesticated salmon are more susceptible to predation. Wild fish live in an environment where early survival is low and there is a huge risk of predation. In contrast, domesticated fish live in a sheltered environment without the threat of predators. This has resulted in domesticated salmon showing a reduced anti-predator behaviour, as compared to wild salmon, when exposed to predators in controlled studies. In the project QuantEscape, a study was carried out in 2015 that suggests that a maladaptive behaviour towards predators results in increased mortality in domesticated salmon relative to wild salmon. The study was carried out in a semi-natural environment where domesticated, wild and hybrid offspring competed for natural food under the risk of predation by older trout.

PROJECT INTEGRATE. CULTIVATION OF SEA SPAGUETTI (*Himanthalia elongata*)

INTEGRATE is an European Project funded by the ERDF through the Interreg Atlantic Area Programme, investigating the next steps in research and commercialization of Integrated Multi-Trophic aquaculture (IMTA) in the Atlantic Area (AA) in Europe. It was born from an initiative by a group of researchers and production experts aiming to foster cooperation for industrial transition towards IMTA. The project will provide tools to increase competitiveness and contribute to removing barriers for growth within the eco-aquaculture sector, while improving the quality and public image of aquatic products.

In within the project we are looking to cultivate new species in IMTA systems. In work package 4, pilot case study 1, the Irish Seaweed Consultancy (ISC) is developing the cultivation of *Himanthalia elongata* (Sea spaghetti) as a potential new species in an IMTA system. For that, eggs and sperm were released twice a month, from August to October 2018. Throughout this time scallop shells were used as a seeding substrate, with good attachment results. Shells cover on fertilise Himanthalia eggs were then submerged in tanks with air waiting to be deployed at sea. The shells were divided in two batches, and were deployed in January and March 2019. Plant growth was followed monthly until September 2019. Some results and images from this work are presented in this poster.

Acknowledgements
INTEGRATE is funded by the ERDF through the INTERREG Atlantic Area 2014-2020 Programme (project grant number EAPA_232/2016). The work at sea has been carried out with the support of the Marine Institute's Aquaculture Research Section.

GENOME-WIDE ASSOCIATION ANALYSIS OF LIPID RELATED TRAITS IN EUROPEAN SEABASS

Anna K. Sonesson[1]*, López Belluga, M. [2], Diaz Gil, C.[2], Gamsiz; K.[3], Houston, R.D.[4] Ruyter, B[1], Herlin, M.[2].

[4] The Roslin Institute University of Edinburgh, Easter Bush, Midlothian, EH25 9RG, Scotland, UK

Background
Lipid related traits are important both for the consumers that buy fish for the health benefits of omega-3 fatty acids and for the fish that also need omega-3 fatty acids to develop healthy cell function and immunity. Other lipid related traits are related to liver health of the fish, because liver is the most important organ for producing and storing fat. Finally, deposition of fat in different body parts, e.g. viscera, liver and muscle are related to production efficienc . In A. salmon, we know that omega-3 content of the fillet and fat content of the muscle and liver are low-mid heritable traits (Leaver et al., 2011; Horn et al., 2018). We also know that genes that regulate lipid contents of liver and muscle differ (Horn et al., 2019). In European seabass, which is a leaner fish species than A. salmon, a heritability of 0.48 has been found for viscera%, and 0.28 for muscle lipid content (Saillant et al., 2009).

The aim of this study is to perform a genomic analysis of lipid-related traits using one yearclass of the Culmarex breeding program of European seabass.

Material & Methods
1000 European seabass with mean weight of 350g coming from three different cages were sampled. These fish were recorded at the slaughterline for round and cascass weights, sex and weights of viscera, heart, gonad, liver, guts and fillet fat content. Subsamples of these fish were analysed for total fat and omega3 fatty acid contents of the fillet and liver and blood contents of ASAT, ALAT, CK and ALP. The fish were also genotyped with the combined SNP array for European seabass and gilthead seabream, containing in total ~55 kSNP.

Results
This data will be analysed for phenotypic and genotypic correlations and heritability. A genome-wide association analysis will also be performed.

This work is done as part of the MEDAID project.

Introduction

Microalgae are promising alternatives to fishmeal and fish oil (Gong et al., 2018; Kiron et al., 2012; 2016; Kousoulaki et al., 2015; Sørensen et al., 2016; 2017). However, their rigid cell walls may prevent accessibility of the valuable nutrients by fish. Nevertheless, nutrient digestibility of microalgae can be improved through disruption of their cell walls. A study was conducted to investigate the effect of bead milling on cell wall disruption and eventually on nutrient digestibility. The aim of the experiment was to investigate the digestibility of dry matter (DM), protein and lipid when Atlantic salmon was fed whole or broken cells from *Phaeodactylum tricornutum* and *Tetraselmis chuii*. Data were also collected to assess the skin and muscle pigmentation and for calculation of weight gain of the salmon.

Material and methods

The microalgae biomass [*Phaeodactylum tricornutum* B58 (PHA) and *Tetraselmis chuii* UTEX LB232 (TET)] were produced at the National Algae pilot Mongstad (NAM) (Mongstad, Norway) in a fed-batch process, in four 800L photobioreactor systems (GemTube MK2-750 from LGem B.V., Netherlands). The microalgae were harvested twice per week, concentrated to a paste by centrifugation (Evodos 50, Evodos B.V., Netherlands), vacuum packed and directly frozen at -20^{o}C before further downstream processing. The microalgae paste, containing 22.9 and 18.7 % DM, in PHA and TET, respectively, was processed by a single pass through a Dyno-Mill Multi Lab bead mill (WAB, Muttenz, Switzerland); using a 0.6 l chamber and small glass beads (0.25-0.4 mm), at 80% chamber filling, 12 m/sec agitator tip speed and 6-9 kg/h biomass flow rate. The whole and cell-wall disrupted biomasses were spray dried to obtain the fine biomass powder that was used for feed production. A reference feed (RD) was formulated to contain 660 g kg^{-1} protein and 150 g kg^{-1} lipid. Four test feeds with whole or broken microalgae were formulated by mixing 700g kg^{-1} of the reference feed and 300 g kg^{-1} of either PHA or TET. All feeds contained yttrium oxide (0.2 g kg^{-1}) as inert digestibility marker. The feeds were produced using extrusion process. For the digestibility trial, Atlantic salmon (315 g) were kept in three replicate experimental tanks (55 fish/ tank) for 44 days. Feces from individual fish were collected by stripping and then a pooled sample was made for each tank. Fish were individually weighed at start and termination of the experiment. Skin and flesh color were measured using a portable spectrophotometer (CM-700d, Konica Minolta Sensing Inc., Singapore).

Results and discussion

The preliminary results show that the average fish weight increased by 40%; growing from a start weight of 315 g to a final weight of 441 g. The corresponding average SGR and TGC values were 0.77% and 2.40, respectively. Fish fed broken TET-feed had significantly lower weight gain, SGR and TGC values compared to the RD-fed fish. However, there were no differences in the growth indices between the other study groups. As for the digestibility of whole cell TET-feeds compared to RD-feeds, the intact cells had significantly lower digestibility of DM and lipid while the corresponding broken cells-containing feeds yielded lower digestibility of protein. The lower growth of the fish fed broken cell TET-feeds may thus be explained by the lower protein digestibility. The experimental setup did not allow measurement of feed intake, however, the lower growth of fish fed broken TET may also be linked to poor palatability of the broken cells. Analyses showed that the predominant phenolic compound in TET is capsaicin, present also in hot chili, which become more available following cell wall disruption. Protein and lipid digestibility of the broken PHA was the highest, comparing the 2 algae, with both whole and broken cells. The Minolta values showed that there were some differences in pigmentation among fish fed the different diets, which can probably be explained by the content of carotenoids and vitamins and other bioactive components with antioxidant effects.

Conclusion

Disruption of cell walls employing bead milling improved apparent digestibility coefficient of protein and lipid of *Phaeodactylum tricornutum* and the procedure seems to be a promising method to improve nutrient utilization of the algae.

OZONATION OF SEMI-CLOSED AQUATIC SYSTEMS

Spiliotopoulou A.[1]*, Martin R.[1] and Andersen H.R[2]

[1]Water ApS, Farum Gydevej 64, 3520 Farum, Denmark
[2]Department of Environmental Engineering, Technical University of Denmark
Bygningstorvet 115, 2800 Kongens Lyngby, Denmark

e-mail: ks@water.dk

Introduction

The water quality in intense recirculating aquaculture systems (RASs) is characterised by accumulation of pollutants, potentially allowing fish pathogens to grow. Although ozonation has been applied for years in aquaculture improving the water quality (Langlais et al., 1991; Bullock et al., 1997; Krumins et al., 2001; Liltved et al., 2006; Summerfelt et al., 2009), there is a lack of knowledge regarding the reaction kinetics, the control of the dosage and side effects of excessive ozonation.

The analytical efforts to detect and monitor organic matter (DOM) in aquatic systems have included among others, absorption spectroscopy of the coloured fraction (CDOM). A part of CDOM also fluoresces (FDOM). FDOM fraction has been widely used in aquatic environments as a quantitative and qualitative measure of DOM. Recently, it was shown that RAS water consists of FDOM (Hambly et al., 2015) which was highly sensitive to ozone, suggesting that fluorescence spectroscopy could be used as an indirect method to determine ozone delivery within these systems (Spiliotopoulou et al., 2017).

This study aims to develop a method to predict the ozone demand for the specific system improving the water quality without compromising the fish welfare and to pursue a more direct approach to measure and control the delivered ozone dosage in RASs using fluorescence spectroscop .

Material and Methods

Water samples from a pilot-scale RAS were subjected to ozonation in bench scale experiments to define the ozone demand and ozone lifetime in this water matrix (Spiliotopoulou et al., 2018). All samples including the non-ozonated control sample were measured with a fluorimeter to define the ozone effect on natural fluorescence degradation (Spiliotopoulou et al., 2017, 2018). The predicted ozone dosages were applied in side-stream to pilot-RAS systems where trout were farmed to evaluate the ozone effect on a wide range of water quality parameters (Spiliotopoulou et al., 2018).

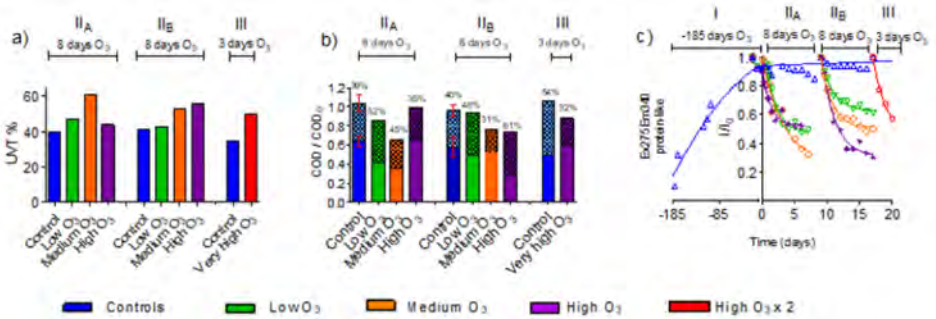

Figure 1. Ozone effect on a) UVT% after 8 days, b) COD after 8 days (the % and the dotted (upper) parts of the bars represent the particulate COD, while the lower part is dissolved COD-normalised data, standard deviation only in control, c) protein like-fluorescence degradation-normalised data.

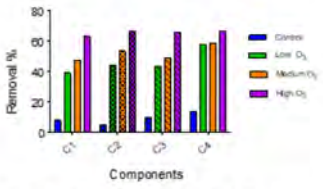

Figure 2: Effect of ozone on FDOM after 8 days of treatment.

(Continued on next page)

Results and Discussion

The analysis of a few mL of water sample in the laboratory was sufficient to determine the ozone demand and the ozone lifetime of the system but also to predict the ozone dosage that was required for the pilot and/or full-scale RAS (Spiliotopoulou et al., 2018). The four ozone dosages, including a control (non-ozonated), that were selected to be tested in pilot-RAS (ranging from 52-130 mg O_3/h, equivalent to 10-25 g O_3/kg feed) improved remarkably the water quality (Fig. 1). Residual ozone was not detected in any trial, not even after the ozone reaction chamber.

Along with the commonly studied water quality parameters in aquaculture water, the effect of continuous ozonation on the FDOM character was also investigated (Fig. 1d,e). A more detailed identification of the different fluorescent fractions was conducted using the coupled EEM-PARAFAC technique (Fig. 2) revealing the presence of four independently varying components. A UV wavelength fluorescent fraction (C4) typical of proteinaceous material was removed by 13-20% immediately after ozone initiation. The remaining fractions that exhibited visible wavelength fluorescence, at first were unaffected but during the following days, were gradually degraded, reaching a removal of 34-66%. By the end of the experiment, the fluorescence intensities of all fractions were diminished up to 60% in all applied dosages.

Conclusions

The method applied to predict the optimal ozone dosage of pilot-RAS based on laboratory studies was efficient with remarkable proximity, achieving improved water quality without affecting the fish health

The high sensitivity of FDOM to ozone and its selectivity to specific fluorescent components, suggested that fluorescence could be used as an online sensor to control the organic matter in a RAS and determine indirectly the delivered ozone dosage in the system. This study attempted to clarify misinterpretations regarding ozonation and to offer new technological concepts to make its implementation safe, convincing the aquaculture managers to integrate ozone in their water treatment processes.

ARTIFICAL WORLD – NEW INSIGHTS ON OCTOPUS EGG REARING AND LARVAL FEEDING BEHAVIOUR

Stefan Spreitzenbarth*, Andrew Jeffs

University of Auckland, 160 Goat Island Road, New Zealand
E-Mail: sspr830@aucklanduni.ac.nz

Introduction

Global demand for octopus as seafood has been increasing but supply is constrainedby the limits of wild octopus fisheries. Establishing octopus aquaculture would help to meet the global demand and could reduce fishing pressure on wild populations (Josupeit 2008). However, rearing the larvae of various species of octopus has proven to be extremely challenging (Iglesias et al. 2007). Larval rearing and feeding behaviour of *Octopus tetricus*, an octopus species native to Australasia, was examined in this study to describe larval development and also to attempt to incubate octopus eggs without a female.

Material and methods

Thirty-six egg-strings were removed from each female three days after the first egg strings were visible. Egg strings were randomly split into groups of three, attached to a PVC-pipe and placed in one of 12 upwelling tanks for incubation. Four experimental treatments representing different culture arrangements were tested. Treatment one (T1) and two (T2) had high sea water inflow (4 l min^{-1}). Treatment three (T3) and four (T4) had low seawater inflow (2 l min^{-1}). Tanks of T1 and T3 had an additional air stone placed beneath the egg strings to increase water circulation around the developing eggs.

Newly-hatched paralarvae were kept under starving conditions in an upwelling tank. Each day a group of 20 paralarvae age 0-, 1-, 2-, 3-, 4- and 5 dph (days post hatch) were removed from the upwelling tank and used for short term feeding experiments. Two different prey items, live brine shrimp (BT) and artificial diets (AT) were used. Total amount of strikes and successful capture of food particle as well as handling time per paralarvae were measured.The experimental duration was 15min, starting when prey items were added.

Results

Hatching success of over 90% was achieved in both upwelling systems were aeration was added (i.e., T1 and T3) compared to a hatching success of 31.4% and 10.3% in the high and low water inflow treatment without aeration.

The percentage of paralarvae that captured at least one food particle increased from 0 dph and peaked at 2 dph and 3 dph in the BT and AT treatment, respectively (Fig. 1). In general, the percentage of paralarvae that had successful captures was always higher in the AT treatment compared to the BT treatment from 1 dph onwards with significant differences between the two treatments at 3 dph. The highest percentage of paralarvae that had a successful capture was 41.7% in the AT treatment at 3 dph.

Discussion

The high hatching success of over 90% which was achieved in two out of four treatments in this study, shows the possibility to rear *O. tetricus* eggs without maternal care. Earlier attempts to culture eggs of *O.* (cf) *tetricus*, *O. vulgaris* and *Enteroctopus megalocyathus* without maternal care have resulted in poor egg survival of between 30-60% (Joll 1978; De Wolf et al. 2011; Uriarte et al. 2016).

Highest feeding success was observed in paralarvae at 2-3 dph in this study. This is similar to *O. vulgaris* where the highest feeding activity was at 2 dph (Iglesias et al. 2006). In both cases paralarvae showed a decrease in success or activity after 2 dph, suggesting that a point of no return in nutritional resourcing might be reached.

These results are encouraging in the further development of octopus aquaculture. However, more research is needed to determine how much of the artificial diet was ingested and which diet features (e.g. texture, buoyancy) are most suitable for promoting consumption of artificial feed by newly-hatched larvae.

(Continued on next page)

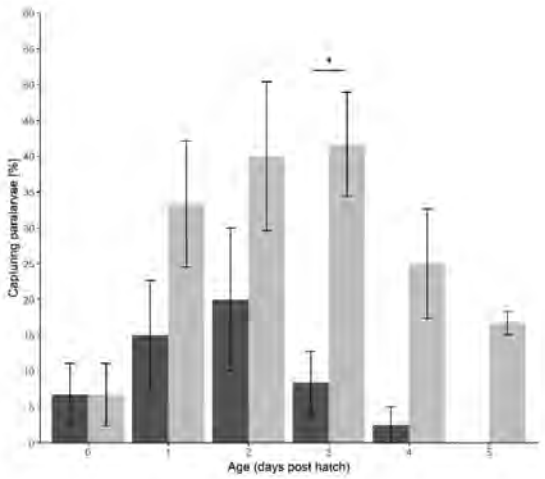

Fig. 1: Mean percentage of paralarvae that performed at least one successful capture of a food particle. Dark grey bars represent the BT treatment (live brine shrimps) and grey bars represent the AT treatment (artificial diet). Error bars indicate the standard error. Stars indicate significant differences: $p < 0.0001$ = ***, $p < 0.001$ = **, $p < 0.05$ = *.

EFFECT OF ORGANIC ACIDS IN GROWTH, SURVIVAL AND CONTROLLING CONTINUOUS MORTALITIES OF *Litopenaeus vannamei* CULTURE AT KATTUKALAVA, WEST GODAVARI DISTRICT, ANDHRA PRADESH, INDIA

[*]R. Srinivas

[*]Devee Biologicals Pvt Ltd, Yellareddyguda, Hyderabad -500 073

Corresponding author email Id: srinidbpl@gmail.com

The present study conducted to find the impact of organic acids when given through feed to the cultured penaeid shrimp *Litopenaeus vannamei*. In this study one control pond and two experimental ponds were taken at Kattukalava, West Godavari district of Andhra Pradesh, India. In the present study, periodic sampling done for estimation of growth & survival rate of shrimp in control pond as well in the experimental ponds. The results were recorded with standard measurements during the culture period.

This study was focused on the growth and survival rates in the control pond and also in the experimental ponds (pond A and pond B) where the control pond without inclusion of organic acids in the feeds was affected with unknown continuous mortalities (Generally known as Running Mortality Syndrome) in both winter and summer crops of the year 2018 when compared with the experimental ponds A & B where the organic acids are added continuously during culture. The findings of the current study concluded that the application organic acids through feed prevents the continuous mortalities in the experimental ponds as well enhance the growth and survival rates in *Litopenaeus vannamei*.

TWO DIFFERENT INSECT MEALS AS FISHMEAL REPLACEMENT FOR EUROPEAN PERCH – *Perca fluviatilis*

Introduction

In recent years, insects have been discussed and advertised to be a sustainable alternative as feed ingredient for a variety of fish species and poultry. One of the most frequently utilized insect species, *Hermetia illucens*, could be grown on food waste and animal manure and thus use a substrate which would otherwise be burned or thrown into biogas plants. Insect meal (IM) has been utilized as fishmeal replacement in several fish species and its success depends on nutritional quality. Especially salmonids can tolerate higher levels of IM compared to other species such as turbot (*Psetta maxima*). Up to now, IM has not been tested in European perch (*Perca fluviatilis*), a commercially important fish species in Switzerland. In this trial, two different IMs (one medium de-fatted containing medium protein level and one high-defatted containing high protein level) were fed in three levels each (25, 50 and 75% fishmeal-protein replacement) to perch fingerlings and compared to a non-IM control diet.

Material and methods

Two different *H. illucens* IMs were used for this experiment. IM1 contained around 30% lipids and 48% protein while IM2 contained 5% lipids and 60% protein. Six experimental diets were formulated for a final concentration of 50% protein, 12% lipids and an estimated digestible energy content of 17.5 kJ/g. In the control diet, 47% of fishmeal served as main protein source besides 20% wheat gluten as minor protein source. Each insect meal replaced 25, 50 and 75% of fishmeal protein (diets IM1-25, IM1-50 and IM1-75 and IM2-25, IM2-50 and IM2-75) while an IM free diet served as control. 420 juvenile perch (approximately 2 g) were stocked into 28 aquaria connected to a recirculation system at 15 fish per aquarium. Each diet was allocated to four randomly chosen aquaria and fish were hand fed 2% of their body mass per day divided into 3 feeding stations during the week and two feeding stations on weekends and holidays. Once a week, the fish were group weighed and feed amount adapted accordingly. After 28 days of experimental feeding, growth (absolute and relative), feed conversion and protein efficiency ratios were evaluated

Table I: Growth, feed and protein utilization of European perch fed with control and insect meal diets.

	C	IM1-25	IM1-50	IM1-75	IM2-25	IM2-50	IM2-75
Initial BM (g)	1.93 ± 0.14	2.08 ± 0.11	1.95 ± 0.11	1.94 ± 0.16	2.02 ± 0.07	1.98 ± 0.05	1.91 ± 0.11
Final BM (g)	2.60 ± 0.23	3.10 ± 0.40	2.65 ± 0.26	2.61 ± 0.18	2.99 ± 0.23	3.12 ± 0.20	2.90 ± 0.28
BM-gain (g)	0.67 ± 0.10^{a}	1.02 ± 0.29^{ab}	0.70 ± 0.15^{ab}	0.67 ± 0.12^{a}	0.97 ± 0.22^{ab}	1.13 ± 0.20^{b}	1.00 ± 0.24^{ab}
BM-gain (%)	34.5 ± 4.23	48.8 ± 11.7	35.5 ± 5.50	34.7 ± 7.51	47.7 ± 10.9	57.2 ± 10.3	52.5 ± 12.8
SGR (%/day)	1.48 ± 0.30	2.10 ± 0.48	1.55 ± 0.35	1.50 ± 0.25	1.98 ± 0.28	2.13 ± 0.22	1.87 ± 0.34
FCR	2.36 ± 0.27	1.83 ± 0.48	2.31 ± 0.32	2.41 ± 0.48	1.78 ± 0.42	1.55 ± 0.25	1.65 ± 0.48
PER	0.88 ± 0.10	1.18 ± 0.28	0.89 ± 0.12	0.88 ± 0.17	1.19 ± 0.26	1.34 ± 0.25	1.28 ± 0.32

Values = mean (N = 4) ± SD, BM = body mass, SGR = specific growth rate, FCR = feed conversion ratio, PER = protein efficiency ratio

(Continued on next page)

Results

All diets were accepted well and feed consumed during the first few minutes after serving. All diets resulted in at least equal growth compared to control diet while the low fat and high protein insect meal (IM2) showed better growth results compared to control and to IM1 except in the lowest replacement level, where IM1-25 grew similarly to IM2-25. Although in BM-gain (%), SGR, FCR and PER relatively large numerical differences were observed between treatments, none of them were significant in a Tukey's B post-hoc test.

Statistical differences were found in absolute body mass gain, where perch fed with IM2-50 showed the highest gain. However, since the starting weights slightly differed, the relative growth would be more meaningful, where again, no significant differences were detected. In total, all insect meal diets resulted at least in a performance as good as the control diet.

Discussion and Conclusion

Due to a delayed start (fish feed had to prepared three times, since the fish did not accept the first two formulations, where, besides fishmeal the minor protein source was soy protein concentrate and had to be replaced by wheat gluten), the fish grew already differently and thus the starting BM differed stronger compared to the day of stocking. Based on the presented data, both insect meals, the high fat and medium protein (IM1) and the low fat and high protein (IM2) meal, resulted in similar performance characteristics compared to the control diet. Despite significant differences detected for relative and absolute BM-gain and SGR and trends for FCR and PER by the overall ANOVA, subsequent Tukey contrast failed to detect significant pairwise differences except for absolute gain. Perch fed with 50% fishmeal-protein replacement by IM2 gained significa tly more weight compared to control fed perch and those fed with 75% fishmeal-protein replacement by IM1. Overall, our data shows, that both insect meals are at least equally well performing compared to a high-fishmeal diet. Although non-significant, the data seems to point towards a positive trend in IM2 fed fis

EFFECT OF DIETARY NON-PROTEIN ENERGY SOURCE (STARCH VS. FAT) ON TOTAL BILE ACID POOL SIZE AND COMPOSITION OF RAINBOW TROUT (*Oncorhynchus mykiss*)

Introduction

Bile acids play a key role in digestion and absorption of dietary fat (Tocher, 2003). Synthesis of primary bile acids occurs in the liver, by oxidation of cholesterol and conjugation with either taurine or glycine. Bile acids are actively secreted into bile and stored in the gallbladder. The gallbladder awaits hormonal signals (cholecystokinin) to contract after a meal, and releases bile into the small intestine (Hagey et al., 2010). The majority of bile acids secreted into the small intestine is actively reabsorbed within the ileum, after which it returns to the liver for reuse (Cai et al., 2007). Under homeostatic conditions, the total bile acid pool is maintained relatively constant, compensating faecal bile acid loss with *de novo* synthesis (Lanzini and Lanzarotto, 2000). The process described above is known as enterohepatic circulation of bile acids (EHC).

Diet macronutrient composition can affect both the rate of EHC and bile acid synthesis. Hepner (1975) showed that the level of gallbladder contraction (level of EHC) in response to a meal regulated the bile acid pool size in humans, with a low fat diet decreasing the rate of contraction and increasing the bile acid pool size. Furthermore, less secondary bile acids were produced in response to decreased EHC, as there is less exposure of primary bile acids to bacteria in the intestine. Dietary fat level and fat saturation level have also been shown to influence bile acid synthesis. Feeding a diet high in fat stimulated bile acid synthesis, while a low fat diet decreased bile acid synthesis in rats (Botham *et al.*,1983). Furthermore, Cheema *et al.* (1997) found that the bile acid synthesis in mice was upregulated (CYP7A1) in response to a diet high in unsaturated fat. Besides dietary fat, also carbohydrates can affect bile acid synthesis. Andersén and Kjell (1980) showed an increase in bile acid synthesis in humans changing diets in which 60% of the energy was respectively supplied by fat and by carbohydrates. The non-starch polysaccharide fraction of the latter increased faecal bile acid loss, leading to increased *de novo* synthesis of bile acids. Quantitative/qualitative data on the effect of diet macronutrient composition on bile acid pool size and composition of fish are lacking. The main objective of this study was therefore to quantify and qualify the total bile acid pool in rainbow trout fed a diet differing in the main type of non-protein energy source (starch vs. fat).

Materials and methods

Two diets with a constant digestible protein to digestible energy ratio were formulated, while differing in either inclusion of corn starch or rapeseed oil as the main non-protein energy source. A vegetable oil was chosen as lipid source for the fat diet to avoid additional introduction of cholesterol, as the latter is known to increase bile acid synthesis. Each diet was tested in triplicate. Fish were housed in 6 experimental units (200 L each) connected to a common RAS-system. Water temperature was maintained between 14 ± 1 °C and water flow was set at 7 ± 0.5 L min^{-1}. At the beginning of the experiment fish were batch weighed and randomly distributed among the experimental units at a stocking density of 25 fish $unit^{-1}$. Fish were hand-fed twice daily to satiation for 44 days. Faeces were collected from week 2 till week 6, and pooled. Diets and faeces were analysed for proximate composition and bile acid content. At the end of the experiment, fish were batch weighed and sampled for proximate body composition and bile acid content.

Results

Diet did not affect growth (SGR), survival and feed intake (RFR), although, the fat diet resulted in a significant better FCR ($P<0.01$) compared to the starch diet. Diet did have significant effects on body composition. Compared to the starch diet, feeding the fat diet significantly decreased protein content, and increase fat and energy content of the fish (figure 1 A and B). Diet did not affect ash content ($p>0.05$) of the fish. Samples are currently still being analysed, and results on digestibility, bile acid pool size and composition will also be presented.

(Continued on next page)

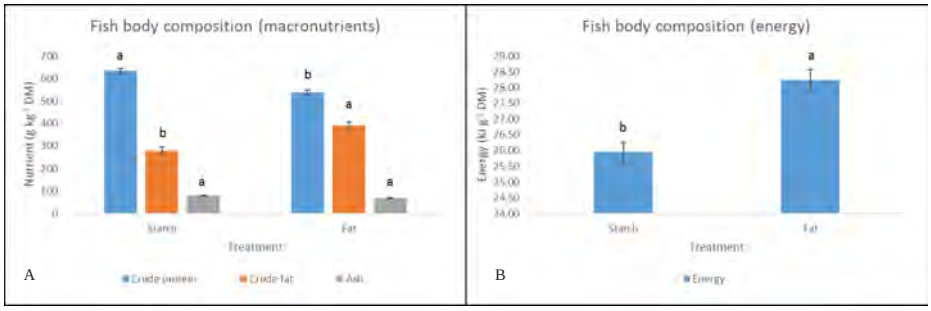

Figure 1: (A) Protein, fat and ash composition and (B) energy content of fish fed the experimental diets. For each parameter, treatments sharing a common letter are not significantly different ($p<0.05$).

Aquaponics is the association of fish and plant farming, exploiting the natural phenomenon observed in aquatic ecosystems. The microbiota transforms the fish waste into different chemical forms that are less toxic for fish and very suited for hydroponic plants culture. Due to its recent and quick development, aquaponics can now be found in a variety of areas of interest such as personal installations, education fields, private and public research projects and reached nowadays the food production at medium and large scales industries.

The diversity found in these installations makes it difficult to identify the mechanisms that rule aquaponics and to generalize the findings to other systems. Few researches established the equations that govern the behaviour of one particular system, in order to estimate the productions and to apply sensitivity analysis. These models often satisfy the goals of the developers but cannot be applied to different system setups.

In this context and as part of a research financially supported by the France-Wallonia-Flanders Interreg program, a generalist model is being developed for aquaponics. The equations are based on aquaculture, hydroponics and aquaponics studies and are implemented using an object-oriented programming in order to generate a completely generic model. The European Smart Aquaponics Project provides numerous systems with different architectures. All these installations are equipped with a full set of aquaponics sensors to generate a strong aquaponic database that will be used for model development.

The computed outputs are various and new ones are regularly added to keep pace with the continuous development of aquaponics. In this case study, the model has been applied to an experimental setup to illustrate the basic calculated parameters such as the dynamical behaviours of: the water volumes and several nutrient concentrations, the vegetal and animal biomasses, the water consumption, a few economic criteria, etc.

MEASUREMENTS OF BEHAVIOUR, STRESS RESPONSES, MONOPEPTIDE LEVELS AND CRYPTIC COLOURATION IN LUMPFISH (*Cyclopterus lumpus*) AFTER INTERACTION WITH ATLANTIC SALMON (*Salmo salar*), WITH FOCUS ON SPECIFIC SENSORY CUES

F. Staven*, D. Patel, JT. Nordeide and T. Kristensen

Faculty of Biosciences and Aquaculture, Nord university (Norway
*E-mail: Fredrik@aqua-kompetanse.no

Introduction

Salmon aquaculture has approached a trending use of facultative cleaner fish to control epidemics of ectoparasitic sea lice. The cleaner Lumpfish (*Cyclopterus lumpus*), endemic to the North Atlantic, is highly sought of due to the species ability to graze sea lice (Imsland et al., 2014a, Imsland et al., 2014b, Imsland et al., 2016) and preferences for lower temperatures (Nytrø, 2013), typically observed along coastal Norway during winter. In addition, rearing of lumpfish has been successful due to prime survivability at larval stages and adaptiveness to given artificial rearing environments (Powell et al., 2017). With annual production and distribution of more than 40 million lumpfish, in Norway only (Powell et al., 2017), an inquiry regarding animal welfare and ethics is shadowing the industry, as a large portion of deployed lumpfish in sea cages vanish during the production period of Atlantic salmon. Commonly cause of death among lumpfish has been related to disease outbreaks (Rønneseth et al., 2016), suboptimal environment (Hvas et al., 2018, Iversen, 2016, Jørgensen et al., 2017), or during handling of Atlantic salmon. In addition, the natural interspecific relationship between lumpfish and Atlantic salmon in nature is not completely understood, and due to little knowledge on how these species interact outside a controlled environment, it is uncertain how they cope together in captivity over time and how adaptive the lumpfish is to the compilation of stressors they are exposed to. The following study focused on the relationship between lumpfish and Atlantic salmon, and how separated Atlantic salmon predatory sensory cues impacted behaviour and physiology in lumpfish. These sensory cues included the introduction of salmon olfactory, perception and live salmon to lumpfish in controlled tank environments. The study hypothesised that different sensory cues could trigger different levels of stress responses, and that lumpfish might show individual variation in boldness during first interaction with the specific cues measured in stress hormones, monopeptides and/or cryptic adaptation.

Material and methods

Experiments were conducted from October to November 2018 in Mørkvedbukta research station in Bodø. A total of 144 lumpfish and 12 Atlantic salmon were used for animal experimentation after permit from the Norwegian Food Safety Authority (FDU 17231) based on the Norwegian Law on Regulation of Animal Experimentation (FOR-1996-01-15-23). The lab facilities had eight tanks (1 x 1 x 1.4 m) with 500 l/h flo , video monitoring and automatic feeders. Lumpfish were first acclimated to the tank environments for three weeks, before all fish were ID tagged with Floy Tags™. After tagging, six lumpfish with unique ID tags visible with video monitoring were put in each tank. After three days of further acclimation, lumpfish were introduced to the different sensory cue treatments. Four treatments split in duplicates, consisted of two tanks with the introduction of water flow from an adjacent tank with Atlantic salmon, two tanks where 3D model salmon were introduced, two tanks where two Atlantic salmon were introduced in each tank and two control tanks. Lumpfish behaviour was monitored 30 minutes prior to the introduction of each specific treatment and 30 minutes after. One hour after lumpfish had been introduced to the treatments, a 3 ml/L dosage of the cortisol-blocking hypnotic Metomidate was added to each tank and recordings stopped. Further, lumpfish were euthanized, and blood was sampled. Next, the telencephalon of the brain was dissected to assess measurements of monopeptides. Additional measurements of morphology included growth measurements and photography of each fish before and after the experiment. Photography was done to observe changes in cryptic blue-green colouration in the epidermis in addition to changes in black and white ratio, from melanophores. The experiment was run three times in total with new fish in each experiment, which gave six replicates for each treatment

Results

No fish died or showed signs of diseases during the experimental period. Lumpfish exposed to salmon odour showed increased vigilance in comparison with lumpfish exposed to 3D model fish, alive Atlantic salmon and control groups. Measurements of monopeptides related to stress and social behaviour showed variations in means of serotonin (5-HT) among the replicates, with lowest measurements among lumpfish exposed to odour. Lumpfish exposed to 3D model salmon were observed inspecting and attaching to the model fish

(Continued on next page)

Discussion

Results from the following study might provide useful knowledge on how lumpfish respond to Atlantic salmon with different predatory cues separated and accounted for through perception of single sensory variables. Any changes in morphology related to stress including changes in blue-green colour or black-white ratio, could be implemented as a non-invasive measurement of stress in field.

FORECASTING CLIMATE CHANGE IMPACTS ON GREEK AQUACULTURE PRODUCTION: A CLIMEFISH CASE STUDY

Orestis Stavrakidis-Zachou[1]*, Konstadia Lika[2] and Nikos Papandroulakis[1]

[1]Institute of Marine Biology, Biotechnology and Aquaculture, Hellenic Center for Marine Research, AquaLabs, 71500, Gournes, Heraklion, Greece

E-mail: ostavrak@hcmr.gr

Introduction

The potential impacts of climate change on fish farming have been well documented. For the Mediterranean, several rising risks and potential opportunities have been recognized in relation to climate drivers such as temperature and extreme events (Brander et al., 2018; Rosa et al., 2012). There are, however, significant knowledge gaps regarding the effect of other drivers such as salinity, acidification, or HABs on both wild and reared fish stocks. It is therefore imperative that future changes are evaluated so that informed management incorporates climate change impacts and ensures sustainable future production. In that regard, the present study simulates mainly the effects of temperature under climate change on Greek aquaculture production for two species, the European sea bass (*Dicentrarchus labrax*) and the meagre (*Argyrosomus regius*), as part of the work conducted for a case study under the ClimeFish project.

Materials and methods

Models based on DEB (Dynamic Energy Budget) theory (Kooijman, 2010) were developed and validated for E. sea bass (Stavrakidis-Zachou et al., 2019) and meagre. These models simulate the bioenergetics of individual fish as a function of temperature and food availability following with an extrapolation to population level. Subsequently, downscaled projections of temperature under climate scenarios RCP4.5 and RCP8.5 were forced to simulate changes in nine Greek regions and for three time periods (2015-25, 2025-35, and 2045-55). In each region two theoretical farms were considered, one inshore and one offshore (>20km from the coastline) and production cycles of three stocking months (March, June, and September) were simulated for a group of fish. Furthermore, using the wind velocity projections from the models, extreme events (storms, i.e. wind velocity >50 km h^{-1} for more than 4 days and heatwaves, i.e. T>29^{o}C for more than 4 days) were defined. For these, an additional mortality was considered together with reduced feeding. The simulations report on variables such as individual growth, biomass, feed consumption and FCR (Feed Conversion Ratio).

Results

With respect to growth, simulations suggest that both species will grow faster in response to higher temperature, requiring shorter periods (up to 3 months, depending on the region) to reach various commercial sizes. The intensity of the trend is influenced by management options (stocking period, harvest size and site selection) with stocking time having the largest effect. An example of such results for RCP4.5 is given in figure 1. However, despite the benefit in growth due to rising temperatures, the effect on a population level is negative when extreme events are also considered. This is due to the extreme events influencing mortality rates and feeding, which can result in substantial losses in total biomass.

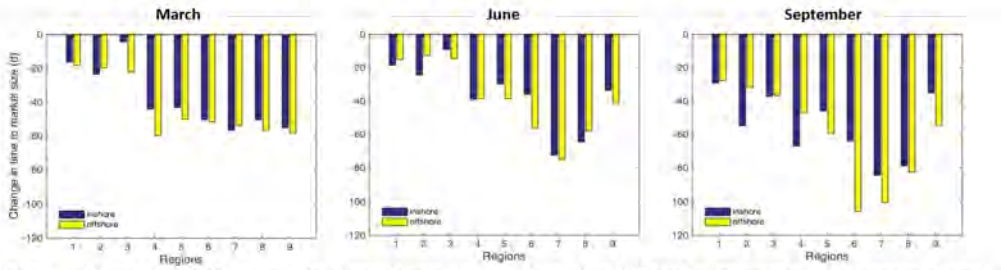

Fig. 1. Absolute differences in time (days) to market size 800g for E. seabass between short (2020)- and long (2050)- term climate projections for the climate scenario RCP 4.5. Inshore and offshore sites within the 9 regions are given in different colours.

(Continued on next page)

Conclusion

The study is a first step towards an assessment of the status of the Greek aquaculture under climate stressors. It considers the effect of temperature and wind velocity on the production of E. seabass and meagre. Simulations show that, overall, temperature will have a positive effect on the growth of both CS species, E. seabass and meagre but extreme events may also induce higher mortality rates and therefore losses in biomass. However, other impacts of climate change that may be severe for the industry have not been addressed. For instance, the positive correlation between pathogens and temperature may lead to increased frequency of disease outbreaks in the future which can be detrimental for production. Therefore, the findings of our study should be critically evaluated and potential threats from non-modelled climate drivers ought to be also taken into account for a more comprehensive assessment of the effects of climate change on aquaculture production.

Introduction

Meagre (*Argyrosomus regius*) is a eurythermal species that is becoming increasingly important for the Mediterranean aquaculture (Duncan et al., 2011). It was recently shown that meagre juveniles prefer temperatures between 26-30°C following acclimation in the temperature range of 18-30°C (Kir *et al.*, 2017). However, the response of the species towards the upper edge of its temperature tolerance range as well as the biological performance under prolonged exposure in those conditions remain largely unknown. The present study investigates the thermal tolerance and the biological performance of meagre in the 24-34°C temperature range.

Materials and methods

Juvenile meagre (mean weight 149g) were reared under three temperature regimes (24, 29 and 34°C) in triplicate tanks ($2m^3$) in a marine RAS for three months. Feeding was provided to satiation twice a day with commercial feeds and a 12D:12L light cycle was implemented. The fish were individually measured for length and weight on a monthly basis and 15 fish per treatment were sacrificed for collection of blood and tissues and subsequent determination of hematological, biochemical and hormonal parameters. Intermittent-flow respirometry was used (16 fish per treatment) to determine the standard (SMR) and maximum (MMR) metabolic rates and calculate the aerobic scope.

Results

Husbandry findings showed that fish performed poorly at high temperatures with growth being maximum at 24°C and ceasing completely at 34°C (figure 1) while the Feed Conversion Ratio (FCR) was the lowest at 24°C. In addition, mortality was particularly high at the highest temperature with more than half of the fish perishing by the second month. Preliminary analysis indicates that most of the considered physiological parameters were significantly different between the 34°C and the other two treatments. Finally, SMR increased linearly with temperature but this was not the case for MMR, resulting in the 34°C treatment exhibiting the lowest aerobic scope.

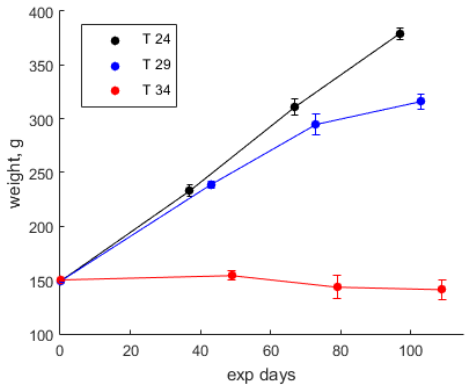

Fig. 1. Evolution of weight (g) during the trial under the three temperature treatments (24, 29 and 34°C). Points denote mean weights at sampling dates and vertical bars express the standard deviation.

(Continued on next page)

Conclusion

Overall, husbandry findings from the long term temperature tolerance experiment showed that fish perform best at 24°C while the temperature of 34°C is sharply close to the upper end of their temperature tolerance range. At 29°C the performance is appreciable, but not as good as at 24°C in terms of growth and FCR. The decreased aerobic scope exhibited at the highest temperature, suggests diminished capacity for metabolic performance while the overall poor physiological status is reflected by the pronounced mortality. The study provides insights into the performance of the species under high temperatures. This is highly relevant for the industry with respect to the exploitation of the species farming potential at a latitudinal scale, and especially in the context of climate change.

SELECTING MICRO-ORGANISMS CAPABLE OF REMOVING THE COMMON RAS OFF-FLAVOR, GEOSMIN

B. Stechele*,L.D.K.Tran, N. Nevejan and P. Bossier

Laboratory of Aquaculture & Artemia Reference Center, ARC, Ghent University
Coupure Links 653, B-9000 Gent, Belgium

Introduction

Off-flavor of aquaculture RAS products is a major problem for the industry that affects market demand and prices (Tucker, 2000). Off flavor can originate from the animal's diet or post-harvest management strategy but is mainly caused by odorous microbial metabolites which are absorbed from the water and deposited in edible tissues (Tucker, 2000; Schrader & Rimando, 2003)»type»:»book»,»volume»:»8»},»uris»:[«http://www.mendeley.com/documents/?uuid=ebfed729-2163-41a3-bb1d-d680c9f57928»]},{«id»:»ITEM-2»,»itemData»:{«DOI»:»doi:10.1021/bk-2003-0848.ch001\r10.1021/bk-2003-0848.ch001»,»ISBN»:»0-8412-3821-9»,»abstract»:»The demand for aquaculture products continues to accelerate worldwide. One of the most economically significant problems encountered in aquaculture is \»off-flavor\» in the cultured product. Off-flavors can be related to the diet of the cultured animal, caused by inadequate post-harvest management strategies, and/or environmentally derived. The latter has received the most attention in terms of research approaches for developing methods to prevent off-flavors in aquaculture products. The production of off-flavor compounds by certain species of cyanobacteria is the greatest contributing factor to off-flavor in fishery products. In this chapter, the types and causes of off-flavor that may occur in a wide variety of aquaculture products are discussed. In addition, the most recent developments in research for the prevention of offflavor in aquaculture are discussed, and recent technological advances in off-flavor detection are presented.»,»author»:[{«dropping-particle»:»»,»family»:»Schrader»,»given»:»Kevin K»,»non-dropping-particle»:»»,»parse-names»:false,»suffix»:»»},{«dropping-particle»:»»,»family»:»Rimando»,»given»:»Agnes M»,»non-dropping-particle»:»»,»parse-names»:false,»suffix»:»»}],»containe -title»:»Off-Flavors in Aquaculture»,»id»:»ITEM-2»,»issue»:»848»,»issued»:{«date-parts»:[[«2003»]]},»page»:»1-12»,»title»:»Off-Flavors in Aquaculture: An Overview»,»type»:»article-journal»,»volume»:»848»},»uris»:[«http://www.mendeley.com/documents/?uuid=377d5050-e1de-4e7b-b197-c368a2d4a4d8»]}],»mendeley»:{«formattedCitation»:»(S. Tucker, 2000; Schrader & Rimando, 2003. The most common description of off-flavor is the musty, earthy smell which originates from geosmin that has been described by Mallevialle & Suffet (1987) and Suffet *et al*. (1999). In this study, micro-organisms, capable of degrading geosmin, were selected, identified, and evaluated on applicability in RAS systems. This research is part of a larger study that aims at developing a biological filter to reduce off-flavor problems in depuration systems or full-scale RAS.

Material and methods

Micro-organisms capable of degrading geosmin were selected from a biofilter by inducing growth on the off-flavor molecule as sole carbon source. Thirteen selected strains of bacteria and fungi were evaluated on several criteria related to applicability in RAS. Growth potential were established on LB (I). Toxicity of the strains was tested on *Artemia* (II). Biolog assays were performed on all strains (III). Strains were identified using ITS4 and 16s sequencing (IV). Cell metabolic activity on geosmin was tested using MTT assays (V). Finally, the selected strains were tested for their geosmin degradation potential using low geosmin concentrations (VI). Geosmin degradation was evaluated using SPME. Growth on goesmin as sole carbon source was evaluated using flowcytometr , formation of flocculants, OD measurement and CFU

Results

A total of 13 strains were selected during two selection experiments. These 13 strains were then identified and evaluated on applicability in RAS.

(I) After a duration of 96 hours, all the strains reached stationary phase. Indicating that all selected geosmin degrading strains are particularly slow growing micro-organisms. Strain F3 was characterized by a very slow growth and a low maximum cell density and was therefore considered unfit for application in geosmin degrading biofilter

(II) In general, mortality of *Artemia* varied widely both between different strains and between repeated experiments. Among the strains tested, strains F5, F6, F7, F11 and F12 showed significant higher mortality towards the control treatments. Since toxicity was tested towards a robust species, these strains were considered unfit for use in aquaculture facilities. Further toxicity screenings are needed before any of the strains can be used in geosmin degrading biofilters

(Continued on next page)

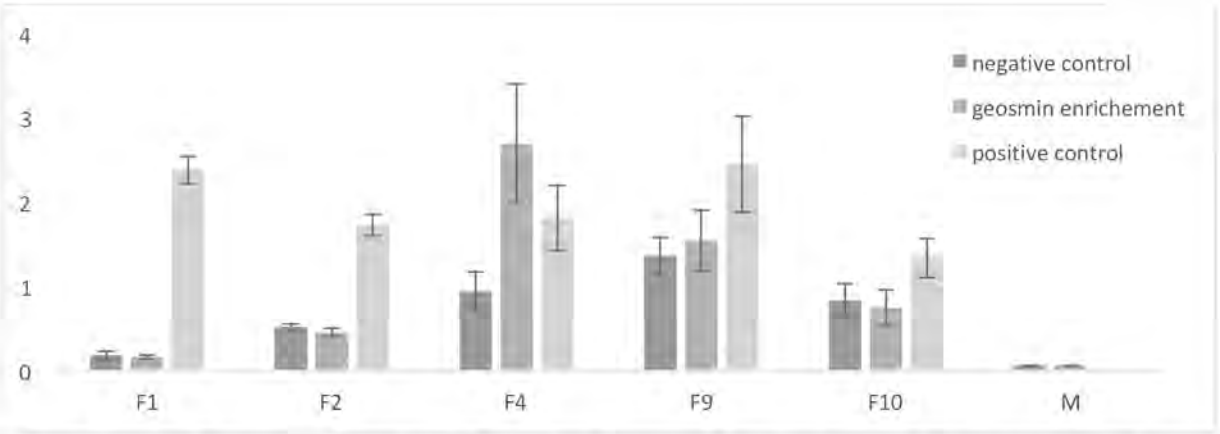

Figure 1. Optical density at 570nm (MTT assay) of treatment with cells suspended in mineral media (no geosmin), mineral media enriched with geosmin and LB.

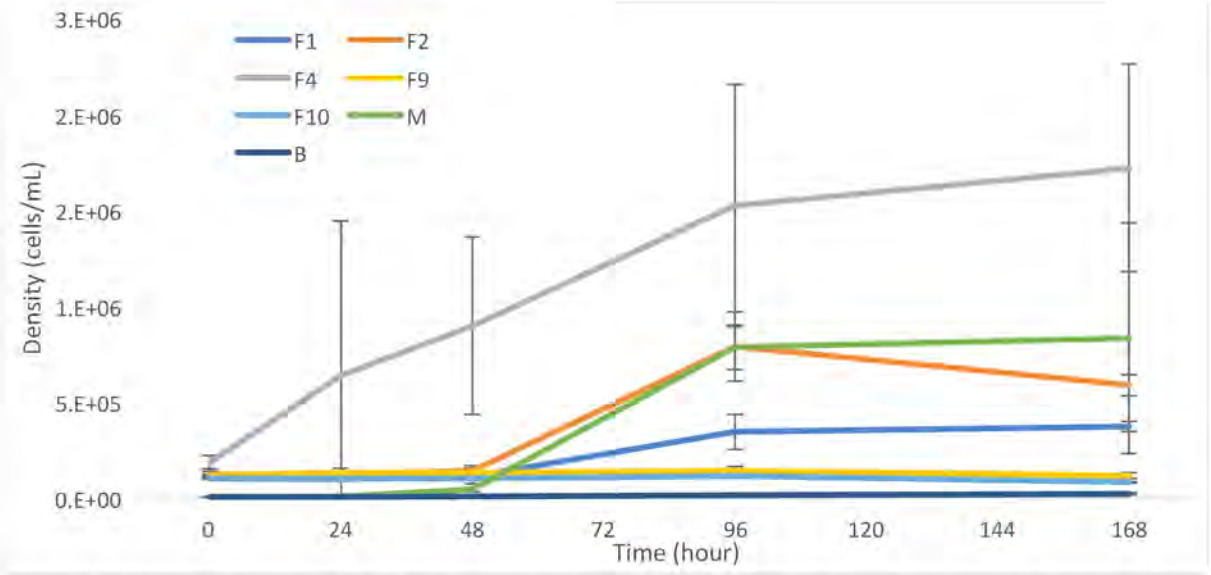

Figure 2. Microbial growth with low concentration geosmin as sole carbon source; cell densities were measured using flowcytometry

(III) Biolog assays indicated that strains varied significantly in affinity for certain C-sources, indicating that strains are metabolically different from each other.

(IV) Identification resulted in the following strains

F1: *Bosea .sp*
F2: *Bosea .sp*
F4: *Mycobacterium .sp*
F9: *Roseomonas .sp*
F10 *Brevundimonas .sp*

(V) MTT assays (figure 1) clearly show that all strains show high metabolic activity in LB (positive control) compared to mineral medium (negative control). F4 and F9 show an increased metabolic activity when grown in a with geosmin enriched environment. MTT assays may therefore suggest that F4 and F9 might have the possibility to degrade geosmin.

(VI) Growth of micro-organisms in media with only geosmin as carbon source resulted in overall slow growth (Figure 2). Strain F4 (*Mycobacterium .sp*) shown best performance compared to others. F9 and F10 showed no growth over the duration of the experiment. Analysis of geosmin concentration showed comparable results; with F4 and F10 being the only strains able to degrade geosmin.

Conclusion

Results from this study are promising, with at least 2 strains (F4: *Mycobacterium .sp* and F9: *Roseomonas .sp*) proven to be able to remove geosmin. To be able to apply these strains in biofilters for aquaculture purposes; further research on toxicity and mechanism of action is required.

DIVERSIFICATION OF GLOBAL SHRIMP FARMING THROUGH TRANSPARENCY – THE NEW ASC METRICS METHODOLOGY

Kathrin Steinberg* and Marcelo Hidalgo

Aquaculture Stewardship Council (ASC), Daalseplein 101, 3511 SX Utrecht, Netherlands

E-Mail: kathrin.steinberg@asc-aqua.org

Introduction

The Aquaculture Stewardship Council (ASC) is an independent not for profit organisation founded in 2010 by World Wildlife Fund (WWF) and the Dutch Sustainable Trade Initiative (IDH) It aims to be the world's leading certification and labelling programme for responsibly farmed seafood. The ultimate goal of all ASC standards is to reduce the environmental and social impact of aquaculture worldwide. The standards are reviewed and revised every 3 – 5 years at a minimum in order to incorporate learning from stakeholders' feedback and from the Monitoring and Evaluation Programme. The revision process can also include adding new species to an existing standard.

The ASC Shrimp Standard v. 1.0 is currently under revision. The Standard currently covers species under the genius *Penaeus* (and *Litopenaeus*) and is oriented towards the production of *L. vannamei* and *P. monodon*. Other species of shrimp are eligible for certification if they can meet the specified performance thresholds. The increased interest in more diversified shrimp farming practices over the last years is not only driven by the market but also by lower susceptibility to certain diseases, easier reproduction, as well as different environmental requirements such as broader optimal temperatures and salinities (Briggs et al., 2004; Laubier and Laubier, 1993). Related to this and advancing technology a species diversification has occurred and should be reflected in the standard

An ASC desk study was facilitated in 2017 in order to identify potential new candidates for the inclusion in the standard. As a result it was decided to further evaluate the potential inclusion of *Penaeus stylirostris* (Blue Shrimp), *Penaeus merguiensis* (Banana Prawn) and *Penaeus japonicus* (Kuruma Prawn). Discussion with various stakeholder further identified *Penaeus ensis* (Greasyback or Pink Shrimp) as a species of interest.

Materials and Methods

The focus of this work was to investigate the necessity to include species specific metrics for the above mentioned species in the revised ASC Shrimp Standard. Therefore producer countries and volumes were identified using FAO data. Information about on farm production was so far collected mainly via literature research. Data from ASC certified farms was also included in order to compare literature data with actual data on ASC certified farms for the potential new species as well as for *P. mondon* and *L. vannamei*.

Results and Discussion

There is only limited data available for *Penaeus stylirostris* (Blue Shrimp). *P. stylirostris* has a similar protein requirement to *P. monodon* (~ 36 – 42%) and comparatively higher survival rates and tolerates higher stocking densities (Briggs et al., 2004). FCR of the two ASC certified farms was reported as 2.3, thus similar to literature data were the FCR was reported as 2.82 ± 0.22 (Hernandez-Llamas et al., 2004).

P. merguiensis is often a by-product of extensive shrimp aquaculture thus there is only little information available on survival rates or feed efficienc .

Penaeus japonicus is often considered the most demanding penaeid in terms of protein requirements (up to 55%) and only little data is available on feed efficiency with FCR fluctuating between 0.47 to 7.04 (Laubier and Laubier, 1993; Türkmen, 2007).

Data availability on *P. ensis* is scarce and literature research is still ongoing for this species.

(Continued on next page)

Overall it appears that both *P. merguiensis* and *P. japonicus* are similar to *P. monodon*, with slightly higher protein requirements. Protein requirements are often overestimated and are likely similar for most penaeid shrimp (Guillaume et al., 2001). It is therefore suggested, to add *P. merguiensis* and *P. japonicus* to the ASC Shrimp Standard, using the same values as for P. monodon.

P. stylirostris appears to be similar to *L. vannamei* in terms of survival rates with slightly higher protein requirements (more similar to *P. monodon*). It is therefore somewhere between the two species. There are currently two farms producing *P. stylirostris* certified to the ASC Shrimp Standard, based on the metric requirements for *P. monodon*. Based on the low production values of only 2,401t it should be considered, whether adding *P. stylirostris* specifically to the ASC Shrimp Standard is reasonable or not. It is therefore suggested to continue certifying *P. stylirostris* according to the metric requirements for

P. monodon.
However, as the obtained data is so far only based on scientific literature research. Including production data in the evaluation of metric requirements is indispensable according to the ASC Metrics Methodology. The ASC is therefore currently working on the acquisition of production data for all three species and requests producers to contact the ASC if they would be able to share data on any of these species.

Introduction:
Fish gills with their large surface area, thin branchial epithelium and high vascularization are a fascinating organ which is involved in oxygen and carbon dioxide exchange, in water and ion transport as well as in the excretion of ammonia. Due to this multifunctional nature and the numerous interactions between the processes taking place in gills, branchial diseases may have serious implications on fish health and can cause several complications for the organism. Fish gill can be infected by numerous pathogens, including parasites, bacteria and viruses. In common carp, *Cyprinus carpio*, the infection of gills with the poxvirus carp edema virus (CEV) is often associated with severe clinical signs including lethargic behavior of the infected fish, a characteristic lying at the bottom of the tank and with progression of the disease the activity of the fish decreases until its eventual death. Because of the characteristic lethargic behavior of clinically affected carp, the disease is assigned as "Koi sleepy disease" (KSD). Because this virus infects predominantly the gills of carp, CEV infection can serve as a unique model for studying branchial disease in carp.

Materials and Methods
Blood, gill and kidney tissue were collected from common carp experimentally infected with CEV and suffering from clinical KSD. The blood samples were subjected to gas analysis and flame photometry as well as global non-targeted metabolomics using GC-MS and LC-QTOF/MS. Tissue samples were subsequently subjected to DIGE based proteomics and RT-qPCR gene expression analyses. A salt rescue model was used for further investigating immune responses by analysing mRNA expression of genes (*cd4*, *cd8*, *igm*, *casp9*, *inos*, *tcr a2*, and *mpo*) involved in different immune responses.

Results
The analysis of blood gasses, ions concentrations and metabolite profiling indicated that observed clinical signs are most likely related to disturbed transport processes across the gill epithelium, resulting in ion dysregulation (drop of the blood sodium level from >600 µmol l^{-1} in control carp to <90 mmol l^{-1} in infected carp) and an accumulation of ammonia in circulating blood rather than effects of hypoxia or hypercapnia. Analyses of over 2,500 metabolites showed changes in the pyrimidine and urea cycle as well as the beta-alanine and amino acid metabolism in blood plasma at day 6 p.i.. The clinical signs can be abolished by the addition of salt to the tank water, which circumvents the drop of sodium levels and also rescues from ammonia accumulation in the blood of infected carp. Haematological analyses confirmed that the KSD affected carp experienced severe leucopenia and granulocytosis, with a 4-fold drop of leucocyte counts by day 6 post infection. The DIGE based proteomic studies of gill tissue from these carp indicated that 86 proteins were significantly changed during the onset of severe KSD. Besides an up-regulation of antiviral and antimicrobial innate immune responses (Mx, LyzC and ApoAI), signs of an immuno-suppression were noticed. This included a down-regulation of the antimicrobial peptide NK-lysin-like, which could indicate lower activity of NK cells, and T-cell responses in KSD affected carp. The Down-regulation of calpain and caspase indicated a pro-apoptotic effect of the infection. Increased inflammation was mediated by the down-regulation of the anti-inflammatory proteins GSN, ANXA1, SCIN. An immuno-suppression in KSD affected koi was also indicated by significantly lower mRN expression levels of the genes encoding cd4, tcr a2 and igm proteins.

The proteomic analysis of gill tissue from KSD affected carp revealed also increased concentrations of several heat shock proteins, which could indicate elevated stress response in infected gills.

Interestingly, the salt treatment eliminated all observed immunosuppressive effects of the CEV infection.

(Continued on next page)

Discussion and Conclusion

Common carp, which is moderately tolerant to hypoxia, has the ability to circumvent the impairment of oxygen availability related to proliferative changes of the branchial architecture during CEV infection. The physiology of KSD affected carp is more seriously affected by the dramatic disturbance of the ionic homoeostasis and the severe accumulation of ammonia in circulating blood. This is impressively documented in the salt rescue experiments; in which the restoration of physiological sodium levels abolished all clinical signs. Even though poxviruses encode multiple immunomodulatory proteins, the results from the salt rescue experiment suggest that the immunosuppression observed in carp suffering from KSD was also related to the increased ammonia level and the loss of the osmotic balance. The suppression of T- and B-cell responses in KSD affected carp could foster the development of secondary infections, which often accompany clinical KSD. In conclusion, the studies on KSD affected carp clearly underline that a disturbance of osmotic balance and ammonia excretion during branchial disease of carp can be decisive for the outcome of the disease and even may impact immune responses to pathogens.

A NEW CONCEPT IN MULTITROPHIC AQUACULTURE; FARM CULTURED EURASIAN PERCH (*Perca fluviatilis*), RAINBOW TROUT (*Onchorhynchus mykiis*), COMMON DUCKWEED (*Lemna minor*) AND GIBBOUS DUCKWEED (*Lemna gibba*)

Introduction

Aquaculture remains the fastest growing food production sector in the world. However, this rapid expansion is increasingly limited by the lack of suitable water sources, availability of suitable sites and by the ecological carrying capacity of the surrounding environment. For this reason, indoor, fully controlled recirculating aquaculture systems (RAS) are attractive. However, at present these systems do not contribute much to global aquaculture production and currently the majority of aquaculture production is realised from more traditional ponds (Hargreaves 2006). Concerns about the environmental impacts of the rapid expansion of intensive aquaculture systems have recently led to increased research interest in integrated multitrophic aquaculture systems (IMTA). Because inland freshwater IMTA is a new practice, a study was conducted to assess water quality in a hybrid system comprised of combined split-pond and duckweed culture lagoons. Here, we present the first data from this unique aquaculture system. A key aspect of the farm trial is the development of a sustainable multitrophic culture system holding European perch (*Perca fluviatilis*), rainbow trout (*Oncorhynchus mykiis*), common duckweed (*Lemna minor*) and gibbous duckweed (*Lemna gibba*), with associated organic status.

Materials and methods

The farm trial is located within a cutaway bog, that has been historically harvested for peat by Bord na Móna company. The site is located in County Offaly, Ireland. The farm itself is powered by a wind turbine. The aquaculture system consists of 4 split (pill) ponds connected with through a duckweed lagoon that acts as a treatment system. The farm is designed to discharge excess water only during heavy rainfall. Water is sourced from existing peat drainage systems using sub-surface water pumps.

The fish are kept at a density that does not exceed the organic farming standard (< 20 $kg.m^{-3}$ for perch), using screens at the D-ends of each split pond (Fig. 1). Each D-end is designed to hold fish of a different size category (mesh size varied from 7 to 25 mm). The space between two D-end fish culture areas is used to treat waste with free living algae and bacteria (in suspension). Algae also produce oxygen during daytime hours which is utilised by the fish. Flow in each split pond is generated and water is circulated using an airlift (SKV-tec GmbH). Each D-end fish culture area is equipped with oxygen and temperature probes (Oxyguard Pacific) connected to paddlewheels (Aquaculture Fishtechnik GmbH) to provide extra oxygen when necessary (when saturation is below 75-85 %). Moreover, a Seneye on-line system is placed in each pond to monitor pH, free ammonia and temperature. The AQUAMONA farm is currently holding European perch and rainbow trout. Lagoons are planted with common duckweed and gibbous duckweed stabilised. These cultures are stabilised with different kinds of shelters to prevent the negative impact of wind. Lagoons are monitored for total duckweed cover every two weeks using a drone (DJI Phantom 4 Pro V2.0). Measurement of cyanobacteria, chlorophyll level and turbidity is performed on daily basis using the AlgaeTorch (bbe moldanke GmbH). Total ammonia, nitrite, nitrate and orthophosphate concentration are measured every 3 days using a HACH DR3900 spectrophotometer and appropriate LCK kits.

(Continued on next page)

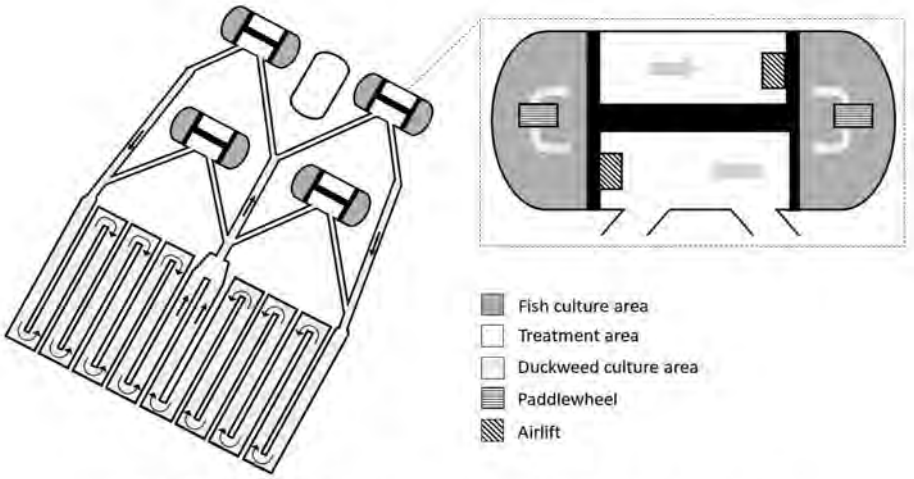

Fig. 1. AQUAMONA farm layout at Mount Lucas (Bord na Móna)

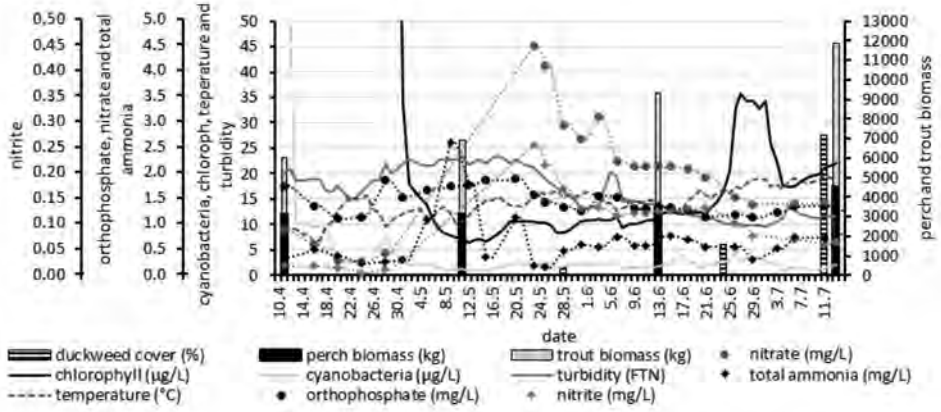

Fig. 2. Development of fish biomass (perch and rainbow trout), feed usage, total ammonia, phosphate, nitrite, nitrate, cyanobacteria, chlorophyll and turbidity level.

Results

Previous results about water quality, fish and duckweed performance are presented in Fig. 2. Values for all critical water parameter was within suitable values recommended for perch and trout. Moreover, oxygen levels (nor shown) varied from 75 to 145 % depend on chlorophyll level and day phase.

Conclusion

The semi-commercial scale system for perch, trout and duckweed production based upon IMTA principles is now successfully in operation in Ireland. Emphasis is now on fine-tuning hydrodynamics, microbial ecology, probiotic effects associated with elevated bacteria and algae densities, and duckweed effectivity.

* E-mail: cedomir.stevcic@jyu.fi

Introduction

The high concentrations of dissolved nutrients in recirculating aquaculture systems (RAS) allow development of technologies for exploiting the waste as a valuable resource (e.g. integrated multi-trophic aquaculture approach) (Martins et al., 2010) and to reduce nutrient release into the surrounding environment. This project evaluates the use of microalgae and filter feeder cultivation in RAS effluent for efficient removal of nutrients. So far we have evaluated (1) the effectiveness of different microalgae species to remove dissolved nutrients from the RAS wastewater, (2) the use of three different LED grow lights with continuous spectra on microalgal biomass production and nutrient removal, and (3) the potential of filter feeding microcrustacean *Daphnia magna* to filter the microalgae from the water. This project produces new knowledge on nutrient recycling and thus supports the concept of circular economy, and conservational and sustainable management.

Material and methods

The wastewater originated from a laboratory scale (total volume *ca*. 1000 L) RAS at the University of Jyväskylä, Department of Biological and Environmental Science, containing whitefish (*Coregonus lavaretus*, Salmonidae) fed with Circuit Silver Opti 2.5 dry feed (Raisio aqua, Finland) with a belt feeder 24 h per day, at *ca*. 17°C.

The growth and nutrient uptake of 10 microalgae strains was assessed in unfiltered RAS wastewater in comparison with an algal growth medium. The experiments were conducted in 400 mL aerated batch cultures that enabled axenic maintenance of the cultures during sampling.

Results

Green microalgae showed a good growth potential and nutrient removal not only in reference medium but also in unfiltered RAS wastewater, while non-green microalgae performed poorly both in wastewater and in reference medium. The densities and specific growth rates of the green microalgae species did not differ between wastewater and reference medium. Microalgae *Acutodesmus* sp. and *Selenastrum* sp. had the highest density followed by *Monoraphidium griffithii*, *Chlamydomonas reinhardtii*, *Scenedesmus obliquus*, and *Haematococcus pluvialis*.

The growth and nutrient removal of *C. reinhardtii*, *M. griffithii*, and *Selenastrum* sp. in unfiltered RAS wastewater did not vary between the three light spectra, whereas the three microalgae differed from each other for growth parameters and nutrient removal.

Waterfleas (*Daphia magna*) increased their dry weights 2-4 times when fed with four different green microalgae (*C. reinhardtii*, *H. pluvialis*, *M. griffithii*, and *Selenastrum* sp.) previously cultivated in filtered RAS wastewater. After 48h, waterfleas removed 80% of *M. griffithii*, 70% of *H. pluvialis*, and 20% of *Selenastrum* sp. from the RAS wastewater.

Discussion and conclusions

The main results obtained from the project: (1) Unfiltered RAS wastewater promotes growth of green microalgae in similar extent as in reference medium at *ca*. 17° C. (2) Biomass production and nutrient removal in RAS wastewater varies among the tested species of microalgae. (3) Green microalgae can be used for RAS wastewater treatment as they improved the water quality by reducing the concentrations of nitrate and phosphate. (4) Continuous spectrum LED lights may be used efficiently to obtain high removal of dissolved nutrients and high microalgal biomass. (5) Waterfleas (Daphnia magna) are capable of filter ng and consuming green microalgae for their growth in RAS wastewater. (6) This technique has a potential to promote circular economy.

Introduction

The rapid growth of coastal-based cage aquaculture has yielded in significant socio-economic benefits but is accompanied by increasing environmental impact. Through continual organic enrichment (uneaten feed and faeces), the receiving benthic environment around fish cages may experience pronounced changes in sediment geochemistry and benthic communities. The seabed eventually becomes acidified and oxygen-depleted because of microbial degradation processes. Because there is a tradeoff between acceptable environmental impact of aquaculture and socio-economic benefits, international regulatory systems for sustainable industrial development with minimal environmental impacts are in place worldwide (Borja et al., 2013). One objective of such Environmental Impact Assessment (EIA) is to determine the (spatial) scale of aquaculture impacts. Traditionally, these monitoring programs rely on the microscopic identification of benthic macroinvertebrates as bioindicators, based on which the ecological quality status is determined via index or metric calculation. However, this is very expensive, time consuming and error prone. Given the growth of the aquaculture sector, and the demand for more frequent and stricter monitoring programs by regulators, there are concerted efforts to develop alternative environmental monitoring strategies. We present a "ready-to-use" pipeline, which infers the ecological quality status of samples from traditional monitoring transects through the exploitation of eDNA metabarcodes obtained from benthic bacterial communities as bioindicators.

Material and methods

In parallel to a traditional macroinvertebrate-based environmental monitoring of salmon farms in Scotland and Norway, we from the same samples have obtained genetic markers (eDNA metabarcodes) of benthic bacterial communities. Therefore, DNA was extracted from sediment samples using Qiagen's PowerSoil DNA extraction kit. According to a protocol described in detail by Stoeck et al. (2018), we then amplified the hypervariable V3/V4 region of the bacterial SSU rDNA gene as taxonomic marker. The obtained PCR products were then subjected to high-throughput sequencing (Illumina MiSeq). Obtained sequence data were then processed and taxonomically assigned according to a standard pipeline as described in Stoeck et al. (2018). Non-metric multiple dimensional scaling (NMDS) was used to compare sample sites with each other based on bacterial community profiles and to relate community patterns to environmental variables and macrofauna-derived ecological quality status groups. Sample site patterns obtained from bacterial DNA markers were then compared to patterns obtained from macroinvertebrate communities from traditional monitoring.

In a next step, two approaches were compared and assessed to infer ecological quality. (a), indicator value (IndVal) inference (Dufrene and Legendre, 1997): indicator values were calculated for eDNA metabarcodes, based on which a variant of the widely used AZTI Marine Biotic Index (AMBI) was calculated to establish ecological quality of the samples analyzed. (b), supervised machine learning (SML) (Cordier et al., 2019): using eDNA metabarcodes and ecological quality information for each sample obtained from macroinvertebrate-based monitoring, we trained an algorithm, which identified indicator eDNA metabarcodes to predicted ecological quality status.

Results

Clustering of sample sites obtained from monitoring transects of salmon farms showed excellent pattern-matching between bacterial eDNA patterns and microscopy-derived macroinvertebrate patterns. Clustering of sites based on bacterial eDNA correlated significantly among others with distance from cage edges, macroinvertebrate-derived metrics and indices, and with ecological quality. Both approaches, SML and IndVal inference for eDNA metabarcodes with subsequent calculation of an AMBI variant performed equally well in establishing ecology quality for the investigated salmon farms. Accuracies of correct ecological status assignments to the investigated samples were ca. 80% for both methods, when compared to traditional macrofauna monitoring results of the same samples. This is a remarkable achievement considering that the number of investigated farms in this study was relatively low for SML and IndVal inference.

(Continued on next page)

Discussion and Conclusion

Our study showed a) the high potential of eDNA metabarcoding of benthic bacterial communities for environmental monitoring of salmon farms, and b) how eDNA metabarcodes can be used to establish ecological quality as known from traditional macrofauna-based monitoring. Metabarcode-based metrics are much cheaper to generate, more objective and are not dependent on a declining pool of taxonomists. Metabarcode-based metrics can be obtained within two weeks of sampling (compared with 3 – 4 months for traditional methods) enabling near-real-time management (e.g. of stock biomass). This near-real time management could be used to prevent a severe ecological impact beyond the allowable zone of effect (AZE). But also, a more frequent monitoring or a modified, more informative monitoring scheme at no additional costs compared to the current macrofauna-based monitoring would be possible through eDNA metabarcoding. Further research efforts are to make this technology ready for the implementation into official regulations. This includes for example the eDNA monitoring of more salmon farms from different geographic areas as well as in different seasons. SML and IndVal accuracies will increase with sample numbers, and, also, we will obtain a better understanding of seasonal and spatial dynamics of bacterial eDNA indicators.

Introduction

Microalgae account for the basis of the food chain in aquatic ecosystems and they are ubiquitously distributed throughout the biosphere (Amaro et al., 2011). This wide span of ecosystems contributes to the myriad of chemical compounds that they are able to synthesize, thus accounting for their unique potential in blue biotechnology. In aquaculture, bacterial infections are nowadays considered as the main responsible for serious mass mortalities and considerable economic losses and antibiotics have been largely used in intensive farming, however, the risk of transferring resistance to humans bacteria have led to a great concern for public health about the misuse of antibiotics. The antimicrobial activity of microalgae has been largely studied and it has been attributed to compounds belonging to several chemical classes – including indoles, terpenes, acetogenins, phenols, fatty acids and volatile halogenated hydrocarbons. In this work different species of microalgae cultivated in ANFACO-CECOPESCA have been studied to check the antimicrobial activity against *Vibrio anguillarum* CECT 522 and *Aeromonas salmonicida* subsp. *salmonicida* CECT 894. Also, amino acid and fatty acid composition of these species have been analyzed to study the correlation among these two parameters and antimicrobial activity results.

Materials & methods

Amino acid composition, fatty acid composition and antimicrobial activity of eight microalgae species (*Tetraselmis chuii, Chaetoceros calcitrans, C. salsugineus, Nannochloropsis gaditana, Pavlova gyrans, Conticriba weissfloggi, Rhodomonas lens* and *Isochrysis galbana*) against two fish pathogens *V. anguillarum* and *A. salmonicida* has been determined.

Microalgae were cultured in 10-L carboys with seawater supplemented with the commercial nutritive solution Goldmedium (Aqualgae S.L., A Coruña, Spain) following manufacturer's directions. Aeration was supplemented with CO_2. When cultures reached early stationary state, cells were harvested by ultrafiltration through a 300 kDa Pall membrane and further spray-dried with a Büchi B-290 unit,

Total protein and amino acid profile were analyzed using Kjeldahl method and high-performance liquid chromatography (Vázquez-Ortiz et al., 1995) and fatty acid using the quantitative SOXHLET method based on the extraction of fat from the sample by ethyl ether and it was performed by gas chromatography based on the separation and determination of fatty acid methyl esters.

Microalgae aqueous and ethanolic extracts were obtained from lyophilized microalgae. The antimicrobial activity of these extracts was tested by agar well diffusion technique (Fajardo et al., 2014) and by spectrometry (Garrido et al., 2013). In the first case, extracts were pipetted in TSA and marine agar previously inoculated with *A. salmonicida* and *V. anguillarum* respectively, and incubated at 26°C and 30°C for 24h, before observing the presence of inhibition halos. In the second case, the growth of both pathogens, in presence and absence of the different extracts, was determined over 24h by quantifying the optical density (at 600nm) of the culture medium in a spectrophotometer; the experimental growth data obtained were fitted with a logistic equation (Falaise et al., 2016).

Results

The percentage of proteins was higher in *R. lens* and *N. gaditana*. In both cases they exceeded 30% of the total composition. Regarding lipids, *I. galbana* showed a fairly high level compared to the rest of microalgae analyzed with a percentage of total lipids close to 10%. AA profile was similar in the majority of the microalgae analised.

Fatty acid profiles showed that *C. weissflogii*, *R. lens* and *P. gyrans* have more saturated than unsaturated fatty acid. *N. gaditana* stands out with more than 70% UFA of which 75% are PUFA. Unlike, *T. pseudonana* has more than 49% of the fatty acids as MUFA.

(Continued on next page)

The test of aqueous extracts by agar diffusion techniques did not allow the formation of inhibition halos for the fish pathogens tested, while the ethanolic ones presented antimicrobial activity; however, the DMSO used for resuspending the extracts may cause part of the inhibition. More tests are needed to confirm the results. On the other hand, promising results have been obtained by spectrometry in liquid medium in 96-well plate, where ethanolic extracts (0.5 and 0.1mg/mL) of all tested microalgae produced a complete inhibition of *A. salmonicida* growth. Also, the aqueous extracts influenced significantly ($p<0.05$) the bacterial growth parameters: *K* obtained after 24h was reduced for all extracts except for those obtained by *R. lens;* some extracts reduced the μmax and increased the *b* of this pathogen. For *V. anguillarum* only concentrated ethanolic extracts gave positive results. Similar results have been obtained previously for *Tetraselmis sp.* and *Chaetoceros sp.*

AQUAPONIC WATER SUPPRESSIVENESS ON *Pyhtium aphanidermatum* ROOT ROT IN LETTUCE AND ITS ORIGIN

Gilles Stouvenakers*; Sébastien Massart; M. Haïssam Jijakli

Laboratory of Integrated and Urban Plant Pathology, University of Liège, Gembloux Agro-Bio Tech, Passage des déportés 2, 5030 Gembloux, Belgium
E-mail: g.stouvenakers@uliege.be

Introduction

In couple aquaponic system, hydroponic plants production, fish rearing and nitrifying bacteria are constituents of the same system and consequently share the same water. Because of this coexistence, phytosanitary treatments for plant diseases management are a delicate matter. Among plant pathogens, fungus-like Oomycetes responsible of plant diseases are among the most problematic because of their possible fast spread linked to zoospores (mobile spores) release in the irrigation water. However, it appears that aquaponic systems could be naturally armed against plant pathogens. This protective action is called suppressiveness (i.e. suppressive action) and refers to the cases where (i) the pathogen does not establish or persist; or (ii) establishes but causes little or no damage (Postma et al. 2008). In *in vitro* laboratory experiments, aquaponic water has shown a direct inhibitory effect on Pythium spp. growth (Gravel et al. 2015; Sirakov et al. 2016; Stouvenakers et al. 2018). To confirm this discovery, *in vivo* experiments using *Pythium aphanidermatum* plant pathogen have been carried out on lettuces growing in aquaponic (AP) water, hydroponic (HP) water or complemented aquaponic (CAP) water. CAP water results from the addition of mineral salts in AP water to obtain identic concentrations of mineral nutrients as the ones contained in HP water.

Materials and methods

Suppressiveness of AP, CAP and HP water were evaluated by comparing root symptoms, leaf yields and root yields of P. aphanidermatum inoculated lettuces with the corresponding negative controls. For each treatments, samples of lettuces rhizosphere, rhizoplan and endosphere have been conserved for microbiota analysis by Illumina high throughput sequencing of ITS and 16S rDNA genes.

Results and conclusions

Results show that root symptoms of inoculated lettuces are significantly lower when they grow in AP water compared to CAP and HP waters. Foliar yield, root yield and leaf turgidity also decrease significantly less when using AP water. These results also highlight that the physicochemical modifications of AP water to make the CAP water probably disturb the natural microbiota and lead to the loss of its suppressive capacity. To elucidate the origin of AP water suppressiveness, a comparative bioinformatics analysis of microbiota diversity and OTU's composition of the different samples is in progress. Moreover, this study could contribute to find novel biocontrol agents for plant pathogens control in aquaponics

A RETROSPECTIVE OF OUR INTERNATIONAL RESEARCH COLLABORATION ON THE USE OF PERACETIC ACID IN AQUACULTURE

D.L. Straus*, T. Meinelt, D. Liu, L.-F. Pedersen, C. Good and J. Davidson

USDA - Agricultural Research Service
Harry K. Dupree - Stuttgart National Aquaculture Research Center
Stuttgart, AR 72160
Dave.Straus@usda.gov

Introduction

Peracetic acid (PAA) is a compound that is produced from acetic acid, hydrogen peroxide (H_2O_2) and water; it also contains a stabilizing agent. The resulting product is an equilibrium solution of these components that has long shelf stability. In addition, PAA breaks down quickly in the environment to water and vinegar. PAA has greater reactivity and lipid-penetrating properties than H_2O_2 alone and is not deactivated by catalase and peroxidase (naturally occurring on organism membranes) which happens with H_2O_2.

Thus, PAA eliminates some unwanted organisms easier and faster. Most importantly, it is eco-friendly and does not leave dangerous residues, such as trihalomethanes and haloacetic acids when it decomposes or reacts with naturally occurring organic matter as many compounds do (e.g., chlorine compounds). It is a potent disinfectant and has replaced chlorine-based disinfectants or sanitizers in many industries. Uses include: sanitation in food/beverage plants, agricultural facilities, wineries/breweries, greenhouse equipment, animal housing, preventing bio-film formation in paper/pulp industries, wastewater treatment, commercial laundries and poultry processing.

Discussion

When we started our collaboration in 2007 (Straus and Meinelt 2019), we recognized that PAA had much potential in aquaculture. But, there was very little information on the use of PAA in aquaculture, both in the U.S. and Europe, so we devised a plan to develop research and promote PAA. We understand that there are other publications on the use of PAA in aquaculture, but there has not been a concerted effort like ours. This collaboration is important because of the expertise of each scientist and the limitations on live fish experiments in the European Union (EU).

PAA has been used in Denmark and Germany for some time to treat saprolegniasis and parasites such as *Ichthyophthirius multifiliis* (Ich). This approval is as a water disinfectant "for cleaning and disinfection of equipment and facilities in the presence, as well as in the absence, of aquaculture animals". Through our research, PAA is now introduced and registered by the EPA for use in U.S. aquaculture, but currently only when fish are not present.

This presentation reviews our collaborative research that has resulted in 19 peer-reviewed publications to date, along with several magazine articles and many presentations. We began with research on Ich and have gained other scientists with expertise in a variety of areas so that our research now includes pathogen control, degradation of PAA, toxicity to fish and use of PAA in RASs.

EFFECTS OF DIETARY MICROPLASTIC (100-400 µm) EXPOSURE ON INTESTINAL PHYSIOLOGY OF RAINBOW TROUT (*Oncorhychus mykiss*)

H. SUNDH*, G. ASMONAITE, N. ASKER, J. STURVE AND B. CARNEY ALMROTH

University of Gothenburg, Department of Biological and Environmental Sciences, Box 463, 405 30 Gothenburg, Sweden
E-mail: henrik.sundh@bioenv.gu.se

Introduction

Microplastics (MPs), plastic particles between 5mm and 0.1 µm in diameter, can be found in the marine environment, seawater, lakes, rivers, estuaries, sediments and many species of biota. Reports show presence of MPs in commercial species of finfis and shellfish in the wild, and in fishery and aquaculture products. Concerns are raised that MPs, and their associated chemicals, represents a risk for fish productivity, fisheries resources with potentially negative effects on food security (Lusher et al., 2017).

The accumulation of plastics in the gastro-intestinal (GI) tract of fish has been documented and ingestion has been proposed as a prominent exposure route for MPs. The GI tract of fish is a multifunctional organ important for osmoregulation, nutrient and fluid absorption, and acts as a barrier towards the external environment (Sundh and Sundell, 2015). The luminal content contains nutrients, ions, fluid and the endogenous microbiota essential for health but also potentially harmful components, such as pathogens, antigens, pro-inflamm tory factors, biological, or synthetic toxins. Uncontrolled passage of harmful substances across the epithelium into the circulatory system can cause disease, tissue damage and/or inflammatory responses. Therefore, a prominent function of the intestinal epithelium is to maintain selective permeability, ie. allow uptake of nutrients, ions, and fluids while harmful substances are restricted from reaching the circulatory system (Sundh and Sundell, 2015).

Despite the fact that ingestion of MPs has been demonstrated in >690 aquatic species, including many fish species (Provencher et al., 2017), biological effects from ingestion of these particles are considerably less documented and potentially negative effects on GI function of fish is unknown. The aim of the current study was to assessing the impact of ingestion of MPs on GI function with emphasis on intestinal barrier and transporting functions in combination with local and systemic inflammatory responses.

Materials and methods

For this study, juvenile rainbow trout (*Oncorhynchus mykiss)* were exposed via diet to polystyrene (PS) particles (100-400 µm, 10mg of PS MPs/fish/day) for a period of 4 weeks. Fish were fed four types of diets: control (no PS MPs) and diets containing untreated PS particles (PS-virgin) or particles exposed to sewage (PS-sewage) and industrial harbor (PS-harbor) effluent. Thereafter, physiological condition and integrity of proximal and distal regions of the intestine was assessed with Ussing chamber technique. Electric parameters, including TER (Ω*cm2), TEP (mV), SCC (µA), were recorded. A time-dependent transport of radioactively-labeled molecules (C^{14}-Mannitol and H^3-Lysine) across metabolically active epithelia was investigated to assess the functional adversity of dietary PS MPs exposure. Histological analysis was performed. Gene expression analysis of immune system-related genes (TGFβ, TNFα, IL-8, IL-10, IL-17, IL4/13A) and tight junction proteins (Occludin, ZO-1, Tricellulin) was additionally performed to examine if polystyrene particles and chemical contaminants induced inflam ation in the intestinal tissue. Additionally, innate immune response (lysozyme stability and complement system) in blood plasma was evaluated to assess the presence of systemic inflammation.

Results

Overall, the findings of the study indicated no or minor functional effects on fish intestinal tissue inflicted by particle exposure. Tendencies towards inflammatory responses were detected and were accompanied by upregulation of tight junction proteins, suggesting activation of intestinal homeostasis processes in response to PS MPs exposure.

(Continued on next page)

Discussion

With present study, we could not show that PS MPs (100−400 μm) act as physical or chemical or immunotoxic hazards upon ingestion. Our results collectively suggested that 4 week dietary exposure to both virgin and environmentally deployed PS MPs had limited impacts on functional integrity of intestinal epithelium in rainbow trout with no adverse effects observed in tissue morphology, barrier integrity, active transport, and/or inflammation. Given the inherent structural and functional complexity of the intestinal epithelium as well as active presence of various agents in the gut lumen (e.g., commensal microbiota, mucus), the intestinal environment represents a complex, dynamic system, which when subjected to particle exposure (and associated chemicals) may have resilience and capacity to cope with this stressor.

Animals living in the natural environment are exposed to a great variety of mineral and organic non-digestible particulates and are likely to possess adaptive protective physiological "housekeeping" mechanisms to counteract unwanted exposure of such indigestible particulates. The rainbow trout inhabits environments with high water turbidity and this species is known to tolerate moderate levels of particulate exposure . Our findings indicating the absence of tissue-specific (functional) effects in the intestine should therefore not be extrapolated to other fish species or animals from other taxonomic groups. One must account for potential differences in anatomical structures of the digestive tract and physiology (e.g., gut retention time, digestive fluid composition, presence of enzymes degrading plastic polymers), and adaptations to different ecological niches. Also, more investigations on MPs-gut lumen interactions are required to confirm, or contradict, the lack of effects on intestinal physiology associated with exposure to other polymers (e.g., having different chemical composition, level of degradation, ability to sorb chemicals, etc.). As dietary exposure to MPs has been shown to cause false satiation and subtle changes in energy metabolism on organismal level, we need to increase current understanding about potential impacts on an organisms' survival and fitness in long-term, under more ecologically relevant scenarios

Introduction

Geosmin and 2-methylisoborneol (MIB) are the best known odorous metabolites produced by several different microorganisms, e.g. actinobacteria, cyanobacteria, proteobacteria and fungi. Geosmin and MIB are the most common causes of off-flavor episodes in fish industry. Geosmin and MIB cause problems already in small concentrations and humans have very low odor threshold for both metabolites. Especially in recirculating aquaculture farms (RAS), the accumulation of geosmin and MIB in fish is problematic and causing economic losses. Currently purging of the fish in clean water is the best method to remove geosmin and MIB from fish. Although purging is effective, it reduces the profitability of fish production in RAS. Objective of this study was to study the presence of different potential geosmin and MIB producers in commercial RAS farms. Additionally, the microbial community composition of farms was studied.

Materials and methods

Five commercial RAS farms were sampled to quantify the potential producers of geosmin and MIB and to study microbial community composition. Water samples were collected from the inlet, fish tank, and outlet of the farm. Biofilm samples were collected from fish tank walls and biofilters. Abundance of the currently known main geosmin producers (*Streptomyces*, *Sorangium*, cyanobacteria, *Myxococcales*) were quantified using real-time PCR (qPCR) with targeted primers. Microbial community composition was analyzed using next generation IonTorrent PGM sequencing targeting V4 region of 16S rRNA gene.

Results and discussion

The diversity of geosmin-producing bacteria and abundance in incoming water had differences between studied farms. The potential producers in incoming water had no direct effect on quantities of potential geosmin producers in fish tank indicating that the conditions and water treatment inside the farms had greater impact. Most of the studied RAS farms had one main geosmin producer and the most common producer was *Sorangium*. Also, *Streptomyces*, *Myxococcales* and cyanobacteria producers were detected from the farms. No potential MIB producers were detected on the studied samples. The microbial community composition was studied in order to identify the key microbial groups in commercial RAS farms. It is crucial to identify the conditions and potential producers of odorous metabolites in order to develop preventive methods in future

CHALLENGING SALINITY TOLERANCE LIMITS OF THE EUROPEAN EEL LARVAE (*Anguilla anguilla)*

E. Syropoulou*, E. Benini, S.R. Sørensen, J. Tomkiewicz and S.N. Politis

Email: e.syropoulou@outlook.com

Introduction

Most fish species are hyper-osmotic in freshwater, where plasma osmolality is higher than the environment and hypo-osmotic in seawater, where plasma osmolality is lower than the environment (Marshall and Grosell, 2005). Thus, in freshwater, fish need to actively take up ions to counteract the diffusive ion loss and osmotic water gain, while in seawater they need to maintain osmotic balance through a desalting process to counteract osmotic water loss. Euryhaline species, such as European eels (*Anguilla anguilla*), have adapted to cope with both, hyper- and hypo-osmotic environments, likely due to regular salinity changes in their habitats (i.e. estuaries) and migrations between freshwater and marine environments to complete their life cycle (Tesch, 2003). Eel offspring naturally occur in a hypo-osmotic environment in the ocean. Interestingly though, reducing salinity during culture of early life history stages, was shown to benefit eel larval ontogeny (Politis et al., 2018). In particular, lower salinity towards a more iso-osmotic environment reduces stress and conserves energy, probably due to lower cost for osmoregulation, resulting in higher survival and growth of early life history stages (Politis et al., 2018). The main objective of this study was to identify efficient technical solutions that accommodate these physiological preferences of eel larvae from a biological and cost/benefit point of view. Thus, we investigated when drastic salinity reduction from 36 to 18 psu should be implemented and how this affected European eel larval biometry (morphology and growth), deformities and survival, in order to identify a cost-efficient rearing protocol.

Materials and Methods

The experiment used seawater, originally pumped into the EEL-HATCH facility Hirtshals, Denmark, and treated through a stepwise filtering process, before entering a conditioning system. Here, salinity was adjusted to 36 psu using artificial sea salt (Blue Treasure Reef Sea salt, Qingdao Sea-Salt Aquarium Technology Co., Ltd., China). Thereafter, water was filled into 2 identical Recirculating Aquaculture Systems (RAS), each consisting of a 22 µm membrane filte , a UV lamp (UltraAqua, Aalborg, Denmark) and a 850 L sump. One system was kept at 36 ± 0.2 psu, while the other was adjusted to 18 ± 0.4 psu. European eel larvae were reared in 12 acrylic 2 L flow through jars (drz400sm hank, JugDesk Type, Taipei, Taiwan) with custom designed bottom inflow and top outflow for 6 days. On the day of hatch (day0), all experimental units were initially connected to the 36 psu system, while 3 jars were transferred to the 18 psu system on day1 (drastic 1), another 3 jars on day2 (drastic 2) and finally another 3 jars on day 3 (drastic 3). The last 3 jars remained in the 36 psu system (control) the entire period (Fig 1). Temperature was maintained at 18.8 ± 0.4 °C (Politis et al., 2017) and light intensity was kept at a minimum (Politis et al., 2014). Water exchange rate was set at ~0.1 L per min. The experiment was repeated 3 times, every time using offspring from a different parental combination. From each batch, larval sampling occurred on day0, 1, 2, 3 and 6 for each treatment and replicate. Here, ~10 larvae were randomly sampled, anesthetized using MS-222 (Sigma-Aldrich Chemie, Steinheim, Germany) and photographed using a zoom stereomicroscope (SMZ1270i fitted DS-Fi2 Camera Head, Nikon Corporation, Tokyo, Japan) for assessment of biometric characteristics (length, body area, oil drop area and deformities). Moreover, ~20 randomly sampled larvae from each batch, treatment and replicate were euthanized by an MS-222 overdose and preserved in RNA later at -20°C for molecular analysis. Furthermore, every day, dead larvae were counted and removed from all experimental units. Additionally, all larvae at the end of the experiment, as well as of all sampled larvae from each experimental unit were enumerated and recorded. Then, larval cumulative mortality was calculated as a percentage from hatch until day6.

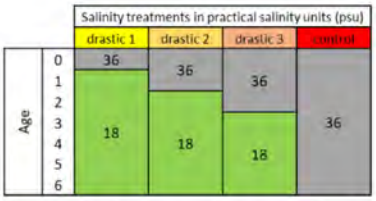

Figure 1 Experimental set-up. Larvae reared in constant 36 psu (control) were compared to larvae experiencing a drastic change in salinity from 36 to 18 psu either on day 1 (drastic 1), day 2 (drastic 2) or day 3 (drastic 3), respectively.

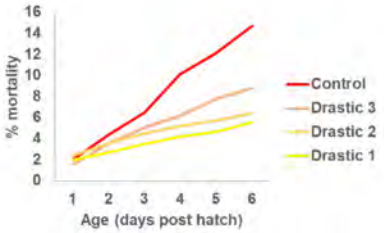

Figure 2 Larval mortality in constant 36 psu (control) vs drastic change in salinity from 36 to 18 psu either on day 1 (drastic 1), day 2 (drastic 2) or day 3 (drastic 3).

(Continued on next page)

Results

Our preliminary results show that larval mortality was highest when salinity was kept at 36 psu (control), but the earlier the drastic salinity regime was introduced, the higher the larval survival, resulting in up to 3-fold increased production (Fig 2). However, samples collected during the experiments will be further analysed leading to a deeper understanding through morphological and physiological measurements in order to define optimized rearing protocols in detail

Discussion and conclusion

The findings are quite interesting, as the control treatment (36 psu) resembles the salinity regime, larvae would naturally encounter in the oceanic spawning area in the Sargasso Sea. Thus, they would naturally never encounter any salinity changes during this period and especially not a physiologically extreme change like the one applied in this study. However, it was previously shown that salinity reduction benefits European eel larvae in terms of lower mortality and improved growth efficienc , which is likely facilitated by an energy surplus associated to lower osmoregulation demands (Politis et al., 2018). The results of this study confirm these observations while providing new insights in terms of methodology, applicability and timing from a hatchery point of view, as we have established the technically most efficient salinity reduction technique from a cost-benefit point of view. We conclude that a drastic salinity reduction can be applied resulting in increased larval survival, by only requiring two stable RAS engines.

The study was conducted on the River Nile around Banha city and Idku Lake. Fishing trips to the studied areas were carried out every three months over a period of one year. Ten fish (*Clariasgariepinus*) samples (from each sex) were collected seasonally from each fishing site. The climatic changes in both sites were recorded. Quantitative determinations of serum steroid hormones (progesterone, P; estrogen, E and testosterone, T) were determined. Serum progesterone concentrations were significant y increased in male than female fishes in autumn and spring from Banha and in summer and spring from Idku Lake. Moreover, (E) levels were significantly increased in male than females in summer and autumn in fishes from Idku Lake. Also, the (T) levels were significantly decreased in male than females in autumn and winter from Banha and in summer and winter from Idku Lake. Climatic changes have a great effect on the reproductive hormones of male and female catfish *C. gariepinus*).

SUPPORTING THE SUSTAINABLE DEVELOPMENT OF THE IRISH FRESHWATER AQUACULTURE INDUSTRY

atahar@ait.ie

Introduction

Irish freshwater aquaculture involves mainly traditional flow-through salmonids production (rainbow trout and smolt) that is generally performed without any inlet/outlet water treatment and with high flow rates to ensure oxygen replacement and good water quality. Various EU and national policies envisage a significant increase in the production of sustainably produced fish based food products. However, due to more and more stringent regulations and to path the way to an environmental practice the expected production increase must be a sustainable intensification aquaculture. EcoAqua is BIM funded project (2017-2019). The main aims of the project is to implement a water quality and energy monitoring program on each of the 4 Irish freshwater stakeholder fish farms. A graphical abstract of the project approach and objectives is presented below (Figure 1):

This particular study had a number of major objectives (i) ascertain the impacts of each site in terms of water quality, energy emissions and other water framework directive (WFD) biodiversity related impacts (ii) leverage this analysis to inform targeted decision making relating to capital investment and operation/control on each site and thus increase the efficiency on site, (iii) to reduce the levels of nutrient discharge of selected farms to meet WFD criteria by implementation of appropriate technologies to treat the wastewater and facilitate re-use of the treated water, thereby reducing both the volumes of extracted and discharged waters and (iv) help position the industry as a sustainable food producing sector with evidence based research.

Materials and methods

The facilities chosen have various configurations (i.e. pond/tank based, trout/salmon smolt/perch production) that are highly representative of the whole freshwater aquaculture industry and was be first benchmarked during year-1 of the program. This involved extensive and regular water quality monitoring – influent and effluent – of the 4 aquaculture sites to assess the performance of each and subsequent identification/benchmarking of their performance. Monitoring was performed weekly throughout a whole year using periodic 24 hour sampling campaigns augmented by remote monitoring using various sensors (e.g. pH, conductivity, dissolved oxygen, ammonium). An example of the approach undertaken for one type of farm (i.e. flow through, tank-based o ganic smolt production) is presented below (Figure 2) :

Results and discussion

Results will be presented on a farm by farm basis regarding the impact these flow through fish farms had on water quality parameters. General recommendations regarding new technologies and systems to be operated to increase aquaculture production in a environmentally sustainable way will be provided and discussed.

If accepted a presentation stating the general layout, objectives, approach and first results of the EcoAqua project will be given.

Email: satomi.takagi.q2@dc.tohoku.ac.jp

Introduction

Our previous research revealed that gonads of the sea urchin *Mesocentrotus nudus* from a barren were highly improved to desirable quality, compared to those from an *Eisenia* kelp bed (fishing ground) by feeding *Saccharina japonica* during May−July. In addition, gonad quality of *M. nudus* fed the basal frond portion of *S. japonica* and sporophyll of *Undaria pinnatifida* were accepted by sushi chefs of sushi restaurants achieved three Micheline stars in Tokyo. The gonads were evaluated as the ones provided to customers in the restaurants. Present study aims to find the appropriate period when gonad quality is improved by feeding two different thallus portions of the kelps.

Materials and methods

We collected 155 sea urchins from a barren in Shizugawa Bay in northern Miyagi Prefecture, Japan on 1 May 2017. These sea urchins were reared in 31 aquaria (5 urchins/10 liter aquarium) with filtered seawater. After rearing all sea urchins without food for nine days, feeding experiment was conducted for nine weeks from 10 May to 12 July. At the start of the experiment, 20 urchins from four aquaria were dissected for measurements and analyses. Sea urchins fed basal frond portion of *S. japonica* (1/3 of frond) (BS) and sporophyll of *U. pinnatifida* (SU) *ad libitum* every 3−4 days were held in each nine of 18 aquaria. Sea urchins in other nine aquaria were reared without food (ST). Sea urchins in three aquaria of each treatment were dissected 3, 6 and 9 weeks after the start of the experiment. Test diameter, body wet weight, gonad wet weight, gonad color (C.I.E. *L*a*b**) and gonad hardness of all dissected urchins were measured, and FAA contents in the gonads were analyzed. Significant differences in these traits among treatments at each time, and among each time by treatment were analyzed by nested ANOVA and Tukey's test.

Results

Gonad indices of BS increased significantly from 8.9 (at the start of experiment) to 13.2 (after 3 weeks) and to 19.5 (after 9 weeks). Those of SU increased significantly from the start to the end of the experiment. After 6 weeks, the indices exceeded 18 which is the minimum size for commercial landing (Agatsuma, 1999), and reached to 24.1 at the end. The *L** value of gonads of BS increased significantly 3 weeks later, and that of SU increased 6 weeks later from the start. Gonad hardness of BS and SU decreased significantly 3 weeks later, and were significantly lower than that of ST until the end of the experiment. Sweet tasting alanine content in gonads of SU increased 3 weeks later. In contrast, that of BS increased significantly from 6 to 9 weeks later (Fig. 1). Although alanine content in gonads of SU was significantly higher than those of BS and ST until the 6th week, it was not significantly different from that in BS after 9 weeks. Bitter tasting FAAs in gonads decreased definitely from the start to the end. Of them, arginine, methionine and valine contents in gonads of BS and SU decreased significantly from the start to 6 weeks later. Arginine content in gonads of BS and SU did not change from 6 to 9 weeks later, in contrast, methionine and valine contents decreased significantly until the end.

(Continued on next page)

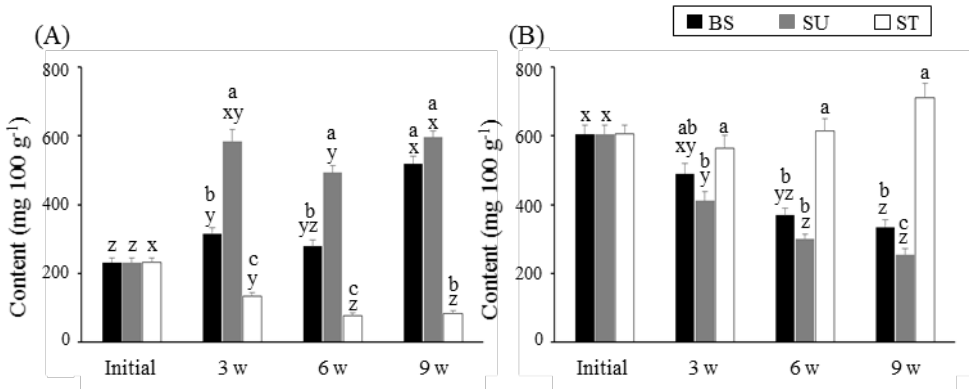

Fig. 1. Alanine (A) and arginine (B) contents in gonads of *Mesocentrotusu nudus* reared in tanks. Initial: at the start of experiment; 3 w, 6 w and 9 w: 3, 6 and 9 weeks from the start of experiment. BS: *M. nudus* fed the basal frond portion of *Saccharina japonica*; SU: *M. nudus* fed sporophyll of *Undaria pinnatifida*; ST: *M. nudus* starved. a, b and c: significant differences among treatments at each time ($P < 0.05$). x, y and z: significant differences among each time by treatment ($P < 0.05$).

Discussion and conclusion

Sweet tasting FAA contents in gonads of all treatments were lower than each threshold value (Kirimura et al. 1969) except for alanine and glycine. Increase in alanine content in gonads enhances sweetness (Takagi et al. 2017). Gonad sweetness of SU was improved 3 weeks after the start, faster than that of BS (9 weeks later). Bitter tasting arginine in sea urchin gonad makes the taste undesirable (Komata 1964). Past studies suggest that decrease in arginine content in gonads contributed to taste improvement and decrease in bitter taste (Takagi et al. 2017; 2018). Significantly lower arginine contents in gonads of BS 6 week later and those of SU 9 weeks later than that at the start would contribute to improvement of gonad taste. Low methionine and valine contents in gonads of BS and SU 9 weeks later compared to those 6 weeks later would also decrease bitterness of gonads.

Feeding basal frond portion of *S. japonica* to *M. nudus* from a barren improved gonad color and hardness 3 weeks later, and gonad size and sweetness 9 weeks later. Feeding sporophyll of *U. pinnatifida* improved gonad size, color and hardness 6 weeks later, and gonad sweetness 3 weeks later. Feeding each of kelp thallus portions could decrease undesirable bitterness of gonads 6 weeks later. Gonad bitterness would further decrease from 6 to 9 weeks later. Clarification of the components affecting the improvement of sea urchin gonad quality in basal portion of *S. japonica* frond and sporophyll of *U. pinnatifida* is needed.

POSITIVE EFFECTS OF SUPPLEMENTING ALGAL 1,3-BETA GLUCAN ON THE SURVIVAL OF ATLANTIC SALMON *(Salmo salar)* IN CHALLENGE CONDITIONS

Alex Diana[1]*, Christophe Bodenreider[2] & Geoff Horst[3]

[1] Kemin AquaScience™ | Toekomstlaan 42, 2200 Herentals, Belgium | alex.diana@kemin.com
[2] Kemin Agrifoods Asia | 12 Senoko Drive, 758200 Singapore
[3] Kemin Industries | 1900 Scott Ave, Des Moines, IA 50317, USA

Over the last decades, aquaculture practices have been intensifying and challenging sustainability and disease management. These two aspects are of great interest to the aquaculture industry that is often limited by them. The recent development of functional feeds has helped to provide balanced diets with feed additives that can improve the performance, health, and resistance to diseases. β-glucans are effective immunostimulants that have proved in several studies how they can improve the immune status and how the disease can be controlled in fish culture. *Euglena gracilis*, a freshwater microalga, used as a candidate for bioremediation and a nutrient source, is identified as a source of linear β-1,3 glucan. It accumulates up to 90% of the cell mass with linear β-1,3 glucan and equal to 50% of its cell volume when cultured under heterotrophic conditions. Genotoxicity tests were done using bacterial reverse mutagenicity and mammalian micronucleus tests to positively demonstrate that it is safe to use as a feed supplement. Safety was also proven with dermal and inhalation studies.

An experiment of a duration of ten weeks assessed the growth and disease resistance of Atlantic salmon (*Salmo salar*), as well as the immune stimulating effects resulting from dietary supplementation of algae-derived β-glucan compared with yeast-derived β-glucan when challenged with Furunculosis (*A. salmonicida*). All tests were performed at Lake Superior State University Aquatic Research Laboratory (LSSU-ARL), in a controlled environmental chamber (10-12 ˚C) with ten tanks of ~113 liters using a total of 300 fish equally distributed. Fish were fed twice daily at a rate of 3% of body weight and water was changed (half volume) every other day. Performance and growth parameters were recorded every two weeks. Two control tanks received standard feed without β-glucan supplementation, two tanks were assigned for the supplementation of yeast-derived β-glucan and the remaining six tanks received algae-derived β-glucan at increasing dosage: 200ppm, 500ppm and 1000ppm. After six weeks the fish were challenged via injection into the peritoneal cavity with *A. salmonicida* (1 x 10^5 CFU/fish; LD50). Mortality was recorded each day of this 4 weeks phase. After two weeks and at the end of the trial period, three fish from each tank were removed and processed via immunological and hematological testing procedures.

A linear correlation was observed between increasing algae-derived β-glucan dosage and survival rate with results comparable to yeast-derived β –glucan (Fig. 1). No statistically significant differences were observed in weight gain, gained length, or hematocrit or red blood cell numbers between any groups at any time points.

Data suggest that supplementation with algae-derived β-glucan can increase the survivability of salmon in a challenging environment. With additional study directed at the mechanisms and metabolic cascades involved, these results could prompt an improved understanding of the role of algae-derived β-glucan in enhancing survival, and significant advances in optimal dietary supplementation with algae-derived β-glucan in fish and shrimp diets

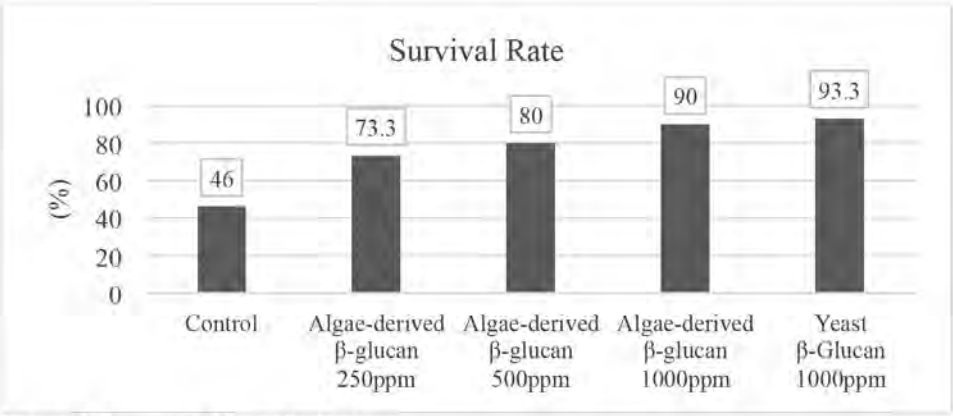

Figure 1 Summary of survival rates

This study was conducted from May to December 2016 and the aim was to investigate the spatio-temporal distribution of Labeobarbus species of Lake Tana. Descriptive statistics was used to present the data. Chi-Square Test was used to compare the spatial variations of species between areas, the temporal variations between seasons. *Labeobarbus intermedius* was the most dominant specie, containing 38.8 % of catch followed by *L. tsanensis*, *L. platydorsus*, *L. brevicephalus* within a catch composition of, 18.96%, 13.1%, 10.5%, respectively. *Labeobarbus dainellii* and *L. gorguari* were rarely collected. *Labeobarbus species* of Lake Tana showed significant variation in catches at four sampling sites ($p<0.01$) and also these species showed significant variation in dry and rainy seasons ($p<0.01$). *L. intermedius*, *L. tsanensis*, *L. brevicephalus*, *L. nedgia*, *L. gorgorensis*, *L. truttiformis* were significantly more abundant in rainy season than dry season. The maximum possible diversity of four sampling site. The highest 'J' value was obtained at Gumara site with the value of 0.5. Effort control regulations, limiting the gillnet fishery in spawning seasons and/or areas, will be appropriate to prevent the Labeobarbus fish species of lake Tana.

HOW DOES TEMPERATURE AFFECT PRIMARY BARRIER FUNCTIONS IN ATLANTIC SALMON (*Salmo salar L.*) POST-SMOLTS?

[a*]Tang, P., [b]Nilsen, TO., [c]Sundh, H., [c]Sundell, [b]Gharbi, N., [a]Osberg, C., [b]Handeland, SO., [b]Ebbesson, L., [d]Käkelä, R., [b]Tronci, V., [b]Pedrosa, C., [b]Balseiro Vigo, P., [a]Stefansson, S.

Environmental temperature has a considerate impact over near all aspects of physiology of both wild and cultured salmonids. In addition to climate change, insight regarding the effects of temperature over physiology is crucial for the aquaculture sector, as seasonal differences in temperature during early open pen rearing of post-smolt salmonids may ultimately be great and variable. For example, fish transferred during summer months will likely experience higher temperatures, whilst low temperatures will prevail during winter months. Due to these seasonal variations in temperature, in combine with the need for better predictability of fish stock robustness, it is essential to know how temperature influences tissue characteristics and modulates physiological functioning and adaptation, which processes maybe challenged during stress, thereby contributing to the stress response and overall robustness of the fish. Here we present how differences in temperature, affects Atlantic salmon (*Salmo salar* L.) post-smolt primary barrier compositions and functioning of osmoregulation in seawater. In this study we aim to elucidate how prior temperature acclimation history affects the capacity of these barrier systems to respond when confronted by an additional acute stress. Our results suggest that primary barrier characteristics change with shifting temperatures, resulting in new physiological set points to match osmoregulatory demand in those conditions. Here, we investigated key changes in gill and skin phospholipid (PL) and fatty acid (FA) compositions utilizing electrospray ionization-tandem mass spectrometry (ESI-MS/MS) and gas chromatography (GC-FID), in concert with changes in qPCR expression profiles of vital genes involved in osmoregulation and Using Chamber data on skin trans-epithelial resistance (TER). Complementation of methodologies allowed for accurate estimations to correlate the link between shifting biochemical and molecular changes at tissue sites with changing performance patterns of primary barriers manifesting at the different acclimation temperatures.

SPREAD OF A NEW DISEASE AGENT FOR RAINBOW TROUT (*oncorhynchus mykıss)* IN TURKEY: STRAWBERRY DISEASE

T. T. Tanrıkul*, E. Dinçtürk

Izmir Katip Celebi University, Faculty of Fisheries, Department of Fish Disease, 35620 İzmir (Turkey)

Introduction

Strawberry disease (SD) is a disease of rainbow trout (*Oncorhynchus mykiss*) which is characterized by bright red, raised inflammatory lesions (Olson et al., 1985; Oman, 1990). The disease was described as a skin disorder with an unknown etiology (Lloyd et al., 2008). It was first recorded in the USA in the 1950s then noted throughout the USA and Europe (Olson et al., 1985). Similar conditions with indefinite etiology have been described as 'warm water strawberry disease' (WWSD), 'cold water strawberry disease' (CWSD) and in some conditions 'red mark syndrome' (RMS) from different researches (Fleury et al., 1985; Ferguson et al., 2006; Verner-Jeffreys et al., 2008; Lloyd et al., 2011). In some sources, WWSD was considered as the same disease with SD (Ferguson et al., 2006). Despite the temperature distinction, WWSD and CWSD are regarded as two separate conditions in order to their epidemiological, pathological and histological differences (Ferguson et al., 2006). Also, RMS was associated with the presence of rickettsia-like organism (RLO) (Lloyd et al., 2011) but the etiology is still under investigation.

Materials and methods

This study reports the diagnosis of SD from market-sized rainbow trout in Turkey. The outbreak was observed in rainbow trout farms for 2 years, especially on warm seasons in the Southwest Aegean Region. 4 different farms were monitored and the diseased fish samples of 300-350g with multiple ulcerated skin swellings were examined. To diagnose the cause of the disease, fish were dissected and from spleen, liver, kidney and also from skin lesions the isolates were streaked on Tryptic Soy Agar (TSA, Oxoid) and Tryptic Soy Agar supplemented with 5% defibrinated sheep blood (BTSA) because of their capability of growing a wide range of bacterium species. Then, the plates were incubated at 20-28°C for 24-48h. Tissue samples were taken in order to get electron microscopy views. Samples were sputtered with gold by QUORUM Q150 RES and examined in a Carl Zeiss 300 VP scanning electron microscope in the Central Research Laboratory, Izmir Katip Celebi University. DNA isolation was conducted using the GeneMATRIX Tissue & Bacterial DNA Purification Kit. For PCR amplification of the 5.8S rRNA gene, ITS1 and ITS4 primers were used. Amplified products of the template DNA were sent to the Macrogen direct sequencing service (Macrogen, Holland) for sequence determination.

Results

The outbreak occurred at about 12-13°C between April-September for two years (2016-2017). Mortality rates were not directly associated with the SD in this case. The infected fish showed no behavior changes during the condition. Single or multiple skin lesions, especially around the abdomen and fin base area were the main pathological signs of the disease. The superficial lesions were usually haemorrhagic with desquamations, central ulceration and redness (Figure 1).

Petechial haemorrhages in the stomach, swim bladder, visceral fat and intestine were detected on pathological examinations. In addition, yellowish mucous content with blood was determined in the intestines. There is no bacteriological growth was observed on TSA and BTSA. From scanning electron microscopy overviews, rod-shaped coccoid bacterium was observed in the inflammatory skin samples of infected fish (Figure 1)

Figure 1. The pathological signs of the disease and SEM overviews

(Continued on next page)

Discussion and conclusion

No pathogenic bacteria was associated with the infected fish during the study. It is known that bacteria which dominate in the aquatic environment may not culturable on conventional bacteriological media (Amann et al., 1995). Verner-Jeffreys et al (2008) indicated that the bacteria may not readily recoverable on standard bacteriological media. Also the 16s rDNA libraries from the skin lesions couldn't identify the main bacterial pathogen associated with the SD. For these reasons, a preliminary diagnosis of the causitive agent with bacteriological and molecular techniques were not effective and successful in this study. The cause of the condition couldn't be identified. Meanwhile, Athanassopoulou et al (2004) claimed that fish were more susceptible to secondary bacterial and parasite infections during the disease. However, neither bacterial nor parasitic agent was detected during the study. The SD may not have effect mortality rate or production period but the inflammatory skin lesions cause problems on the marketing and processing of the fish. If the lesions heal, it remains a remarkable patch on the surface of the skin. This situation affects the carcass quality and lowers the value of the product. In conclusion, further research is necessary to identify and understand the agent in detail. If the significant association will be asserted between the SD and the agent, treatment and vaccine procedures could be developed to prevent this economic loss.

ASSESSMENT OF WOMEN'S PARTICIPATION IN AQUACULTURE POST-ECONOMIC STIMULUS PROGRAM IN KENYA

V.C. Tarus* J. M. Amadiva, and H. Egna

[1]Chief Officer Livestock and Fisheries Uasin Gishu Count , Kenya P. O Box 40 -30100, Eldoret Kenya
Email: vctarus@yahoo.com

Introduction

Fish farming in Kenya was introduced by colonialists in Kenya in the 1920s and in the 1960s Ngugi et al. (2007). Women are at the forefront of the rapid growth of the aquaculture sector, especially in activities such as farming, processing, and marketing. Women's participation along the aquaculture value chain is typically higher than in capture fisheries. In particular, improving women's income, access to information, technology and decision making processes have a profound effect on the quality of life at household level and by extension at the community level. It is against this background that the Kenyan Government sought to establish aquaculture as an income generating activity through a national *Economic Stimulus Program (ESP)* in the Financial Year 2009/2010. The program was geared towards commercializing aquaculture in the then 140 political constituencies. Each constituency received funds for the construction of 200 fish ponds, purchase of 15 kilograms of fertilizer and 1000 fingerlings. The second phase of the project was executed in 2011/12 financial year during which an additional 20 constituencies received funds for 300 fish ponds. The 140 constituencies that had received funds in the previous financial year received additional funding to construct another 100 ponds. In total, 48,000 ponds were constructed at a cost of 15 million US dollars (Watsuma, Bernard and Henry, 2012). Since then no assessment has been done to assess the impact of the program on the women participation in aquaculture.

Materials and Methods

A cross sectional survey design was used for a target population of 25 women in 5 counties namely; Busia, Kakamega, Vihiga, Bungoma and Uasin Gishu. Data were collected through unstructured interviews with women farmers and stakeholders in the aquaculture value chain, field visits, and desk reviews of relevant document

Results

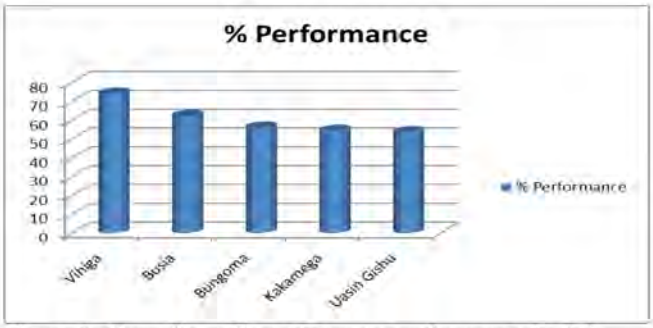

Figure1: Overall ranking of county performance in fish farming under Economic Stimulus Program

Table 1: Summary of findings from the 25 women interviewed in the 5 counties

Indicator	Percent
Ownership of ponds (by women)	100
ESP funded	81.2
Improved livelihoods as a result of ESP	78.5
Tilapia farmers	81.8
Post ESP farmers	65.6
Farmers with more than one pond	63.6
Trained farmers	85
No. of ponds that collapsed after ESP	30
Self-employed farmers	90

(Continued on next page)

Discussions and Conclusion

The study shows a positive impact of ESP on the women in the sampled counties. According to T. Nduku 2015, the overall efficiency of the counties in implementation of the Economic Stimulus Program was 65 per cent. This study shows that there is a positive correlation between ESP and women's participation in aquaculture. It is evident that the more gender is mainstreamed at higher governance levels, the more gender issues will feature in national fisheries and aquaculture policy documents. There is therefore need to carry out gender audits and best practices in successful gender integration in the work place and in the field among stakeholders in aquaculture. It is also apparent that women in aquaculture face a number of challenges that affect their quest towards commercialization of aquaculture. These challenges call for interventions which include capacity building and effective implementation of policies.

The assessment showed that most of the female farmers rely on government interventions in order to engage in aquaculture. This overreliance on government subsidies and other interventions is not sustainable. The study recommends more training and improved access to credit to enable the farmers to be self reliant in the aquaculture ventures.

Introduction

Although aquaculture production improved in the last decades some issues still persist, especially in terms of sustainability FAO (2018). Fish meal is the major cost in aquaculture and a major effort is being made to optimize feed composition and finding sustainable feed ingredients. A ^{1}H NMR metabolomics approach may provide an accurate and high-throughput data in the context of fish nutrition. Our research focused the inclusion of glycerol (0%, 2.5%, 5%) in the feed of European seabass (*Dicentrarchus labrax*). Glycerol is a cheap carbon substrate expected to enter metabolism through the glycolytic pathway, Rito et al. (2019).

Material and Methods

The fish (224 ± 35g) were kept in 3 x 350 L RAS system (22 ºC, 30 ‰ salinity) and fed 60 days. Five fish per condition were sacrificed (331 ± 59g) at 6 h and 24 h after feeding and blood was sampled. 450 µL of filtered plasma (<3 KDa) were run on Varian 600 MHz, *noesypr1d* sequence on a 5 mm triple resonance probe followed by an automated NMR spectral profiling analysis provided by Bayesil platform (http://bayesil.ca/), Ravanbakshs S et al. (2015)

Results

Spectra were successfully analysed with the automated Bayesil routine. We were able to identify and quantify 51 metabolites. The fish digested the glycerol within the first 6 h and are able to clear the circulating glycerol within 24h in the 2.5% diet. However, due to the supraphysiological concentrations of glycerol, namely in the 5% diet, the Bayesil algorithm is not able to properly integrate the signals.

Discussion and Conclusion

To our knowledge, this is the first time a high-throughput automated routine is applied to NMR data in aquaculture research framework. This approach is ideal for quantitatively assay several metabolites at once. Although supraphysiological concentrations of aqueous dietary nutrients, such as glycerol in this case, may require manual adjustments, we are able to quantify aqueous metabolites in the range of µM to mM.

OPTIMIZING PRODUCTION OF MITIGATION MUSSELS

D. Taylor*, C. Saurel, P. Nielsen, F. Bak, N.P. Nielsen, J.K. Petersen

Danish Shellfish Cente , DTU Aqua, Øroddevej 80, 7900 Nykøbing Mors
Email: dtay@aqua.dtu.dk

Leveraging bivalve ecosystem services to counter eutrophication, and integration into water management plans, is a growing focus in many regions. Wild and cultivated bivalve assemblages assimilate nutrients bound in organic matter, can enhance nutrient cycling, and provide potential for net nutrient extraction through harvest. Intensive cultivation of mussels (*Mytilus edulis*) designed for maximizing nutrient extraction in eutrophic estuaries is developing in terms of technical and policy implementation. In Denmark, mussel mitigation culture is under consideration as a management tool within the third management cycle of the Water Framework Directive. Intensive research in optimization and further refinement in production outputs has been carried out by the Danish Shellfish Center (DTU Aqua) to document the mussel mitigation production volumes and nutrient removal for different productions technologies and environmental conditions.

Over two growing seasons (2017-2019), six test-line sites and three full-scale mitigation mussel farms were monitored for production potential in Denmark. As principle factors, linear density of settling material, vertical coverage, cultivation substrate, and relative position within the culture unit were analyzed for yield in terms of total mussel biomass and condition. In the 2017 growth cycle, differing configurations of traditional long lines were tested, yielding ~1300 t per model farm (18.8 ha) in Limfjorden. In 2018, different technologies were tested; preliminary results demonstrate capacities for exceeding 3000 t per model farm (Figure 1). High resolution biomass sampling demonstrated significant clustering of mussel condition within farm units, indicating meso-scale carrying capacity limitations, however, larger farm-scale yields were not demonstrably different between sites or by substrate quantity; indicating mitigation farms within Limfjorden conditions can be appropriately applied to reduce nutrient loads within the marine environment. In other tested estuaries, settlement and growth of mussels have been positive, suggesting mitigation culture can be applied as a nutrient management tool for many coastal waters.

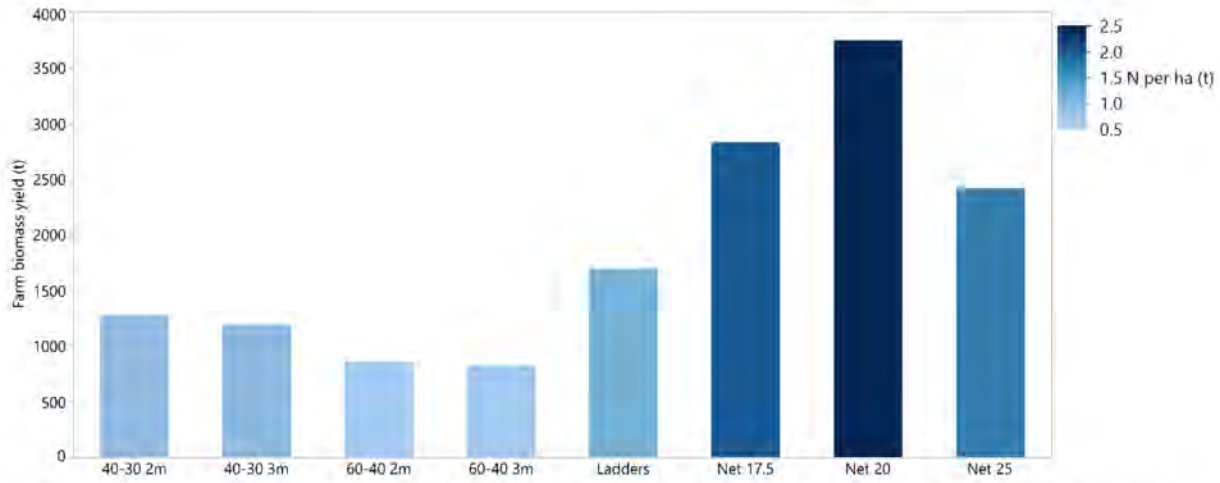

Figure 1. Potential farm (18.8 ha) mussel biomass yield and harvestable N-content per hectare by cultivation technology. 40-30 refers to 30cm spat collector spacing, 60-40 is 60cm spacing, 2 and 3m refer to spat collector depth. Ladders refer to a linear gridded collection system, and Net treatments refer to respective mesh size (cm) on 100m long, 3m deep nets.

FIGHTING THE PARASITIC CHALLENGE IN MODERN FISH FARMS: ALTERNATIVE REDUCTION STRATEGIES AGAINST *Ichthyopthirius multifiliis*

Introduction

The control of parasitic infections is one of the major challenges for the European aquaculture. In particular *Ichthyophthirius multifiliis* poses a serious threat to farmed fish. Especially trout are affected, where aggravated by limited water supply and increasingly warm weather conditions an infection can lead to substantial losses. Since anti-parasitic treatments like the use of malachite green oxalate or other therapeutics are merely impossible in modern fish farms due to drug legislation, as of today environmental disinfection is the last resort in battling infections with *Ichthyophthirius multifiliis*. Besides the economic impact the lack of effective methods of treatment against *Ichthyophthirius multifiliis* poses also an ethical dilemma. In times where animal welfare and sustainable production are becoming more important it is not tolerable to just relay on rather ineffective environmental disinfection as a control measure. In this study filtration of parasite stages from the water and vaccination protocols against the parasite were followed to contribute to the solution of the urgent need for alternative strategies to control parasitic infections and produce healthy, ecological sustainable fish.

Material and methods

Two strategies to reduce infections with *Ichthyophthirius multifiliis* were tested. By filtering out the theronts from the water by nanofiltration the life cycle of the parasite should be interrupted. For this purpose two different filtration units were tested under controlled conditions in a lab scale keeping facility. Infected trout and carp were kept in two separated recirculating aquaculture systems (RAS) with four keeping-tanks each. On one of these RAS the filtration unit was implemented. The fish were evaluated for their parasitic burden every other day over a period of two to four weeks under a binocular. Additionally water samples were filtered and tested for parasite cells with a PCR developed and established for this purpose

As fish develop immunity following infection with *Ichthyophthirius multifiliis*, resulting in both specific and nonspecific immune responses, different preparations of *Ichthyophthirius multifiliis* were used in vaccination trials. On top of that preparations of the ciliate *Tetrahymena* sp. were tested for their ability to induce cross-immunity. In addition to living theronts, formalin and isopropanol inactivated theronts and isolated cilia of *Ichthyophthirius multifiliis* were used as well as living *Tetrahymena* sp. and also formalin and isopropanol inactivated *Tetrahymena* sp.. The living parasite stages were administered intraperitoneally while the other preparations were administered via a bath treatment. In the case of the fish vaccinated in the bath treatment, it was additionally examined whether the immunity would be stronger after enhancing the antigen intake by inducing micro-lesions in the skin with fine needles or the use of ultrasound to irritate the mucosa directly bevor vaccinating compared to a simple bath vaccination. The vaccinated fish and an untreated control group were marked by chip to be able to evaluate them individually. After a period of 30 days and a minimum of 450 day-degrees (°C) in which the immunity could build up, the fish were challenged for 8 hours with theronts harvested in a lab cycle. Afterwards they were distributed evenly to the four tanks of one RAS described above. The parasitic burden of the fish was evaluated after 7 day post infection.

Results and discussion

First results on nanofiltration indicate that the number of parasite stages in the water can be reduced by this measure. However practicability in commercial aquaculture seems to be questionable and will be investigated further.

Unfortunately a cross-immunity of *Tetrahymena* and *Ichthyophthirius multifiliis* seems to be not sufficient to protect the fish whereas preparations with *Ichthyophthirius multifiliis* seem to have a positive impact.

These approaches should now be optimized and put into testing under field conditions in fish farm

Conclusion

Parts of the methods used in this study are promising for a preventative take on *Ichthyophthirius multifiliis*. Especially vaccination might be part of the solution. However one major challenge remains partly unresolved. As tenacious *Ichthyophthirius multifiliis* is in the environment and in our aquaculture the fast, easy, cheap and controlled production of large numbers of theronts in the laboratory for example for the preparation of vaccines remains difficult and needs to be investigated further.

EFFECTS OF OXYTETRACYCLINE THERAPEUTIC TREATEMENTS ON GROWTH PERFORMANCE AND IMMUNITY IN NILE TILAPA (*Oreochromis niloticus*) JUVENILES

Introduction

Oxytetracycline (OTC) is one of the most commonly used antibiotic in aquaculture (Reda *et al.*, 2013). Antibiotics have been associated with negative effects on the immune system of fish (Guardiola *et al*., 2012) and dysbiosis (Pindling *et al.*, 2018). The aim of this study was to evaluate the effects of OTC medicated feed on growth performance, immunity, liver and kidney functions, histopathological findings and microbiota in Nile Tilapa (*Oreochromis niloticus*).

Materials and Methods

A group of 315 Nile tilapia (average body weight 118±0.8g) was randomly distributed among nine tanks (300 L; 35 fish each tank) in a freshwater recirculating system (23ºC, 10h light /14h dark) at UTAD (University of Trás-os-Montes e Alto Douro, Portugal) facilities. All animals were acclimated to the experimental conditions and fed with a control diet (CTRL) that fulfilled the known nutritional requirements for Nile tilapia during 15 days. Then, animals from six tanks started to be fed with a medicated feed supplemented with OTC at a therapeutic dose (55mg/Kg body weight/day) whereas fish from the other three tanks continued to be fed with the CTRL diet. During OTC treatment, water from those tanks where not shared and freshwater was continuously added daily (at same temperature) to allow water renewal (50% d^{-1}). The fish was feed twice a day) at 2% of body weigth. After 10 days of medicated feed administration, Nile tilapia from three tanks were fed with the control diet (OTC-CTRL) while fish from the other three tanks were fed with an extreme diet, rich in vegetable nutrients (OTC-ED). Several samplings (n=9 per tank) were performed: i) at 15 days to determine health condition and gut microbiota prior to OTC treatment; ii) at 25, 26 and 33 days to evaluate effects of the medicated feed; iii) at 40 and 55 days to evaluate the recovery. Blood was collected to evaluate immunological and biochemical parameters, intestine tissue and faeces to evaluate microbiota, gene expression and histopathology, and liver to evaluate oxidative stress status. The methodology used was described by previous studies (Guardiola *et al*., 2013; Almeida *et al*., 2014 and Machado *et al*., 2015).

Results

This study showed a decrease in weight gain in Nile tilapia fed OTC-ED (74.1 ± 5.6 g) compared to those fed CTRL (91.8 ± 6.9 g) at the end of the experimental period (i.e. 55 days). Haematocrit and red blood cells were higher in animals fed OTC-ED than in those fed CTRL at 26 days, whereas anti-proteases activity in plasma showed the opposite pattern with higher levels in fish fed CTRL than in those fed OTC-ED also at 26 days. Moreover, circulating white blood cells (WBC) and peroxidase activity in plasma increased in fish fed CTRL compared to those fed OTC-ED and in fish fed both CTRL and OTC-CTRL compared to those fed OTC-ED at 55 days, respectively. Total proteins in plasma were higher in medicated groups than those fed CTRL at 40 days.

Discussion and Conclusions

Serezli *et al.* (2005) found an increase of total erythrocyte and leucocyte numbers after oral administration of OTC in seabream, but in the present trial, only haematocrit and erythrocyte cells were increased. The decrease in WBC observed in Nile tilapia fed OTC-ED at the end of the trial could be indicative of a possible suppression action of both OTC and the extreme diet in circulating leukocytes. While the present study showed a decrease of plasma anti-protease and peroxidase activity after oral OTC administration, other authors did not find such differences in the serum peroxidase activity in gilthead seabream Guardiola *et al*. (2012). Further analyses will be performed to evaluate the effects of oral administration of OTC in intestinal microbiota, gene expression and histology and liver oxidative stress.

AN 'AQUACULTURE SUSTAINABLITY TOOLBOX' FOR FLEXIBLE LICENSING AND REGULATION OF AQUACULTURE IN EUROPE

Hanne Kaas[1], Anne Lise Middelboe[1], Lynne Falconer[2] and Trevor Telfer[2]*

[1]DHI A/S, Agern Allé 5, DK-2970 Hørsholm, Denmark
[2]Institute of Aquaculture, University of Stirling, FK9 4LA
Email: t.c.telfer@stir.ac.uk

Introduction

The EU Horizon 2020 'Tools for Assessment and Planning of Aquaculture Sustainability' (TAPAS) is a four-year project from March 2016. Its aims are to evaluate existing aquaculture regulatory practices and the methods, tools and technologies used for implementation, to identify gaps, needs and bottlenecks and propose improved approaches for licensing and regulation of aquaculture in Europe. An overall objective is to establish a comprehensive 'toolbox' to support transparent and efficient licensing that will enhance sustainability, aquatic food security and blue growth in all marine and freshwater environments for different types of aquaculture systems and species.

The target users of the Aquaculture Sustainability Toolbox are aquaculture regulators, for evaluating license applications efficientl , and producers or their consultants in preparing license applications. A further aim of the 'toolbox' is to improve access of information on aquaculture production and regulations to the public, through a communication platform, to improve understanding and perception of aquaculture practice throughout Europe.

Development of the 'toolbox' has been guided by extensive stakeholder consultation and development of recommendations for improved flexible approaches to licensing, in other parts of the TAPAS project. This ensures it is fit for purpose and fulfils the needs of the end-users

"Tools", in the context of the Toolbox, is a broad term including various types of instruments such as licensing and monitoring guidance, new and existing evaluated analysis tools (e.g. for environmental and socio-economic assessments) for impact analyses and site selection, and case studies illustrating the use of the tools.

Aquaculture Sustainability Toolbox structure

The structure of the 'toolbox' has been constructed to be intuitive and follow licensing procedures and guidelines under the EU Environmental Impact Assessment Directive (85/337/EEC and amendments). This allows the user to "enter" the toolbox from a number of points, i.e. seeing if a location is suitable for aquaculture, carrying out an EIA for the licensing process or, for more advanced users, using models and tools directly with data collected. This can help inform licensing procedures or as a guide to carrying out these procedures. Figure 1 illustrates the prototype of the front navigation page of the toolbox.

The Toolbox, comprises a HOME page and several supplementary pages addressing specific subjects and giving links to relevant tools and licensing models as well as tool pages, with the option to search for tools and a "Get meta data" link. All pages are linked so that it is possible to move around in the Toolbox as efficiently as possible for the user (see Figure 2). Users wanting to go directly to the tools can use the navigation panel which is in the header of all pages

The Aquaculture Sustainability Toolbox will be developed to a proof of concept stage (TRL6/7) at the end of the TAPAS project (Feb 2020). Future exploitation after the project is being explored. At present this is likely to take the form of a public decision support platform with industry/producers, regulators and the public as its end-users. It will be web-based and freely available to all. A strategy for the different components of this framework and its future management is under development and will be presented.

Acknowledgements

This work has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No. 678396 (TAPAS).

Introduction

Aquaculture is currently one of the most fast-growing animal production sectors. However, the expansion of the sector requires higher sustainable practices. Economic and environmental sustainable feeding practices in aquaculture may imply a higher inclusion of plant ingredients in fish diets. However, these sources are often limited in methionine (Met) and their use in fish diets requires its supplementation. This essential amino acid is involved in protein synthesis, transmethylation reactions and antioxidant defence. Therefore, DL-methionine (DL-Met), L-methionine (L-Met) and calcium bis-methionine hydroxyl analogue (MHA-Ca) are commonly methionine sources supplemented in animal diets. However, the biological efficiency of the different methionine sources may differ considerably. The biological efficiency of sources of methionine may be assessed by key performance indicators (like growth and diet utilization, among others) and methionine metabolic fate.

In this context, this work intended to 1) evaluate the effect of dietary supplementation with different methionine sources on growth and feed conversion and, 2) to understand how different dietary methionine sources are utilised by Nile tilapia juveniles.

Material and Methods

Nile tilapia (Silver Natural Male Tilapia™) juveniles were obtained from Til-Aqua International B.V. (The Netherlands) and transported to the Centre of Marine Sciences facilities (Faro, Portugal). Fish were maintained at 26ºC in a recirculating aquaculture system and fed a commercial diet during acclimation period.

After this period, fish were allocated into nine 100L cylindrical tanks (50 fish per tank, with an initial mean body weight of 2.27 ± 0.01g). Eight fish from the initial stock were sampled for analysis of proximate composition and amino acid content.

Triplicate tanks were randomly assigned to one of the three dietary treatments (REF, DL-Met and MHA). The experimental diets were formulated to be isonitrogenous (32% crude protein) and isoenergetic (19 MJ/kg gross energy), using only plant ingredients as protein sources. REF was a basal diet and no methionine was supplemented, DL-Met and MHA diets were supplemented with 0.11% of DL-methionine and 0.13% calcium bis-methionine hydroxyl analogue, respectively. Fish were fed by hand to visual satiety, three times a day and feed intake was recorded daily for 57 days.

At the end of the feeding trial, each tank was bulk weighed. In addition, 10 fish from each tank were individually weighed and measured, of which five fish were sampled for analysis of proximate composition and amino acid content, and the other five were individually weighed (total, liver and viscera weight) and measured to calculate the condition factor as well as the hepatosomatic and viscerosomatic indexes. Fish were fasted for 24h before initial and final samplings

At the end of the growth trial, to understand how different dietary methionine sources were absorbed and metabolised in tilapia juveniles, a time-course metabolic trial was performed. The DL-Met and MHA diets were labelled with ^{14}C-DL-methionine and ^{14}C-calcium bis-methionine hydroxyl analogue, respectively and tube-fed to fish from the correspondent dietary treatments. Dietary methionine source effect, based on the metabolic fate of the ^{14}C-DL-Met and ^{14}C-MHA was determined at 1, 2, 3, 4 and 6h after ingestion.

Results and Discussion

At the end of the experiment, fish fed the DL-Met diet presented a significant higher body weight and lower feed conversion ratio (FCR) than fish fed the REF diet. No significant differences were detected between fish fed the MHA and the REF diets regarding growth and FCR. There were no significant differences among treatments in feed intake, condition factor, viscerosomatic and hepatosomatic indexes. Dietary methionine source effect based on the metabolic fate of the ^{14}C-DL-

Met and ^{14}C-MHA in juvenile fish is currently under analysis. Our study demonstrates that DL–methionine in plant-based diets promotes growth and reduces FCR in Nile tilapia juveniles. A higher sustainability of aquaculture sector can be ensured through an optimise efficiency of diet utilisation by fis

Introduction

Interest in using insects as animal feed is growing, mainly in the aquaculture sector. Compared to other animal protein sources, insects -- in particular flies -- have several advantages, which have attracted the attention of the aquafeed industry (Lock et al. 2018). Produced by dried insect larvae, insect meal is extremely rich in proteins (60-80%), essential amino acids (EAA), vitamins, and minerals (Henry et al. 2015). Insects are also a good source of lipids (31-43%); however, their total lipid content and fatty acid composition depend on rearing conditions and technological treatments (Meneguz et al. 2018) Accordingly, we investigated the effects of substitution of fishmeal (FM) with insect meal from *Hermetia illucens* larvae in the diet of rainbow trout (*Oncorhynchus mykiss*), on fish growth performance, and gut microbiota composition. High-throughput 16S rDNA sequencing (MiSeq platform, Illumina) was applied to characterize gut microbial community profile in trout. The use of Next Generation Sequencing (NGS) approaches permit to obtain a large number of sequence reads that are orders of magnitude larger than those produced by previous culture-independent techniques.

Materials and methods

H. illucens larvae were grown on a substrate of fruit and vegetables provided by the wholesale market. At the prepupal stage, larvae were harvested and then processed to be transformed into insect meal.

Four diets were formulated with increasing percentages of Hi larvae meal as substitutes for FM: one control diet with 0% (Hi 0) and 3 experimental diets with 10% (Hi 10), 20% (Hi 20), and 30% (Hi 30) of Hi meal as fed basis inclusion.

A 12-week feeding trial was performed on 348 rainbow trout of 66.5 ± 1.7 g initial mean body weight. Fish were randomly distributed in 12 indoor rectangular fibe -glass tanks of 1 m^3 connected to a flow-through open system supplied with artesian well water. The apparent digestibility coefficients (ADC) of DM, CP and EE of each diet were assessed through an in vivo digestibility trial.

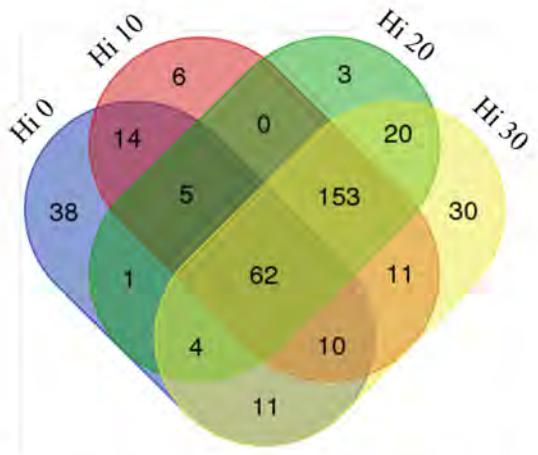

Figure 1. Venn diagram representing unique and shared OTUs among all dietary groups. For this study, the core microbiome was defined as the OTUs present in 80% of the samples regardless of diet.

(Continued on next page)

At the end of the trial, 6 fish/diet were sampled. The intestine was aseptically removed from each fish and squeezed to collect the fecal matter. For microbiome analysis, bacterial DNA was extracted from each faecal sample. The high-throughput sequencing of 16S rRNA gene was applied to analyse and characterize the gut microbial communities of rainbow trout. The obtained sequencing raw data were analyzed using the QIIME software. A Two-way ANOVA was applied to test for differences in mean values of bacterial taxa between the experimental groups using STATISTICA software (StatSoft, Inc.). A $p\text{-}value<0.05$ was considered significant.

Results and Discussion

During the 12 weeks of feeding fish promptly accepted the experimental diet and mortality was negligible, i.e., lower than 1%. At the end of the feeding trial, all fish had tripled their initial body weight, and growth performance parameters (WG and SGR) were not affected by diet composition. Similarly, FCR was comparable among the treatments and remained lower than one in all groups, meaning that all fish grew efficiently and including the H. illucens meal did not negatively affect diet palatability. No differences were reported among treatments for the feed digestibility. Crude protein digestibility was high and above 90% in all treatments.

The 24 fecal samples were sequenced on one paired-end MiSeq run (Illumina, Italy) and the sequencing raw generated were analysed using the QIIME pipeline. The number of reads taxonomically classified according to the Greengenes database was 1,140,534. We identified 450 OTUs at 97% identity in trout fecal samples; 62 OTUs constituted the core gut microbiota (Figure 1). *Actinobacteria*, *Firmicutes* and *Proteobacteria* represented the dominant phyla in both experimental groups. Among them, the abundance of *Actinobacteria* and *Proteobacteria* was significantly influenced by including insect meal in the diet.

In conclusion, our findings clearly indicated that insect meal positively modifies fish gut microbiota, increasing its richness and diversity and in particular, increasing the amount of beneficial lactic acid- and butyrate-producing bacteria, which contribute to the global health of the host. In addition, based on our present and previous studies, we believe that the prebiotic effect of insect meal is principally due to fermentable chitin.

Introduction

The Norwegian farmed salmon chain is a global food value chain with farming based in Norway and production of feed ingredients, processing and consumption distributed around the world. A significant proportion of feed ingredients like soy protein concentrate, fish oil and fish meal for salmon are sourced from South America. The processing of whole fish into fillets and value-added products is carried out in hub-markets in Europe while end-consumers for Norwegian salmon are spread across the world with Europe being the biggest market (Norwegian Seafood Council, 2018). The production of Norwegian salmon is projected to increase to 5 million tonnes by 2050 which is a five-fold increase from today's level (Sintef, 2012) and therefore it is important to assess the impact of this projected increase. The climate change impact associated with salmon supply chain has previously been analysed (Zeigler et al., 2013) but there is a need to extend the assessments to include more environmental and social impacts. The goal of this study was to evaluate the overall impact and identify hotpots in the salmon value chain to provide a basis for strategic and operational advice for managers and policy makers.

Material and Methods

This study adopted a holistic approach from raw material extraction to waste disposal known as 'cradle-to-grave' based on ISO standard 14040:2006 on principles and framework for Life Cycle Assessment (ISO, 2006). The investigated environmental impact assessment focusses on key impacts governed by EU legislations: greenhouse gas emissions (European Climate Change Programme), freshwater eutrophication (Water and Nitrate Framework Directives), acidification (Air Quality Directive, Ammonia regulations). The social impacts are based on the UNEP-SETAC guidelines which include quantitative social indicators, such as working hours, health and safety, and public living conditions (Unep-setac, 2009). In order to identify the most relevant social indicators and rank them in order of importance, an opinion survey was conducted in Norway.

Results

The results identified feed production by terrestrial agriculture as an important environmental hotspot. Transporting fresh salmon by air freight was also an important factor that contributes to the total environmental footprint of Norwegian salmon. Domestic waste also plays an important role for all impact indicators.

About 50 respondents from the aquaculture industry in Norway including farming companies, researchers and consumers ranked the social indicators identifying the health and safety of workers as the most important. Based on the quantitative analysis the social impacts in the chain are mainly associated with the farming stage and were identified as an important hotspot.

Discussion and Conclusion

The environmental and social hotspots analysis provided a greater understanding of impacts from the salmon value chain and identified the supply chain stages and value chain actors that are affected by these. The results of the analysis provide insight for decision-makers such as regulatory bodies and businesses to identify the improvement opportunities for the salmon value chain.

This study has been conducted as part of the research activity in H2020 project VALUMICS where the hotspot analysis of the salmon chain will be provide input to the logistics optimisation models as well as agent based models focussing on fairness in food value chains and will be tested for various future scenarios forming a basis for policy recommendations for a more sustainable and resilient salmon value chain.

Introduction

Interferon regulatory factors (IRFs) are one of the central transcription factors which induce the interferon signaling (Lu, 2008)macrophages and dendritic cells. A series of recent studies have further demonstrated critical functions for IRF4 and 8 at several stages of B-cell development including pre-B-cell development, receptor editing, germinal center reaction and plasma cell generation. Collectively, these new studies provide molecular insights into the function of IRF4 and 8 and underscore a requirement for IRF4 and 8 throughout B-cell development. This review focuses on the recent advances on the roles of IRF4 and 8 in B-cell development.”,”author”:[{“dropping-particle”:””,”family”:”Lu”,”given”:”Runqing ”,”non-dropping-particle”:””,”parse-names”:false,”suffix”:””}],”containe -title”:”Trends in Immunology”,”id”:”ITEM-1”,”issue”:”10”,”issued”:{“date-parts”:[[“2008”,”10”,”1”]]},”page”:”487-492”,”publisher”:”Elsevier Current Trends”,”title”:”Interferon regulatory factor 4 and 8 in B-cell development”,”type”:”article-journal”,”volume”:”29”},”uris”:[“http://www.mendeley.com/documents/?uuid=515fb2d4-0a53-3238-bd42-3b589dcef25b”]}],”mendeley”:{“formattedCitation”:”(Lu, 2008. Mammalian IRF6 regulate the keratinocyte differentiation and maturation (Leslie et al., 2012).

Methodology

IRF6 of big belly seahorse (*Hippocampus abdominalis*) (HaIRF6) was molecularly and functionally analyzed for their sequence, transcription and antiviral capacities. Transcriptional levels with time defendant manner were detected upon Poly (I:C) LPS, and S*treptococcus iniae* and un challenged conditions. Subcellular localization were detected.

Results

Gene expression of HaIRF6 was detected in vivo against immune stimulants. At poly I:C challenge, expression was significantly induced at early time points with compared to the other two challenges in blood and gill. VHSV Viral gene transcription was significantly reduced at 24h and 48 h. cellular localization of HaIRF6 was observed in cytoplasm

Discussion and Conclusion

Fish IRF6 function is considerably deviated comparative to the function of mammalian IRF6. These findings revealed the importance of seahorse IRF6 in the immune defense system against pathogen and their antiviral tolerance against VHSV infection.

Introduction

Stress response in teleosts is mediated by the Hypothalamus-Pituitary-Interrenal (HPI) axis whose final hormonal product is cortisol (corticosterone in rodents) (Mommsen *et al*., 1999). The effects of cortisol on the organism's stress response are regulated by two receptors, the mineralocorticoid (MR) and glucocorticoid (GR) receptors. These effects spread on a molecular, cellular, physiological and behavioral level (Prunet *et al*., 2006)a mineralocorticoid receptor (MR. Blocking the GR signaling has been known to lead to compromised cognitive abilities. In several teleosts there are two Gr isoforms, Gr1 and Gr2, while on the contrary zebrafish contain only one Gr isoform (Alsop & Vijayan, 2009)we examine whether molecular components involved in the functioning of the hypothalamus-pituitary-interrenal (HPI. Zebrafish Gr-KO lines have been generated with various genetic manipulation technologies; gr^{s357} zebrafish have shown chronically elevated cortisol levels and anxious behavioral phenotype (Ziv *et al*., 2012), CRISPR/Cas9 Gr-KO lines have displayed physiological responses linked to GC-resistance, such as overstimulation of basal HPI axis associated with unresponsiveness to a prolonged mechanical stressor (Facchinello *et al*., 2017). In our experiments we exposed heterozygous as well as homozygous adults of a Gr-KO zebrafish line to two behavioral tests, and assessed their response to novelty and their shoal cohesion

Materials & Methods

Experiments were performed at the installations of the Fish Physiology Laboratory of the University of Crete. Fish were provided by the laboratory of Luisa Dalla Valle (Facchinello *et al*., 2017) and housed in a stand-alone system (Tecniplast), water temperature set at 28 °C and photoperiod at 12D:12D. The novel tank test involves the introduction of each fish into a glass rectangular 2L tank. The tank consists a novel environment, given that the individuals had never been exposed to this apparatus. Fish were left to move freely and explore the tank for 6 minutes, while their behavior was recorded. At the end of each trial, fish were netted back to their mother tank. After 7 days shoal cohesion was tested and fish were separated in groups/shoals of 4, 6, 8 and 12 and left overnight to interact. The next day, their behavior was recorded for 10 minutes. The trials of both tests were performed between 10:00 and 14:00. Videos obtained from the ethological experiments were analyzed using the specialized behavioral analysis software Ethovision XT (Noldus). The analysis focused on the quantification of various behavioral parameters of exploratory and anxious behavio .

Results

The parameters analyzed for both tests (novel tank and social preference) were (i) time spent in the three zones of the tank (lower, medium, upper for the novel tank test and closer, medium and far from conspecifics for the second test), (ii) frequency of visits in the three zones, (iii) velocity, (iv) distance travelled and (v) freezing behavior, and representative traces of each trial were produced by the software as depicted in Figures 1 and 2. Differences in the above parameters were observed among the different genetic lines (WT, $gr^{+/-}$, $gr^{-/-}$) (data not shown).

Discussion

Novel tank test has been widely used as an ethological protocol to assess an animal's response to novelty, often considered a stressful stimulus. It has been previously shown that this response is hugely affected by numerous factors such as the genetic line, sex and specific pharmacological manipulations. A zebrafish s natural response to a novel tank includes an initial diving in the bottom of the tank and a gradual exploration of the rest of the tank. An increased latency to the upper part of the tank and reduced exploration of the upper part, along with increased duration of erratic swimming and freezing behavior draw a picture of significant levels of stress. These behaviors have been successfully replicated by exposing fish to anxiogenic stimuli, as alarm pheromone and exposure to a predator. Our results are in accordance with the stressful phenotype observed in gr^{s357} mutants (Ziv *et al*., 2012), where homozygous mutants exhibited significantly higher levels of freezing behavior and lower exploratory activity, when compared to the control group. Generally, this preliminary study shows the effects of gene editing on the behavior and social perception of adult zebrafish. Further analysis will hopefully shed more light on the implication of the HPI axis on the exploratory behavior and social abilities and tendencies of zebrafish.

Introduction

IL-11 is first identified as a pleiotropic cytokine with lympho-hematopoietic effect. Further studies have revealed the anti-inflammatory function of IL-11 by reducing inflammatory mediators such as TNFα, IL-1β, IL-12, IFN↑ , and nitric oxide (Trepicchio et al., 1996). IL-11 has been identifie as an active player in the host immune response in pathogenic infection of teleost fish. The IL-11 is an IL-6 family or gp130 family member cytokine which transduce the signaling through the JAK-STAT pathway. It activates the nuclear translocation of STAT3 and inhibits the NF-κB nuclear translocation (Trepicchio et al., 1997). The current study was aimed at cloning and functional characterization of IL-11 ortholog from redlip mullet (*L. haematocheila*) revealing its transcriptional expression during the pathogenic invasion and functional capacity to regulate the inflammation

Materials and methods

The coding sequence of IL-11 was identified from a previously prepared cDNA library of redlip mullet. Various software and online bioinformatics tools were utilized to characterize the coding nucleotide sequence and the predicted amino acid sequence of redlip mullet IL-11. Healthy redlip mullets were purchased and acclimatized to laboratory conditions. Eleven different tissues (peripheral blood cells, kidney, head kidney, spleen, liver, gill, intestine, brain, skin, heart, and stomach) were sampled from five fish and pooled for investigating the tissue-specific mRNA expression of IL-11. Groups of fish were challenged with LPS, Poly I:C and *Lactococcus garvieae.* Peripheral blood cells sampled from challenged fish were sampled in 0, 6, 24, 48, 72 hours after the challenge. Sampled tissues from both experiments were subjected to mRNA extraction followed by cDNA synthesis. The cDNA was used to evaluate the tissue-specific mRNA expression of IL-11 and investigate the transcriptional variation of IL-11during pathogenic invasion in fish. The open reading frame of redlip mullet IL-11sequance was amplified using sequence-specific primers and cloned to pMAL-c5X expression vector. After the confirmatio of sequence, successful clones were transformed into E*scherichia coli* BL21 strain. The recombinant IL-11 was overexpressed with Maltose Binding Protein (MBP) tag and purified using pMAL™ protein fusion and purification system. Purified *r*IL-11 was treated to redlip mullet kidney cells with 100.00 ngμL^{-1}concentration using MBP as the control. LPS (2.00 μgmL^{-1}) was used to induce inflamma ion in cells. Cells were lysed and subjected to mRNA extraction and cDNA synthesis in 0, 1, 3, 6 and 12 hours intervals. qPCR was performed to investigate the transcriptional variations of STAT3, TNFα, IL-1β in IL-11 treated redlip mullet kidney cells.

Results

The complete ORF of redlip mullet IL-11 was 603bp in length and the deduced amino acid sequence has 200 residues. The predicted molecular weight and isoelectric point (pI) of redlip mullet IL-11 were 23.16 kDa and 9.16 respectively. The three-dimensional modeling of redlip mullet IL-11 shows that it has four alpha-helix bundle structure. The polypeptide chain contains a 26bp long signal peptide. The multiple sequence alignment demonstrated that the sequence of the signal peptide, alpha helix A, alpha helix B, and D are barely conserved among fish but less conserved with other phyla. The phylogenetic analysis demonstrated that mullet IL-11 is cladding with other fish IL-11 sequences. The identity similarity analysis showed that redlip mullet IL-11 has 92.5% identity with *Tetraodon nigroviridis*. The tissue specific mRNA expression analysis showed that stomach and intestine have the highest IL-11 expression during ordinary conditions. IL-11 expression in PBC was upregulated by LPS and poly I:C in the acute phase of the challenge. Upregulation of IL-11 in *L. garvieae* challenge was observed in later phase of the challenge experiment. The transcription of STAT3 and NF-κB p65 was downregulated by IL-11 in mullet kidney cells. Similarly, the transcription of LPS induced TNFα and IL-1β were downregulated in IL-11 treated cells.

(Continued on next page)

Discussion and conclusion

Redlip mullet IL-11 sequence has four alpha-helix bundle structure as other members of IL-6 family cytokines. The IL-11 sequences of fish are barely conserved. The gastrointestinal tract is one of the primary sites that can make the entrance of pathogenic microbes. Thus, the cells may undergo continuous pro-inflammatory state, the IL-11 may use to control the inflammatory conditions in the gastrointestinal tract. IL- can inhibit the nuclear translocation of NF-κB, hence interrupt to the transcription of downstream pro-inflammatory cytokines such as TNFα and IL-1β (Trepicchio et al., 1997). LPS and poly I:C is pathogen-associated molecules and *L. garvieae* is live pathogen to redlip mullet. The challenge may induce an inflammator condition in the blood cells of mullet. It may upregulate the IL-11 transcription to prevent continuous pro-inflammatory state, due to the pathogenic stimulants. STAT 3 is the transcription factor which involves in signal transduction of IL-11 through JAK-STAT pathway. In the STAT3 transcription factors can bind into the promoter regions of pro-inflammatory cytokines such as TNFα, IL-6, and iNOS (Carpenter and Lo, 2014). In order to prevent continuous transcription of such pro-inflam atory cytokines by STAT 3, the transcription of STAT3 may be downregulated as a feedback controlling mechanism. The downregulation of TNFα and IL-1β may due to the blockade of NF-κB (Trepicchio et al., 1997) or reduced transcription by IL-11treatmant. Overall, the IL-11 can control the proinflammatory cytokine production in LPS induced redlip mullet kidney cells. This may use as a therapeutic measure in pathogen-induced inflammations in cultured fish.

Introduction

To ensure year-round supply of right-sized juveniles for sea-lice control, off-season production of fertilized lumpfish eggs is important (Imsland et al., 2018)control of the sexual maturation cycle is critical for a sustainable production of the species. For year-round reliable production of juvenile lumpfish of the appropriate size for stocking salmon cages, there is a need for basic and applied knowledge on the control of sexual maturation in cultured lumpfish broodstock. Lumpfish (initial size 219g and 16.9cm. This will allow development of methods for management of broodstock. However, little is known about the reproductive biology and the subsequent control of sexual maturation in farmed lumpfish. To produce fertilized eggs year-round to the aquaculture industry, studies in teleost reproduction are important (Lubzens et al., 2010). Photoperiod and temperature are primary regulators of temperate finfis reproduction, and studies demonstrate that, manipulations of photoperiod and temperature affect sexual maturation and spawning in farmed species (Taranger et al., 2010). Subjecting lumpfish to continuous, and then compressed photoperiods resulted in higher growth and advanced spawning (Imsland et al., 2018)control of the sexual maturation cycle is critical for a sustainable production of the species. For year-round reliable production of juvenile lumpfish of the appropriate size for stocking salmon cages, there is a need for basic and applied knowledge on the control of sexual maturation in cultured lumpfish broodstock. Lumpfish (initial size 219g and 16.9cm. Imsland et al. (2019) found that, compressed and phase advanced natural photoperiods cause advanced spawning in lumpfish. Gametogenesis and its response to photoperiod and temperature manipulations in lumpfish is not yet known. This study was conducted to describe ovary and testis development stages, and temporal changes of plasma sex steroid levels in lumpfish under di ferent photoperiod and temperature regimes.

Materials and methods

Lumpfish acquired for this experiment were reared under continuous light from hatching. On 21st September 2017, the fish were 18 months old, weighing on average 697.9g (± 364.1g), and with average length of 25 cm (±3.8cm). Four tanks (1500 l each) were stocked with the fish at 75 fish tank^{-1}, and a M:F sex ratio of 1.08. The tanks were grouped into two (2) photoperiod groups, one continuous light (CDL0T) and one short day length (SDL0T, 8 hours light, 16 h darkness), both kept at ambient temperature (AT, 4–9 °C). Four months later, the temperature in one tank for each photoperiod was increased by 3°C (CDL3T and SDL3T), and photoperiod in both SDL tanks changed back to CDL. All tanks were maintained for further 1.5 months, before termination in March 2018. There were four sampling points, in which, body and gonad weights were measured. Blood plasma for changes in sex steroid levels and gonad sections for histological gonad development were also acquired. Based on oocyte types, ovaries were categorized into: pre-vitellogenesis, early vitellogenesis, late vitellogenesis, final maturation and ovulation. Testes were categorized based on the cell types: spermatogonia, spermatocytes, spermatids and spermatozoa.

Results

No significant difference in growth was observed between any of the groups. Females in the SDL groups generally had higher GSI than those in the CDL groups, and higher temperature resulted in higher GSI. Only pre-vitellogenic and early vitellogenic ovaries were observed at the start in September 2017. In January 2018, the most developed ovaries were at late vitellogenesis and final maturation in the CDLAT group. In February 2018, the SDLAT group had most ovaries in final maturation. In March 2018, the largest proportion of ovaries in ovulation was observed in the SDLAT group. Estradiol 17- β (E2) and Testosterone (T) levels in females increased with time and were higher in the SDLAT groups than CDLAT groups, even higher at high temperature. Testes showed a high variation in development, and mature males were observed from the start throughout the experiment. T and 11-Ketotestosterone (11-KT) levels in males were highest in February 2018 and decreased towards March 2018. The SDL groups had a shorter spawning period (February) than the CDL groups, which were spawning earlier and had a more prolonged spawning period (December – February). The ambient temperature groups spawned earlier than the elevated temperature groups during the last 1.5 months.

(Continued on next page)

Discussion and conclusion

The absence of difference in growth between the groups was different from the observations by Imsland et al. (2018)control of the sexual maturation cycle is critical for a sustainable production of the species. For year-round reliable production of juvenile lumpfish of the appropriate size for stocking salmon cages, there is a need for basic and applied knowledge on the control of sexual maturation in cultured lumpfish broodstock. Lumpfish (initial size 219g and 16.9cm, in which, continuous photoperiod accelerated somatic growth in lumpfish. Ovary development was higher in the short photoperiod groups, similar to previous observations that continuous photoperiods may delay or inhibit gonadal development (Davie et al., 2007). The low levels female sex steroids in the continuous photoperiods agree with low testosterone and estradiol 17-β levels related with exposure of haddock to continuous photoperiod (Davie et al., 2007). The role of temperature in timing of maturation and spawning observed in wolffish (Tveiten and Johnsen, 1999) tempts to suggest that, lumpfis ovary maturation is affected by temperature, due to the observed effects of increasing temperature. Spawning differences among the photoperiod groups agree with Imsland et al. (2019), who found that, lumpfish spawn sparsely under continuous photoperiod, but distinctly under compressed photoperiods. This is the first study to describe gonad development in farmed lumpfish histologically. It is further demonstrated that, photoperiod and temperature manipulations can be applied to control sexual maturation and spawning of broodstock, for better broodstock management and ensured year-round supply of right-sized lumpfish juveniles. This is a pilot study for a more comprehensive experiment which is currently running.

THE POTENTIAL OF ARTIFICIAL INTELLIGENCE TO SUPPORT AQUACULTURE FARM MANAGERS: PRELIMINARY RESULTS OF THE APPLICATION OF MACHINE LEARNING ALGORITHMS FOR THE EARLY PREDICTION OF BATCH PERFORMANCE

D. Thomaz

Aquanetix Limited, 22a Lena Gardens, London W6 7PZ, United Kingdom
diogo@aquanetix.co.uk

Introduction

Shrimp and fish farming are complex operations due in part to the large number of factors that affect performance of stocks in production. From biological and genetic to nutritional, water quality and environmental parameters to management, human performance and engineering factors, all affect the way a batch of fish or shrimp performs and therefore all affect the performance of the farm as a business.

Good managers have the capacity to, often subconsciously, process many of these factors and make good day-to-day decisions that aim at improving performance of their stock. However, it is not possible for humans to take into account, rationally, large sets of data for all factors mentioned and therefore there are limits to even the best managers in the industry.

Machine Learning (ML) algorithms allow Artificial Intelligence (AI) to be trained (learn) and then AI can be used to aid managers in their daily decisions. ML can process very large data sets and take into account hundreds or thousands of factors when interpreting results making them ideal tools for fish and shrimp farming data

The aquaculture production management software Aquanetix was designed as a Cloud service and is today one of the largest databases of day-to-day data for dozens of farmed species from many production systems in various countries.

Training of ML algorithms requires complete batch (from stocking to harvest) data sets where final performance is known and in Aquanetix we have thousands of such data sets for more than 20 different species of fish and shrimp. This is an ideal system therefore to test the application of ML to aquaculture data.

Methods

ML algorithms increase in their capacity to model complex data as we move from linear regression, logistic regression and to neural networks of varying complexity. In this paper we have focused on developing algorithms that predict performance of tilapia batches from data collected in the first 6 weeks of grow-out. We will present results from the three main ML methodologies and show how using Neural Networks we can develop predictive models that have accuracy greater than 90%.

Data used are stocking details (number of fish stocked, mean weight of fish), weight data and mortality data in the first 6 weeks as well as site, harvest year and harvest week and we predict final production cost (cost per kg) as well as final survival. These results can be used to recommend actions early in the lifecycle of production that will improve performance of batches by harvest time.

Discussion

There are many potential applications of AI to aquaculture operations, from risk avoidance (pathologies) to size dispersal control, performance forecast and adjustment and eventually to everyday advice for managers on what to feed, when to split/grade or even harvest fish or shrimp batches. In order to get there, we need to collect large real-life datasets using systems such as Aquanetix and to start developing learning models that will take into account the many factors involved. The use of IoT (Internet of Things) technologies such as environmental monitoring probes, video footage from cages during feeding and feeding system delivery data will enrich the dataset and add more information for ML algorithms to result in better, more sophisticated and precise models.

THE EFFECT OF DIFFERENT WATER SOURCES ON THE POTENTIAL H_2S-FORMATION WITHIN RAS

Introduction

In the last years, several of the serious incidents involving acute fish mortalities in recirculating aquaculture systems (RAS) for Atlantic salmon (*Salmo salar*), have been caused by hydrogen sulphide (H_2S). These incidents have mainly occurred in seawater systems, e.g. post-smolt production. H_2S is formed by sulphate-reducing bacteria which uses sulphate (SO_4^{2-}) and organic material under anaerobic conditions (Muyzer and Stam, 2008). Seawater contains 1000 times more SO_4^{2-} than freshwater (Gerardi, 2006), increasing the potential risk for H_2S production. However, using seawater is pivotal to avoid desmoltification and preparing salmon for seawater transfer (Mortensen and Damsgård, 1998). The project where this preliminary study is from, propose the idea of removing sulphate from seawater through membrane filtration as a measure for reducing fish mortalities caused by $_2S$.

The aim of this preliminary study was to understand what microbial environments in RAS have the highest potential risk for H_2S-formation and to gain a better understanding of the dynamic between organic material and sulphate concentration for H_2S formation in RAS-water.

Materials and Methods

Three main environmental sources where H_2S could potentially form in a commercial RAS were selected: sludge, biofilter elements and RAS-water. A small-scale batch experiment was conducted where each of these three potential sources were exposed to seawater, freshwater, brackish water and treated water (freshwater + filtered seawater). The filtered seawater was provided by a membrane filtration technology developed during the same project that this study is a part of. The H_2S kinetics and production rate was measured for each test. The organic material was also measured in form of COD (chemical oxygen demand) and organic carbons as fatty acid. Anions such as NO_3^- and SO_4^{2-} and other water quality parameters were assessed.

Results

The results of this experiment are still under development and analysis and will therefore be presented at the European Aquaculture Society conference.

Introduction

Feed additives to prevent mycotoxin effects on aquatic animals have been increasingly used since mycotoxin contamination of aquaculture feed and feed ingredients is an ongoing global problem. Recent chemical modification of zeolite (clinoptilolite E567/568; Minazel-Plus®) surface with addition of organic cations has been shown to increase selective adsorption of both polar and non-polar mycotoxins in contaminated feed. However, the effects of this new additive on Nile tilapia (*Oreochromis niloticus*) health and production parameters during mycotoxin exposure have not yet been studied. We report the preventive effects of Minazel Plus used as feed additive in diets naturally contaminated with aflatoxin and fed to freshwater young of the year tilapia.

Materials and Methods

To investigate effects of mycotoxin dietary exposure on fish health parameters, Nile tilapia were fed basal diet (control), and diet naturally contaminated with a mix of aflatoxins (AFs; AFB1and 2, AFG1 and 2) at level of 16 µg/kg (AFs group). To investigate safety and efficac of surface-modified clinoptilolite adsorber as part of both polar and non-polar mycotoxin control and prevention strategies, we supplemented control and aflatoxin contaminated diets with Minazel-Plus® at level of 2 g/kg (MZ, AFsMZ, respectively) for 8 weeks. Effects of AFs and the protective role of Minazel-Plus® on fish health were evaluated using growth performance and hepatosomatic index (HSI), hematological parameters, innate immune and antioxidant responses, bioaccumulation of mycotoxins in liver and musculature, and histopathological assessment of liver and kidney tissues.

Results and Conclusion

Significant differences in production and health parameters were observed between AF vs Control and MZ supplemented groups, including decrease of red blood cells/RBCs, hemoglobin/Hb, and blood packed cell volume (PCV), changes in dynamics of leukocyte counts (specifically neutrophils), and decrease in serum lysozyme and bactericidal activity. Further, increase in Malondialdehyde (MDA) and decrease in catalase (CAT), reduced glutathione (GSH) and superoxide dismutase (SOD) activity were observed in AFs group compared to other groups. Aflatoxin residues were detected in both liver and musculature at 1.292 and 0.263 µg/kg respectively. Supplementation of Minazel-Plus® decreased AFs residues to 0.09 (liver) and 0.022 (muscle) µg/kg. Histopathology showed marked changes in liver and kidney of fish from AFs group.

Reported results strongly suggest that supplementation of low-level aflatoxin contaminated feed with 2 g/kg of Minazel-Plus® prevents negative health effects of aflatoxicosis in Nile tilapia. The authors propose that feed-mill monitoring and prevention strategies for aflatoxin levels in fish feed ingredients need to be routinely implemented and strictly enforced due to possible illegal use of highly contaminated feed, and inadequate or missing regulations of safety level of aflatoxins in fish feed

SAPRISTI, AN INNOVATIVE MODULAR TOOL IN THE IMPLEMENTATION OF A METHODOLOGY FOR THE RECOVERY OF FISH FARMING EFFLUENT BY AQUAPONICS

Thomas Tomson*; M. Haïssam Jijakli

Laboratory of Integrated and Urban Plant Pathology, University of Liège, Gembloux Agro-Bio Tech, Passage des déportés 2, 5030 Gembloux, Belgium
E-mail: t.tomson@uliege.be

Introduction

The conversion of a traditional flow through system to a recirculated aquaculture system (RAS) allows a fish farm to drastically reduce water requirements and reach optimal growth conditions by controlling the physicochemical parameters of the water. To further improve these intensive fish farming systems, we have to address other challenges such as the recovery of RAS effluents (sludge and renewal water) which is a way to improve energy efficiency (water and sludge treatment) and decrease the environmental impact (discharges of effluents). Aquaponics is a technique which can meet these challenges as the discharged water and the sludge containing nutrients can be used for the growth of plants of commercial interest. From a fish farmer point of view, the interest of a coupled aquaponics is to improve biofiltration by removing nitrates transformed by bacterial communities. On the other hand, a decoupled aquaponics can support or replace effluent treatment. Within the Laboratory of Integrated and Urban Plant Pathology of the University of Liège, the study of these scenarios is now possible by the implementation of SAPRISTI (System Aquaponics and Pilot for Research and Innovation in Science and for Transfer to Industry). It is a modular tool that allows simultaneous comparison of decoupled aquaponics, coupled aquaponics, fish farming alone and hydroponics alone by simulating the physico-chemical parameters of the water encountered in a fish farm. This tool has been tested with the commercial company Belgian Quality Fish (BQF) producing sturgeons.

Materials and methods

SAPRISTI consists of three identical RAS-type units designed for the rearing of different species of temperate or tropical freshwater fish. A sludge collection system was installed in each RAS at the outlet of the drum filter to study its mineralization. Each element is by-passable (UV, biofilte , etc.) to study the impacts on the system, mainly on the bacterial communities that make it up. Each RAS forms a decoupled aquaponics system by the possible connection to a horticultural greenhouse where different hydroponic systems are available (DWC, NFT, Drop, Ebb & Flow). The water sent to this greenhouse can be sent back to fish production through a network of pipes and pumps, forming a decoupled aquaponics system. For the case study with BQF, the RAS were loaded with sturgeons (*Acipenser gueldenstaedtii*) with a density of 25kg/m³. Each hydroponic unit consisted of an NFT subunit, a DWC subunit and an Ebb & Flow subunit. One hydroponic unit had no connection with the fish, the other two were each connected to a RAS, either partially (decoupled aquaponics) or completely (coupled aquaponics). Finally, a RAS ran as a single fish farm unit

Results and conclusions

Two successive trials are underway. During these tests, the fresh and dry weight yield of lettuce (*Lactuca sativa*), their micro- and macronutrient content, as well as the monitoring of water quality and nutrients will be carried out, with a greater focus on nitrogen cycle. Water and energy flows related to the operation of aquaponic systems will also be monitored and compared to those same flows applied to fish farming and hydroponics alone These results will be presented.

SAPRISTI can be also used to develop a methodology for other species and for different farming practices, allowing advice on the most appropriate hydroponic technique to choose, and estimation of the expected yields and substantial savings in water and energy from fish farming

FLAT OYSTER (*Ostera edulis*) RESTORATION IN OFFSHORE WIND PARKS: AN OPPERTUNITY FOR INNOVATION OF SCOUR PROTECTION

Linda Tonk[1*], Pauline Kamermans[1], Remment ter Hofstede[2], Tony van der Hiele[3], Tjeerd Bouma[4], Tom van der Have[5], Karin Didderen[5]

[1]Wageningen Marine Research, Wageningen University and Research, Yerseke, The Netherlands

[5]Bureau Waardenburg, Culemborg, The Netherlands
Email: linda.tonk@wur.nl

Introduction

The potential for offshore wind parks in the North Sea to contribute to nature-inclusive development and achieve biodiversity goals, restore ecosystem functions and enhance ecosystem services is gaining commitment through governmental policy aims. This includes restoration of flat oyster (*Ostrea edulis*) beds in the Dutch North Sea that once were an important species and habitat providing natural hard substrate (Kamermans *et al.*, 2018). The disappearance of flat oyster reefs is predominantly caused by overexploitation and subsequent habitat destruction by intensive bottom trawling (Gercken & Schmidt, 2014).

Several opportunities for the development of flat oyster populations (*Ostrea edulis*) in existing and planned wind farms in the Dutch section of the North Sea exist. However, knowledge that enables selecting the optimal moment and procedure for oyster spat treatments, prior to outplacement to offshore field locations, including optimizing survival of oysters and reducing the risk of outplacing non-native species is needed. The designation of Borssele V as an innovation site situated in the Borssele Wind Park, 20 km located off the coast of the Netherlands provides an opportunity for oyster reef development and to gain knowledge on best restoration practices.

Within the project plan Borssele V- EcoScour different outplacement methods for long-term establishment of live European flat oysters on the two scour protections of Borssele V are tested. For the success of a restoration project, selecting the right substrate is important. As part of the objective to test outplacements methods different substrates for oyster spat settlement will be tested to provide insight in which substrate is most likely to be successful in collecting spat.

The knowledge gained with these experiments contributes to the return of oyster beds. Restoring self-sustaining populations of wild oysters to a significan level benefits the supply of wild oyster larvae. In addition, insight in the factors that are important for reproduction, growth and survival of flat oysters in restoration projects can provide useful information for oyster aquaculture. Besides relieving the pressure from oyster fisheries, flat oyster aquaculture can assist oyster reef restoration by supplying in the high demand for live oysters necessary for reef restoration.

Methodology

Ten different substrates are tested with 5 replicates per type. The tests are carried out at 3 locations during the summer period when larvae are present and include an area with disease-free oysters.

To determine the right deployment moment for the substrates larval samples are collected and analyzed. Spat settlement is manually counted per substrate type.

Results and discussion

The results of oyster spat settlement on the experimental substrates in the three test locations will be discussed as well as the application for oyster reef restoration projects. These results will contribute to guidelines for innovative eco-designs of scour protection that may have positive effects on the maritime environment and practical guidelines for best restoration practices using oyster outplacement.

Introduction

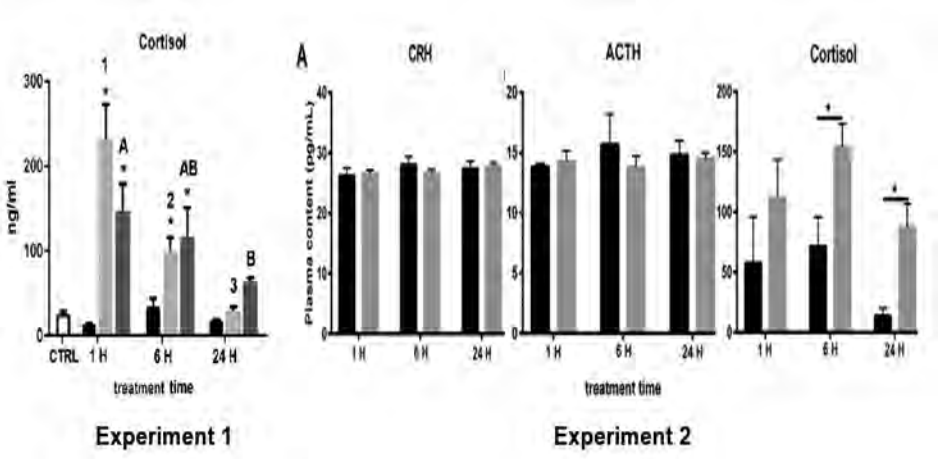
Vaccination is a widely used therapeutical strategy in aquaculture (Plant and LaPatra, 2011), but whether vaccination elicits stress responses in the central neuroendocrine system by itself and enhances the crosstalk between immune and endocrine systems in the brain or pituitary after vaccination remains unclear (Khansari et al., 2017, 2018). To answer this question, two experiments using two different vaccine exposure routes, i.e., waterborne vaccine bath or intraperitoneal injection, were carried out on gilthead seabream (Sparus aurata L.).

Materials and methods

Two types of vaccines were used in this study. In the first experiment, the stress responses of fish subjected to waterborne *Vibrio anguillarum* bacterin were analyzed and compared with responses obtained after air exposure or the combination of both procedures. In the second experiment, fish were subjected to an intraperitoneal injection of *Lactococcus garvieae* bacterin, the central stress response was assessed and we investigated whether or not a significant immune response was induced in brain and pituitary. Blood, brain and pituitary tissues were collected at 1, 6, and 24h post stress for hormone determination and gene expression analysis.

Results

Results indicated that bath vaccination induced a moderate central stress response compared to air exposure which stimulated both brain and pituitary stress genes. In the second experiment, vaccine injection showed unchanged plasma stress hormones except cortisol that raised at 6 and 24h time points. Similarly, non-significant or slight changes on the transcription of stress-related genes were recorded, including the hormone genes of the hypothalamic-pituitary-interrenal (HPI) axis and other stress gene indicators such as *hsp70*, *hsp90* and *mt* in either brain or pituitary. However, significant changes were observed in *crhbp* and *gr*. In this second experiment the immune genes *il1β*, *cox2* and *lys*, showed a robust expression in both pituitary and brain after vaccine administration, notably *il1β* which showed more than 10 fold increase.



(Continued on next page)

Discussion and conclusions

It is not precisely known what are the particular mechanisms of interaction between hormone elements and immune agents. Due to the protection of the blood brain barrier, pathogens can hardly access to the brain or pituitary. However, mediators such as cytokines could play a role of connecting antigens and response pathways (Banks et al., 1995). In previous works of our group we observed that both the medium from *the in vitro* cultured spleen and recombinant IL1β induced a significant effect on the immune response of trout pituitary tissue (Liu et al., 2019). Thus, the immune response in the central neuroendocrine system might be regulated by some mediators produced and released into the bloodstream by lymphoid organs as a response to the bacterin delivered by intraperitoneal injection.

Overall, vaccination procedures, although showing a clear cortisol response, did not induce other major stress responses in brain or pituitary, regardless the administration route and the type of vaccine at the doses tested. Other than these main results, the alteration of specific genes such as *crhbp* and *gr* suggests that these particular genes could play a relevant role in the feedback regulation of HPI axis after vaccination.

Moreover, from the results obtained in this work, it is also clearly demonstrated that the immune system maintains a high activity in both brain and pituitary tissues after vaccine injection, as shown by the enhanced activity of the relevant immune associated cytokine genes as well as the innate immune genes assessed in these tissues.

Introduction

The end hormone of the hypothalamus-pituitary-interrenal (HPI) axis, cortisol, is probably the most often measured indicator of stress in fish (Schreck and Tort, 2016). Nevertheless, obtaining blood involves certain degree of invasiveness which is not always possible or suitable and raises the consequent point of invasiveness and welfare issues. Over the last years, skin mucus has been developed, which is a far less invasive method, but as blood, this method potentially provides a brief window of information of the HPI axis activity. (Bertotto et al., 2010; De Mercado et al., 2018).The recently described cortisol measurement in fish scales provides another integrated measure of the HPI axis that may be useful for measuring long-term activity in this axis in fish (Aerts et al., 2015; Hanke et al., 2019).). Although cortisol in skin mucus or in the scales cortisol present practical advantages, there are still several issues that remain unclear related to their biological relevance, particularly under both acute and chronic stress situations. Therefore, we evaluated whether cortisol levels in skin mucus and scales can be a reliable measurement for stress response when subjecting fish to prolonged, continuous stressful conditions.

Materials and methods

A total of 64 rainbow trout were randomly divided into 8 groups. Five stress groups were confined at a high-density (30 kg/m3), each group in a different keepnet (45 cm×25 cm×25 cm) thus maintaining the confinement but also not modifying the total water volume. Three control non-stressed groups were kept undisturbed in different holding tanks at a low-density (2.6 kg/m3). One control group was sampled for blood, skin mucus and scales at the start of the experiment in order to obtain pre-stress levels (0 h). Three stress groups were sampled for blood and skin mucus at 1, 6 and 24 h after starting the confinemen stress (early phase of the stress response). The remaining four groups were kept under control or stressed conditions for 14 and 30 days (late phase of the stress response), and at each period, blood, skin mucus and scales were sampled from a control and a stress group. One individual from the 14th day control group died during the study.

Results

A significant increase in plasma and mucus was detected one hour after confinement stress. In plasma, cortisol levels remained significantly higher than pre-stress levels up to 24 h whereas in mucus, cortisol levels decreased significantly at 24 h compared to the initial peak, although remaining above pre-stress levels. At day 14 and 30 plasma and mucus decreased significantly compared to the cortisol at 1, 6 and 24 h with no differences at days 14 and 30. In mucus, no differences were detected between controls and stressed fish at day 14, while at day 30 stressed fish presented higher mucus cortisol than controls. Significant differences in scales were detected between stressed and control fish at day 14 and 30, although showing a decrease from day 14 to day 30 of the study. Finally, the control group displayed a significant increase in scale cortisol at day 14, but returned to pre-stress levels at day 30.

Discussion and conclusions

The present study shows that the measurement of cortisol in skin mucus reflects plasma cortisol concentrations when fish are subjected to a strong activation of the HPI axis. Our results also demonstrate that the cortisol content in scales strongly correlates with circulating plasma cortisol levels in fish subjected to chronic stressed. Our results also indicate that scales cortisol assessment may provide a retrospective measure of the past stress experience in fish. Overall, while this study offers a good basis for future research on the measurement of stress responses by applying the mucus and scales cortisol assessment, the present results open the question of whether these new matrices receive additional sources of cortisol other than plasma, and which should be the route of cortisol incorporation or diffusion in such a case. Further work should deep into the general robustness and stability of the cortisol content in scales cortisol when fish is subjected to prolonged stress. This will help to understand the dynamics of hormone fluctuations in this matrix

Introduction

The value of sea vegetables in a healthy human diet is becoming increasingly recognized and supported throughout Europe. Sea vegetables provide a rich source of vitamins, minerals, proteins, fatty acids, and antioxidants. Sustainable aquaculture of sea vegetables will be necessary to supply the increasing demand for these functional foods, as natural harvests are limited and cannot keep up with demand. Different methods can be used to cultivate sea vegetables, including flow through systems with natural seawater, or recirculating aquaculture systems (RAS) with artificial seawater. The latter provides strict control over the growth conditions and water quality in order to provide a high quality and traceable final product. Environmental conditions such as salinity, temperature, and light can be modified to optimize the concentration of functional ingredients in sea vegetables. To date, most research efforts have been focused on quantifying the concentrations of functional ingredients in different species from different geographic regions, as well as identifying seasonal trends in wild sea vegetables. There is less information available on how to optimize these functional ingredients in aquaculture. Therefore, we performed controlled experiments to optimize the activity of antioxidants in sea vegetables grown in RAS.

Materials and Methods

We investigated the effects of daylength and light quality on the growth, oxygen production and free radical scavenging activity of *Ulva* sp. using the ABTS radical cation decolorization assay (Re et al. 1999). Additionally, we investigated the effects of salinity, desiccation, daily photon dose, and UV light on the growth and free radical scavenging activity of *Gracilaria vermiculophylla*. Both species were grown under climate-controlled conditions (15°C) with artificial irradiance provided by LEDs.

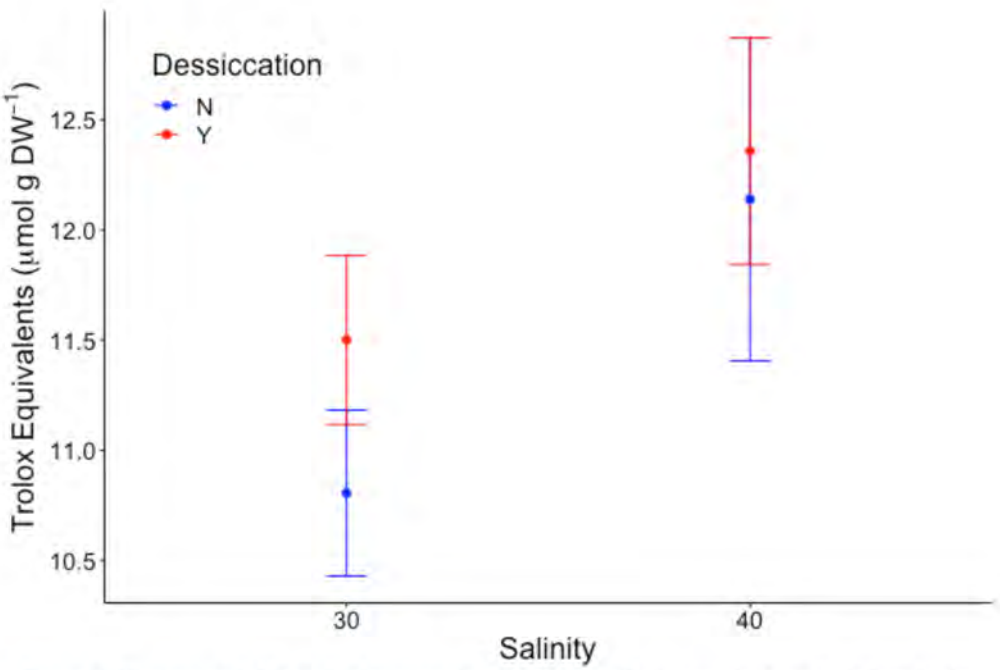

Figure 1. The mean (±SE) radical scavenging activity (as Trolox equivalents) of *Gracilaria vermiculophylla* under different salinity conditions with (Y) and without (N) exposure to desiccation.

(Continued on next page)

Results

We show that the conditions for optimal antioxidant activity are not necessarily optimal for growth or photosynthesis. For example, preliminary results show that high salinity combined with desiccation in *G. vermiculophylla* resulted in poor growth rates and quantum efficiency of Photosystem II ($_{v}/F_{m}$), but the highest antioxidant activity (Fig. 1).

Discussion

We show that antioxidant activity in two sea vegetables can be optimized in RAS culture. The environmental conditions should be optimized for growth to produce biomass, followed by a short acclimation phase to increase antioxidant activity. We discuss the implications of our experiments for future sea vegetable aquaculture activities, and provide recommendations for optimization of antioxidant activity in the two species investigated.

EFFECTS OF FISH & PLANT OILS REPLACEMENT WITH MICRO-ALGAE OIL ON GUT MICROBIOME, GENE EXPRESSION AND GROWTH PERFORMANCES OF NILE TILAPIA FRY(*Oreochromis niloticus*)

S. Trevi, C.G. De Leaniz, S.C. del Olmo, T. Uren Webster

Swansea University College of Science, Singleton Park, Swansea (United Kingdom) SA2 8PP
E-mail: 988171@swansea.ac.uk

Aim:
This experiment will assess the effects of microalgae lipids on gut microbiota, gene expression and growth performances of Nile tilapia fry. While tilapia is the second most farmed fish on the planet information about its gut microbiota, especially on how it develops from early life stage, is still missing. In this experiment we will characterize the gut microbiome of Nile tilapia and we will observe how it is influenced by the change of lipid's origin in the diet. In particularly we will observe how the replacement of conventional fish and plant oil with micro-algae oil affects the microbiome and how it is associated with the health and fitness of the fish (growth performances, immune gene expression

Materials and methods:
At the start of the experiment 1620 tilapia fry (mixed sex) were purchased from Stirling University and housed in 18 tanks of 25 litres. Each tank will contain initially 90 fish. Three tanks were randomly assigned to each of the 6 experimental diets. The diets for the tilapias were made in CSAR following the same methodology illustrated in the study of Royes and Chapman (2003). The diet composition of the control diet (CON) is the same of the Nile tilapia "reference diet" used in the experiments of Teuling, Wierenga et al. (2019) and Teuling, Schrama et al. (2017). The positive control diet (+CON) is the same of CON but with 100% fish oil (no soya oil). The negative control diet (-CON) is the same of CON but with 100% soya oil (no fish oil). The microalgae diets are three, each one with a raising percentage of microalgae oil in it up to 100%. The microalgae used as oil source is Schizochytrium. This microalgae-oil not only doesn't affect negatively the welfare of tilapia, it also improves its growth performances as demonstrated in the studies of Watters, Rosner et al. (2013); Sarker, Gamble et al. (2016) and Sarker, Kapuscinski et al. (2016). The diet Algae33 is the same of CON but with 33% of fish&soya oil replaced by microalgae oil. The diet Algae66 is the same of CON but with 66% of fish&soya oil replaced by microalgae oil. Finally, the diet Algae100 will is the same of CON but with 100% of fish&soya oil replaced by microalgae oil. At the start of the experiment 3 fish per tank were sacrificed (using a Schedule1 method, overdose of anaesthetic) for initial microbiome-sampling and length &weight measuring. The fish are fed to satiation three times per day. The experiment will last 8 weeks, but it will be most likely extended to observe the long term development of the gut micro-biome. At day 21 of the experiment, 4 fish per tank were sacrificed for microbiome- sampling. After day 21, sampling of 4 fish per tank will occur every 2 weeks for the remaining duration of the experiment. At the end of the experiment, a final microbiome-sampling and length & weight measuring will be undertaken. The samples taken are gut and liver stored in RNA-later solution for both microbiome and gene expression analysis. Weight and length of the sampled fish is also recorded for assess the growth performances. The gut microbiome will be characterized with the 16S ribosomal RNA sequencing, meanwhile gene expression in both gut and liver will be evaluate via microarray analysis and reverse transcription polymerase chain reaction (RT-PCR). Because this trial is still underway at the moment, results and discussions are not yet available.

Introduction

Genomic selection is increasingly applied in aquaculture breeding to expedite genetic gain for key production traits such as disease resistance. Its effective application in breeding programmes depends on large training datasets of phenotypes and genotypes. In livestock breeding, genotype information on large populations can be achieved in a cost-effective manner through genotype imputation, which allows to infer high density genetic information from low density genotype data. In typical aquaculture breeding programmes where large full-sibling families sharing large genomic segments are available, the value of imputation is yet to be fully assessed.

The aim of this study was to evaluate strategies for the use of low density SNP panels and genotype imputation in Atlantic salmon breeding programmes. Our study focuses on two economically important traits, namely resistance to sea lice (sea lice count) and body weight. Sea lice is the most costly disease-related problem in all major salmon-producing countries (Gjerde et al., 2011). Previous studies (Tsai et al., 2015; Tsai et al., 2016) have shown the existence of genetic variation in resistance to sea lice (heritability of 0.22-0.33) and body weight (heritability of 0.5-0.6), and both traits were found to have a polygenic genetic architecture, hence lend themselves to genomic selection.

Materials and Methods

This study focused on a Scottish Atlantic salmon breeding programme population challenged with *L. salmonis* (Landcatch, UK) (Tsai et al., 2015). All samples were genotyped with the Affymetrix Axion 132K Atlantic salmon SNP chip (78362 SNP markers) (Houston et al., 2014). The analysis comprised three main parts: (a) identifying high density (HD) SNP panels with optimal density and composition; (b) testing the imputation accuracy when offspring were genotyped at a range of low densities (LD) consisting the imputation panels, and parents were genotyped at HD; and, (c) comparing the genomic prediction accuracies of each of the datasets, with and without imputation. All analyses were performed via an in-house built software pipeline, using R and Shell for selection of HD and LD SNP panels, calculation of genomic relationship matrices, and cross-validation; FImpute for genotype imputation; and, ASReml for estimating breeding values.

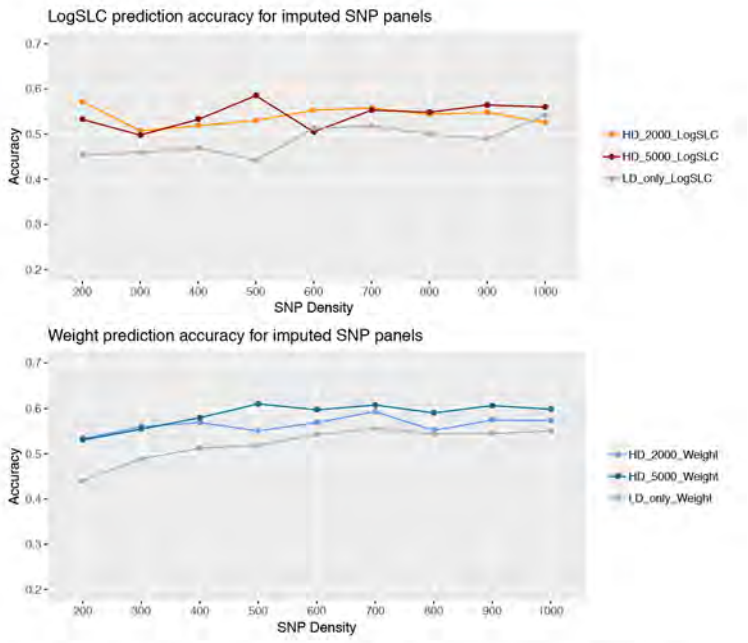

Figure 1. Mean cross-validated prediction accuracy for sea lice count and weight.

(Continued on next page)

Ten replicates of SNP panels of varying densities were constructed by random sampling of SNPs (i) across the genome, or, (ii) within each chromosome proportionally to its length. Mean genomic prediction accuracies were calculated over 50 replicates of 5-fold cross-validation as:, where was the correlation between phenotypes and predicted breeding values, and h the square root of the genomic heritability.

Results and Discussion

The heritability estimated using the genomic relationship matrix was 0.19 (0.07) for sea lice resistance, and 0.57 (0.07) for weight. Reducing the SNP panel density from the full HD SNP panel (76,488 SNPs) to 200 SNPs resulted in a 14.5% decrease in genomic prediction accuracy for sea lice resistance, and a 27.9% decrease for body weight. This loss of accuracy started between 2,000 and 5,000 SNPs for both traits, therefore these densities were tested as the optimal target HD SNP panels for imputation.

Imputation accuracy increased with increasing imputation SNP panels density. Genomic prediction accuracy using imputed genotypes was only marginally higher for body weight when increasing the density of the imputation SNP panel, and for sea lice resistance there was very little difference between lower and high density imputation panels (Figure 1). The benefits of imputation were highest at the lowest imputation panel densities. For example, genomic prediction accuracy using 200 SNPs without imputation for sea lice resistance was 0.45, whereas with imputation to 5000 SNPs it was 0.53, which corresponds to a 17.47% increase due to imputation (Figure 1).

In conclusion, genomic prediction using LD genotypes imputed to medium densities (e.g. 5000 SNPs) can provide better accuracies than using LD true genotype data alone. There is large variability in the genomic prediction accuracy from LD SNP panels, depending on the SNPs randomly selected on the panels, thus using LD SNP panels with imputation is likely to be cost-effective.

DELTAMETHRIN RESISTANCE IN SALMON LICE: MITOCHONDRIAL AND NUCLEAR SINGLE NUCLEOTIDE MARKERS

C. Tschesche[1*], M. Bekaert[1], J. E. Bron[1], A. Sturm[1]

[1]Institute of Aquaculture, University of Stirling, Stirling, United Kingdom

Introduction

The salmon louse *Lepeophtheirus salmonis* (Krøyer, 1837) is a copepod fish parasite causing huge economic damage in the farming of Atlantic salmon. Salmon lice infections can be controlled by bath treatments with the pyrethroid deltamethrin (DTM, AMX®, PHARMAQ), which is believed to act by blocking voltage gated sodium channels (Na_v1). However, the use of DTM for salmon delousing is threatened by resistance development (Aaen *et al*., 2015). In insects, a common mechanism of DTM resistance involves target-site mutations rendering Na_v1 insensitive (knock down resistance, *kdr*). Alternatively, resistance can be based on increased metabolic detoxification due to up-regulation of cytochrome P450s or esterases (Carmona-Antoñanzas *et al*., 2017). In *L. salmonis,* DTM resistance has been shown to be mainly inherited maternally, and to be associated with mitochondrial (mt) mutations (Carmona-Antoñanzas *et al*., 2017; Bakke *et al*., 2018). This suggests a novel, yet uncharacterised, resistance mechanism and implies the presence of mt targets for toxicity in susceptible lice. In addition, a putative *kdr*-type mutation has been identified in one of three *L. salmonis* Na_v1 homologues (Carmona-Antoñanzas *et al*., 2018). In order to obtain insights into the mechanisms of DTM resistance in *L. salmonis,* pharmacological and genotyping approaches were combined in this study, investigating DTM susceptible and DTM resistant salmon lice.

Materials and methods

L. salmonis used in this study originated from laboratory strains (IoA-00: EC_{50} 0.28 µg l^{-1}; IoA-02: EC_{50} 40.1 µg l^{-1}), farm bioassays (Farm 1: EC_{50} 1.7 µg l^{-1}; Farm x: EC_{50} >>2 µg l^{-1}; Farm y: EC_{50} 12.63 µg l^{-1}), and a cross between a DTM resistant male and a DTM susceptible female. DTM susceptible and resistant *L. salmonis* were genotyped for selected single nucleotide polymorphisms (SNPs), which were associated with DTM resistance in previous studies (Carmona-Antoñanzas *et al*., 2018; Carmona-Antoñanzas *et al*., 2017). Genomic DNA was extracted from individual lice. Allele specific PCR assays were carried out using the KASP system (LGC Genomics) and designed to detect the mt SNPs t3338c (COX3), t8600c (COX1), a8134g (ND1), and a5889g (ND5) and the Na_v1 SNP a3041g. In addition, *L. salmonis* bioassays were performed with the pseudo-pyrethroid etofenprox, which cannot be metabolised by esterases. Bioassays were performed using adult male and preadult II female lice. Lice were exposed to toxicants (DTM: 30 min; etofenprox: 24 h) and allowed to recover in seawater (DTM: 24 h; etofenprox: no recovery) before being rated as affected or unaffected (Carmona-Antoñanzas *et al*., 2017). A seawater control and at least seven toxicant concentrations were tested (duplicates, five males and females each). Lice were classified DTM resistant when remaining unaffected after exposure to ≥3 µg l^{-1} DTM and classified susceptible when a fected after exposure to ≤1 µg l^{-1} DTM.

Results

The allele frequencies of the putative *kdr* mutation a3041g in Na_v1 did not differ ($p>0.05$) between DTM resistant and susceptible lice from farm sites and did not correlate with DTM resistance of F2 progenies from a cross between a DTM resistant male and a DTM susceptible female (Table I). Compared to the susceptible strain IoA-00, strain IoA-02 was resistant to DTM but susceptible to etofenprox (Table II).

The allele frequencies of the mt SNP alleles g3338a, t5889c, g8134a, and t8600c were higher in DTM resistant lice than in susceptible lice ($p<0.001$). Only SNP t8600c in COX1 was present in all DTM resistant lice but also in a few susceptible lice (Table III).

Discussion and conclusion

In insects, *kdr* mutations cause cross-resistance to etofenprox (Carnevale *et al*., 1999). In contrast, DTM resistant *L. salmonis* included in this study were not cross resistant to etofenprox. The allele frequency of the putative *kdr* mutation a3041g did not correlate with DTM resistance. Thus, DTM resistance in *L. salmonis* seems to be unrelated to target site mutations in Na_v1. Significantly higher allele frequencies of all tested mt SNPs in DTM resistant lice than in susceptible lice indicate an association with DTM resistance. However, while SNP t8600c, leading to the missense mutation Leu107Ser in COX1, was present in all DTM resistant lice, it was also found in some susceptible lice. A previous study showed that Leu107 is located on the surface of the COX1 protein structure and thus, might represent a potential DTM binding site (Bakke *et al*., 2018).

Introduction

The salmon louse *Lepeophtheirus salmonis* (Krøyer, 1837) is a copepod fish parasite causing huge economic damage in the farming of Atlantic salmon. The pyrethroid deltamethrin (DTM, AMX®, PHARMAQ) is a licensed bath treatment for the control of salmon lice infections. However, the use of DTM for salmon delousing is threatened by resistance development (Aaen *et al*., 2015). In insects, pyrethroid resistance typically involves mutations of the compound's molecular target site or increased detoxification by enhanced expression of biotransformation enzymes such as carboxylesterases (CaEs), cytochrome P450s, or glutathione-S-transferases (Ranson *et al*., 2011).

The CaE gene family is functionally very diverse. CaEs possessing a catalytic triad, which can hydrolyse the central ester bond of pyrethroids, and thus promote its degradation (Montella *et al*., 2012). In *L. salmonis*, DTM metabolism involving cleavage of the central ester bond has been recently reported, with higher rates of metabolism in DTM resistant than susceptible lice (Bakke *et al*., 2016).

The aim of this study is to obtain insights into *L. salmonis* genes potentially involved in DTM hydrolysis. CaEs are identified in sequence databases and phylogenetic relationships are established for *L. salmonis* CaEs. Their transcript expression will be assessed in laboratory *L. salmonis* strains differing in susceptibility to DTM.

Materials and methods

L. salmonis CaEs homologues were identified by homology searches in an *L. salmonis* transcriptome assembly (EBI ENA reference ERS237607) and genome assembly LSalAtl2s (metazoan.ensembl.org), using the entire complement of *Drosophila melanogaster* CaEs as queries (E-value cutoff = 10^{-10}).

Phylogenetic analyses of *L. salmonis* CaEs sequences retrieved by this strategy took into account CaEs of *D. melanogaster* and *Apis mellifera*. Full and partial protein sequences were aligned using the programme Clustal Omega and then subjected to phylogenetic analysis using the RAxML package.

CaEs transcript expression is currently being studied in relation to DTM exposure in female and male *L. salmonis* from DTM resistant and susceptible laboratory-maintained strains.

Preliminary results and discussion

The. *D. melanogaster* and *A. mellifera* genomes contain 35 and 24 CaEs, organised in 11 and 9 clades, respectively, which assign to three major classes (Claudianos *et al*., 2006). The first class contains catalytically active intracellular enzymes covering dietary and detoxification functions (clades A-C). The second class contains enzymes that are catalytically active, secreted, and not membrane-bound (clades D-H), and the third, most ancient class, contains catalytically inactive membrane-associated proteins with neuro/developmental functions (clades L, M), uncharacterised proteins (clades I, K), and catalytic active acetolycholinesterases (clade K). CaEs conferring pesticide resistance occur in all three classes but most CaEs associated with metabolic resistance to pesticide belong to the first class (Montella *et al*., 2012).

In *L. salmonis*, 27 CaEs were identified, of which 17 CaEs occur in five clades in two classe

L. salmonis has 16 members of the third neuro/developmental class, including two putative achetylcholinesterases, 12 putative neuroligins, and one putative gliotactin and neurotactin. Thus, *L. salmonis* has twice as many neuroligins as *D. melanogaster* and *A. mellifera*. Neuroligins are postsynaptic cell adhesion proteins involved in formation and specificatio of synapses (Dean and Dresbach, 2005). *L. salmonis* has only one member of the second secreted catalytic class in the small clade D, containing integument esterases (Montella *et al*., 2012).

(Continued on next page)

None of the *L. salmonis* CaEs could be assigned to the first class, providing detoxificati n functions. Similarly, *L. salmonis* has been shown to possess a markedly reduced number of detoxifying ABC transporters (Carmona-Antoñanzas *et al*., 2015). The low number of detoxifying genes in *L. salmonis* may have arisen because salmon lice only ingest host product when feeding and are partially protected from environmental toxicants during host-attachment. Similarly, the human body louse *Pediculus humanus,* which is an obligate blood feeder, and *A. mellifera*, which maintains a mutualistic symbiotic relationship with flowering plants, possess only 3 and 9 CaEs in the detoxifying class, respectively (Lee *et al*., 2010; Claudianos *et al*., 2006). In contrast, the expansion of detoxifying class CaEs in *D. melanogaster* (13 CaEs), *Anopheles gambiae* (16 CaEs), *Bombyx mori* (55 CaEs), or *Tribolium castaneum* (26 CaEs) is likely due to their polyphagy throughout their life cycles (Oakeshott *et al*., 2010; Carmona-Antoñanzas *et al*., 2015).

CaE genes evolve rapidly, which complicates phylogenetic analyses (Montella *et al*. 2012). Ten out of 27 identified *L. salmonis* CaEs could not be assigned to clades, which are present in insects. Their function has yet to be clarified

Ongoing analyses will show whether certain identified CaEs are differentially expressed between DTM resistant and susceptible, and female and male *L. salmonis*, in the absence or presence of DTM exposure.

Introduction

While the effects of stress on the mammalian brain are under thorough investigation, only few explored how distress and eustress affect the brain of teleosts (Schreck et al. 2016). Being the center of an elaborate nervous system, the fish brain is likely to be influenced by current and past stress and may also alter the perception of future stressors

Many stimuli which fish in aquaculture encounter are processed by the brain, making the latter the place where most stressors first affect the fish irrespective of their quality and quantity. A better understanding of this primary stress response may lead to deeper insights in how stress influences fish and how negative effects might be lessened while positive ones may be utilized.

For this purpose, the expression levels of several genes in carps were compared between different brain areas at different time points after the fish experienced either a positive, a negative or no stresso .

Methods

70 juvenile carps (*Cyprinus carpio*) from a local supplier were held in a recirculating aquaculture system till a mean weight of 58g at standard conditions. In addition to the commercial pellet feed, the fish were trained to receive mosquito larvae in the morning by hand feeding. 30 pairs of fish were transferred to a 40 l glass tank with a flow-through system for an acclimatization phase of 40h where water parameters were held stable and equal to before and fish were hand fed twice a day. Thereafter both carps in the tank were subject to the same of 10 treatment groups. Eustress groups were hand fed with mosquito larvae and sampled after 10min, 30min and 60min after the feeding. Distress group were exposed to air for 1min and sampled after 10min, 30min and 60min after the exposure. The control groups were only visually checked and sampled after 0min, 10min, 30min and 60min after the check. Sample size was 6 individual fish i.e. three pairs for each group

Fish were caught with hand nets and placed in a MS222 solution (150mg/L), after the loss of the swim reflex blood was sampled from the caudal vein within three minutes from capturing. Fish were measured and brains were dissected and stored in RNAlater while blood samples were centrifuged, and plasma kept at -80°C.

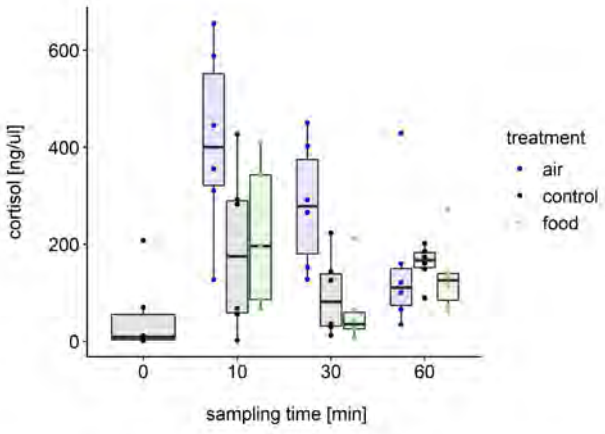

Fig. 1: Plasma cortisol levels for each treatment group. Air exposure: blue, food reward: green and control check: black. Sample size was 6 per treatment group, except for food10 (n=5).

(Continued on next page)

Cortisol values of the plasma were analyzed using HPLC methods. The brains were split in 4 parts, the telencephalon, the optical tectum, the hypothalamus and the cerebellum and gene expression levels were analyzed using quantitative real-time PCR. Relative gene expression levels were normalized based on three house-keeping genes and expressed as ddCt values. In the focus of the analyses were immediate early genes indicating activity of the corresponding brain area as well as genes known to be part of the hypothalamus-pituitary-interrenal (HPI) axis.

Results

Cortisol analyzes of the blood plasma show the effect of the distress treatment resulting in an increase of the stress hormone after 10min with a following decline over the later sampling points (fig. 1). Similar to the air exposure the feeding treatment and the control led to higher cortisol levels after 10min with a decline afterwards. However, the peak levels are higher in the distress group.

Statistical analysis and preliminary results of the qPCR measurements will be available for the second submission date in July and all data will be ready for presentation at the conference.

Discussion

Despite considerable individual differences the cortisol levels in the plasma show a stress response to the treatments which was stronger in the distress groups. The differential influence of the identity, the severity and the frequency of a stressor on the primary and secondary stress response in fish is known (Pavlidis et al. 2015). And now the gene level analyses will show the patterns in different brain areas after different stressors. The immediate early genes will reveal which of the four brain parts are activated by the different treatments and the expression of the stress related genes will shed light on the relevant brain parts.

The first preliminary results show how important the structuring of the teleost brain is when investigating the effects of stress on fish. Taking into account that different brain areas also have various functions and therefore may also be affected differently by stress is crucial to any future investigation as whole brain analyses are likely to cover relevant signal being restricted to specific areas

In a next step the relevant brain parts and genes will be analyzed in a chronic setting allowing a better understanding the effects of prolonged stress on fish. The data will pave the way to a potential bio indicator of stress in fish enabling a better assessment of handling practices and husbandry conditions and their effect on fish welfare in aquaculture

Introduction

\Gilthead sea bream (*Sparus aurata*) is an important species in the Mediterranean market among other cultured marine fish. Still, the occurrence of skeletal anomalies and reduced growth are problems to be solved in the production of juveniles of this species. The stages of larval development are crucial for the recognition and identification of abnormalities in skeletal structures. Also, during this developmental phase, major changes occur in the skeletal system. Zinc (Zn) is an essential trace element that intervenes in a wide series of metabolic processes, including ossification, bone development and growth (Yamaguchi, 1998). Dietary deficiency of Zn in fish causes reduced growth, high mortality, low tissue Zn and dwarfism (Ogino and Yang, 1978; Watanabe et al., 1997). In larvae of another sparid, the red sea bream (*Pagrus major*), Zn deficient larval diets increased the incidence of bone anomalies (Nguyen et al., 2008). However, the information about mineral nutrition in marine fish larvae, and particularly gilthead seabream is still scarce. This study aims to investigate the effects of the dietary supplementation of Zn on skeleton health and growth performance in gilthead sea bream larvae.

Materials and Methods

Diets. Four isoenergetic and isonitrogenous diets were supplemented with different levels of Zn at concentrations of 0, 20, 40 and 200 mg/kg.

Fish and experimental conditions. Gilthead sea bream larvae were randomly distributed into twelve light grey color fibreglass tanks (2200 individuals/ 200-L FRP tank) filled until 170 L. Initial mean body length and weight were 8.96 ± 0.86 mm and 0.78 ± 0.11 mg. Fish larvae were fed with one of the 4 experimental microdiets every 45 min from 8:00-20:00. The total amount of diet fed daily was 4 g and increased 0.5 g each week. A siphon was used to clean the bottom of tank every day at 14:00 and uneaten feed was weighted and recorded during the feeding period. Photoperiod was kept at 12h light: 12h dark at light intensity of 1700 lux. Flow of filtered seawater was maintained at an increasing rate of 0.3 – 1 L/min along the feeding trial. Larval tanks were continuously aerated at 125mL/min to attain 5-8 g/L dissolved O_2 and saturation ranged between 60% – 80%.

Growth was monitored by measuring the weight and length of larvae after 8, 15 and 21 days (Final sampling) of feeding. At day 8,15 and 21 of samples were also collected for gene expression relative to bone and mineral metabolism (30 larvae/ tank) and cartilage stain (30 larvae/tank). At the end of the study live larvae were sampled for weight and length (30 larvae/ tank), histology (15 larvae/tank), whole mount stain with alizarin red for calcified skeletal structures (100 larvae/tank), gene expression (30 larvae/tank), TBARS (300 larvae/tank) and remaining larvae for mineral analyse. Daily mortality was calculated for survival rate. Experimental diets and whole larvae of biochemical composition were analyzed following standard procedures. Mineral analysis of diets and whole larvae were conducted using an inductively coupled plasma mass spectrometer (ICP-MS) (Thermo Scientific, Massachusetts, USA)

Statistics. All data were tested for normality and homogeneity of variances and means compared by Ducan test and one-way ANOVA ($P < 0.05$).

Results

After the 21 days of feeding survival rate was no significantly different ($P > 0.05$) among larvae fed the different Zn dietary levels (Figure 1). Fish fed a diet without supplemented Zn showed the lowest body length and weight, whereas increase in dietary supplementation up to 20 and 40 mg/kg significantly increased growth (Figure 2, 3). No significant differences were observed in growth of larvae fed diets supplemented with 20, 40 and 200 mg/kg of Zn.

(Continued on next page)

Figure 1. Daily mortality of gilthead sea bream larvae fed diets with different supplementation level of Zinc

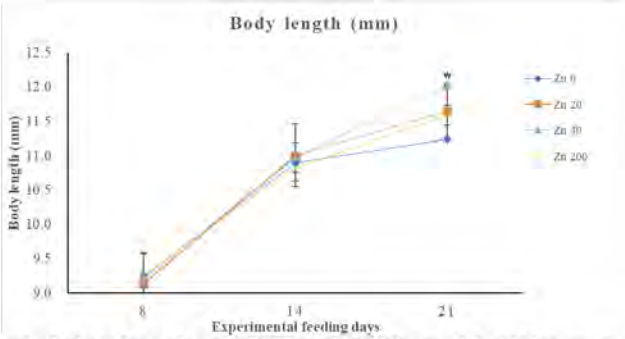

Figure 2. Body length of gilthead sea bream larvae fed diets with different supplementation level of Zinc

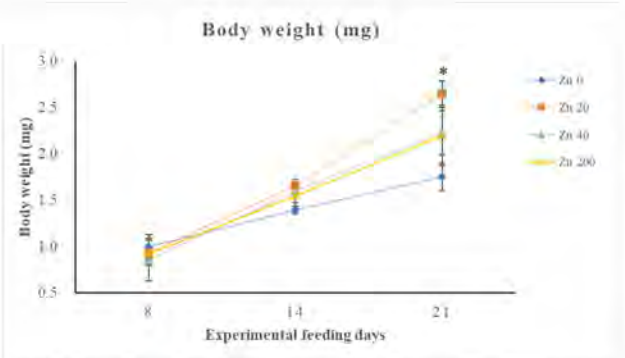

Figure 3. Body weight of gilthead sea bream larvae fed diets with different supplementation level of Zinc

Discussion and conclusion

The present study showed the positive effect of Zn supplementation on microdiets for gilthead sea bream. These results are in agreement with the positive effect of increased dietary Zn levels found in other sparids (Nguyen et al., 2008), and the increased body weight and length found in first feeding rainbow trout (*Oncorhynchus mykiss*) (Shahpar and Johari, 2018). In juveniles of malabar grouper (*Epinephelus malabaricus*) increased dietary Zn levels up to 28.9-33.7 mg/kg also increased weight gain (Chen et al., 2014). Our previous study in gilthead sea bream has shown that supplementation of microdiets with a combination of Zn, selenium (Se) and Manganese (Mn) also led to an increase in total length compared to larvae fed the unsupplemented diet (Izquierdo et al., 2016). Besides, dietary minerals supplemented group showed a better mineralization pattern than non-supplemented group and reduced malformations in bones that form around a cartilaginous anlage. However, in that study it was not possible to identify which of these minerals were responsible for seabream performance improvement. The present study confirms the importance of Zn supplementation in microdiets to improve sea bream growth, complementing the previous study. Studies on skeletal anomalies, bone mineralization and larval morphology will provide more information about the effects of Zn on larval gilthead sea bream.

Introduction

The most frequent and detrimental ectoparasites of Mediterranean cage-reared gilthead sea bream (*Sparus aurata*) and European sea bass (*Dicentrarchus labrax*) are the monogenean *Sparicotyle chrysophrii* and the cymothoid isopod *Ceratothoa oestroides*. In order to better understand their transmission and epidemiology, knowledge pertaining to the genetic structure of parasite assemblages infecting wild and farmed hosts is critical. In the current study, Mediterranean-wide genetic structure of *S. chrysophrii* and *C. oestroides* collected from the wild and farmed hosts was evaluated using genome-wide SNP markers generated by ddRADseq (Peterson et al., 2012), trying also to identify and validate distinctive markers to differentiate the two ectoparasites across wild and farmed fish populations. This is the first time in parasite epidemiology, and across an extensive geographic area.

Materials and Methods

Sampling of parasites sampling was carried out across four large Mediterranean farming areas in Spain, Italy, Croatia and Greece. DNAs were extracted using QIAamp DNA Mini kits (Qiagen), and checked for quality and quantity by agarose gel electrophoresis and fluorimetr , respectively. The ddRAD library preparation protocol used has been that detailed elsewhere (Manousaki et al., 2016). Five libraries were constructed in total following exactly the same procedure. Particularly, 310 *C. oestroides* (16x parental generation, 138 Croatian/Farmed and 156 Croatian/Wild) and 330 *S. chrysophrii* (54 Croatian/Farmed, 39 Croatian/Wild, 69 Greek/Farmed, 10 Greek/Wild, 58 Italian/Farmed, 22 Italian/Wild and 78 Spanish/Farmed). For each sample c. 20 ng DNA were co-digested by two high fidelity restriction enzymes: *SbfI & SphI,* barcoded adapters were ligated and size-selected fragments (400 bp to 700 bp) were PCR amplified (15 cycles), column purified and finally quanified by fluorimetr . Each ddRAD library was sequenced on a separate Illumina MiSeq run (300 cycle kit, 162 bp paired end reads). The raw sequence data produced were analysed with STACKS (v2.3) (Catchen et al., 2013). SNPs surviving the filtering criteria were imported to STRUCTURE (Falush et al., 2003) to infer the most likely population structure. PCA analysis was conducted to assess the relatedness of individuals.

Results

SNPs that were detected in more than 30% of the parasites were used for population analysis , i.e. 246 SNPs for *S. chrysophrii* and 313 SNPs in *C. oestroides*.

Discussion and conclusions

In *S. chrysophrii*, taking relatedness indices into account, each sampled farmed population from Greece, Italy, Croatia and Spain was genetically differentiated, whereas all wild samples closely clustered, showing the probability that they might be at the source of any sample encountered at the ends of the distribution. In *C. oestroides*, it seems that there is no clear genetic differentiation between isopods found in aquaculture and wild fish either using population structure or relatedness analyses. Taken together, the generated knowledge on the population structure of the two parasites suggests that water marine currents and distance among fish cages holding fish with different age/size classes in the aquaculture site have to be carefully considered to mitigate propagation of two parasite species. In addition, placement of cages at higher depth and management of wild fish stock could help to decrease parasitic incidence

Introduction
Gilthead seabream (*Sparusaurata*) is a teleost of considerable economic importance in Southern European aquaculture. The aquaculture industry shows a growing interest in the application of genetic methods that can locate phenotype-genotype associations with high economic impact. Through selective breeding, the aquaculture industry can exploit this information to maximize the financial yield. One of the main avenues to genetically improve the cultured stock is to identify associations between genetic variants and traits of interest, such as growth, disease resistance, fat content, etc. Here, we conducted a Genome Wide Association Study (GWAS) Through double digest Random Amplified DNA (ddRAD) Sequencing, we generated a per-sample genetic profile and tested for association with phenotypes related to growth

Materials and Methods
The experiment was conducted on 112 samples belonging to seven different seabream families collected from a Greek commercial aquaculture company. Through a ddRAD protocol (Manousaki et al. 2016) we sequenced the samples on an Illumina Hiseq4000 instrument. Then, ddRAD data were analysed using the software STACKS (Catchen et al. 2013) to obtainedhigh quality Single Nucleotide Polymorphisms (SNPs). These profiles were tested for association with four phenotypes of major financial importance: Fat, Weight, Tag Weight and the Length to Width ratio. Prior to the association analysis, we conducted a clustering of the individuals based on their genetic profile to ensure that genotyping results agree with the family relationships of the studied individuals. Then, we applied two methods of association analysis. The first is the typical single-SNP to phenotype test, and the second is a feature selection (FS) method through two novel algorithms that are employed for the first time in aquaculture genomics and produce groups with multiple-SNPs associated to a phenotype (Tsagris et al. 2018).

Results
Data analysis led to the discovery of 2,258 high quality SNPs. Based on those we clustered the individuals revealing the expected structure based on the seven families (Figure1). Then, our association analysis revealed multiple significant SNPs. In total, we identified nine single-SNPs and six groups of SNPs associated with weight related phenotypes (Weight and Tag Weight), two groups associated with Fat, and 16 groups associated with the Length to Width ratio (Figure 2). Six identified loci were present in genes associated with growth in other teleosts or even mammals, such as semaphorin-3A, and neurotrophin-3.

Discussion and conclusions
Our study presents, in a small scale example, the availability of the tools necessary for the application of Next Generation Sequencing results (i.e. GWAS using SNP markers) in an important Mediterranean aquaculture species. Moreover, the combination of the novel loci, presented in the results, may lead to the selection of brooders based on specific genetic signatures and demonstrate the feasibility of Genomic Selection (GS), a selection method that can have a great effect on the efficiency of the aquaculture.

Introduction

In the era of next generation sequencing, new genomes are being sequenced and published in an unprecedented pace. However, sequencing a genome using solely short reads in high depth has limited the contiguity of newly built genomes leading mostly to draft assemblies comprised of thousands short contigs. This drawback is being tackled by employing long read technologies that can be used to fill the gaps and lead to high quality chromosome-level assemblies. Here, we have focused on the two most significant fish members of Mediterranean aquaculture, the Gilthead seabream (*Sparus aurata*) and the European seabass (*Dicentrarchus labrax*). Both species have been sequenced at a draft assembly level. The first genome draft for sea bass has been released in 2014 (Tine et al.), while a seabream draft genome was produced in 2018 (Pauletto et al.). In either case, the assembly quality is not sufficient to have large contiguous chromosome-level scaffolds, which is essential for spatial organization of genes, SNPs identification, and mapping of SNPs obtained through genotyping-by-sequencing.

Materials & Methods

DNA was extracted with a Qiagen QIAamp mini kit from fresh blood from one seabream and one seabass individual. Size was estimated by gel electrophoresis in a low-percentage megabase agarose at a low voltage. Standard ONT library preparation protocol was followed. The DNA was sheared only in a few runs to increase the quantity of reads obtained, while when not sheared the reads obtained had greater length. Then, six flow cells were run on a MinION machine for seabream and four for seabass. All runs have been base-called with Albacore v233 (https://github.com/dvera/albacore) on IMBBC, HCMR high performance computing platform. Nanoplot (https://github.com/wdecoster/NanoPlot) was used to assess the basic statistics for each run.

Table 1. Sequencing statistics for gilthead seabream and European seabass. Filtered reads have a quality threshold of 7.

Seabream	Sequencing kit	shearing rpm	raw Gbases	>Q7 Gbases
Run1	108	6500	13.81	12.14
Run2	108	6000	9.87	8.94
Run3	108	6500	13.38	11.45
Run4	109	no	15.47	13.78
Run5	109	no	10.21	8.77
Run6	109	no	6.55	5.87
Sum			**69.28**	**60.95**
Seabass				
Run1	109	no	6.69	6.26
Run2	108	5200	19.299	17.10
Run3	109	no	11.596	10.81
Run4	109	no	8.340	7.86
Sum			**45.93**	**42.03**

(Continued on next page)

Results

We built a dataset of Oxford Nanopore sequencing for both focal species yielding a high coverage genomic resource. Especially for gilthead seabream, we obtained ~60Gb sequencing throughput leading to >60x coverage of the genome (Table 1). For European seabass we obtained 42Gb leading to >40x coverage of the genome respectively (Table 1).

Conclusions

The long reads produced will be used to produce an improved genome assembly for both species leading to an improved gene annotation, SNP discovery, QTL mapping. This development will allow a better genomic selection and selective breeding programmes for the two species, ultimately developing the Mediterranean aquaculture sector.

Introduction

The limited and variable shelf life of chilled fish, mainly due to bacterial activity, is a major problem for their quality assurance and commercial viability. Modified atmosphere packaging (MAP) can effectively alter and delay the spoilage process and extend the shelf life of fresh fish (Tsironi and Taoukis, 2018). CO_2 inhibits the development of the respiratory organisms like *Pseudomonas* spp. and *Shewanella putrefaciens*. Despite the increasing importance of MAP technology in fish industry and the several studies evaluating the effect of MAP on fish products, a limited number of predictive models for quality deterioration and shelf life have been proposed, including the combined effect of temperature and gas concentration in the packaging environment (Koutsoumanis et al., 2000). An Arrhenius-type model has been developed by Tsironi et al. (2011) as an effective tool for predicting gilthead seabream (*Sparus aurata*) fillet quality and shelf life under different chilled storage temperatures (0-15°C) and modified atmospheres (20-80% CO_2) and its applicability has been validated in the real cold chain. On the other hand, a disadvantage of ordinary MAP is its demand for high gas to product volume ratio. Increased concentration of CO_2 in the headspace and high gas to product volume ratio may result in increased dissolution of CO_2 in the fish flesh, due to a higher partial pressure of CO_2 (Devlieghere et al., 1998). Optimal gas mixture depends on the type of the packed food.

The objective of the study was to select appropriate MAP parameters for farmed gilthead seabream and European sea bass and to develop predictive models for quality deterioration and shelf life of chilled MAP fish

Materials and methods

Whole, gutted, gilthead sea bream (*Sparus aurata*) and European sea bass (*Dicentrarchus labrax)* packed under modified atmospheres ($40\%CO_2/40\%N_2/20\%O_2$) were provided by Selonda S.A. Two alternative packaging types were tested, i.e. 1-3 specimens/package, corresponding to different levels of gas to product volume ratio in the package headspace. Samples were stored at controlled isothermal conditions in the refrigerated range (0-10°C) in high-precision (±0.2°C) low-temperature incubators (Sanyo MIR 153, Sanyo Electric, Ora-Gun, Gunma, Japan) for shelf life evaluation. Temperature in the incubators was constantly monitored with electronic, programmable miniature data-loggers (COX TRACER®, Belmont, NC). The composition of the headspace of package was measured using CheckMate 9900 O_2/CO_2 (PBI Dansensor, Ringsted, Denmark) gas analyzer. Quality assessment of fish was based on microbiological analysis (total viable count, *Pseudomonas* spp., lactobacilli, *Enterobacteriaceae* spp. and H_2S-producing bacteria), pH and sensory scoring. Samples were taken at appropriate time intervals to allow for efficient kinetic analysis of quality deterioration. Values of the different measured indices were plotted versus time for all temperatures studied and the apparent order of quality loss was determined based on the least square statistical fit. The experimental data for microbial growth were fitted to the Baranyi model (Baranyi and Roberts, 1995), using DMfit software of IFR (Institute of Food Research, Reading, UK), and the kinetic parameters of microbial growth were estimated (maximal growth rate, k and lag phase duration, lag). Temperature dependence of the deterioration rate constants, k, was modelled by the Arrhenius equation (Taoukis et al., 1997).

Results

CO_2 concentration in the package headspace decreased during the initial hours of storage (up to final CO_2 level of 20%), which was related to CO_2 dissolution in the fish flesh, especially at the lower gas to product volume ratios. Afterwards, $\%CO_2$ level increased, due to metabolic activity of spoilage bacteria, reaching highest levels at the end of storage period. With regards to O_2 concentration, it showed a descending trend, while at the end of shelf life O_2 concentration exhibited zero levels, which was related to increased microbial population of total viable counts. Shelf life estimation of MAP fish was performed based on the correlation of microbial load of total viable counts and the sensory evaluation of the samples. At all studied conditions, the time of sensory rejection coincided with an average total viable count of 10^7 cfu/g. The developed mathematical models were adapted into user friendly worksheets that allow the prediction of microbial

(Continued on next page)

growth and shelf life of gutted gilthead sea bream and European sea bass packed in MA and stored under different time-temperature conditions. It is apparent that the selection of optimal MAP parameters (i.e. initial headspace gas composition and gas to product volume ratio) is a complex issue and is a very important step in the design of MAP systems for fish products. Selection depends on the effect on microbial growth, desired food quality and shelf life, as well as the appearance of a package. CO_2 emitters, which produce CO_2 in contact with water that is obtained from liquid leaking from the fish flesh may enable reduced gas to product volume ratios in MAP fish and further increase shelf life.

Discussion and conclusion

Since shelf life extension of MAP fish requires in pack CO_2 concentration maintenance, a smart label monitoring CO_2 levels in package headspace would ensure this. The combined use of the developed shelf life models with an indicator with function of CO_2 detection and a Time Temperature Indicator (TTI) would provide useful information on the probability of the quality deterioration of packed fish, allowing better management and optimization of the cold chain from manufacture to consumption.

QUALITY ENHANCEMENT AND SHELF LIFE EXTENSION OF FRESH MEDITERANNEAN FISH BY NONTHERMAL AND MINIMAL PROCESSING

Theofania Tsironi*, Ioanna Semenoglou, Dimitris Machairas, Athina Ntzimani, George Dimopoulos, Petros Taoukis

Laboratory of Food Chemistry and Technology, School of Chemical Engineering, National Technical University of Athens, Greece

Introduction

Fish begins to spoil immediately after it has been harvested, caused by rapid rigor mortis, enzyme activity and bacteria. Fish preservation methods are mostly based on storage temperature decrease, i.e. refrigerated ice storage in the range 0 to 4°C, super-chilled storage in the range -4 to 0°C and frozen storage at -18°C. The development of new fish processing and packaging methods or novel combinations of existing technologies is sought by the industry in the pursuit of producing alternative products, achieving shelf life extension, and management and reducing food waste (Taoukis and Tsironi, 2013). The advantages of nonthermal processing over classical thermal methods include the better retention of nutritional and sensory properties. Several studies have been conducted recently on the efficacy of washing and sanitizing treatments in reducing microbial populations on food products (Gil et al., 2009; Thi et al., 2015). Osmotic dehydration (OD) is a technique used to reduce water activity (a_w) in foods in order to improve nutritional, sensorial and functional properties of food. It consists of an immersion of the product into a concentrated solution (i.e. sugar, salt, sucralose etc.). By reducing the water activity of the food matrix, microbial growth is reduced or inhibited. Additionally, processing in concentrated aqueous solutions can decrease the microbial load due to decontamination induced by high solute concentrations at the product/solution interface. Pulsed electric fields (PEF) treatment is a novel nonthermal processing technique which has the potential to alleviate the need for thermal processing of foods. PEF involves the application of high-voltage pulses to electroconductive foods which are placed between the electrodes. The resultant electric field induces movements of ions and permeabilization of cell membranes called electroporation (Tsironi and Taoukis, 2019).

The objective of the study was to investigate the effect of nonthermal i.e. osmotic dehydration (OD), pulsed electric fields (PEF), and minimal processing methods (i.e. surface decontamination of fish) on the quality and shelf life of farmed gilthead seabream and European sea bass during refrigerated storage.

Materials and methods

Gilthead seabream (*Sparus aurata*) and European sea bass (*Dicentrarchus labrax*) were treated using OD or PEF (Elcrack-5kW, DIL, Germany) as alternative approaches to the conventional post-harvest fish processing methods The incorporation of natural organic acids (i.e. lactic acid, citric acid) at different concentrations in the washing water was also tested for its efficacy to reduce initial microbial load and prolong shelf life. Untreated (Control) and samples treated with the alternative methods were stored under controlled isothermal and variable conditions (0-15°C). Samples were taken in appropriate time intervals to allow for efficient kinetic analysis of quality deterioration. Quality assessment was based on microbiological analysis (total viable count, *Pseudomonas* spp., *Enterobacteriaceae* spp., lactic acid bacteria, etc.), chemical quality indices (pH, lipid oxidation, total volatile basic nitrogen), colour and texture measurement and sensory scoring.

The microbial growth was modeled using the Baranyi Growth Model (Baranyi and Roberts, 1995). For curve fitting the program DMFit was used (available at http://www.combase.cc/index.php/en/). Kinetic parameters such as the rate (k) of the microbial growth were estimated. Values of the different measured indices were plotted vs time for all temperatures studied and the apparent order of quality loss was determined based on the least square statistical fit. Temperature-dependence of the deterioration rate, k, was modeled by the Arrhenius equation (Taoukis et al., 1997).

Results

The results of the study indicated that the application of OD led to improved quality stability during subsequent refrigerated storage in terms of microbial growth, physicochemical and organoleptic degradation of the fillets and significant shelf life extension of fish (7 days and up to 18 days for untreated and osmo-treated samples at 5°C, respectively). PEF did not affect significantly the initial microbial load, flesh quality and shelf life of fish fillets. Initial surface decontamination up to 1.5 logcfu/g by the addition of organic acids in the washing water resulted in 2-3 days shelf life extension of fish fillets at 0°C. At all temperatures studied, the time of sensory rejection coincided with a *Pseudomonas* spp. level of 10^7 cfu/g for whole fish and 1 ^{6} cfu/g for fillets

(Continued on next page)

Discussion and conclusion

The results of the study indicated that the application of nonthermal and minimal processing led to improved quality stability during subsequent refrigerated storage and significant shelf life extension, in terms of microbial growth, physicochemical and organoleptic degradation of the fillets

Introduction

Aquaponics is a closed-loop system which combines fish and plants production through recirculating aquaculture system (RAS) and hydroponics. In aquaponics, nutrients which are important for plant growth are often lower than hydroponics and several studies have shown that the addition of fertilizers in aquaponics, such as potassium (K) and iron (Fe) favors plant growth and yield (Delaide et al., 2016; Rafiee et al. 2019). Nevertheless, one of the main advantages of the aquaponics is nutrient recovery and re-use between the three components (i.e. fish, bacteria, plant), thus minimum external inputs would benefit the equilibrium as well as the environmental footprint of the system. This is a multifaceted issue since it depends on fish and plant species involved, stock density and system physicochemical parameters yet requires an extensive study of fish and plant physiology under the prevailing conditions. In regard to plants, the relevant literature is restricted to growth and yield evaluation. Although effective measures of the productivity potential of an aquaponic system, these are inadequate to describe alone the performance of the system when several variables change. Alternatively, the study of the functional responses of plants could address the above-described issues by identifying system constraints and indicating possible management practices. In this frame we investigated the functional responses of lettuce (*Lactuca sativa* L. var. Romana) and the growth of red tilapia (*Oreochromis* sp) in an aquaponic system when no fertilizers were applied in comparison with Fe and Fe+K addition.

Materials and Methods

The experiment took place at the University of Thessaly from March 1st to April 15th of 2019. It was conducted in three indoor aquaponic systems. Each system had the following characteristics: total water volume of 630l comprising of a fish tank (400l), mechanical and biomechanical filte , water pump, media bed (clay) hydroponic unit of 1m^2 (50l), air pump to oxygenate the water and one HPS light bulb 600W over each grow-bed (PAR 450-500μmol m^{-2} sec^{-1}; photoperiod 10L:14D). Thirty red tilapias were placed in each fish tank and after 10-day acclimatization, they were weighed and that was considered the initial weight of the experiment. The same day eight 15-day-old plants were placed in each grow-bed. Fishes were fed twice a day (10:00 and 16:00) *ad libitum* for thirty minutes with commercial fish food of 47% protein content. The food was weighed before and after each meal and the daily amount administered was calculated. Each system comprised a treatment, thus 3 treatments were realized: a) control (C), where no fertilizer was added, b) Fe, where only Fe was added in Fe-DTPA form in order to reach the target water concentration set by hydroponics practice for lettuce (i.e. 40umol L^{-1}, Sonneveld and Straver (1994)) and c) Fe+K, where Fe was added as in the previous treatment along with K in K_2SO_4 form (10mmol l^{-1}). During the experimental period pH was measured on a daily basis, photosynthesis (Li-Cor 6400XT, Li-Cor Inc.) and chlorophyll a *in vivo* fluorescence (as an early indicator of stress, Handy-PEA, Hansatech) on a weekly basis and fish body weight on biweekly basis. The experiment lasted for 45 days and at the final harvest, various plant growth parameters were measured (leaves and roots fresh weight, leaf area, biomass) and the final weight of the fishes was recorded.

Results

pH showed a downward trend in all three systems. In order to keep pH constant and with-in tolerance limits of fish, water changes were performed and almost half of the water volume (300l) was changed in each system. The mean value of pH of the whole experimental period was 7.22, 7.10 and 7.12 for C, Fe+K and Fe treatment respectively. Initial and final weights of fishes did not show statistically significant differences between treatments, while no mortality was evident. Tilapias had an initial average weight of about 16 grams and reached about 60 grams, exhibiting a specific growth rate (SGR%/day) of 2.68, 2.98 and 2.81%/day for C, Fe+K and Fe groups respectively. The daily amount of fish food supplied was almost equal between groups and ranged from 19 to 22g/day. At the last days of the experiment, the fishes in the control tank were reproduced, while eggs were observed in female's mouth in the Fe+K treatment.

(Continued on next page)

Statistically significant differences in plant growth were observed between treatments. Plants treated with Fe+K had an average fresh weight of 493g while 250g and 220g were measured in the Fe group and control respectively. In total, 3.9kg of lettuce was produced in the Fe+K treatment, while 2kg in the Fe and 1.7 kg in the control group. The same pattern appeared in the roots, leaf area and biomass.

Discussion and conclusion

The downward trend of pH reflects a robust nitrification process which produces acid according to Rakocy et al. (2004) who reported a daily pH decrease in their aquaponic system. Consistent with ours are the results of Rafiee et al. (2018) as they observed a decrease in pH (below 6) mainly in the first 4 weeks. Delaide et al. (2016) compared the effects of aquaponic solution (AP) and complemented aquaponic (CAP) in which several nutrients were added. Their principal finding was that CAP solution promoted shoots and roots growth outperforming AP, which is in agreement with the results of the present experiment.

The results of the present study highlight the beneficial effect of the addition of Fe+K on lettuce growth in a small-scale aquaponic system, in comparison with no external inputs. Ongoing analysis of photosynthesis and fluorescence parameters will shed light into the functional responses of the photosynthetic apparatus to the various treatments and contribute to the identification of the constraints imposed by the system as they were reflected in the control treatmen

Introduction

Yearly fish production in Czechia fluctuates between 20,4 – 21,0 thousand tons per year (Ženíšková et al., 2017) with majority of the production originating from ponds covering an area of 52 000 ha (Adámek et al., 2012). Since aquaponics technologically consists of a recirculating aquaculture system (RAS) and hydroponic system, succesful introduction of aquaponics on the market may be dependent on functionality and establishment of RAS and hydroponics. Estimated annual production from RAS in Czechia is around 500 t (Kouřil et al., 2015). There are only five large hydroponic farms specializing in tomato production (ČT, 2018). Our research question was if there are functioning, profitable aquaponic businesses in Czechia. The minor part of our research was related to the status of organic aquaponics in Europe.

Materials and methods

For carrying out the national survey, we have used a questionnaire for aquaponics entrepreneurs according to Love et al. (2014). To find relevant respondents, online desktop research was carried out using the Google Search engine set up for Czech interface. We entered the following keywords in Czech language: "akvaponie" [aquaponics]; "akvaponické systémy"[aquaponics system]; "akvaponická farma"[aquaponics farm]. The search was done on 25. 6. 2019. Obtained results from Google search were sorted into four categories: Producers, Services, Media and Blogs, Education. Respondents in category Producers were chosen for the questionnaire survey. Producers were further size-classified according to Palm et al. (2018). Questionnaires were filled in person. Organic certification possibilities were reviewed using EU Commission legislation for the organic sector. Additionally, results were consulted with relevant stakeholders at the Ministry of Agriculture of the Czech Republic.

Results

We found 117 results, from which only four were producers (3 %). The major category was media and blogs (69 %), followed by service providers (24 %) and education (4 %).

Two large-scale commercial farms, one intermediate system and one domestic, however commercial system were found. The only intermediate system was profitable in the last 12 months, as the only respondent incorporating also non-production related services. This respondent is also the only services provider who has built commercial-scale aquaponics in Czechia. The largest system in Czechia has a 215 m^3 volume in the aquaculture part of the system and 1 000 m^2 of plant area. The farm has reached the production of 3 t of fish and 226 kg of plants. The profitability in this enterprise is expected in the next 12 months.

(Continued on next page)

According to EU Commission legislation Section 3, Article 25g of EU regulation 710/2009 recirculating aquaculture cannot be certified as organic food production, citing "**Closed recirculation aquaculture animal production facilities are prohibited**". To certify plant production as organic, plants must be grown in soil. Therefore **hydroponic production is prohibited** (EU regulation 2018/848 on organic production and labelling of organic products and repealing Council Regulation (EC) No 834/2007, Annex II, Part I, paragraph1.2).

Discussion and conclusion

From 117 results only one was a commercial aquaponics producer (and yet not-profitable), suggesting "media bubble" around aquaponics and it´s attractiveness. Other farms had negligible production. Villaroel et al. (2016) only one respondent had production higher than 10 000 kg of fish per annum. Love et al. (2015) stated 9 respondents having higher production than 4 537 kg. **The system recorded in the presented study, now has in stock 17 000 t of fish, therefore could be considered as one of the biggest aquaponic systems in Europe.**

Following EU regulation 710/2009 and 2018/848 **aquaponics in Europe cannot be recognized as organic.** Without soil nutrition, we can talk of "plants on drips". However, in U.S. the USDA National Organic Standards Board has labelled aquaponics production in 2008 as organic (Miličić et al., 2017). Nowadays The Coalition for Sustainable Organics Center for Food Safety delivered a petition (<http://www.coalitionforsustainableorganics.org/>) to the U.S. Department of Agriculture to end organic certification of hydroponic and aquaponic production.

DEVELOPMENT OF BSC AND MSC FISHERIES AND AQUACULTURE DEGREE PROGRAMS IN MYANMAR

Kay Lwin Tun*, Kevin Fitzsimmons, Hillary Egna, Hendrik Stolz, Uwe Scholz, Peter Buri

Fisheries and Aquaculture, University of Yangon, Kamayut Township, 11041, Yangon, Myanmar
Email: (kaylwintun@gmail.com)

Myanmar is one of the top fifteen countries on fisheries and aquaculture production and it has considerable future aquaculture potential due to its geography and abundance of natural resources. However, traditional extensive farming methods are practiced and the production is generally low when it is compared to neighboring countries such as Thailand and Bangladesh. To improve the aquaculture sector in a sustainable way, one important obligation is to develop the capacity of human resources who have strong knowledge in aquaculture and fisheries. Therefore, universities and vocational training centres play an important role in support of developing a sustainable aquaculture and fisheries sector. Until 2013, specialization for fisheries and aquaculture had not been established in Universities in Myanmar. In most universities, syllabus regarding ichthyology is extremely limited and embedded in the Departments of Zoology.

In 2014, USAID's project 'Developing a Sustainable Seafood Industry Infrastructure in Myanmar' had been launched at University of Yangon (UY) to expand the capacity of higher education institutions in Myanmar to support the development of an intensive marine and inland fisheries sector. During the three years of the project, we developed a Seafood Safety Laboratory in UY. That laboratory has been established not only as a teaching and research laboratory, but also for training and laboratory service for faculty, students and farmers. More than 450 faculty members and students from 44 universities have been trained. A total of 12 faculty members and students have been supported to attend short-term training in Bogor Agricultural University (Indonesia), Cantho University (Vietnam), Nong Lam University (Vietnam), Universiti Tunku Abdul Rahman (Malaysia), and the Tamil Nadu Fisheries University (India). Through the USAID project, we were able to select the human resources who can conduct the fisheries and aquaculture education in universities across Myanma .

In 2015, the Dutch public-private capacity building (Knowledge to Knowledge or K2K) program provided short-term trainings to selected faculty members of Department of Zoology on how to develope competency-based curriculum for MSc Aquaculture based on the stakeholder needs. The faculty members were taught how to collect the needs of stakeholders, how to develop the job profiles based on the needs and how to develop the courses

In 2017, according to the country needs, Ministry of Education and Ministry of Agriculture, Livestock and Irrigation selected UY to establish a new undergraduate study program for Bachelor of Science (BSc) in Fisheries and Aquaculture within the Academic Year 2018. This is the first Fisheries and Aquaculture program in tertiary education in the country.

Based on the needs of Government and private sector, Deutsche Gesellschaft für international Zusammenarbeit (GIZ) launched the 'Myanmar Sustainable Aquaculture Programme (MYSAP)'. Main targets of MYSAP in education sectors are the promotion of vocational and university education and strengthening universities' research capacities. Thus, it supports the development and establishment of a Bachelor of Science (BSc) and a Master of Science (MSc) degree curriculum in Fisheries and Aquaculture. Within the 4 years implementation phase (2018-2021), the programme has assisted a series of workshops for selected faculty members from seven universities to facilitate fisheries and aquaculture bachelor and master degree classes. MYSAP has invited international experts to develop the competency based curriculum together with faculty members from UY, staff from Department of Fisheries (Ministry of Agriculture, Livestock and Irrigation) as well as the private sector, on both, local and international levels. Furthermore, the programme assists to establish national research networks and to connect to international aquaculture as well as education networks such as ASEAN Fisheries Education Network.

MYSAP equipped the teaching facilities such as two classrooms, three laboratories and the wastewater treatment system for the laboratories at the Yangon University Rearch Center. The private sector, Myanmar Fisheries Federation, has donated a fully-equipped computer laboratory.

(Continued on next page)

In December 2018, the first bachelor degree program (BSc Fisheries and Aquaculture) was launched in University of Yangon with 40 students. The curriculum in the new courses have been based on competency which is divergent from our traditional teaching method and guarantees to improve the communication skills, lifelong learning activities, and presentation skills of the students. In addition to the laboratory trainings and field trips, various practical trainings opportunities and internships in cooperation with private sector like in hatcheries, on farms, and processing industry are included. The program has been selected as a model program in University of Yangon for the other departments to enhance the modification of traditional curriculum to competency-based curriculum.

Recently, application for the second intake of the bachelor degree program has been opened. The MSc Fisheries and Aquaculture program will be launched in 2020 academic year for the students who have graduated with in Zoology or Marine Science. In the near future, globally competent faculty and students from UY will coordinate research, teaching and service activity to develop the sustainable fisheries and aquaculture sectors in Myanma .

NUTRITIONAL PROGRAMMING OF LIPID-METABOLISM IN GILTHEAD SEA BREAM: TRANSGENERATIONAL EFFECTS OF BROODSTOCK SELECTION AND FEEDING

S. Turkmen*, H. Xu and M. Izquierdo

Aquaculture Research Group (GIA), Institute of Sustainable Aquaculture and Marine Ecosystems (ECOAQUA), Universidad de Las Palmas de Gran Canaria, Crta. Taliarte s/n, 35214 Telde, Spain

Introduction

Nutritional programming is described as the "events during critical or sensitive periods of development that may "program" long-term or life-time structure or function of the organism" (Lucas, 1998). The "nutritional programming" concept presumes that alterations of the environment during the early life stages of an organism affect its phenotype at later-life stages. Environmental changes during critical early periods, such as embryogenesis or early development (referred as developmental plasticity periods), provide a tool to the organism to forecast potential environmental challenges in later life and give the opportunity to adjust its metabolism for a better adaptation increasing its chances to survive and reproduce.

These adaptational changes can be used in favour to obtain individuals better adapted to the feeds used in animal production systems. In production systems, diets are formulated to supply the necessary nutritional components, selecting appropriate ingredients based on their nutritional characteristics, cost and availability. Thus, restrictions in the availability of a high-quality feedstuff lead to the search for alternative ingredients. Consequently, there has been an increasing interest in aquaculture to find out different ways to maximize the capacity of fish to use alternative sources in a species dependent manner. Recent studies in commercially important aquaculture species have been showed, nutritional programming may be a new novel strategy to create individuals have better capacity of using the alternative ingredients in feeds. In some marine fish species, complete replacement of fish oil (FO) is still a main challenge in aquaculture diets, due to their low ability to synthesize n-3 LC-PUFA and the lack of these fatty acids in vegetable oils (VO). For this reason, studies on nutritional programming have also aimed to increase marine fish capacity to utilize low n-3 LC-PUFA diets. This review summarizes the data obtained from six years and five different broodstock groups. The results include offspring growth gene expression on stress-related genes (Turkmen et al, 2019), lipid metabolism related genes (Izquierdo et al., 2015; Turkmen et al., 2017) and potential epigenetic mechanisms involved (Turkmen et al, submitted).

Materials and methods

Briefl , in each trial a nutritional stimulus was applied to the broodstock fish during the spawning period, at least for 1 month before seeding the eggs for rearing the progeny, in order to modify the egg fatty acid profiles. Those eggs obtained from differently fed broodstock groups were produced under the same conditions and fed commercial feeds and feeding protocols until the desired juvenile stage. Afterwards, juveniles were nutritionally challenged with low FM FO diets in order to test the performance of the offspring during the juvenile stage. In all studies, the gilthead sea bream used were produced and reared in different facilities of the EcoAqua Institute (Telde, Canary Islands, Spain). A general schematic presentation of the experimental design showed in Figure 1.

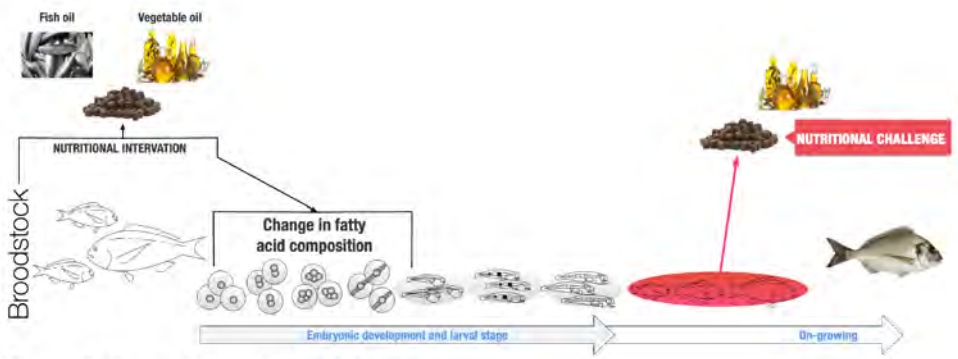

Figure 1. General experimental design

(Continued on next page)

Results and discussion

FO replacement by VO equal or higher than 80% in gilthead seabream broodstock diets may have negative consequences for spawn quality, larval growth and even juveniles. Thus, FO replacement by LO up to 80–100% in broodstock diets for gilthead sea bream not only markedly reduce fecundity and spawn quality, but also the size of 45 days after hatch (dah) and 4-month-old juveniles, as well as the *fads2* expression in larvae. On the contrary, 60% replacement of FO by VO, leading to a reduction in LC-PUFA and an increase in the LA and ALA precursors, did not negatively affected offspring production, demonstrating the interesting potential of early nutritional programming of marine fish by broodstock feeding to improve long-term performance of the progeny. Parental feeding with FO replacement by VO induced long-term changes in PUFA metabolism, leading to an increased production of PUFA and the up-regulation of *fads2* expression, affecting also the expression of other lipid metabolism related genes. For instance, replacement of FO with LO in parental diets affected offspring transcription of *lpl*, *cpt1* and *elov6*, genes related to regulation of energy metabolism in liver, allowing a better utilization of diets high in VO and VM. The persistent long-term effect of nutritional programming of gilthead sea bream through broodstock feeding and the efficiency of feeding a 'reminder' diet during juvenile stages to improve utilization of low-FM/FO diets.

Selection of gilthead sea bream broodstock with high *fads2* expression when fed a low FM and FO diet produces offspring that performs better, even when they are challenged with a low FM and FO diet. Besides, selection of high *fads2* broodstock induced regulation of genes such as *elovl6* and *cpt1* in juvenile stage if challenged with a very low FM FO diet. The results showed that methylation of CpG islands in the *fads2* promotor, particularly in positions CpG2 and CpG3, are among the potential epigenetic mechanisms for regulation of gene expression in nutritionally programmed fish

Introduction

Mortality and skeletal anomalies in cultured marine fish larvae are among the major drawbacks in hatcheries to produce high quality juveniles at more effective production costs. Nutritional unbalances regarding micronutrients may be partly responsible of these losses due to the scarce knowledge available regarding the optimum levels of these nutrients on larval diets. Vitamin D is a fat-soluble micronutrient that has various functions in bone development, calcium absorption, mineralization and cellular proliferation. Vitamin D_3 (cholecalciferol) is the most active form, which gets hydroxylased in liver of fish to form 1,25(OH)D3 (calcitriol) to bind Vitamin D receptors. Unfortunately, information regarding optimum dietary Vitamin D levels in diets for gilthead sea bream larvae is very scarce. Hence, considering this research gap, the main aim of the present study was to evaluate the effect of several levels of Vitamin D_3 in practical microdiets on survival and skeletal development of gilthead sea bream larvae.

Materials and Methods

Diets: Four different isoenergetic and isonitrogenous supplemental diets were formulated with a varying level of Vitamin D_3 such as 0IU (D1), 1500IU (D2), 2000IU (D3) and 20000IU/Kg (D4) of diet. *Fish and experimental conditions:* 2100 gilthead sea bream larvae obtained from one single spawn from the GIA-Ecoaqua Progensa fast growing selected broodstock were randomly distributed into twelve 170L circular tanks. Initial (26 day post hatching (dph)) mean total length 8.84 ± 0.86 mm; body weight 0.86 ± 0.83 mg (mean ± s.d). *Sampling:* Growth was monitored by measuring the total length (TL) and weight of larvae for every 8 days interval. Daily mortality was monitored and at the end of the study (47 dph) all the live larvae were counted and sampled for TL, weight, histology, whole mount stain, gene expression, Thiobarbituric Acid Reactive Substances (TBARS) and High Performance Liquid Chromatography (HPLC). *Statistics:* All data were tested for normality and homogeneity of variances and means compared by Tukey test ($P < 0.05$).

Figure 1: Final biomass of gilthead sea bream larvae fed diets with different level of vitamin D_3

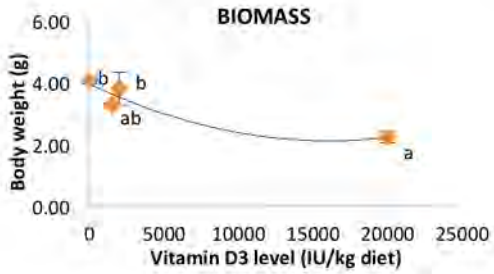

Figure 2: Mortality rate of gilthead sea bream larvae fed diets with different level of vitamin D_3 for 21 days

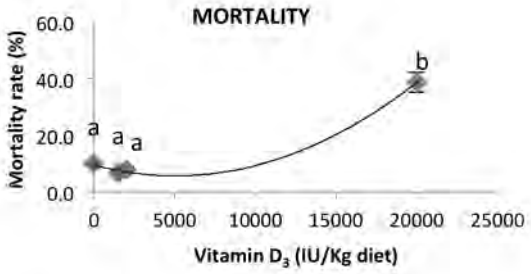

(Continued on next page)

Results

After 20 days of feeding the experimental diet there was a dropping mortality found in larvae fed the highest level of Vitamin D_3 (D4) that lasted until the end of the trial and reduced survival rate. However, larvae fed with other levels of Vitamin D_3 showed no significant differences in length, weight and survival. The final biomass (Fig. 1) and daily mortality rate (Fig. 2) of each treatment were calculated and it shows significant difference in D4 with other treatments. A high incidence of skeletal anomalies was observed in fish fed diet D4. Biochemical and molecular studies are being conducted to further understand the physiological mechanisms involved.

Discussion and conclusion

Despite the importance of feeding marine fish larvae with formulated inert microdiets to substitute rotifers and artemia (Kolkovski *et al*., 2009), the optimum nutrient contents of these diets have been only determined for few nutrients (Hamre *et al*., 2013). Paticularly, there is an almost complete lack of studies aiming to determine the optimum dietary levels of vitamin D in microdiets for marine fish larvae. Besides, there is a large variation in the nutrient composition of commercial rotifer diets and a resulting large variation in the nutrient composition of rotifers fed to marine fish larvae at an industrial scale (Hamre, 2016). Our study has shown that the highest larval biomass is obtained with a diet not supplemented with vit D_3 suggesting that the basal levels were sufficient to fulfil the vit D requirements of gilthead sea bream larvae. However, supplementation with vit D_3 up to 20,000 IU/Kg diet lead to high mortalities and skeletal anomalies. These results are in agreement with the higher incidence of skeletal anomalies found in Japanese flounder larvae fed over 20,000 IU supplemented as vitamin D_3 (Haga et al., 2004). The results also agree with the higher incidence of skeletal anomalies found in european seabass fed over 40,000 IU (Darias et al., 2010), although the levels were double than those supplemented in the present study. Vitamin D_3 level in rotifers enrichment diets markedly differ for different marine fish hatcheries and ranges from 2.8 IU to 15200 IU/kg (Hamre, 2016), which is extremely higher than the requirements stablished for juvenile fish (NRC, 2011). Hence, the present study has shown that increase in Vitamin D_3 supplementation up to 2000 IU/kg of diet has no significant effects on growth and survival. But the highest level of supplemented Vitamin D_3 (20000 IU/kg of diet) reduced final survival and total biomass, indicating a potential toxicity in gilthead sea bream larvae. Further analyses are being undergone to understand the effects of vitamin D_3 supplementation.

CLEANER FISH BEHAVIOUR IN FULL SCALE SALMON PRODUCTON UNITS – AN ACOUSTIC TELEMETRY APPROACH

J. B. Ulvund*, T. Kristensen, H. A. Urke & J. A. Alfredsen

Faculty of Biosciences and Aquaculture, Nord University (Norway)
*E-mail: john.b.ulvund@nord.no

Introduction

In order to control the infection level of the parasitic sea louse, *Lepeophteirus salmonis* (Krøyer, 1873) in aquaculture production of Atlantic salmon (*Salmo salar*), cleaner fish, and especially lumpfish (*Cyclopterus lumpus*), have seen an exponentially growth in productions numbers over the last few years (McVicar, 2004; Krkosek et al 2005; 2006; Imsland, at al 2014). In Norway a total of 27 038 000 lumpfish were used for combatting sea-lice in 2017, amounting to a first hand investment cost of approx. €50 mill. (www.fiskeridi .no). Lumpfish are a relatively new species in aquaculture. Nevertheless, as for all species in aquaculture, preservation of good animal welfare through fulfillment of the requirements of the animal welfare act must be ensured. New knowledge on all aspects of the fish biology and requirements must be established when introducing a new species in commercial-scale production. The objectives of this study were to conduct behavioral studies of lumpfish to assess their performance and welfare in fully stocked industrial-scale salmon cages. The study also involved development and adaptation of an acoustic fish telemetry system to obtain observations of individual fish behavior in a challenging environment

Material and methods

The study was performed in a commercial salmon farming site in Norway (64° 36.165' N: 10° 51.220' E, Kråkholmen, Bjørøya AS) using standard circular production cages (circumference: 160m; depth: 15 – 20m). Implantation of acoustic tags in six lumpfish followed a well-documented surgical protocol described e.g. in Mulcahy (2003) and Urke et al. (2011).

The fish horizontal position was obtained by using GNSS time-synchronized acoustic receivers and employing time difference of arrival (TDoA) calculations to signals received in parallel on three receivers placed in known locations along the fish cage perimeter (Fang, 1990). Fish swimming depth was determined by a pressure sensor embedded in the tag with its measurements conveyed through digital modulation of the acoustic signals. Benchmarking using test tags at known locations demonstrated a typical positioning accuracy of 1.1m. Fig 1. shows an example of the data output by the fish positioning system.

Results

Data on lumpfish spatial behaviour were collected from a commercially stocked salmon production cage from early November until late December 2016. No fish died or showed signs of unnatural behaviour caused by the surgical implantation and handling. Cleaner fish hides were deployed over the north, west and south sides of the sea cage during the period, and there was a strong correlation between the individual fish preferred location and the locations of the hides (Fig 2.). Moreover, of a total of 16 357 positions acquired during the study, 95% remained closer than seven meter from the net wall, indicating a tendency of the lumpfish to reside close to the sea cage perimeter and almost never dwell in the central parts of the cage. The observations also showed that lumpfish were inclined to occupy the north-western areas of the cage. This specific aquaculture site has a dominating northerly current direction, which may contribute to the observed distribution of the fish

Discussion

Results confirm the lumpfish preference of hides, staying almost 50% of the time at rest at the same depth within the hide locations. The clear tendency towards fish detections in the northern and western areas suggests that tide and currents may have a strong impact on the overall distribution of lumpfish in sea cages. The results indicate the importance of cleaner fish hides for lumpfish and emphasise the need for further investigations on lumpfish behaviour to assess its efficiency as a sea lice relief strategy and to secure animal welfare in aquaculture.

(Continued on next page)

IMPROVING PROTEIN NUTRITION STATUS THROUGH FISH CONSUMPTION: AN ASSESSMENT OF KNOWLEDGE, ATTITUDE AND PRACTICES OF LOW INCOME EARNERS IN NIGERIA

B. I. UNEKE

Dept of Applied Biology, Faculty of Science, Ebonyi State University, Abakaliki (Nigeria)

Introduction

Fish is among the healthiest foods on the planet which is packed with important nutrients, such as protein, vitamin D and omega-3 fatty acids, which are highly important for human body and brain (Ruxton *et al*., 2004). Fish is generally considered to be among the best foods to eat for a healthy heart. Studies have shown that people who eat fish regularly seem to have a lower risk of heart attacks, strokes and death from heart disease (Buscemi *et al*., 2014). Therefore this research seeks to generate scientific information that will inform policy for improvement of nutrition among low income earners by determining of the knowledge of the target population concerning fish based nutrition, evaluating the attitudes and assessing the practices of target population regarding fish consumption

Materials and methods

Seventy pieces of questionnaires were created based on the scientific information that will determine of the knowledge, evaluate the attitudes and assess the practices of target population regarding fish consumption. These questionnaires were distributed among the low income earners in the Abakaliki metropolis of Ebonyi state. The data collected via the questionnaires was analyzed using the methods developed at McMaster University Canada (Johnson and Lavis 2009). The main parameter measured was participants' perceptions of their own knowledge/understanding. The analysis is based on mean rating (MNR), median rating (MDR) and range. For instance the figures represent Likert rating scale of 1–5 points, where 1 point = grossly inadequate; 2 points = inadequate; 3 points = fairly adequate; and 4 points = adequate; and 5 points=very adequate.

Results

The outcome of the respondents' knowledge of fish nutritional value, individual attitude towards fish consumption and practices regarding fish consumption is presented in Table 1 below.

Discussion and Conclusion

This study indicated sufficient knowledge about the nutritional value of fish which is in agreement with an analysis of 20 studies involving hundreds of thousands of participants who indicated that eating approximately one to two 3-ounce servings of fatty fish (salmon, herring, mackerel, anchovies, or sardines) a week reduces the risk of dying from heart disease by 36 percent (Mozaffarian and Rimm (2006). However, there was insufficient knowledge on effort/policy of the government to improve fish availability for consumption. A positive attitude towards fish consumption was indicated and in line with the findings of FAO (2009) which stated that fish is still nutritionally important in many African countries as well as in Asia and Oceania and in other words, a large majority (73%) of the countries where fish is an important source of animal protein are poor and food deficient countries. Low frequency in consumption was in agreement with this statement by UNSCN (2009), that poor households have generally limited income for food consumption therefore they tend to prioritize certain food items to purchase. Also inadequate effort of the government to encourage small scale production to enhance local availability was indicated.

The most important factors responsible for low frequency in consumption and advocacy are availability, accessibility and affordability of fish for consumption. The effort and policy of the government will improve fish availability for consumption and the establishment of more government owned fish ponds /farms for fish production (aquaculture) will boost access to fish products for consumption. Policy makers in all related fisheries organisations should make policies that will make fish products more abundant and reachable for consumption by the poor masses.

Table 1: Scientific information that will inform policy for improvement of nutrition among low income earners.

Knowledge of fish nutritional value Question	Range	Median	Mean
1. To what extent can you rate your knowledge about nutritional value of fish?	1-5	4	3.81
2. How would describe your understanding about the cost of fish-based meal?	1-5	3	3.11
3. How would you describe your knowledge of preparation of fish-based meal?	1-5	4	3.50
4. How would describe your knowledge of the source of procurement of fish for consumption?	1-5	3	3.28
5. How would you describe your knowledge of the effort/policy the government to improve fish availability for consumption?	1-5	2	2.66
Attitude towards fish consumption Question			
1. How would you describe your willingness to eat fish-based meal as main source of protein?	1-5	4	3.98
2. How would you describe your willingness to buy fish at present cost for consumption instead of other animal sources of protein?	1-5	4	3.58
3. How would you describe your willingness to support the effort/policy of the government to make fish available for the population?	1-5	4	3.50
Practices regarding fish consumption Question			
1. How would you describe the frequency of your fish consumption?	1-5	3	3.01
2. How would you describe the frequency of use of fish for your meal preparation?	2-5	3	3.39
3. How would you describe the effort of the government to encourage small scale production to enhance local availability?	1-5	2	2.80
4. How would you describe the frequency of your advocacy for fish consumption?	1-5	3	3.16

Introduction

The main aim of „Development of a new risk management model system for increasing water and food safety in fish production line", or so called „HappyFish" project, supported by the National Research, Development and Innovation office is to understand and define the criteria of good quality fishmeat and to recommend limits for further legislative regulations. These unfortunately are missing in the case of fish products.

Traditionally, pond aquaculture is done in earthen ponds, and producers have very limited information about the quality and complexity of the soil of the ponds (mud, sediment, soil) or the quality parameters of the producing medium, the water. The majority of the produced fish is carp (close to 85%), and its meat quality (texture and taste) depends greatly on the production technology, and the water and soil parameters.

Materials and methods

The project is halfway through, and here are the main statements:
More than 400 pesticides and 100 medicine residues have been tested in the waters of fish ponds, in the water, in the sediments and in the fishmeat
The most frequent and highest concentration of pesticide in fish pond water and sediment is glyphosate, but its concentration – where there is existing regulation – is always below the limit in the sediment;
Almost every fish sample and still the water samples contained traces of DDT: the metabolites (DDD, DDE) of this insecticide that has been banned for half a century are still present in the ecosystem;
There are no determined limits for the majority of pesticides and medicine residues found in concentration near detection limits in pond water and fish meat
The controlled environment and technologies applied in fish ponds – the removal of mud, among others – may contribute to maintaining the self-cleaning abilities of the fish ponds and to avoid pesticides and medicine residues posing a threat to the ecosystem and to human health.

Results

The results of the project support the expectations of producers and consumers that fish is a healthy and saf product. The further tests will examine this area in an even wider range, with deeper analyses and with more high-tech technology.

Introduction

Research for natural alternatives of currently used synthetic antioxidants have been and are a major topic in the food industry. As a rich source of carotenoids, vitamins, and phenols, microalgae could provide novel and food-grade approved antioxidant molecules with the potential in the prevention of lipid peroxidation and extending shelf-life of food products (Goiris et al., 2012). The value of target compounds obtained from microalgae could easily be enhanced by their relatively fast and easy growth, high yields, use of low quality (waste)water, CO_2 consumption and possibilities of future genetic improvements. However, insufficient knowledge and limited reports concerning the relationship between microalgae phenolic content and antioxidant activity is still a barrier in understanding their metabolism and implementation, using them as an alternative for current large-scale industries and making them economically viable. Further research in the future must be made to provide solutions for sustainable microalgae industry. The main objective of this study was to determine the antioxidant activity of marine and freshwater microalgae extracts, depending on their water content and used extraction solvents.

Materials and methods

Microalgae *Dunaliella tertiolecta* and *Chlorella kessleri* were cultured in f/2 enriched seawater medium (Guillard and Ryther, 1962) and Bold's Basal Medium (Bischoft and Bold, 1963), respectively, in batch bioprocess, under constant illumination of $6.5x10^3$lux, linear shaking 100rpm and 25°C. After 20 days, cultures were harvested and extraction was performed using two solvents, distilled water, and methanol, in a bead beading homogenizer for 3min, $1.5x10^4$rpm for both wet and dry biomass samples (dried at 70°C until constant mass). Obtained extracts were centrifuged and supernatants were used for further analysis. Total phenolic content in microalgae extracts was determined using the Folin-Ciocalteu (FC) method according to Singleton and Rossi (1965). Absorbance was measured at 750nm and results were expressed in gallic acid equivalents (GAE) per 1g of biomass. The ability of the extract to prevent the bleaching of β-carotene was determined according to the β-carotene linoleic acid assay (BCLAA) (Koleva et al., 2002).

Results

All of the *D. tertiolecta* extracts showed similar total phenolic content in mg of gallic acid equivalents (GAE) per 1g of biomass as can be seen in Figure 1. *C. kessleri* dry biomass extracts showed higher total phenolic content in comparison to their wet biomass extracts. Higher β-carotene preservation rate was obtained for wet *C. kessleri* biomass water extracts (76.35%) in comparison to their dry biomass extracts (71.38%). Conversely, for methanol extracts a higher percentage of β-carotene preservation rate was observed in dry *C. kessleri* biomass in comparison to dry biomass extracts (92.01% vs. 81.30%). A similar pattern was obtained for *D. tertiolecta* water extracts (88.53% β-carotene preservation rate for wet extracts in comparison to 63.04% for dry extracts), and methanol extracts (72.08% β-carotene preservation rate for dry extracts in comparison to 63.04% for wet extracts).

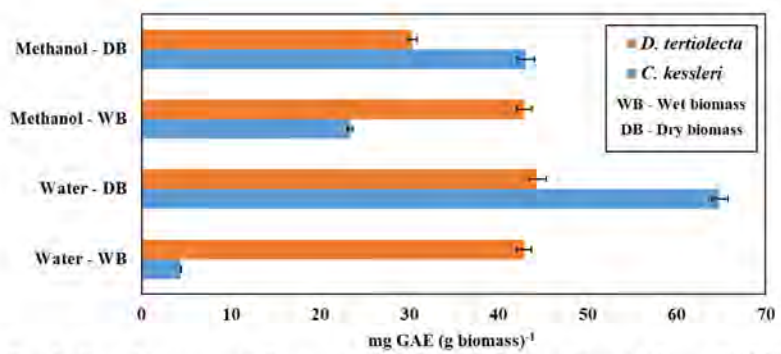

Fig.1. Total phenolic content of extracts in mg of gallic acid equivalents (GAE) per 1g of biomass depending on the microalgae biomass and used extraction solvent.

(Continued on next page)

Discussion and conclusion

Results obtained using FC method provided information of total phenolic content in different extracts. The results differ depending on the extraction conditions and microalgae morphology. *D. tertiolecta* is a cell wall lacking microalga in comparison to *C. kessleri* (Oukarroum et al., 2012). Since the cell wall is a strong mechanical structure it firstly has to be destroyed in order to provide a good extraction of microalga content. Obtained results for wet *C. kessleri* biomass had shown that extraction was time dependent, i.e. extraction was not long enough to break the cell wall and provide good extraction results. The drying process has induced the disruption of the cell wall of *C. kessleri* and enabled better extraction of total phenols. Using the BCLAA method, the oxidation of linoleic acid generates hydroperoxide free radicals which oxidize the highly unsaturated β-carotene and causes loss of colour. Oxidation of β-carotene by hydroperoxides can be neutralized by the presence of antioxidants in extracts (Kumaran and Karunakaran, 2006). *C. kessleri* extracts in all cases had a higher β-carotene preservation rate then extracts obtained from *D. tertiolecta* and therefore a higher antioxidant capacity. Results obtained using BCLAA are in accordance with results of FC method for all tested extracts. Phenols contribute to the total antioxidant capacity of extracts and result in a higher β-carotene preservation rate.

Further studies should involve different extraction methods for the analysis of total phenols and their antioxidant activity in different microalgae. The acquired data could provide a better understanding of metabolic processes and their secondary metabolites which could improve current industrial production and increase the yield of high-value products.

LOCALLY PROCESSED LAND ANIMAL BY-PRODUCTS AS POTENTIAL CANDIDATES TO REPLACE FISHMEAL AND FISH OIL IN PRACTICAL DIETS FOR EUROPEAN SEABASS

Introduction

The sustainability of European aquaculture, both economic and environmental, relies on the feed industry's ability to produce high quality diets able to respond to consumer's demand, at the most competitive prices, while respecting the environment. Moreover, the agro-food industry generates large amounts of by-products that after proper processing can be valid fishmeal and fish oil substitutes in aquafeeds. Using these locally generated by-products as feedstuffs would not only increase aquaculture sustainability, but also contribute to a functional circular economy by reintroducing such by-products into valued production chains. The ANIMAL4Aqua project aimed at the identification and valorization of processed land animal by-products to replace the traditional, unsustainable and expensive fishmeal and fish oil in diets for European seabass (*Dicentrarchus labrax*).

Materials and methods

Locally processed animal by-products were selected as candidates to replace fishmeal (FM) and fish oil (FO) in practical diets for seabass and characterized in terms of nutrient composition and availability: poultry by-product meal, steam and enzymatically hydrolyzed feather meal, FO from rendering fish by-products, poultry fat (PF) and mammal fat (MF, about 70% lard and 30% beef tallow), also from rendering by-products. The most promising by-products as protein or lipid sources were then incorporated in practical diets as FM or FO replacement, respectively, and evaluated in growth trials with seabass juveniles to establish the maximal level of replacement while assuring good growth performance, nutrient utilization and tissue fatty acid (FA) profile

Results

The protein and the essential amino acids' apparent digestibility coefficients (ADCs) were high in all tested alternative protein sources (> 84%). Considering these results, market availability and price, steam hydrolyzed feather meal (HF) was selected as the best candidate to replace FM in seabass diets. The replacement of 28, 55 and 76% FM by HF in an 18 weeks' growth trial did not affect growth performance, nutrient gain, muscle fatty acid composition and humoral non-specific immune parameters of seabass juveniles. Also, the dietary inclusion of HF improved phosphorus ADC, significantly decreasing P emissions into the environment (Campos et al., 2017).

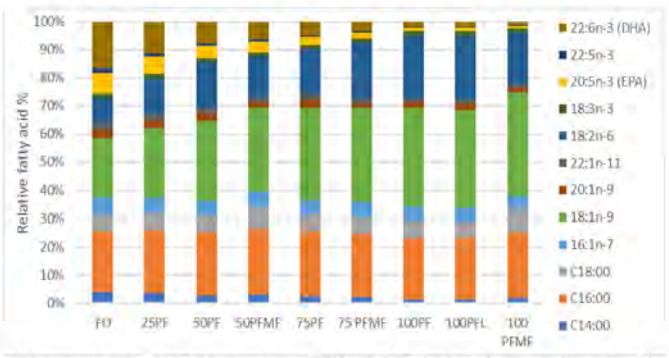

Figure 1 Flesh fatty acid profile of fish fed increasing levels (25-50-75-100%) of PF and/or MF.

(Continued on next page)

Both PF and MF had good ADC results (>86, 87 and 92% for energy, lipids and protein, respectively), and an overall high ADC for individual FA was reported in PF (90%). Both fats were further tested as FO replacement in two growth trials: one using PF to replace 25, 50, 75 and 100% FO, and the other one using a PF and MF mixture (50:50, PFMF) as 50, 75 and 100% FO replacement (Monteiro et al, 2018; Campos et al, 2019). An emulsifier (soy lecithin) was also tested in the 100PF diet (100PFL).

FO was completely replaced by PF without impairing feed intake, growth performance and nutrient utilization, but this was only possible up to 75% with PFMF (37.5% PF + 37.5% MF). The inclusion of soy lecithin in 100PFL attenuated liver lipid deposition and improved triglycerides digestibility. The FA profiles of the analyzed tissues generally reflected those of the diets, increasing MUFA and decreasing PUFA content. However, despite the changes in muscle FA profiles (Fig 1), seabass fed diets with up to 75% FO replacement (by either PF or PFMF) still provided the EPA and DHA levels recommended for human consumption (0.25-0.5 g per 100 g portion of fish)

Discussion and conclusion

In conclusion, HF is well digested by European seabass and can replace 76% of the dietary FM without impairing growth, nutrient gain, immune status or EPA and DHA levels in the muscle, suggesting that this can be a very good protein source for this species.

PF seems a better alternative lipid source than MF and can totally replace FO without impairing feed intake, growth performance and nutrient utilization. Yet, the FO replacement should not overpass 75% in order to assure the recommended levels of EPA and DHA for human consumption. Using rendered by-products as fishmeal and fish oil substitutes will reintroduce them into the local economy, contributing to a circular economy and reducing the environmental impacts of the aquaculture industry.

EFFECT OF DIFFERENT CONCENTRATIONS OF NITRATE IN THE PRODUCTION OF TOMATO (*Solanum lycopersicum* cv Grape) AND SHRIMP (*Penaeus vannamei*) IN LOW SALINITY WATER

Cesar Luque-Gamez[1], Wenceslao Valenzuela-Quiñonez[2]*, Adolfo Dagoberto Armenta-Bogorquez[2] and Ely Sara Lopez-Alvarez[2], Nadia Vázquez-Montoya[2] and Mariel López-Espinoza[2]

[2]Instituto Politécnico Nacional-CIIDIR Unidad Sinaloa
Departamento de Acuacultura
Boulevard Juan de Dios Batís Paredes # 250, Guasave, Sinaloa 81101, México

The objective of the present work was to evaluate the technical feasibility of using shrimp effluents (*Penaeus vannamei*) with low salinity to irrigate tomato (*Solanum Lycopersicum* L cv Grape) under an aquaponics system supplying different concentrations of nitrates. An alternative to food production is the use of aquaculture recirculation systems, which are intensive systems whose main characteristic is that the rate of water exchange is less than 10% of the total volume until it even operates in zero replacement. These operating conditions are carried out promoting the recycling of nutrients, which allows the constant reconditioning of water. Four treatments were evaluated, three with shrimp effluents compensating the deficiencies with synthetic fertilization in three of them, to which they were given 0, 100 and 200 mg l^{-1} of KNO_3^{-}, while the remaining treatment was administered Steiner solution. The flow of water in the system was continuous at a rate of 1 l/m. For the experimental design, a completely randomized treatment was used in the aquaculture component while in the hydroponic component a randomized complete block treatment was applied; both treatments were carried out with three repetitions. Tomato seedlings were transplanted in a zigzag arrangement at a density of 3.5 plants per linear meter. The densities in the system were 100 shrimp m^{-3}. In the aquaculture system, physicochemical variables, weight, length, survival and mortality were evaluated, and in vegetative variable plants, macronutrients present in each stage of the crop and fruit production. A record of the physicochemical parameters was taken out of normal and a final weight of 18 g was obtained for shrimp. Shrimp survival was 40% and the highest yield was at the level of 744 NO_3^- (1 kg m^{-2}) on average and the lowest (0.6 kg m^{-2}) at the level of 0 mg l^{-1} of NO_3^-, even if the grape tomato is small fruits of lower demand for nitrates. Further work to obtain information on the density of organisms required per plant, since the integration of fruit horticultural crops with nutritious shrimp solutions by adding synthetic fertilizers optimizes the use of water resources, food sources are produced in two different integrated systems, synthetic fertilizers are saved and the impact on the environment is minimized by aquaculture discharges.

THE EFFECT OF ENCAPSULATED *Lactobacillus plantarum* KC426951 AS A PROBIOTIC IN DIET ON GROWTH AND BLOOD FACTORS OF RAINBOW TROUT (*Oncorhynchus mykiss*)

In this research, the probiotic effect of *Lactobacillus plantarum* KC426951 on growth and blood factors of rainbow trout (*Oncorhynchus mykiss*) were investigated. The bacteria were combined into diets of 3 different treatments including two treatments with 10^7 and 10^8 cfu/g *Lactobacillus plantarum* (T_1 and T_2 respectively) coated with calcium alginate and a control diet without *Lactobacillus plantarum* bacteria (T_0). 90 Fish with an average weight of 12.94±0.35 were randomly assigned to 9 tanks of 500 liters (10 fish per tank) and fed with different diets for eight weeks. For each treatment, three replicates were considered. The fish were fed twice a day at 5% body weight in the first month and 3% in the second month. According to the results of comparison of T_1 and T_2 treatments with control treatment, T_1 treatment significantly had the highest weight gain (WG), weight gain percentage (PWG), lowest food conversion ratio (FCR) and the highest Specific Growth rate (SGR) ($P < 0.05$). However, there was no significant difference in survival percentage among treatments ($P > 0.05$). The results of this study showed that the number of white blood cells (WBC) in T_1 and T_2 treatments was significantly higher than control ($p < 0.05$). However, there was no significant difference in the number of red blood cells (RBC), hemoglobin (HB), hematocrit (HCT), mean corpuscular volume (MCV), mean corpuscular hemoglobin (MCH), and mean hemoglobin concentration in red blood cells (MCHC) ($P > 0.05$). According to the results obtained in this study, it can be suggested using of encapsulated *L. plantarum* with 10^7 cfu/g in rainbow trout diet for improving the growth indices and some blood factors.

SUITABILITY OF MICROALGAE CULTURED IN NITROGEN-LIMITED MEDIUM FOR ROTIFER PRODUCTION

Introduction

Marine finfis hatchery production requires the production of other organisms to be delivered as live prey during the early larval stages. Rotifers are the first live prey for the main finfis species. Its availability during the first critical period of finfis development, the onset of the exogenous feeding, depends on a suitable management of its mass scale production. Rotifer production is based on the use of microalgae and baker's yeast as food, and currently several microalgae-based commercial products are available. Microalgae species commonly used are *Tetraselmis* sp., *Isochrysis* sp. and *Nannochloropsis* sp., due also to their contribution to rotifer's lipid and fatty acid composition. Microalgae total lipid and fatty acid profile can be modified by changing culturing conditions such as light, temperature, salinity or culture media (Converti et al. 2009); but these modifications can also change other chemical profiles (Ribalet et al. 2007), with potential consequences on rotifer culture growth. In the present study, rotifer culture growth based on microalgae cultured in standard conditions or in nitrogen-limited conditions has been compared.

Materials and methods

Three experimental cycles were performed, one per microalgae species: *Nannochloropsis oculata*, *Tetraselmis suecica* and *Isochrysis galbana*. Microalgae were cultured with Guillard's culture medium in two 120L annular photobioreactors. Additional nutrients were added one week after the onset of microalgae culture in photobioreactors: the standard composition in one photobioreactor, the standard composition without sodium nitrate ($NaNO_3$) in the other. Four days later microalgae were used for feeding rotifer cultures in 6L containers, 5 containers per experimental group: control (fed with S.Parkle®, INVE Technologies, Dendermonde, Belgium; 0.5g per million of rotifers), standard (fed with microalgae cultured in standard medium; 7 x 10^6 cells mL^{-1}) and modified (fed with microalgae cultured in medium without $NaNO_3$; 7 x 10^6 cells mL^{-1}). Two days before the onset of rotifer growth experiments, rotifers (*Brachionus plicatilis*) were stocked in clean seawater and fed with 0.75g yeast per million of rotifers. One day before the onset of rotifer growth experiments, rotifers were stocked in clean seawater and kept starved. Rotifer growth experiments started in 2L of seawater containing 200 rotifers mL^{-1} plus 0.2g S.Parkle® or 14 x 10^9 microalgae cells. A total volume of 0.5L of seawater containing the amount of S.Parkle® or microalgae cells, based on microalgae and rotifer densities, was added daily to each container. Microalgae density, rotifer growth, temperature, salinity, oxygen and pH were monitored daily for 7 days. Microalgae density was counted with a Neubauer chamber at the inverted microscope (Leica DM IRB, Leica, Weitzlar, Germany). Total rotifers, total females with eggs and total females with 1, 2, 3, 4 or 5 eggs were counted in subsamples of known volume at the stereomicroscope (Leica MZ8, Leica, Weitzlar, Germany). Temperature, salinity and oxygen were measured with a multiparametric probe (Hach HQ40d multi, Hach, Loveland, CO), pH was measured with a pHmeter (Crison pHmeter 507, Hach, Loveland, CO).

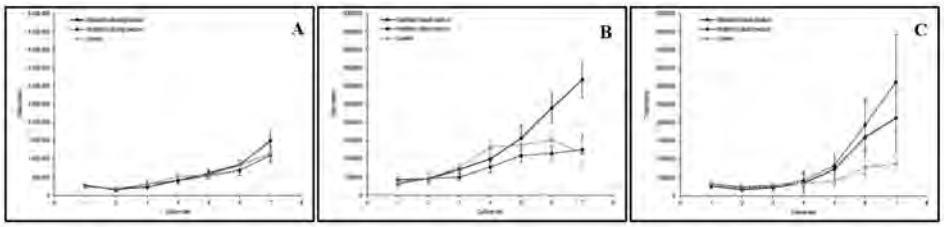

Figure 1. Total rotifers (mean ± SD) based on *N. oculata* (A), on *I. galbana* (B) or on *T. suecica* (C) cultured in standard or modified Guillard's medium. Control groups were fed with S.Parkle®.

(Continued on next page)

Results

Rotifer growth based on *N. oculata* did not differ between microalgae culturing conditions neither to control growth, and was lower than the obtained with the other two microalgae species (Figure 1A). *Isochrysis galbana* cultured in standard medium brought a higher growth than the same species in modified culture medium or the control groups (Figure 1B). Rotifer growth based on *T. suecica* was more variable between containers, higher than in control groups, and better in those fed with microalgae grown in modified culture medium (Figure 1C).

The maximum percentage of females with eggs was reached on day 1 when fed with *I. galbana* (41% average in standard groups and 37% average in modified groups), on day 2 when fed with *N. oculata* (36% in standard groups and 44% in modified groups) or *T. suecica* (43% in standard groups and 42% in modified groups) and on day 2 or 3 when fed with S.Parkle® (44% average). Females with 3 and 4 eggs were present in rotifer cultures fed with *T. suecica* from day 3 onwards; females in cultures fed with *N. oculata* and *I. galbana* presented a maximum of 2 eggs.

Discussion and conclusion

Nitrogen limitation in microalgal culture medium had a different impact on rotifer growth depending on the microalgae species. *Nannochloropsis oculata* cultured in nitrogen limitation conditions doubles its lipid content (Converti et al. 2009) but this change does not improve neither reduce rotifer growth. The composition of *I. galbana* and *T. suecica* cultured in standard medium is more suitable for rotifer growth, although the performance obtained with *T. suecica* is variable among experimental replicates and is in agreement with the unexpected crashes in rotifer cultures observed during large-scale production (pers. obs.). The presence of toxic compounds (Ribalet et al 2007) in *I. galbana* cultured in nitrogen limited conditions should be explored.

HATCHERY PRODUCTION OF FLATHEAD GREY MULLET, *Mugil cephaluS,* JUVENILES

D. Vallainc*, F. Leggieri, B. Loi, G. Brundu, G. Giménez Papiol

IMC International Marine Centre, loc. Sa Mardini, Torregrande, 09170 Oristano, Italy
E-mail: d.vallainc@fondazioneimc.it

Introduction

Mediterranean aquaculture diversification has targeted flathead grey mullet *Mugil cephalus*, an euryhaline omnivorous fish with a world-wide distribution, as a species of interest. A Sardinian regional project contributed to develop aquaculture techniques for this species by designing protocols and a production pipeline suitable for Sardinia specificities. Fully mature wild females (oocyte diameter 550 – 600 mm) were induced to spawn (63.6% success), and survival to 30 mm total length (TL) juveniles ranged from 1 to 6% in indoor conditions (Vallainc 2017).

The availability of wild females in tertiary yolk stage advanced vitellogenic oocytes (550 – 600 mm) is unpredictable, while secondary yolk stage vitellogenic oocytes (<550mm) are more abundant in coastal lagoons during the spawning season. Juvenile growth up to 60 mm TL was obtained in outdoor conditions, and little is known about growth and survival of hatchery produced individuals in indoor conditions. The present work focuses on investigating the spawning induction of females in secondary yolk stage vitellogenesis, and provides additional data on egg quality, growth and survival of juveniles up to 60 mm TL, underlining the frailties encountered in rearing the flathead grey mullet indoo .

Materials and methods

All procedures regarding broodstock capture, transport, spawning induction, egg incubation, larval and juveniles rearing followed the protocols reported in Vallainc (2017). Twelve females were captured during the spawning season and induced to spawn in an indoor recirculating aquaculture system (RAS). The 50% of the females were induced to spawn with a single hormone injection, the remaining were treated twice. Oocyte maturation was monitored by ovarian biopsies up to a maximum of 122 h after treatment.

Spawned eggs were incubated in a RAS and a sample of fertilized eggs was used to determine egg quality by culture plate (EIA plate). Larvae were reared in two indoor RAS, each one consisting of three circular fibe glass tanks of 2,000 L volume. Individuals were considered to shift from larval to juvenile stage at 34 days post hatching (DPH).

Fish were periodically sampled for growth measurement. Survival was determined by image analysis at 170 DPH. Dead juveniles older than 90 DPH were examined under a light stereoscope.

Results

Two treated females spawned but it was not possible to practice the biopsy before the treatment. In both cases the spawning occurred spontaneously 22-24 h after a single dose treatment. The female with bulging abdomen and red papilla (Female 1) spawned a good quality batch: 100% hatching rate, ~55% mortality at 3 DPH (Figure 1), 5% deformities. The other female (Female 2) did not show the external features and spawned a batch of lower quality: 45% hatching rate, more than 90% mortality at 3 DPH (Figure 1), 11% deformities. All the other females failed in spawning and showed bad quality pre-ovulation oocytes.

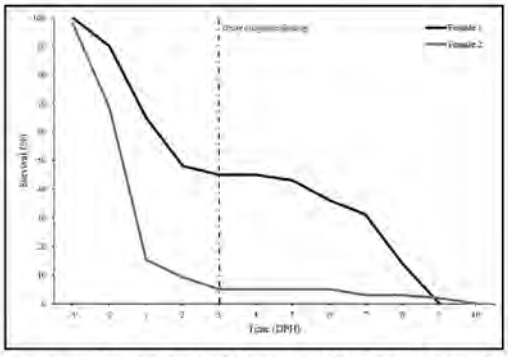

Figure 1. Hatching rate and survival of larvae obtained from two spawning females. Dotted line highlights 3 DPH, the onset of exogenous feeding.

(Continued on next page)

A total of 1.5 ± 0.6 (mean ± SD) million eggs were incubated and showed growth and survival similar to previous batches. Juvenile daily growth rate (GR) was 0.14 ± 0.04 mm day^{-1} TL and 0.003 ± 0.002 g day^{-1} WW. Survival at 170 DPH (~ 34 mm TL) was ~2%.

Dead juveniles presented different characteristics: 1) small and mainly deformed individuals with evident signs of starvation, 2) bulging abdomen and mainly protruded intestine and 3) big and seemingly healthy individuals with pale gills and steatosis -like liver. No pathogen could be linked to the mortality recorded during the juvenile stage.

Discussion

Maturation stage influenced the quality of the eggs. The female not showing the external advanced maturation features spawned lower quality eggs in contrast to the one featuring a bulging abdomen and red papilla. No spawning neither good quality pre-ovulation oocytes were obtained by double treating the females, and the only batch of eggs obtained from a not fully mature female was by a single injection treatment.

Female maturation stage and stress play a crucial role in spawning success (Crosetti and Blaber 2015). The hormone treatment was successful in inducing the maturation toward the tertiary yolk stage but the quality obtained was too low. Stress due to capturing and handling should be reduced, as confirmed by the poorer results obtained by double treatments.

Growth and survival of juveniles up to 30 mm was similar to previous batches managed with the same protocol (Vallainc 2007). Previous growth rates were 0.18 ± 0.04 and 0.2 ± 0.03 mm day^{-1}. The features of dead juveniles and our personal observations point to feed availability and characteristics, feed formulation and rearing parameters as the most likely points to improve during this stage.

EUROPEAN SEAWEED VALUE CHAINS IN AN INTERNATIONAL PERSPECTIVE

Sander van den Burg*, Maggie Skirtun, Miriam Bernard

Wageningen University and Research, Droevendaalsesteeg 4, 6708 PB, Wageningen, The Netherlands
E-mail: sander.vandenburg@wur.nl

Introduction

The global seaweed industry is currently dominated by Asian countries, with China and Indonesia being the main producers of raw material. Processing facilities are increasingly concentrated in China and a large part of the seaweed biomass produced in Indonesia and Chile is now exported as raw material to China for further processing (Bindu and Levine 2011). The European seaweed sector historically relied on the harvesting of wild seaweeds, particularly in France, Ireland and Norway. Harvested seaweed biomass is used by companies such as Dupont, Algaia and FMC for the production of alginates.

Recently, interest in the cultivation of seaweeds in European seas has grown considerable. Now that there is evidence that seaweed aquaculture in various European seas is feasible, seaweed cultivation is recognized as an important future source of agricultural production. Start-ups and established companies have stepped into this sector, developing new production systems and machinery required for efficient large-scale production and harvesting, and exploring new consumer products, feed and non-food applications. The increasing interest in seaweed is also reflected in (policy) documents, such as the draft "Klimaatakkoord" and Noordzee 2030, and in the financial support for research and upscaling of production provided by European governments through research projects such as the GENIALG (www.genialgproject.eu) and ProSeaweed (www.proseaweed.eu).

From an economic and value-chain perspective, the inevitable question is how the nascent European cultivated seaweed sector relates to the dominant global producers, concentrated in Asia. Earlier studies have pointed to the significant differences in cost of production, warranted by selling the products in high value niche markets (van den Burg, 2019). Large-scale seaweed production in Europe means accessing the global seaweed value chain.

Objective

This paper report on recent investigations into the joint development of sustainable and circular seaweed production systems for the Chinese and Dutch seaweed sectors. It addressed the question if there is an opportunity to strengthen ties with the Chinese seaweed sector, identify and discuss shared solutions that will ensure a sustainable development of the seaweed sector in both the Europe, with a focus on the Netherlands, and China.

Methodology

The global value chains framework is used to analyse how local actors (firms, communities, workers) are linked to and affected by major transformations in the global economy, using the core concepts of governance and upgrading – activities aimed at generating higher value for a product (Gereffi and Fernandez-Stark 2016). Upgrading strategies followed in Europe and in China are identified. These are assessed by looking closer at the value chain through the features of the market, governance and context.

Various phases of data collection are identified. In the first phase, a review of literature and policy documents was be conducted to gain insight into the key issues at hand for both the European and Chinese seaweed sector. A social network analysis on the Chinese seaweed sector was conducted, seeking out the different stakeholders involved in seaweed research, production and processing in China, and the actors who are key nodes in the network (Borgatti et al. 2009).

The second phase identified priority areas for further investigations. The network of companies partnering within the Stichting Noordzeeboerderij (+/- 90 organizations) were be consulted through interviews to identify key opportunities for collaborations from a Dutch perspective. Confronting the priorities of the Dutch seaweed sector with the social network analysis on China, most relevant stakeholders were identified and approached

In the third phase, a field trip to China was organised to visit key Chinese stakeholders. Through interviews with these stakeholders, key priorities of the Chinese seaweed sector were identified and conditions for cooperation with the Dutch sector were discussed. In the fourth phase, the data collected in document analysis and interviews in Netherlands and China was used to conduct a SWOT to identify the overlapping areas of interest on which consortium building must focus.

(Continued on next page)

Results

The European sector currently focusses on into niche markets and development of new high-value products and new markets. Developing new standards for seaweed, e.g. for sustainability and product quality , is another attempt differentiate from ‘global’ seaweeds.

A first analysis of strengths and challenges in respectively Netherlands and China highlights the long-standing experience of China in seaweed breeding and cultivation, and availability of an infrastructure for production and processing. The European and Chinese seaweed sectors appear to be worlds apart, with their own challenges for the future. However, on closer examination the solutions to overcome these challenges may not be so dissimilar. The European seaweed sector is young and in its early stages of development. Upscaling will depend on the availability of high quality seeding material, mechanisations to reduce costs and positive perception by the public. To achieve the latter, and to satisfy consumers and retailers alike, the sector will need to demonstrate low or positive environmental impacts of its production processes with a high degree of transparency. The Chinese seaweed sector, on the other hand, is well established but it has shown little innovation in recent years. It still relies on heavy manual labour and has a troubled track-record in terms of environmental impact and sustainability.

Based on the preliminary analysis, there is ample room for cooperation between China and the European seaweed sector, particularly in developing sustainable practices of breeding, production and harvesting. Shared concerns are the improvement of production processes through technological advancements, higher quality seedlings and transparency in the value chain are needed.

POTENTIAL FOR USING MUSSEL FARMING (*Mytilus edulis)* IN NUTRIENT REMEDIATION IN ESTUARIES OF THE UNITED KINGDOM

A. van der Schatte Olivier*, S.K. Malham, L. Le Vay, M. Christie, J. Wilson, S. Allander, S. Schmidlin, J. Brewin and L. Jones

School of Ocean Sciences, Bangor University, Menai Bridge, UK
E-mail: avdsolivier@bangor.ac.uk

Introduction

The Nitrates Directive (Council Directive 91/676/EEC) aims to reduce water pollution from agricultural sources and to prevent further such pollution, together with the Water Framework Directive (WFD) is one of the key instruments in the protection of waters against agricultural pressures. While ground and surface water quality in the EU have improved over the last decade, there is an ongoing need for improvements and assessment of mitigation measures (European Commission, 2018).

Bivalve molluscs can benefit coastal ecosystems by providing ecologically and economically important ecosystem services (Dalrymple and Carmichael, 2015; van der Schatte Olivier et al., 2018)we compared N in tissue, shell, and biodeposits between juvenile and adult oysters. Juvenile oysters assimilated 165 ↑ 8 mg (↑ SE. These include nutrient uptake, mediated by filter feeding on particulate organic matter including phytoplankton (Newell et al., 2005; Saurel et al., 2014) and their biodeposits (feces and pseudofeces. The use of bivalves as a mechanism of reducing the impact of catchment-derived nutrients in estuaries and coastal waters has been proposed (Rose et al. 2014) and demonstrated as cost-effective in sheltered fjord environments (Petersen et al., 2014)Denmark where biological and economic parameters related to nutrient removal was monitored throughout a full production cycle (1yr. The UK represents an interesting case for investigating the potential for shellfish farming in coastal nutrient remediation, due to the wide ranges of conditions including nutrient loading in catchments, hydrodynamics and coastal morphology.

To quantify the nutrient removal by shellfish, one approach is to estimate the total nutrient content of harvested stock and to consider that as removed from the marine system. This has been applied to global estimation of ecosystem services provided by bivalve shellfish farming (van de Schatte Olivier et al 2018). To achieve this, total biomass yields can be estimated from national or farm-level harvest aquaculture statistics but there are significant gaps in information on the nutrient content of shellfish and how these vary seasonally as well as across sites with different nutrient loading and environmental conditions. Hence, the effects of environmental nutrient loading on uptake rate in mussels and seasonal variation in nutrient composition of mussels were investigated, prior to a nationwide survey of potential nutrient removal by mussels across a range of sites.

To investigate the effects of environmental nutrient loading and seasonality, two sites were selected in the same geographic region in North Wales; one low nutrient (Menai Strait) and one high nutrient (Afon Briant), see Figure 1. At each site, samples of mussels were collected monthly from January 2018 to January 2019. Mussels were also sampled from a further 12 sites with varying nutrient loads and conditions around the UK, within a single seasonal period between September and October 2018.

Figure 1 Location of mussel and nutrient sampling sites around the UK. The temporal sites are marked with a star and the other sites are marked with circles.

(Continued on next page)

Discussion and conclusion

Initial results show significant seasonal trends in nitrogen and phosphate content of mussels, that can inform timing of harvest to optimise nutrient removal from the environment. There are also significant differences in nitrogen and phosphate content of mussels between the high and low nutrient loading sites. These latter results will be integrated with the UK-wide survey of nitrogen and phosphate content in mussels. This can then be used as a basis for estimation of current nutrient removal at all sites based on aquaculture production and fishery landings, with cost-benefit projections for potential future strategic increases in nutrient mitigation using shellfish farms under a range of environmental settings.

HOW TO GENETICALLY INCREASE FILLET YIELD IN FISH: RELEVANT GENETIC PARAMETERS AND METHODS FOR THE ESTIMATION OF GENETIC GAIN

Marc Vandeputte[1,2,*], Clémence Fraslin[1,2], Pierrick Haffray[3], Anastasia Bestin[3], François Allal[2], Martin Prchal[4], Martin Kocour[4], Mathilde Dupont-Nivet[1]

Introduction

Fillet yield (i.e. the proportion of edible muscle in a fish) is a key economic trait for species sold as fillets. Its genetic improvement is complicated by several of its characteristics 1) it is a ratio trait, 2) its numerator (fillet weight) and denominator (body weight) are strongly correlated (correlations in the range 0.89-0.99) 3) it offers little phenotypic variation and 4) it cannot be measured on a live breeding candidates.We formerly showed that it could still be improved by selection, using fillet yield, residual fillet weight or a ratio-specific linear index as selection indices. However, previous research showed that the genetic parameters of ratio traits do not permit a reliable prediction of genetic gains. As predictability of genetic gains is a key requirement to define breeding programs, we investigated how genetic gains in fillet yield could be predicted by the genetic parameters of fillet yield, residual fillet weight and of the component traits of the linear index. To this end, we compared simulated genetic gains with those estimated by classical prediction methods.

Material and methods

In order to perform simulations of fillet weight, body weight and waste weight with realistic values, we first estimated their genetic and phenotypic parameters, using 9 datasets of carcass traits recorded during 7 experiments on 4 species: Europeans sea bass (*Dicentrarchus labrax*), gilthead sea bream (*Sparus aurata*), common carp (*Cyprinus carpio*) and rainbow trout (*Oncorhynchus mykiss*). All fish used to estimate parameters were from factorial or partly factorial designs with mixed families, with pedigree recovered by microsatellites genotyping. The estimations of genetic parameters were performed using an animal model with VCE version 6.0.2, with specific fixed fects for each population.

We simulated, using the genetic parameters specific to each dataset
- non-trimmed fillet weight (FW) and waste weight (WW), which were correlated with additive genetic correlation $r_A$fw_ww and phenotypic correlation rPfw_ww, waste being composed of viscera, head and bones of the fish
- non-trimmed fillet weight (FW) and body weight (BW), which were correlated with additive genetic correlation $r_A$fw_bw and phenotypic correlation rPfw_bw.

Phenotypes were simulated for the initial (G_0) generation, phenotypic selection applied and a next generation of G_1 offspring produced, with 5 selection indices:
- Fillet yield FY=FW/BW
- Fillet ratio FR=FW/WW
- An linear index LIN_FY=αFW+βBW optimising response in FY, following linear index theory (Lin, 1980)
- An linear index LIN_FY=γFW+δWW optimising response in FR (Lin, 1980)
- resFW, the residual of the regression of FW on BW.

Then, we compared simulated gains (average FY in G_1-average FY in G_0) with expected genetic gains obtained from:
- selection index theory on ratios, as proposed by Lin and Aggrey(2013)
- phenotypic variance and heritability of FY in the base population, using the breeder's equation
- phenotypic variance and heritability of resFW in the base population

As Gunsett (1987) showed that the reliability of ratio traits heritability was dependent on selection intensity, all this was performed with 3 selection intensities for each set of genetic parameters (p=50%, p=20%, p=5%), thus 27 data points were available for each index tested (3 intensities * 9 fish populations)

Results

The simulated genetic gain was best with the linear indices, and hardly lower (95-96% of linear index value) with FY and resFW.

Linear index theory was extremely efficient in predicting genetic gains, as the correlation between predicted and simulated gains was always higher than 0.995, with a regression coefficient between 0.99 and 0.999

Prediction from the genetic parameters of FY was much less efficient, the simulated gain was on average only 82% of predicted gain. In addition, this was quite population specific, as the simulated gain could range from 65% to 135% of the predicted gain

Prediction from the genetic parameters of resFW was more efficient albeit imperfect, as the simulated gain was on average 93% of predicted gain. This was much less population specific, as the simulated gain ranged from 80% to 102% of the predicted gain.

Discussion and conclusions

The present study, using real genetic parameters from 9 fish populations in simulations, showed that as expected, the phenotypic and genetic parameters of fillet yield are not reliable to predict genetic gains for this trait. On the contrary, linear index theory predicted gains with a high efficienc , irrespective of the fact that the genetic and phenotypic parameters used were related to FW and WW or to FW and BW. One point of attention is that, especially for FW and BW, the phenotypic and genetic correlations are extremely high (0.972-0.994 and 0.982-0.997, respectively) and must thus be estimated with high precision for the estimated gains to be meaningful.

An alternative phenotype, residual fillet weight, provided genetic and phenotypic parameters that led to gave reasonable estimates of predicted gains in fillet yield. As it is simpler to use than composite indices, and easier to correlate to potential predictors, residual fillet yield may be an appropriate surrogate for fillet yield in the context of fish selective breedi

Introduction

Common carp is in the largest quantity produced freshwater fish species in Hungary. Wild populations of *Cyprinus carpio* (the European subspecies) are continuously decreasing due to hybridization with domesticated stocks. The wild common carp is listed on the IUCN Red List as '*vulnerable*' since 2008 but the River Danube subpopulation (*Cyprinus carpio carpio morpha hungaricus* Linnaeus, 1758) belongs to the '*critically endangered*' status (Freyhof & Kottelat 2008). Lake Hévíz is the biggest, biologically active natural thermal lake (38 degree) in Hungary. The high temperature and the individual chemical composition of Hévíz Lake resulted of a unique biological community (Ponyi, 2002). According to our knowledge, one of the last genetically pure *Cyprinus carpio carpio morpha hungaricus* population can be found isolated in the lake. The improvement of the artifici l propagation can support the conservation of this important wild carp subpopulation. The subspecies conformed to the special environment with a small adult size (Hévíz "dwarf" carp). The aim of the study was to improve sperm cryopreservation methods and to establish spermbank in the mentioned carp subspecies. The optimized methods can support the reintroduction and protection of the native population at Lake Hévíz (Cabrita et al. 2010).

Materials and methods

In our work, 2 different experiments were carried out to establish a spermbank, optimized the cryopreservation method and to avoid the sperm agglutination following thawing in stress sensitive *Cyprinus carpio carpio morpha hungaricus (N*=23*)*. The spermiation was hormonally induced using carp pituitary. Sperm was collected with syringes. The progressive motility (pMOT) in both fresh and cryopreserved samples was recorded with a CASA system (Computer-assisted Sperm Analysis, Sperm VisionTM v. 3.7.4., Minitube of America, Venture Court Verona, USA) using 50mM NaCl solution with 1% BSA. In our study 2 different extenders were compared Grayling extender (200 mM glucose, 40 mM KCl, 30 mM Tris, pH: 8.0 ± 0.2, Horváth et al., 2012, Bernáth et al., 2016) and the Pike extender (150 mM glucose, 75 mM NaCl, 30 mM KCl, 1 mM Na2HPO4×12H2O, 1 mM MgCl2×6H2O, 1 mM CaCl2×2H2O, 20 mM Tris, and 0.5% BSA, pH: 8.0 ± 0.2, Várkonyi et al. 2018). Diluted sperm was loaded in 1:9 dilution ratio with 10% methanol as an intracellular cryoprotectant into 0.5 straws (Minitube GmbH, Tiefenbach, Germany). In our study 2 different cryopreservation method was used in Polystyrene box (P.box) at 3 cm above the surface of liquid nitrogen for 3 minutes (Horváth et al. 2003) and in a controlled-rate freezer (CRF (cooling program (7,5ºC to -160ºC, cooling rate: 56ºC/min)), (IceCube 14 s, IceCube Series v. 2.24; Sy-Lab, Neupurkersdorf, Austria). The straws were thawed at 40 °C using a waterbath for 13 seconds (Horváth et al. 2012).

Experiment 1. Sperm cryopreservation in RAS kept broodstock

Samples (*N*=9) were diluted with Grayling extender and loaded into straws. Freezing was carried out in a Polystyrene box. Motility parameters was compared in fresh and cryopreserved groups as well groups.

Experiment 2. The optimization of the cryopreservation method

Freshly stripped samples were diluted with Grayling and Pike extender. Diluted sperm was cryopreserved in Polystyrene box and in controlled-rate freezer. Motility was compared in all groups (CRF-Grayling (CG), CRF-Pike (CP) extender; P. box-Grayling extender(BG) P. box-Pike extender (BP).

Results

In *Experiment 1.* significantly higher pMOT (94±3) was recorded in the fresh control group compare to the cryopreserved (65±9%). In *Experiment 2.* Moderate pMOT wasrecorded in all groups CP (14±3%), CG (33±12%), BP (24±8%) and BG (38±14%). No significant difference was recorded between the two cryopreservation methods iusing the two extenders. A significantly higher pMOT was observed using the Grayling extender with the CRF in comparison with the Pike extender. Sperm agglutination phenomenon was observed in our experiment using Grayling extender compare to the Pike extender which showed a regular pure homogenous sperm suspension after thawing.

(Continued on next page)

Discussion and conclusion

In conclusion, sperm cryopreservation was successfully carried out in the stress sensitive and genetically pure population of *Cyprinus carpio carpio morpha hungaricus*. According to our results, both the Polystyrene box and the controlled-rate freezer are suitable for the Hévíz dwarf carp sperm cryopreservation. In our experiments, both Grayling and Pike extenders showed a similar efficienc . However, Pike extender successfully eliminated the sperm agglutination following thawing.

Introduction

Limited availability of ingredients in aquaculture feeds is crucial in order to maintain the increasing demands of aquaculture industry Gamboa-Delgado & Márquez-Reyes 2018). However, to safeguard sustainable exploitation of natural resources, the use of capture fisheries-based fishmeal and fish oil needs to be reduced in conventional fish feeds (Tacon & Metian, 2015). Accordingly sources with high quality protein and essential nutrients are imperative need otherwise fish performance (Kousoulaki et al., 2012), health status and final product quality (Kousoulaki et al., 2016) may be jeopardized when substituting dietary fish meal by alternative ingredients of lower nutritional value. The main objective of this study is to test ingredients and design formulations for commercially relevant tailored-made aqua feeds, ensuring high performance, maintaining or enhancing nutritional value and environmental friendliness.

Materials and methods

Ten experimental feed mixes were prepared (Table I). The levels of conventional and trimmings fish meal and oil and that of the novel feed ingredients, balanced to same proximate composition, EPA+DHA and total phospholipid content with rapeseed or fish oil, soy lecithin, wheat and wheat gluten, were predetermined by a chosen range in the applied three component mixture design. Juvenile European sea bass of an initial average body weight of 5.72±0.72g were fed the experimental diets. Fish were weighted individually at the beginning and end of the experimental trial under mid anesthesia with clove oil. Fish were fed *at libitum* twice a day. Mortalities and feed consumption were recorded daily in order to be able to evaluate accurately values for feed utilization (FCR, SGR, % daily feed consumption).

Results and Discussion

The results so far show that there is a significantly positive effect in sea bass performance of moderate dietary inclusion of innovative ingredients in the presence of minimum 10% conventional fish meal and 2.7% conventional fish oil. The inclusion of fish trimmings at any level had negative effect on fish performance. In the absence of any kind of fish meal, and the highest inclusion level of bacterial, yeast, microalgae and sunflower meal, feed intake was lowest (Figure 1- able II).

Introduction

Commercial salmon feeds used in Norwegian aquaculture industry are based on a mixture of plant and marine ingredients. Over the last decades the proportion of the plant ingredients in the feeds have increased while marine ingredients decreased. The current ratio of plant : marine ingredient composition is 70:30 (Ytrestøyl et al., 2015). Plant proteins used in the feeds are derived from protein concentrates, usually with reduced content of antinutritional factors (ANFs). Nevertheless, amino acid imbalance and presence of ANFs are still a concern of the aquafeed industry. Furthermore, plant lipids have an unfavorable ratio of n-3:n-6 and does not provide the recommended EPA and DHA to the fish. Hence, ingredient composition of feed may have an effect on the health of the fish (Torrecillas et al., 2015). In addition, dietary administration of probiotics can influence the mucosal immune system of the fish (Hoseinifar et al., 2015). Skin, which is the largest first line defense organ of the fish, plays a key role in protecting the fish from the surrounding environment which is rife with opportunistic pathogens. Therefore, skin mucous morphology (Vatsos et al., 2010) which is considered as an indicator of fish s skin health, may be affected by several environmental factors including those linked to feeds. This study investigated the histo-morphological alterations of the skin of Atlantic salmon (*Salmo salar*) fed different diets with or without probiotics.

Material and methods

A feeding experiment was conducted with Atlantic salmon (mean weight of 146.97 ± 4.9g SD). The fish were fed three types of feeds with different basal diets with or without probiotics. The ingredient composition of the diets were, Diet 1: fish meal/ fish oil based, Diet 2: a commercial like diet dominated by plant ingredients (plant : marine is 70:30), and Diet 3: a fish meal/ fish oil based diet in which soybean meal replaced 20% of the fish meal. Dietary probiotic was cultured in the laboratory and vacuum coated on the diets. Dorsal skin samples were collected from 12 fish (mean weight 201.4 ± 37.8g SD) per treatment and fixed in 4% formalin. Samples were decalcified with 10% formic acid for 5 hours, prior to processing. After paraffin embedding, tissue sections of 4µm were prepared and stained with Hematoxylin and Eosin (H&E) and Alcian Blue – Periodic Acid Schiff (AB-PAS). Images (n= 9/ fish, N=108/ diet) from different locations of skin were acquired using light microscope. Quantitative analysis of skin morphology was performed; average area of mucous cells (AAM), ratio between total area of mucous cells and total area of epithelium (TAM/ TAE), and number of mucous cells per epithelium (M/E) were determined. The analysis was done using Image J (1.52a).

Results and discussion

The results did not reveal any significant differences in the average area of the mucous cells (AAM), and ratio between total area of mucous cells and total area of epithelium (TAM/TAE). However, the number of mucous cells per epithelium (M/E) was significantly influenced by diet and probiotics. Fish fed Diet 2 and 3 had significantly more M/E compared to those fed Diet 1. Addition of probiotics to Diet 1 increased the M/E, an indication of a strengthened skin barrier.

Conclusion

The results of this study revealed that the ingredient composition of diets directly influence the number of mucous cells per epithelium. Dietary administration of probiotics increased the number of mucous producing cells per epithelium, and this increase may have improved the barrier function of the skin of Atlantic salmon.

NON-IONIZED AMMONIA ASSESSMENT MODEL IN *Chirostoma estor estor* INTENSIVE CULTURE USING ARTIFICIAL NEURAL NETWORKS

José Luis Vázquez Burgos*

Centro de Investigación en Computación – Instituto Politécnico Nacional. Av. Juan de Dios Bátiz s/n, Nueva. Industrial Vallejo, Gustavo A. Madero, Ciudad de México, C.P. 07738, México
E-mail: luis.vb24@live.com

Introduction

The *Chirostoma estor estor*, commonly known as white fish, is an endemic species of great importance in the area of Lake Patzcuaro, located in the state of Michoacan, Mexico (Llorente & Ocegueda, 2008). This represents a large income in the local economy, unfortunately it is currently in danger of extinction due to the pollution of the lake and its excessive fishing (Guevara et al., 2015). National institutions, through aquaculture farming, have made efforts in the conservation of this type of fish, however there is still a lack of penetration of the scientific sector in this problem (INAPESCA, 2016). This paper presents a computational model for the evaluation of non-ionized ammonium which is highly toxic and of vital importance in aquaculture farming systems. Using an Artificial Neural Network (ANN), a relationship is established between non-ionized ammonium (NIA) and parameters such as pH, temperature and total ammonia (TAN). Data bases obtained from measurements in culture ponds and generated by similar models have been proposed to generate efficient RN training.

Materials and methods

The computational model is divided into four stages (figure 1), in the first a database was simulated using the model proposed by Kennet et al., (1975). Which made a table at different temperatures at different pH concentrations, calculating the percentage of NIA for each case, this database, together with the measurements obtained in culture ponds, were used in the training of the ANN. In the second stage it has a pre-processing so that the efficiency of the ANN is not diminished by a poor selection of patterns (Principe et al., 2000, Carbajal et al., 2017). The third stage consists of an ANN whose topology is given by the expression , which indicates that it consists of two inputs, a number of hidden layers with neurons in each hidden layer and one output. Finally, in the last stage the value of NIA is obtained.

Results

The lowest MSE was the criterion for the choice of ANN configuration, both in the training set and the test set, and this was obtained with the topology , which indicates that it consists of only two hidden layers and twenty neurons in each of them. The results obtained by the training of the RNA show a learning rate of 99.91% of success in the approach. In the visualization of these results it is important to underline that each parameter (temperature and pH) individually affects differently the behavior of the NIA, for which the evaluation of the RNA for each of these was carried out individually (figure 2)

Discussion and conclusion

In this work, a new computational model has been designed to evaluate the non-ionized ammonium in white fish culture systems based on artificial neural networks. Given that there are currently no systems, sensors or methods to calculate this important and toxic parameter, this work represents a great innovation in the aquaculture area. Taking into account the factor of 99.91% accuracy, it points to this system as a viable, accurate and economical option in obtaining the NIA, calculating it from two parameters on which it depends enormously and which are easy to obtain: temperature, and the pH. It is of great importance to point out that the system can be considered as a full-fledged virtual sensor, since it is enough to obtain values from the aforementioned two parameters, introduce them to the artificial neural network already trained and this will deliver an accurate value of NIA. Finally, it is proposed for future work the implementation of this computational model, in field measurements to obtain more results of this toxic paramete .

LEVELS OF BIOACTIVE COMPOUNDS IN *Ulva* spp. GROWN IN DIFFERENT INTEGRATED SYSTEMS

F.V. Machado, H. Quental-Ferreira, C. Cardoso, and M. E. Cunha

Portuguese Institute for the Sea and Atmosphere (Portugal)
E-mail: fcfvm96@hotmail.com

Introduction

Ulva spp. grow in sheltered, eutrophic coastal waters, covering large areas and being sometimes considered a nuisance. However, they have valuable bioremediation capabilities that, associated with the fast growth rate, provide important ecosystem services mainly in respect to waste nutrient impact mitigation (Buschmann et al., 2017). Other very important *Ulva* properties are associated to its biochemical composition characterized by several compounds that can be used in fields like medicine (antioxidant, anti-inflammator , anti-fungal, and anti-cancer), nutraceuticals, animal feed, and bio-material construction (e.g. bioplastic) (Holdt and Kraan et al., 2011; Helmes et al., 2018). Their cultivation efficiency in closed systems (Lamprianidou et al. 2015, Neveux et al. 2017) and efficient nutrient uptake (particularly ammonium) makes them valuable macroalgae for integrated multitrophic aquaculture (IMTA). The present work used two different water sources with different nutrient concentration and two different IMTA production systems (semi-intensive and extensive) to study the temporal and spatial effect of nutrient concentration and production system on the productivity, nutrient uptake, and bioactive properties of *Ulva* spp. biomass.

Materials and Methods

Ulva spp. biomass was cultured in 0.7 m^3 floating cages (extensive production) placed at a reservoir (R) and settling pond (SP) of an aquaculture research station. In order to compare the efficiency of these floating cages against raceway tanks for *Ulva* semi-intensive production, water from the SP was also pumped into 6.3 m^3 fibre glass raceway tanks (K) coupled with bottom centred aeration. Growth, nutrient uptake, proximate composition, polyphenol content, antioxidant and anti-inflam atory activity were estimated in *Ulva* from the floating cages and raceways. Water environmental parameters (temperature, dissolved oxygen, turbidity, salinity and irradiation) were daily recorded. *Ulva* samples grown from 30/01/2019 to 06/02/2019 (T1), 06/02 to 13/02/2019 (T2), 27/03 to 03/04//2019 (T3) and 03/04 to 11/04 /2019 (T4), were analysed as representative of Winter and early Spring growth conditions. T1 and T2 culture were kept initially at 1.0 kg/m^3 with 50% day^{-1} intermittent water renewal in the raceways, whereas in T3 and T4, were at 0.5 kg/m^3 with 100% day^{-1} continuous water renewal. Ferric Ion Reducing Antioxidant Power (FRAP) technique was applied to *Ulva* spp. biomass in accordance to Benzie and Strain (1996).

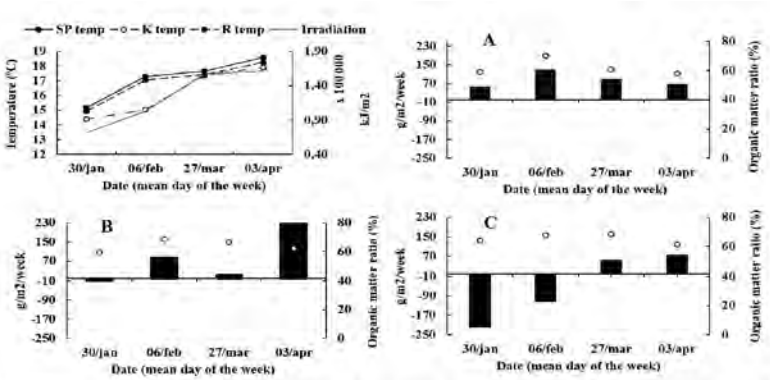

Fig. 1. Mean *Ulva* productivity during the sampling period: A – settling pond (SP); B – raceways (K); C – reservoir (R). Circles correspond to organic matter (%) and columns to growth (g/m^2/week). Top left: Left axis: Temperature; Right axis: irradiation during the sampling period.

(Continued on next page)

Results and Discussion

Results show higher growth rate in early Spring than in Winter, which is probably related to seasonal temperature and irradiation increase (Fig. 1, top left). Differences in growth were observed between settling pond and reservoir at T1 and T2 ($p < 0.05$) and within T1, T2 and T4 in the raceways ($p < 0.05$). A correlation was observed between growth and organic matter percentage on SP samples (R^2: 0.98). The FRAP antioxidant power of the aqueous *Ulva* extracts was correlated with temperature, radiation and growth (R^2: 0.92; R^2: 0.94; R^2: 0.95, respectively) in the reservoir samples.

The analysis of bioactive compounds in the samples from SP and K is still under way and the results will be presented in the poster. Though there is still scarce information on the spatial and temporal influence on bioactivities and composition of *Ulva* spp., it is expected to observe differences in some aspects of the chemical composition like the polyphenol content and trace metals between the systems and time as indicated in the literature (Helmes et al., 2018; Roleda et al., 2018).

Introduction

Aquaculture industry is expected to fulfill an increased demand of fish for human consumption, and challenges in long term sustainability for this industry, such as diseases outbreaks, water pollution and global warming, need to be met. Viral nervous necrosis (VNN) also known as viral encephalopathy and retinopathy (VER) is one of the main infectious diseases affecting marine aquaculture. Caused by a *Betanodavirus* of the family *Nodaviridae* (OIE, 2016), VNN is endemic in the Mediterranean and affects wild and farmed populations of European sea bass (*Dicentrarchus labrax*), which is one of the most valuable farmed Mediterranean fish with aquaculture production valued at approx. 1.1 billion USD during 2017 (FAO, 2019). Despite the approval of a commercial vaccine to protect sea bass against the most common genotype of VNN in the Mediterranean, its use on mass scale is still limited due to its cost as single vaccine, technical and logistic problems presented when combining with other vaccinations against Vibriosis and pasteurellosis. In addition, global warming trend and temperature dependent nature of VNN remains a treat for the sustainable production of this species (Costa and Thompson, 2016)the causative agent of viral encephalopathy and retinopathy (VER. Selective breeding has been proved to be an effective tool to accumulate genetic gain on a desired trait such as disease resistance (Gjedrem and Rye, 2018) , and the use of new tools for marker assisted selection (MAS) have provided ways to implement individual selection in disease resistance traits leading to higher genetic gains compared to more traditional methods (Dekkers, 2007).

In our work, we present results of a challenge test against RGNNV in a commercial European sea bass breeding program performed during two consecutive years. In addition, tissue samples of challenged fish were sent to genotype on high-density SNP array specific to the species. Results of accuracy using traditional and MAS methods will be presented including expected genetic gains.

Material and Methods

A challenge test was performed during two consecutive years on a captive population of Sea bass under selection. During the year 2017, approx. 30 individuals from each of 89 families were grown separately till individual tagging at body weight 11g, and sent to be challenged, using a sea bass RGNNV isolate, virus was isolated from a commercial fish farm outbreak in 2013, via intramuscular injection. Average weight of the fish challenged was of 15g. Mortalities were recorded every 4 hours during 28 days after infection. Same procedure was followed during 2018 where ~30 individuals from 92 families were sent to be challenged against VNN with an average weight at challenge of 25.4g. In addition, prior to challenge, tissue samples from each individual fish was taken and preserve in 95% ethanol and stored at -4°C

After finalizing the second challenge test, a subsample of tissue from dead and survival fish of 30 and 32 families from challenge test 2017 and 2018 respectively was sent to genotype using a 57K SNP array specific for this species.

Genetic parameters were estimated for survival at end of test using BLUP methodology. In addition, a GWAS analysis was performed for each marker including the marker as random effect and the polygenic effect using a relationship matrix constructed with all markers except for the marker under test.

Finally, accuracy of EBVs and GEBVs were tested using fivefold cross validation. Expected genetic gains using each of the methods were estimated.

(Continued on next page)

Table I: Genetic parameters for survival at end of VNN challenge test

Dataset	Animal linear model		Threshold sire-dam model	
	h^2	c^2	h^2	c^2
Year 2017	0.15±0.04	0.00±0.00	0.21±0.04	0.00±0.00
Year 2018	0.15±0.06	0.02±0.02	0.20±0.08	0.03±0.03
Year 2017+2018	0.18±0.03	0.00±0.00	0.24±0.03	0.00±0.00

Table II: Genetic parameters and predictive ability of end of VNN challenge test using GBLUP

	N	Heritability	Predictive Ability
GBLUP (Gmat)	1795	0.17±0.03	0.26
GBLUP (Hmat)	4851	0.18±0.02	0.27

Results

Mortalities started to appear during the first and second day after infection in 2017 and 2018, respectively, reaching a peak during day 5 for both challenge tests. Mortalities ceased before termination of trial approx. on day 20 after challenge, when accumulated mortality had reached respective 58.2 and 58.8% in 2017 and 2018.

Genetic parameters estimated based on traditional pedigree evaluations are presented in Table I including the effect of common rearing of full-sibs prior tagging (c^2). Results for genomic BLUP (GBLUP) and predictive ability from five-fold cross validation are presented in Table II.

Additional, expected genetic gains of selection candidates using either traditional or MAS methods will be presented.

Introduction

Microalgae are increasingly being used in aquaculture feed for marine organisms, since they are a natural source of protein, essential polyunsaturated fatty acids, pigments, antioxidants and other bioactive compounds, which give them apart from nutritional also functional properties (Spolaore *et al*., 2006). In this contest, the *Isochrysis* sp. combines medium-high level and quality of protein with high lipid and DHA contents (Sánchez *et al.,* 2000). *Seriola dumerili* (Risso 1810), has a great potential for the global industry and in order to the diversification of aquaculture owing to its rapid-growing and adaptive characteristics (Mazzola *et al*., 2000). Although some research belongs to nutritional aspects are reported in the last years, there is a lack of functional ingredient knowledge for this species. Therefore, in this study the growth performance, biometry, and colour parameters, proximal composition and liver morphology of amberjack fed increased levels of a freeze-dried biomass of *Isochrysis* sp. were determined.

Materials and methods

-*Feeding conditions:* Four diets with 4 levels of *Isochrysis galbana* were formulated (CONTROL 0%, ISO 3%, ISO 5% and ISO 10%). Thirty amberjack juveniles, having a mean initial body weight of 5.53±1.08 g, were randomly allocated in triplicate groups in 150L fibreglass tanks. Fish were fed the experimental diets to apparent satiation (five times a day) for 30 days. Water temperature and dissolved oxygen were monitored.

-*Analysed parameters:* Growth and biometric was recorded in all fish along the trial. At initial and final samplings, 12 fish were sacrificed and immediately subjected to individual skin colour measurements. All specimens were then subjected to biometry measurements in order to evaluate yield individual. Finally, the objective tissues were used for biochemical and histological analysis.

Results and discussion

Water temperature and dissolved oxygen measured along the trial were 23.3±0.67 °C and 5.55 ± 0.34 mg l^{-1}, respectively. Lowest growth values were found for those fish fed 10% ISO diet, with 5% ISO responses close to control diet ($P<0.05$, table 1). In the case of the specific growth rate (SGR) feeding up to 5% ISO give equal responses respect to the control diet being the smaller only for 10% ISO SGR ($P <0.05$, table 1). Regarding feed ingestion ratio (FIR), a trend for lowering values was observed as ISO increase in the diets with significan ly lower intake for those fish fed 10%ISO respect to 3ISO and 5%ISO. Accordingly, feed conversion responses (FCR) were in parallel to intake in growth, except for the 5%ISO which shows similar growth and FCR responses respect to the control diets, although with significantly lower feed intake ($P>0.05$, table 1).

Regarding skin colour, all parameters were significantly affected by feeding ISO respect to CONTROL (table 2). Higher lightness (L*) was observed in fish fed the control diet, following the 5%ISO treatment ($P < 0.05$). Relative to controls, there was a marked increase in the a* (redness), b* (yellowness) and colour saturation (Chroma) in fish fed the ISO diets ($P < 0.05$), with the highest values in 10% ISO fish $P < 0.05$).

DEVELOPMENT OF A PRACTICAL REPETITIVE STRESS CHALLENGE MODEL FOR SEAWATER ATLANTIC SALMON (*Salmo salar*)

Luisa M. Vera*[a], Eric Leclercq[b], Karina Gajardo[c]; Mathieu Castex[a*], Hervé Migaud[a]

Increased reliance on non-medicinal health interventions has unequivocal benefits but may impose frequent exposure to severe stressors susceptible to chronically compromise health and performance. Developing strategies that mitigate physiological stress and bolster mucosal robustness is therefore critical to support non-medicinal treatments and practices. The study benchmarked the impact of a repetitive exposure to severe stressors on the oxidative, immune and mucosal status of the stock under controlled conditions. The aim was to obtain a commercially relevant repetitive-stress challenge model that goes beyond the primary response to a single stressor and allows exploring mitigation measures.

A 10-week, triplicated tank-based trial was performed using 500 g Atlantic salmon (37 fish / tank). Following a 5-week resting period, the "repeated-stress" (RS) group was crowded and netted-out at weekly interval for immersion into 2 freshwater bath (1h) prior a hydrogen peroxide bath (H_2O_2; 30min; 1,500 mg/L) then given a 2-week recovery period. The "single-stress" (SS) group was exposed to the H_2O_2 bath only. Sampling was performed at the end of the resting-period (T_1); prior to H_2O_2 exposure (T_2), 1 h after (T_3), 48 h after (T_4) and 2-week after (T_5, trial end) H_2O_2 exposure. A range of biological parameters were investigated targeting growth, feed performance, stress response, anti-oxidant status, mucosal integrity, innate immune parameters and plasma biochemistry.

Prior exposure to repetitive stressors significantly elevated chronic plasma cortisol level (T_2, Fig 1) but lessened the acute primary response to an immediate stressor (T_3, Fig 1). The antioxidant status appeared significantly altered with, e.g., a depletion of super-oxide dismutase (SOD) at circulating (Fig 2) and skin level (Fig 3). Some innate immune defenses appeared damped down by RS based on blood and skin mucus biochemistry. Growth was not statistically affected but feed intake tended to be lower in the RS group. The other parameters assayed will be discussed including mucosal integrity and molecular work.

The study describes the effect of repetitive stressors on salmon physiology and suggests that prior RS exposure reduce the capacity of the stock to cope with a subsequent intervention or health challenge. A "repeated-stress" challenge model is proposed along with selected biomarkers towards the testing of improved practices and mitigation solutions.

Introduction

Intestinal epithelium is characterized by a rapid cell turnover to ensure an effective barrier function in the harsh intestinal environment allowing, at the same time, the absorption of all the necessary nutritional principles (Barker et al., 2012). This implies a constant adaptation not only in response to pathological situations but also to less stressful stimuli like those induced by diet changes. Whereas qualitative changes have been well characterized in the past, quantitative measurements are not so widely available in aquaculture species. Furthermore, limited information is available on the mechanisms at play. In particular intestinal stem cells (ISC) have been characterised only in Medaka (Oryzias latipes, Aghaallaei et al., 2016). Aim of this work was to quantify the changes taking place in the rainbow trout intestinal epithelium in response to growth and diet changes and to broaden the array of molecular tools required for the characterization of ISC and their cell niche. The data will help to define more accurately even subtle changes in response to different diets and, when specific tools will be fully developed, to widen our understanding of the cellular and molecular mechanisms.

Materials and methods

Segments of anterior intestine were collected from 5 rainbow trout of 7, 10 and 12 months weighing approximatively 50, 150 and 500 g, respectively. These stages correspond to stepwise increase of digestible energy: 18 MJ/kg up to 50 g, 18.5 MJ/kg from 50 to 150 g and 19 MJ/kg up to 500 gr (Optiline, Skretting). After fixation, dehydration and paraffin processing, sections were stained with hematoxylin and eosin (HE) for morphological investigations and stereological quantifications; periodic acid-Schiff (PAS)-Alcian Blue (AB) for the characterization of goblet cell mucus content; phloxine tartrazine stain for the identification of Paneth cells; immunohistochemical staining of Proliferative Cell Nuclear Antigen (PCNA) for the localization of proliferating cells; endogenous Alkaline Phosphatase (AP) activity for the determination of fully differentiated enterocytes in the epithelium. Villi height and villi width were measured with NanoZoomer Digital Pathology 2.7.2 software. Transverse sections stained with HE were used to estimate the volume density of each intestinal layer using a point-count stereological grid following the Delesse principle. Expression of LGR5 and SOX9, well-known intestinal stem cell markers, was investigated by qualitative PCR using sequences annotated in ncbi.nlm.nih.gov/gene/.

Results

Given the wide variation among their length, villi were arbitrarily divided in two categories: below or above 400 µm. Short villi were longest at 150 g while long villi were significantly longer and more branched at 500 g (Table I).

Table I: Proximal intestine villi morphometry

	Proximal intestine			
Trout weight	Short villi length (µm)	Long villi length (µm)	Villi width (µm)	Villi branching
50g	$251.0^{a} \pm 6.0$	$469.2^{a} \pm 30.5$	$94.3^{a} \pm 5.5$	-
150g	$310.3^{b} \pm 19.9$	$555.8^{a} \pm 28.7$	$122.2^{b} \pm 3.9$	+
500g	$245.6^{a} \pm 16.9$	$660.3^{b} \pm 21.4$	$114.7^{b} \pm 6.2$	++

$^{a-b}$ Different superscripts in the same column indicate significant differences ($P<0.05$). Values are expressed as means ± SEM.

Table II: Histochemical characterization of Goblet cells mucus composition.

	Goblet cells mucus composition		
Trout weight	Neutral	Acid	Combination of neutral and acid
50g	$20.8^{a} \pm 3.4$	$79.2^{a} \pm 3.4$	-
150g	$6.0^{b} \pm 1.3$	$94.0^{b} \pm 1.3$	-
500g	$7.2^{b} \pm 0.9$	$92.7^{b} \pm 0.9$	-

$^{a-b}$ Different superscripts in the same column indicate significant differences ($P<0.05$). Values are expressed as means ± SEM

(Continued on next page)

Stereological evaluation showed that mucosa is the predominant layer of the proximal intestine and the epithelium:lamina propria ratio remained unchanged along development. PAS/AB stain indicated that goblet cells contain either neutral (bright magenta) or acid (blue) mucus, whereas no cells containing a mixture of the two were observed. At 150 g we observed a sharp decrease of neutral mucus containing cells (Table II). Phloxine tartrazine positive cells were detected within the upper portion of villi epithelium, in the lamina propria and in the submucosa, irrespectively of the fish age. Fully differentiated enterocytes were localized in the upper part of the villi and did not superimpose with the proliferative compartment localised in the bottom part and $PCNA^{+}$. Both LGR5 and SOX9 were expressed in the intestine at all stages of development.

Discussion and conclusion

In this study, we provide a detailed quantitative analysis of rainbow trout intestinal mucosa morphology during the first year of development. Dividing villi in two populations, based on their length, enabled the identification of changes along development that otherwise would have been unnoticed. Since the two types of villi change in an independent way during growth and in response to the changes of diet, they may play a different function. Furthermore, long villi became progressively more branched from 150 g and, at the same time, we observed a sharp increase of goblet cells containing acid mucus. Whereas in mammals these changes have been associated with alterations in the intestinal homeostasis, we observed a constant epithelium:lamina propria ratio that indicates a healthy intestinal tract. This suggests that diet changes taking place in this experiment, induced some stress, possibly due to the increased lipid content, but did not lead to a pathological state. Phloxine tartrazine positive cells in the submucosa were previously described also in the Atlantic salmon (Sveinbjornsson et al., 1996), but their localization within the upper intestinal epithelium and in the lamina propria was not described before. However, none of these locations is expected for *bona fidae* Paneth cells. Finally, the expression of LGR5 and SOX9 indicate that these ISC markers can be used also in rainbow trout. However, due to the presence of many paralogs further work is necessary to define which ones are more relevant in the intestine.

Introduction

In recent years, efforts have been made to establish pikeperch (*Sander lucioperca* L. 1758) as a farmed fish in recirculation aquaculture systems (RAS) in European aquaculture. However, the development is still in its initial stages and is accompanied by high losses in the early ontogenesis, especially through the conversion to exogenous feeding and intensified cannibalism. Furthermore, pikeperch is considered a highly stress-susceptible species (Baekelandt et al., 2018). The choice of optimal husbandry conditions, including central factors such as water temperature, at least for juvenile fish, is more focused on economic considerations than on welfare concerns. For instance, optimal growth rates in juveniles have been reported at temperatures up to 28°C (Frisk et al., 2012; Rónyai and Csengeri, 2008). Here, energy allocation to maintain homeostasis is optimal, allowing maximal energy to be allocated to growth. But, in contrast to the established salmonid aquaculture with a selection of trait-based breeding lines, so far, there are no accompanying genetic studies on development and stress physiology in pikeperch that could enable and support marker-based breeding and the instant querying of their welfare status.

Using temperature changes from 15°C to 25°C, we have investigated a set of genes for the purpose of selecting an informative panel of inducible genes that will contribute to the establishment of a multiplex assay for stress detection in finfis aquaculture. Moreover, we aimed to examine the general expression patterns of key genes during the early ontogenesis of pikeperch.

Material & Methods

All fish used in this study were reared at the pikeperch facility of the Mecklenburg-Vorpommern Research Centre for Agriculture and Fisheries (Hohen Wangelin, Germany). For analyses of gene expression pattern during pikeperch development, we sampled fertilized eggs, yolk sack larvae (4dph), larvae fed with artemia (7dph), larvae weaned on dry food (18dph), as well as liver tissue from 3- and 5-month-old fingerlings. For the temperature experiment, 8-week-old fish were transferred to the Leibniz-Institute of Freshwater Ecology and Inland Fisheries (Berlin, Germany) and distributed randomly into 50-L freshwater tanks. After acclimation the water temperature was gradually elevated from 15°C to 25°C by 1°C on a daily basis. Every day, the gills and liver of 3 fish each were sampled.

Real-time qPCR gene expression analysis of a gene set (development: 23, temperature challenge; 38) was performed by using the Roche LightCycler96 or Biomark HD systems. In addition, for the temperature experiment liquid chromatography/ mass spectrometry was used to assess the individual levels of glucocorticoids.

Results

We created a gene-profiling panel for different developmental stages and the detection of stress in pikeperch. It included genes involved in development, metabolism, stress and immune response (heat-shock and acute-phase proteins, hypoxia-induced genes, stress hormones, adaptive immune system), as well as transcription factors. In addition, we evaluated suitable reference genes for transcriptional analysis in juvenile pikeperch illustrated in Fig. 1.

(Continued on next page)

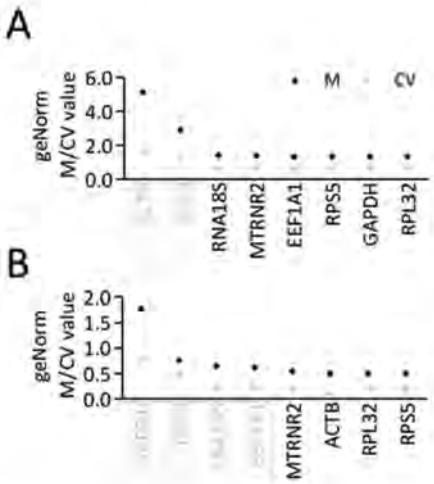

Fig. 1. **Evaluation of suitable reference genes for transcriptomic analyses in pikeperch.** Reference genes were evaluated for each particular set of samples from (**A**) liver and (**B**) gills based on the geNorm parameters M (black dots) and CV (grey dots). Reference genes that passed quality check are indicated by black gene symbols; others are indicated by grey gene symbols.

Discussion & Conclusions

In order to reduce the high losses in the early ontogenesis of pikeperch and to optimise their rearing conditions, it is necessary to gain basic knowledge of the physiology and underlying genetics of this species. On the one hand, our study provides basic expression patterns of development-specific marker genes in pikeperch. It also provides an extensive set of stress biomarkers for future assessment studies on the imbalanced homeostasis of the fish by means of molecular tools

This work was funded by the European Maritime and Fisheries Fund (EMFF) and the Ministry of Agriculture and the Environment in Mecklenburg-Western Pomerania (grants: MV-II.1-RN-001, MV-II.1-LM-001).

Background:
Glycerol is a simple compound, water-soluble, almost colourless, odourless, viscous, hygroscopic liquid that can be found in triglycerides, acting as a structural backbone. It is virtually nontoxic to human health and environment, when administered at physiological levels, and it is a by-product of biodiesel production. Once absorbed, glycerol can be metabolized as a glycolytic, gluconeogenic or lipogenic substrate for subsequent metabolism. This potential of glycerol to be used as a dietary alternative source of energy was already tested in several farmed terrestrial animals (pigs, poultry and bulls), but also fish species such as Nile tilapia, catfish and gilthead seabream. Rainbow trout (*Oncorhynchus mykiss*) is an important carnivorous fish species in aquaculture which is adapted to high levels of dietary protein, but with recent studies unravelling its capacity to utilizing dietary carbohydrates. We hypothesize that glycerol could effectively compete with dietary amino acids for gluconeogenic carbons thereby sparing their conversion to glucose/glycogen. This was evaluated by a series of sequential trials involving the evaluation of zootechnical parameters, growth performance and feed conversion efficienc , but also metabolic, metabolomic and enzymatic analysis.

Methods:
Three isoproteic, isolipid and isoenergetic diets were formulated while fulfilling the known nutritional requirements of the species (Sparos Lda., Loulé, Portugal). Briefl , a control diet with no glycerol (D0); and two experimental diets, supplemented with 2.5% (D2.5) or 5.0% (D5.0) glycerol (at the expense of cellulose) were tested.

Nine groups of 25 fish (average body weight 20.2 ± 0.1 g) were randomly distributed between 9 fibe glass tanks (volume 300 L, water flow rate: 120 L h^{-1}), in a flow-through freshwater system (15±1°C temperature; 6.7±0.1 pH; exposed to natural photoperiod). The diets were randomly assigned to 3 tanks each and fish were hand-fed twice daily until apparent satiety. At the end of 8 weeks, classical zootechnical parameters were evaluated. Fish were also sampled 6 and 24 h after last meal and sampled for plasma and liver tissue to evaluate the enzymatic regulation of the main metabolic pathways. The remaining 72 fish (24 per diet; 8 from each replicate tank) were kept in tanks with fresh water enriched with ~4% ^2H_2O, in a well-aerated recirculation system equipped with an external filtering unit and UV unit for another 6 days of feeding. Twenty-four hours after the last meal, animals were anesthetized, measured, weighed and sampled for several tissues. These were freeze-clamped in liquid nitrogen and kept at -80°C until further processing.

Results and Discussion:
Growth performance was overall unaffected by the dietary inclusion of glycerol after the 8-week feeding trial, although voluntary fed intake was significantly higher in trout fed a 5% glycerol diet. Liver glycogen and hepatosomatic index were affected by diet while plasma glucose, triglyceride and glycerol levels remained unchanged. Most genes coding for enzymes evaluated from the main metabolic pathways (glycolysis, gluconeogenesis and lipogenesis) responded significantly for post-prandial timing (6 vs. 24 h) but not for dietary glycerol. Incorporation of ^2H-labelling into several metabolites was evaluated by NMR. While sources of blood glucose remained unaltered, sources of hepatic glycogen significantly increased at the triose-phosphate level, indicating the utilization of dietary glycerol. Labelling of triacylglycerol in the liver, indicative of *de novo* lipogenesis was also unaltered by increased dietary glycerol. The same was observed in the muscle, where newly synthesised triacylglycerol was not significantly di ferent with glycerol supplementation.

(Continued on next page)

Conclusion:
Rainbow trout are able to efficiently utilize dietary glycerol without compromising growth and metabolic performance. Glycerol, which is considered a lipogenic substrate, did not enhance lipid accumulation, both in liver and muscle. This may represent a novel and economically viable strategy for minimizing the catabolism of dietary protein in farmed carnivorous fish

PHOSPHORUS REMOVAL FROM RECIRCULATING AQUACULTURE SYSTEMS (RAS) EFFLUENT BY REACTIVE COLUMN FILTERS

G. Renman[1], A. Renman[1], J. Pulkkinen[2] and J. Vielma[2]

[1]KTH Royal Institute of Technology, Stockholm, Sweden
[2]Natural Resources Institute Finland (Luke)

Introduction

RAS farms typically discharge wastewater streams containing increased concentrations of phosphorus (P)[1]. Drum filter and biofilter backwash water, tank sludge cones and various types of settling columns, swirl separators or radial settlers collecting sludge, are units emitting P. These wastewater streams have high solids concentration and thus contains most of the P not retained in fish growth. Another wastewater stream has low solids levels but contains most of the nitrogen not retained in fish growth. Albeit being the major nitrogen source, this stream is still high in P, and due to the stringent effluent regulation, RAS farms would benefit from further P removal. However, P is present mainly in soluble form, and cannot be efficiently removed by conventional coagulants and flocculants We report phosphorus removal of an up-flow packed bed reactor (PBR) filled with three reactive filter media; the calcium-silicate-hydrate Sorbulite, the calcium-silicate Polonite and, Polonite in combination with Vermiculite.

Material and methods

The column experiment was performed at RAS research systems of Luke's Laukaa fish farm, Finland, during 6 weeks from 24 April to 5 June. The pilot scale RAS run at 500 liters of replacement water per kg feed delivered the wastewater to the duplicate PBR's, of four treatments. Treatment 1 consisted of Sorbulite, treatment 2 of Polonite, treatment 3 of Sorbulite and Vermiculite (1:1 by volume) and, treatment 4 consisted of Polonite and Vermiculite (1:1 by volume). Each column was filled with approximately 6 of material. The Vermiculite was placed over the Polonite and Sorbulite materials.

Peristaltic pumps delivered wastewater to the columns with a continuous average flow of 9.1 mL/minute. Column effluent grab samples were taken one to three times per week and at the same time samples on the influent wastewater. Total-P and dissolved phosphate phosphorus (PO_4-P) concentration were analyzed using the SEAL Auto Analyzer (AA3) instrument.

Results and discussion

The results are shown in figure 1a and 1b. Total-P concentrations of the influent wastewater varied between 1.43 to 2.27 mg/L while PO_4-P concentrations ranged from 1.22 to 2.02 mg/L. The filter media Polonite and Polonite+Vermiculite efficiently removed Total-P and PO_4-P to concentrations of 50.8 µg/L and 9.4 µg/L respectively at the end of the experiment. The Sorbulite medium alone and with Vermiculite did not remove P very well. Column effluents had concentrations of Total-P as high as 1.93 mg/L.

The filter media Polonite has a well-documented efficiency to remove P from wastewater [e.g. 2] and in the case of fish farm wastewater it does not seem to be an exception. It should rather be an advantage since the used wastewater has a very low concentration of organic matter which can disturb the P sorption. Phosphorus breakthrough was not expected because of the short trial period. Complete breakthrough was not either shown for the Sorbulite medium, however the influent and effluent concentrations were close to each othe .

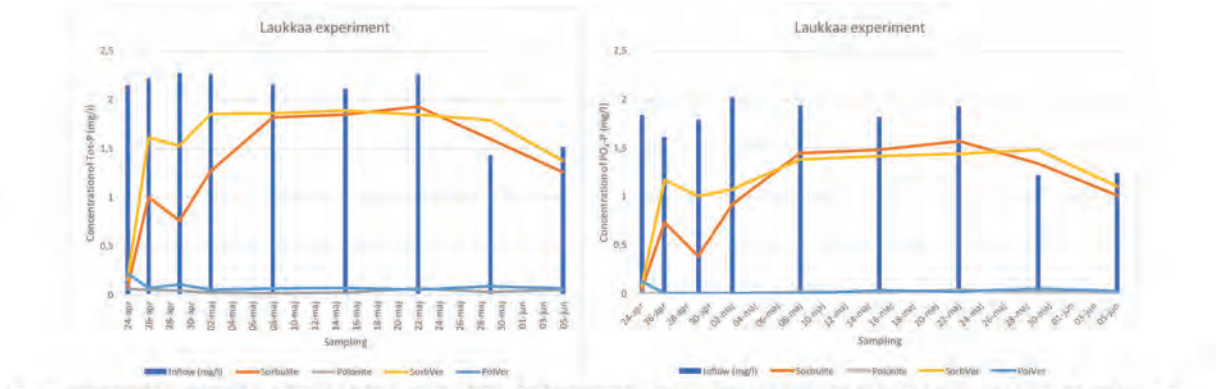

Figure 1: a) Removal of Total P and b) PO_4-P from fish-farm wastewater during a period of six weeks.

(Continued on next page)

Vermiculite was introduced in the filter system because of its known capacity to remove nitrogen (N). The removal data on N will be published elsewhere. The P removal efficiency of Vermiculite was probably very limited which is found from the results in figure 1a and 1b. Higher efficiency was expected by Sorbulite but this material has a long reaction time for P sorption and the retention time for wastewater in the columns was probably too short.

Conclusion

It is concluded that the reactive filter media Polonite is able to remove P from RAS effluent, where the P concentration is generally low, to reactive phosphate concentrations which can meet very stringent effluent criteria for discharge to sensitive water bodies. Sand beds after Polonite filters can be applied to reduce effluent Total-P concentration as small calcium particles with bound P leave the filters. A study with pilot-scale filter beds should be done to investigate the long-term performance, creating basis for cost estimations of a full-scale system.

WATER QUALITY INDICATOR FOR *AQUACULTURE* IN INTENSIVE CULTURE USING A FUZZY ANALYTICAL HIERARCHY PROCESS

*Midory Esmeralda Vigueras Velázquez
(Corresponding autor- midory.vigueras@gmail.com)
Jose Juan Carbajal Hernández, Luis Pastor Sánchez Fernández, Margarita Hernández Martínez

Aquaculture is the activity focused on the culture of aquatic organisms for its consumption or for the preservation of a species that are endangered due to the high levels of pollution seen in its ecosystem and severe overfishing. A fuzzy analytical hierarchy model for assessing water condition (subsequently FAHP-WQI) from whitefish in intensive culture ponds was developed. FAHP-WQI combines analytic hierarchy process and fuzzy logic.

Temperature, pH, dissolved oxygen and ammonia were considered. Based on the measurements of them, FAHP-WQI obtained an indicator of regarding the water quality condition as a good or bad. It was tested and evaluated in intensive ponds. Additionally, individual weights are computed and allocated according to the parameter importance on the water evaluation.

Water Quality Modelling

n aquaculture, environmental parameters have some concentration limits, where low or high concentrations (depending of the parameter) that can be harmful for the organism. Following these behaviors, it is possible to implement a fuzzy hierarchical model considering that those limits and changes in the ecosystem can be used for determining when a concentration is good or bad for fish, and how the combination between them, affects the water quality stability in the habitat. This strategy will be helpful for detecting potential crisis of cultured ponds in order to prevent stress in the organism and reduce mortality rates. The computational model can be consulted in Fig. 1.

This was compared with similar models and the proposed index shows a good performance in real environments. Due to index proposed by National Sanitation Foundation (NSF) provides a good basis for the freshwater quality assessment because a weight is assigned to each parameter according to their importance. In Fig.2 is possible to appreciate that NSF shows greater quality, the origin of this difference is in the importance assigned to dissolved oxygen, where practically the result depends primarily on this parameter.

Then, FAHP-WQI was compared with Canadian Council of Ministers of Environment Water-Quality Index (CCME), which is not composed of a weight system. CCME is calculated using different equations, which they take into account the scope, frequency and breadth. As reflected in Fig.3, CCME shows quality in maximums values, this is because it is an average of all the parameters involved is done, which is why can compensate bad conditions of one parameter with the good ones of another.

This model emerges as an alternative, suitable and reliable tool for the aquaculture of any aquatic species, only ranges must be set up for each species.

SELECTION FOR STRESS RESISTANCE AT EARLY STAGES OF DEVELOPMENT IN COMMON CARP:AQUACULTURAL AND BIOLOGICAL CHARACTERISTICS OF OFFSPRING

Vinogradov E. V., Simonov V. M., Recoubratsky A. V.

Filial of Freshwater Fisheries of Russian Federal Research Institute of Fisheries and Oceanography (Russia)

Email: vinogradus11@gmail.com

Introduction

The success of fish farming depends on the ability of the young to withstand the effects of biotic, abiotic and man-made factors. To reduce the effects of stress, new methods of broodstock formation with increased stress resistance are being developed. (Lomakina, Chernorotov, 1998). New breeding methods based on the selection of resistant groups in the early stages of development have been created. (Simonov, Vinogradov, 2012).

The aim of this work is to determine how the artificial selection for resistance to dehydration at the larval stage of development affects the aquacultural and biological characteristics of the offspring.

Material and methods

A material of this study was mature fish, eggs, larvae, fry and two years old carps. Three females and three males of each breed were crossed in a complete diallel pattern. Nine families were obtained. Part of each family in triple repetitions (1000 larvae) was subjected to dehydration. Three progeny with high survival after exposure were designated as experimental groups, and families with low survival were mixed and designated as controls. Rearing was carried out in separate ponds with the same conditions. After the catch, the fish characteristics of the each offspring were taken into account. Their resistance to acute hypoxia (Klyashtorin, 1982; Urbakh, 1964), as well as fluctuation of glucose level during and after handling (Romanova, 2004), were evaluated. Morphological differences were determined (Pravdin, 1966; Tyurin, 2010). Statistical processing was performed using Statistica 8.0 (ANOVA, Discriminant analysis).

Results

The average weight of the fingerlings did not have serious differences, for experimental groups it was 34.6 ± 0.74 g., and for control - 31.8 ± 1.18 g. The survival rate of the control group was 26.79 ± 2.56%, (4823 pcs.), which is almost two times lower than the experimental groups, 50.05 ± 3.69 (9090 pcs.). Hence, the low fish productivity of the control was 297.6 ± 17.8 kg / ha, while the experimental groups had 618.93 ± 50.39 kg / ha. On average, two-year-olds of all groups had no significant differences in either average weight or survival. This was due to the low growth rate and the survival rate of one of the experimental offspring, whose performance was lower than that of the control. However, the other two groups had an average weight advantage of 12%.Thus, despite the lag of one experimental group, the growth rate of control was lower than that of experience.

The resistance of the offspring to acute hypoxia was expressed after the time of death of 50% of the individuals. LT-50 for experimental groups was 191.2 ± 14.32 minutes, and for control -261.25 ± 18.26 minutes. Survival rate of the control under conditions of autogenous acute hypoxia was significantly higher than that of the experimental groups. The reaction to handling was determined by the fluctuation of blood glucose in the intact and stressed condition. In the intact state, the glucose level in the blood of all groups was the same and amounted to 26.2 ± 2.39 mg / dL and 27.5 ± 4.92 mg / dL for the experiment and control, respectively. After exposure, the level of stress in control was significantly higher, the glucose level was 45.6 ± 6.64 mg / dL and in the experimental group -32.65 ± 4.57 mg / dL. According these data, stress in control group at the equal impact was higher than in experimental group. Differences between groups were evaluated by morphotype based on measurements and calculations of body indices by Mahalanobis distance (Table1).

Discussion and conclusion

Based on the results of the work, it should be noted that the selection for resistance to the effects of stress at the larval stage of development leads to an increase in aquacultural properties after rearing in ponds. Also, the selection affects the physiological resistance of the organism to the adverse factors of natural and anthropogenic nature, as well as the morphometric parameters of farmed fish

Introduction

The aquaculture sector has rapidly expanded worldwide to meet the increasing demand for seafood; consequently, increasing amounts of raw feed materials are needed by this industry to sustain this rapid growth (Ganga et al. 2015). To date, fish meal (FM) and fish oils (FO) has been the most important protein source in aquafeeds, especially for carnivorous fish species, because it is an excellent source of high quality protein, essential nutrients, attractants, and potentially unidentified growth factors (Hardy, 1996). Consequently, the aquaculture feed industry requires suitable and sustainable ingredients alternative to FM and FO. Unfortunately, few studies have reported the effect of FM replacement by microalgae in fish innate immune parameters after bacterial challenge. Therefore, the aim of this study attempts to evaluate the immunostimulatory impact on several immune-related enzymes and bactericidal activity in plasma and skin mucus in European sea bass (*Dicentrarchus labrax* L.) fed diets that replaced fishmeal with *Chlorella* sp. and *Nannochloropsis* sp. during 12 weeks.

Material and methods

Healthy European sea bass (*Dicentrarchus labrax*) (24 ± 1,2 g mean body weight) were obtained from a commercial hatchery (Acuinuga, Spain). Fish were randomly distributed into 24 identical tanks (25 fish per tank) where the following groups were established in quadruplicate. Six diets were formulated, positive diet (positive control, PC) formulated with 30% FM and fish oil as the only lipid source; negative diet (negative control, NC) based on plant ingredients (15%) and low FM (15%), including a mixture of fish and vegetable oil (40/60) as the lipid source. Four test diets were formulated similarly to the negative control, replacing 7.5% and 15% FM by freeze-dried biomass of microalgae *Chlorella* sp. (Chrl7.5 and Chrl15) and *Nannochloropsis* sp (Nanno7.5 and Nanno15). The fish were fed until saturation, during 12 weeks. Fish were sampled after 1 and 12 weeks of feeding. At the end of trial, the fish were anaesthetized and inoculated by intraperitoneal injection (i.p.) with killed *Photobacterium damselae* subsp. *piscicida* (Phdp, strain PP3), while the same groups were i.p. injected with sterile PBS (control groups). The bacteria concentration was 10^5 cfu/per fish. Challenged and unchallenged fish were sampled for plasma and skin mucus at 4, 24 and 48 h post injection. Fish were maintained in the same system and same conditions as during the growth trial but in separate tanks. The methodology of all immune-related activities is described in detail elsewhere (Guardiola et al. 2016).

Results

Our results revealed that the lysozyme, protease and antiprotease activities were unaffected in plasma of fish fed all experimental diets after 1 and 12 weeks. After 1 week of feeding, a significant increase in peroxidase activity plasma was observed in fish fed Chlrl15 diet respect to the values found in plasma of fish fed Nanno15 diet. Interestingly, the bactericidal activity against *P. damselae* was higher in plasma of fish fed Nanno7.5 compared to the other experimental groups. At the end of the trial (12 weeks), an increase in the bactericidal activity against *Vibrio anguillarum* and *P. damselae* was observed in the plasma of fish fed Chlr7.5 and Chlrl15 diets respect to NC and PC diets, respectively. The complement activity was higher in fish fed Nanno 15 compared to the results observed in the fish fed PC diet and both Chlr diets (7.5 and 15)

After bacterial challenge, any variations were observed in the activities measured at 4 hours post-challenge. However, the bactericidal activity against *P. damselae* was higher in the plasma of challenged fish fed Nanno15 respect to unchallenged ones, after 24h, and in challenged fish fed Chlrl 7.5 decreased respect to the fish fed Nanno 15, after 48h. In the challenged fish a decrease in the lysozyme plasma in fish fed Chlr7.5, after 24 hours was observed. The antiprotease activity was higher

(Continued on next page)

in challenged fish fed Chlr7.5 diet respect to PC diet after 24h. Interestingly, decrease in the bactericidal activity against *V. anguillarum* after 4 h were observed in the unchallenged fish fed Chlrl 7.5 diet respect to the fish fed NC diet, and the challenged fish fed Nanno 7.5 diet respect to the fish fed PC diet. Interestingly, the increase in peroxidase activity were observed in challenged and unchallenged fish fed Chlrl 7.5 respect to the fish fed PC diet, after 24 and 48h. Haemolytic complement activity increased in the challenged fish fed Nanno 15 diet, compare to the fish fed PC diet. Interestingly, nitric oxide activity increased in the challenged and unchallenged fish fed Chlrl 7.5 diet respect to the fish fed PC diet, after 24h. The values of protease activity increased in the unchallenged fish, fed Chlrl 15 diet respect to the challenged one. In the case of skin mucus, the values of lysozyme activity decreased in the fish fed Chlrl diets respect to other experimental groups at 1 week, whilst the peroxidase activity showed an increase in the fish fed Chlrl 15 diet respect to other experimental groups after 12 weeks of feeding. However, the antiprotease activity increased in fish fed Chlrl 7.5 compared to the other experimental groups at the end of the trial (12 weeks). Interestingly, the bactericidal activity against *Vibrio anguillarum* exhibited a decrease in skin mucus of fish fed Chlrl 15 diet respect to control diet at both sampling times.

Discussion and conclusions

Nannochloropis sp. with 7.5 and 15 % replacement of fishmeal, did not have any negative effects in the systemic and local immune response. In fact, in the present work has even been observed that some immune parameters were improved in fish fed Nanno diets. Therefore, Nanno diets could be considered a good fishmeal partial replacement whilst Chlr diets with 7.5 % and 15% replacements of fish meal seem to be inadequate for aquafeeds

emente@uth.gr

Introduction

An aquaponic system combines a closed aquaculture system with hydroponics in a symbiotic environment with invisible beneficial bacteria. Thus, an aquaponics system has the fish, the plants and the crucial bacteria. Water containing fish waste provides to the plant's valuable nutrients and in exchange "excess nitrogen-free" water returns to the fish tanks in a repetitive circle (Somerville et al. 2014). The nitrification process which takes place in the bio filter first converts the toxic ammonia from fish waste to nitrite and then the nitrite is converted to nitrate with the help of the «*Nitrosomonas sp.*» and the «*Nitrobacter sp.*» bacteria. The biofilter provides a large surface area, proper temperature, pH and dissolved oxygen for the bacteria to accommodate them and keep the system healthy. The aim of this study was the set up and the conditioning of a small-scale brackish water aquaponic system under two different salinities (8 ppt and 20 ppt).

Material and Methods

The study was carried out at the aquaponics lab of the University of Thessaly where six autonomous aquaponics systems were designed and constructed. Two metal benches were built into which the aquariums of the fish and the grow beds of the plants were placed in a parallel arrangement, thereby allowing the water to flow due to gravity from the grow bed to the fish tank and from there in turn to the sump filte . For each aquaponic system a 55 L fish tank, a 55 L raft type grow bed and a 30 L biological sump filter was constructed as described by Vlahos et al. (2004).The sump filter was divided into three different parts with surface areas (455 cm², 214.5 cm² and 214.5 cm²)for the mechanical filte , biological filter and reservoir tank respectively. All of the piping circuits used in each aquaponic system for the water flow were PVC pipes (32mm). The water flow of all the systems was continuously flowing thereby creating a constant flow rate of 1496 cm^3 / min and a filtration rate of 2.24 cm / min. For each aquaponic system air pumps were used and oxygen was supplied by aeration through an air stone to ensure better diffusion of air into the water for both fish tank and plant grow beds. The lighting was provided using sodium vapor lamps which were placed in reflectors. The photoperiod was set at 12 hours dark 12 hours light. The filter conditioning of each aquaponic system was achieved through the methodology described by Vlahos et al. (2013) and Mente et al. (2016). Initially, in order to achieve complete evaporation of chlorine from the water, the aquaponic systems were operated for 24 hours and then 2-3 grains of a filter media (e.g lava grain) from an aquarium of satisfactory functioning were added into the filters for the growth of the bacteria of the biological filte . To initiate the filter procedure, 0.2 g of NH_4Cl was added as a source of ammonia to the filter (Vlahos et al. 2004). Total ammonium nitrogen (T.A.N), nitrite (NO_2^-) and nitrate ions (NO_3^-), pH and O_2 were measured twice a week. The oxidizing capacity, the active depth of the filter and the waste load of the fish were calculated as described by Hirayama (1966) and by Spotte (1992). Active depth of the filter is the depth in which half of the ammonia produced is oxidized to non-toxic nitrate ions per water recirculation. Data were analyzed using the independent t-test to determine the significant differences between the means of all groups at $p<0.05$. Data were checked for normality and homogeneity test through Levene' s test (Zar 1999).

Table 1: Functional characteristics of a brackish aquaponic system under two different salinities. Data were expressed as means ± S.E.M (n=6).

	8 ppt	20 ppt
Hydraulic Loading Rate (HLR) (m/day)	1.85±0.005 [a]	1.85±0.005[a]
Rerciculation rate (r) (min)	0.014±0.003[a]	0.014±0.003[a]
Water Retention time (min)	9.7±0.01[a]	9.7±0.02[a]
Specific Surface area (SSA) (m^2/m^3)	162±0.30[a]	224±0.31[b]
Volume media (V_{media}), (m^3)	6.73±[a]	6.94±0.08[b]
Filter's Volume (V) (L)	32.13±0.001[a]	32.13±0.001[a]

(Continued on next page)

The results showed that the conditioning of the aquaponic systems was observed when TAN eliminated to 0.05 mg/Land nitrate ion was continuously increased until reach their maximum value which was 160 mg/L. The oxidizing capacity of the filter was 0.17 mg O_2 and the active depth of filter bed was 4.5±0.05cm for all aquaponic systems. Spotte (1992) reported that the half depth of the filter bed when TAN was reduced by 50% was lower than 10 cm depth.

The active depth was characterized as the ability of the filter to remove the maximum produced waste pollutants of the fish due to their metabolism (Table 1). In addition, the hydraulic loading rate (HLR), the recirculation rate, the retention time of the water into the filter (t), the specific surface area of the filter (SSA), the volume of filter media (V_{media}) and the filter volume (V)were summarized on Table 1.Endut et al. (2009) suggest that the best HLR for a fresh water aquaponic system was 1.28 m/day because it provides the best production performance for fish (SGR: 1.80%/day)and plant growth (1.75 cm/day). In the present study the HLR (1.85 m/day) was higher. However, it provides also higher growth performance for fish (SGR: 3.17%/day) and plants (PGR:1.87 cm/day for 20 ppt and 0.99 cm/day for 8 ppt, respectively) in a brackish aquaponic system.

Introduction

In bivalve species, metamorphosis, the transition from a free-living larva to a juvenile (spat), is regulated by a complex interaction of neurotransmitters and neurohormones. The actual regulatory pathways, however, are still poorly understood. Catecholamines such as epinephrine are neurotransmitters routinely used in oyster hatcheries to induce metamorphosis and settlement when single-seed production (spat not attached to a substrate) is desirable. However, epinephrine only induces metamorphosis in certain species of bivalve molluscs, and there is limited understanding of the pathways involved (Joyce and Vogeler, 2018), thus making it difficult to apply existing knowledge when developing hatchery protocols for new species. Therefore, our current work aims to better understand the signalling pathways involved in regulating bivalve metamorphosis by investigating the N-methyl-D-aspartate (NMDA) receptor pathway and the nitric oxide (NO) pathway as two potential regulatory drivers of metamorphosis; two concepts that have not been considered previously for bivalve development.

Methods

Competent larvae (approx. 100 pediveliger larvae ready for metamorphosis) of the Pacific oyster (*Crassostrea gigas*), Eastern oyster (*Crassostrea virginica*), hard-clam (*Mercenaria mercenaria*) and soft-shell clam (*Mya arenaria*) were exposed to known vertebrate NMDA receptor antagonists, MK-801 and ifenprodil, and to epinephrine. Metamorphosis success was assessed after 24h. Pacific oyster larvae were also exposed to known nitric oxide synthase inhibitors (NOS, key enzyme involved in NO production) such as s-methylisothiourea sulfate (SMIS), aminoguanidine hemisulfate salt (AGH) and 7-nitroindazole (7-NI) as well as to ODQ, an inhibitor to the guanylyl cyclase, which is an enzyme for the production of cGMP and activated by nitric oxide. NMDA receptor subunits were cloned and their gene expressions were quantified in competent Pacific oyster larvae and larvae treated with NMD receptor antagonists by quantitative real-time PCR. The NMDA receptor subunit CgNR1 was localised in competent Pacific oyster larvae by *in-situ* hybridisation.

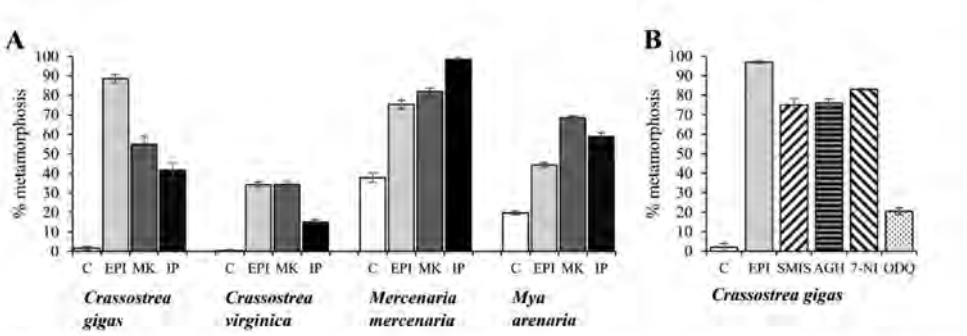

Fig. 1: Percentage of metamorphosis after 24h in (**A**) oyster or clam larvae after exposure to epinephrine at 10^{-4}M (EPI), MK-801 at 10^{-4}M (MK) and ifenprodil at 10^{-7}M (*Crassostrea. virginica*) or 10^{-6}M (remaining species), and in (**B**) *Crassostrea gigas* larvae after exposure to SMIS, AGH, 7-NI and ODQ. All treatments were significantly different to each species' respective no-treatment control (C).

(Continued on next page)

Results

Exposure of competent larvae to the NMDA receptor antagonists significantly induced metamorphosis in all four bivalve species with optimal concentrations ranging from 10^{-4}M to 10^{-7}M (Figure 1A). In particular, both clam species were highly responsive to the NMDA receptor antagonists with e.g. *M. mercenaria* displaying almost 100% induction to ifenprodil at a final concentration of 10^{-5}M and 10^{-6}M. In *C. gigas*, the three NOS inhibitors as well as the guanylyl cyclase inhibitor ODQ induced metamorphosis with the NOS inhibitors resulting in the strongest effects with metamorphosis rates ranging from 75% to 83% (Figure 1B). The NMDA receptor subunits, CgNR1 and two CgNR2 (CgNR2A and CgNR2B) were successfully cloned and expression studies showed all subunits are expressed in competent oyster larvae, although their expression was not affected by the different treatments. *In situ* hybridisation has shown that the NMDA receptor subunit CgNR1 is mainly expressed in areas where the pedal nerve fibres and apical ganglion are located in competent larvae

Discussion

NMDA receptors are ligand gated ion channel receptors located in signalling cell membranes in the nervous system. Based on the exposure experiments it seems that metamorphosis is negatively regulated by an NMDA receptor pathway given that metamorphosis can be induced after exposure to NMDA receptor antagonists. Furthermore, NMDA receptor subunits in competent Pacific oyster larvae are located in nerve structures, which are connected to the larval foot and apical organ (at the base of the velum), two organs lost during metamorphosis and suspected to partially function as sensing organs for external settlement cues. NMDA receptors are known to regulate specific signalling pathways by increasing the intracellular calcium concentration. We hypothesise that this increase in intracellular calcium concentration is activating the NOS, the key enzyme for the production of NO. Nitric oxide, a gaseous signalling molecule and neurotransmitter, potentially inhibits bivalve's metamorphosis through a series of negative cell responses (i.e. inhibition of apoptosis) as it has been previously proposed for other invertebrate species (Leise et al, 2004; Comes et al, 2007). However, to our knowledge the effect of NO on bivalve larvae has not been investigated and our theory is supported by the increasing metamorphosis rate in Pacific oyster larvae after exposure to different NO pathway inhibitors. This new concept of the NMDA receptor and NO pathway regulating bivalve metamorphosis could potentially provide the missing information to identify new external chemical inducers for metamorphosis in different bivalves to optimize hatchery productivity.

A GIS SUITABILITY ANALYSIS FOR SELECTING MUSSEL FARM SITES IN THE SOUTH-WESTERN BALTIC SEA

M. von Thenen*[1,2], H.S. Hansen[2] and K.S. Schiele[1]

Introduction

Mussel farming is one of the most sustainable forms of aquaculture due to the mussels' filtering capacity and may be used as a mitigation measure for eutrophication or to mitigate some of the negative impacts of fish farms. In Denmark there is a halt for new fish farm permits in marine areas due to environmental concerns regarding eutrophication, which is, in particular, a problem in the Baltic Sea. Therefore, mussel farming has increasingly come into focus. This study presents a GIS based suitability analysis that is combined with an ecological model. It shows where mussel farming is possible in terms of ecological suitability and spatial availability and investigates the identified sites in more detail to determine which site has the highest potential in terms of mussel harvest and effects on water clarity. The latter is an important criterion for site selection in eutrophied seas, such as the Baltic Sea.

Methods

The suitability analysis was applied to a case study in the south-western Baltic Sea. It consists of a Multi-Criteria analysis that is implemented in GIS using raster data. Criteria include existing maritime activities, as they put constraints on the available area, and environmental conditions that determine mussel growth. For each criterion a parameter-specific suitability function (PSSF) (Longdill et al. 2008) was identifie on a scale between 0 and 1 (unsuitable-suitable) or on a binary scale (unsuitable or suitable). The suitability maps created for the area were used to identify potential suitable locations for mussel farms. These locations were further analysed with a dynamic energy budget model (DEB) that is implemented into a 3D farm scale model. The model simulates the dry weight and shell length of blue mussels. These parameters were used to estimate the amount of nutrients removed by harvest and impacts on water clarity.

Results

The GIS analysis shows that large parts of the case study area are unsuitable for mussel farming due to spatial restrictions and insufficient environmental conditions. The suitability maps pinpoint to the area of Hjelm Bay in Denmark as a potential location for mussel farms. The three sites selected for investigation in the ecological model show a potential harvest of up to 4t ha^{-1} after 2 years and an increase in water transparency of up to 50% in the summer time.

Discussion and conclusion

The GIS analysis serves well for screening marine areas with regard to suitable locations for mussel farming. It requires data on maritime activities and environmental conditions in the areas of interest, which can be an obstacle for the application in marine areas with low data availability. This was not the case in the study area, however. The screening was followed by a more thorough analysis of the identified potential suitable sites to get an idea of the potential mussel harvest from these locations and to estimate the effect on water clarity. This two-step approach – screening for potential locations of mussel farms and more detailed investigation of identified sites – is a suitable method to support mussel farm site selection. The GIS analysis will be converted to a user-friendly tool as part of the Decision-Support System developed by the BONUS BASMATI project. Via this platform, end-users will be able to access it and apply it to different areas.

Introduction

The capacity of a fish to deal with oxidative stress depends among other factors on the contribution of nutrients or dietary compounds that via different mechanisms define anti-oxidative defenses (Birnie-Gauvin et al., 2017)in favour of the former. In recent years, the associationbetweenoxidativeprocesses,environmentalchangeandlifehistorieshas receivedmuchattention.However,moststudieshavefocusedonavianandmammalian taxonomicgroups,withlessattentiongiv entofish,despitetheirecologicalandsocio-economicrelevance.Herewepresentareviewoftheextrinsicandintrinsicfactors that influence oxidative processes in fish, using a comparative and evolutionary approach. We demonstrate that oxidative stress plays a key role in shaping fish s responses to environmental change as well as life history strategies. We focus on representative examples to compare and contrast how levels of oxidative stress respondtochangesintemperature,salinityand oxygenavailability.Furthermore,we describe how emerging threats (i.e. pollution. Feeding carnivorous fish, like salmonids, with diets rich in plant derived ingredients have shown to disrupt the oxidative balance in different tissues, poiting to an increase in the demand for dietary antioxidants (Wacyk et al., 2012)"ISSN":"00448486","abstract":"The objective of the study was to evaluate the effect of dietary protein source on fish growth, nutrient utilization, plasma variables and hepatic gene expression in juvenile rainbow trout (Oncorhynchus mykiss. The inclusion of polyphenol rich products has shown to improve antioxidant defenses in different tissues of mammals and chickens (Brenes et al., 2016), however information regarding similar benefits in carnivorous fish fed diets supplemented with this type of ingredients, is lacking. The objective of the present work was to evaluate changes in hepatic gene expression and antioxidant capacity (ORAC) in the plasma of rainbow trout (RBT) in response to the dietary inclusion of a grape marc extract in plant rich diets.

Material and Methods

Red wine grape marc microencapsulated using maltodextrin as wall material and used to formulate three experimental diets. Four hundred and fifty RBT juveniles (90 g) were randomly distributed to nine 380 L tanks and fed the three experimental diet. One plant-based control (0% grape marc), and two plant-based diets with 1 and 2% grape marc inclusion were extruded using industry settings. Diets were randomly distributed and delivered three times a day (2% BW) during the experimental period. Hepatic and blood samples were taken from 3 fish per tank at 0, 4, 8 and 12 weeks.

Results

Preliminary results, (first 24 hours) show that the inclusion of grape marc in rainbow trout diets is able to cause significant changes in plasma antioxidant capacity (Fig 1. a). The inclusion of 2% grape marc consistently elevated ORAC in the plasma of the sampled fish in this period when compared with the rest of the experimental treatments. Results also show, significant differences in terms of circulating iron (Fig 1. b), however, not a clear trend of the inclusion of grape marc over the plasma levels of this mineral. Similar response was observed for other plasma parameters evaluated in the present study.

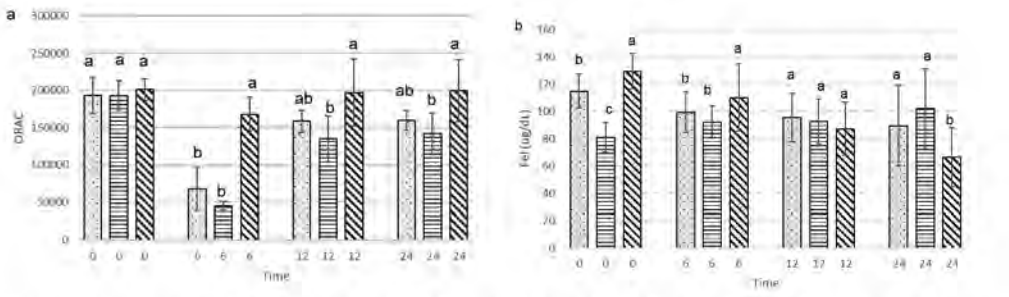

Fig. 1. Plasma antioxidant capacity (ORAC) and Iron (Fel) levels in Rainbow trout plasma fed diets with 0% (▒) 1% (▤) 2% (▨) grape marc inclusion. n=3, different letters indicate statistical difference (p<0,05). Time in hours post feeding. ORAC units umol Equiv. Trolox.

(Continued on next page)

Discussion and conclusion.

The present data indicate that the inclusion of grape marc microencapsulated has the potential to improve plasma antioxidant capacity without altering other variables of fish plasma. This seems to be in agreement with increases in antioxidative defenses previously reported in chicken for this type of product (Chamorro et al., 2015). There are just few reports in fish using polyphenol rich product from grape, with no direct evaluation over antioxidant defenses, nonetheless reporting, improvements in growth and immune response (Magrone et al., 2016; Zhai et al., 2014). Current data on the use of polyphenol rich products derived from grape, including grape marc indicate that seem to be suitable ingredients to be use in carnivorous fish diets. Further research is needed to better evaluate effect over the fish and optimize the product inclusion in the diets.

APROPOSAL TO INCREASE CARRYING CAPACITY OF HIROSHIM BAY ECOSYSTEM TO INCREASE OYSTER CULTURE PRODUCTION WITH SIMULTANEOUS MAINTAINING THE SPECIES DIVERSITY

Wahyudin* and T. Yamamoto

Graduate School of Biosphere Sciences, Hiroshima University, Japan
*Email: wahyudinps@outlook.com

Introduction

Hiroshima Bay (HB) has a long history of Pacific oyster or Japanese oyster (*Crassostrea gigas*) culture. The way of hanging oysters under a floating raft has been used for culture since 1958 (Kusuki,1981). The raft used for oyster culture is rectangular in shape with 20 m x 10 m. It is suggested that a large number of oyster rafts (ca. 12,000) placed in northern Hiroshima Bay (nHB) is supposed to be working as "artificial hanging reef" (Matsuda et al., 2000). Ecologically, oysters are providing a wide range of ecosystem services, by improving water quality through their filtering activity (Newell et al., 2004), and provisioning habitat for fishes (Peterson et al., 2003). The objective of the present study is to evaluate quantitatively the biomass of organisms attached and associating with oyster rafts. We also estimate how to function the oyster raft as an artificial reef in terms of the material cycle using the prey-predator numerical model

.

Materials and methods

Biomass of organisms was estimated by field observations for those associating with oyster rafts at three oyster rafts in addition to those at 7 stations at shoreline in June, July and August 2016. Animals attached on hanging oyster clusters and those attached on concrete walls and natural rocks in the shoreline were identified and counted. Fish gathering under the oyster rafts were also identified and counted by video recordings

To understand material cycles in nHB, we constructed a numerical model to express phosphorus flows in prey-predator interactions. The dominant organisms whose biomass was higher than 5% of the total weight were selected to be incorporated in the model. As a result, 22 compartments were placed in the model. The model was developed using a software Stella Architect (version 1.4.3), running with a time step of 0.02 days by the fourth-order Runge-Kutta method.

Results

The video camera records showed three commercial fish species (black seabream, pufferfish, and black rockfish) were dominant under the oyster rafts. Among the animals attached on the oyster clusters, oysters were largest in weight (67.2±2.2 g) compared to mussels (0.4±0.2 g) and barnacles (3.4±1.7 g) but were less abundant in numbers compared to the latter twos.

As shown in Table 1, the increasing of oyster (OYS) biomass decreased the biomass of all animals such as attached organisms and fish associating with the oyster rafts. Analyses of material flow revealed that larger amount of materials produced by phytoplankton go to OYS and the rest were shared by the other filter feeders

Table I. Summary of percentage responses of animals attached (OYS: oyster, MUSS: mussel, BARN: barnacle) and associating dominant fish (BSE: black seabream, PFI: puffer fish, BRO: black rock fish) to increasing/decreasing of OYS biomass.

Compartment	Present value (mg P m^{-3})	OYS biomass (0.141 Ind. m^{-3})					
		+30%	+50%	+100%	-30%	-50%	-100%
MUSS	0.118	-4%	-7%	-12%	+2%	+4%	+10%
BARN	0.002	-3%	-7%	-12%	+2%	+4%	+8%
BSE	0.019	-3%	-6%	-10%	+2%	+3%	+8%
TSF	0.053	-4%	-7%	-12%	+2%	+2%	+11%
PFI	0.100	-4%	-7%	-12%	+2%	+2%	+11%
JSB	2.819	-1%	-3%	-6%	+1%	+2%	+3%
BRO	1.22	-1%	-3%	-6%	+1%	+2%	+3%

(Continued on next page)

Discussion and conclusion

It was revealed that increasing of oyster biomass may decrease the biomass of all the other living things by monopolizing the products by phytoplankton. Since mussels and barnacles are food sources for some fish species (BSE, TSF, and PFI), the decrease of mussel and barnacle production also effect on fish production. This could lead to low species diversity even if the oyster production can be increased.

Cultured oyster production in HB has been decreasing to 2/3 since the 1980s in addition to the decrease of fish catch. It is pointed out that the government measure to reduce phosphorus and nitrogen loads since 1980s is the major cause of the decrease of fisheries production (Yamamoto, 2003). Since the phosphorus load is very small (880 kg P day^{-1}in 2016) compared to those in 1980s (~80 ton P day^{-1}), we cannot attain the level of large oyster production as we had in 1980s unless the input of phosphorus and nitrogen are increased, because of the shrinkage of carrying capacity of the bay ecosystem. In the other areas, relaxation of sewage effluent from treatment plants has started, but the effect is limited because of dilution with the large volume of seawater. Since the government is nervous on the risk of red tide generation by the operation, the relaxation is practically conducted to the level of the upper limit of allowance, whereas fishermen s request to remove the allowance limit.

An alternative is to apply fertilizer in a raft scale, which may be efficient as proposed by Yamamoto et al. (2017). They actually increased ca. 20% in the oyster individual weight in average by an application of fertilizer. We would like to propose a measure to increase the carrying capacity of the bay by application of fertilizer in addition to the relaxation of sewage effluent which can increase oyster production with simultaneously sustaining the species diversity in the ba .

BIOINFORMATIC ANALYSIS AND IMMUNE-STIMULATED TRANSCRIPTIONAL ANALYSIS OF THE IFP35 COUNTERPART FROM ROCK BREAM (*Oplegnathus fasciatus*)

W.S.P. Madhuranga and Jehee Lee

Department of Marine Life Sciences and Fish Vaccine Research Center. Jeju National University, Jeju Self Governing Province 63243, Republic of Korea

Introduction

Interferon-induced protein-35 (IFP35) is a 35kDa protein that was first discovered in HeLa cells stimulated with IFN-γ(Bange et al., 1994)named IFP 35, whose expression is regulated by interferons (IFN. It is a leucine zipper protein, and it is induced in the regulation of gene expression(Bange et al., 1994)named IFP 35, whose expression is regulated by interferons (IFN. However, the physiological and biological roles of the IFP35 are not known. IFNs are major cytokines in the immune reaction regulations and regulating the immune and inflammatory reactions(Schneider et al., 2014). There are three types of IFNs have been identified according to their amino acid sequences(Randall and Goodbourn, 2008)if not all, virus infections in the absence of adaptive immunity. However, viruses can still replicate and cause disease in vivo, because they have some strategy for at least partially circumventing the IFN response. We reviewed this topic in 2000 [Goodbourn, S., Didcock, L. & Randall, R. E. (2000. IFP35 initially found in mitochondrial located in the cytoplasm. This protein can translocate to nucleus from the cytoplasm through stimulating the IFNs(Chen et al., 2000). When viruses are attacked to the cell, IFNs are secreted into the extra cellular matrix to bind their related receptor on neighboring cells(Altmann et al., 2003)IFN-beta, IFN-omega, IFN-delta, IFN-kappa, and IFN-tau is a large group of cytokines involved in the innate immune response against various microorganisms. Genes for IFN have been cloned from a variety of mammalian and avian species; however, IFN genes from lower-order vertebrates have not been forthcoming. Here, we report the cloning and characterization of the IFN gene from the zebrafish, Danio rerio. Zebrafish IFN (zfIFN. This activated signal stimulates a group of antiviral proteins such as antigen presentation proteins, apoptotic proteins, GTPases, chemokines and heat shock proteins(Sen, 2000).

Materials and methods

Rock bream (*Oplegnathus fasciatus*) Interferon-induced protein-35 (*RbIFP35*) homolog was identified, and its biological functions were characterized. Rock bream complete cDNA of IFP35 got from rockfish cDNA transcriptomic database. *RbIFP35* protein characteristic and structural features were analyzed by several bioinformatic tools, such as ExPASy PROSITE, NCBI BLAST programme, and SignalP online server. The expression level of mRNA in rock bream was analyzed by quantitative real-time PCR technique. Conserved domain parts of the *RbIFP35* were determined by using multiple sequence alignment tool, Clustal W. The phylogenetic tree analysis was constructed according to the Neighbor-joining (NJ) method by MEGA 5.0 software. The putative 3D structure of the *RbIFP35* was constructed by I-TASSER server. To measure the immune response of *RbIFP35* on stimulant or pathogens, healthy rock breams were used to experiment. Each group of rock bream was injected with rock bream iridovirus, *Edwardsiella tarda*, *Streptococcus iniae*, lipopolysaccharide and polyinosinic: polycytidylic acid. Phosphate buffered saline (PBS) was injected into the control group. For each treatment, various tissues were collected from the challenged rock bream from different time intervals. Then total RNA was extracted from each tissue and did the qPCR assay.

Results

The two NID domains in the *RbIFP35* open reading frame(ORF) were identified by using online software tools. The *RbIFP35* mRNA was highly expressed in rock bream gill tissue compared with others. *Lates calcarifer* IFP35 gene was aligned with *RbIFP35* with more than 70.6% identity in the pairwise homology analysis Phylogenetic tree analysis represented that the *Larimichthys crocea* IFP35 and *RbIFP35* have a closer evolutionary relationship with each other. The putative 3D structure of the *RbIFP35* was constructed by I-TASSER, and the two NID domain parts were identified. The significant increment of the mRNA expression level of *RbIFP35* in blood tissue after the post challenged. In response to the infection with Poly: IC, *RbIFP35* mRNA expression was significantly increased from 6 to 24h, peaking at 12h. Following the LPS administration, mRNA expression upregulated to at 24h. *E. tarda* infection, mRNA expression level upregulated at 12h. RBIV infection and *S. iniae* significantly increased *RbIFP35* expression, with the peak of 2.47-fold and 2.26-fold increases in expression levels peaking at 24h, respectively.

(Continued on next page)

Discussion and conclusion

We analyzed the functional aspects and molecular structure of recombinant *RbIFP35*. *RbIFP35* is a protein composed of 368 aa. The presence of two NID domains in *RbIFP35* suggested its Nmi-Nmi protein interaction ability(Chen et al., 2000). *RbIFP35* represent high aa sequence identity with fish homologs, but low identity with reptiles, mammals and bird's homolog. We find the evolutionary stage of that gene in vertebrate evolution. We identified the *RbIFP35* mRNA content in various tissues and assessed that was upregulated with the certain immune stimulants and pathogens. Findings of the current study represent the overall informative information related to the IFP35 gene of the rock bream.

SUSTAINABLE AQUACULTURE OF ATLANTIC SALMON (*Salmo salar*) ON BOARD A LARGE SAIL SHIP

U. Waller[1]*, K. Kimmerle[1], S. Boehmer[2], U. Köhler[2]

[1]University of Applied Sciences Saarbruecken, Goebenstrasse 40, 66117 Saarbruecken, Germany
[2] Sailing Cargo Schifffahrtsbeteiligungs GmbH, Versmannstr. 24, 20457 Hamburg, Germany

E-mail: uwe.waller@htwsaar.de

Introduction

Atlantic salmon is a core product of the European seafood trade. The European aquaculture production of Atlantic salmon is exceeding landings from fisheries by 700 times, or 1000 times in view to the global scale. It is desirable to change and improve an aquaculture technology which is more and more faced with severe environmental issues.

Most of European salmon aquaculture is situated along the coast. The coast lines are affected by climate change and previously favorable hydrographic conditions change for the worse. The biological temperature preferences of aquaculture fish species such as Atlantic salmon (*Salmo salar*) may not be met anymore (Wade et al. 2019). Thermal stress in fish affect metabolic expenditure and eventually weakens the immune response of fish living in dense aquaculture populations.

The attempt to bring European salmon aquaculture on land into RAS is resource-intensive. A production area of several thousand hectares is required if a safe RAS technology (Orellana et al. 2014) is employed. The energy demand to maintain a cold-water environment for salmon is tremendous. Thus, the idea emerged to bring salmon aquaculture into the ocean in quantities that fit the market requirements. The attempt in the industry to produce bigger and bigger cohorts in giant oceanic installations is in conflict with the environment because they represent point sources of pollution which is a core problem of industrialization. In contrast, our key idea is to develop an environmentally sound and sustainable novel aquaculture technology. This includes the use of wind power to move the aquaculture ship and to run the process technology on board.

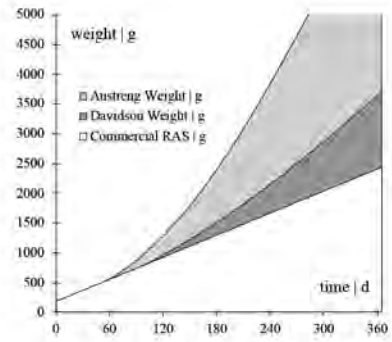

Fig. 1: Evaluation of Atlantic salmon growth redrawn with data from Austreng et al. (1987), marine net cage; Davidson et al. (2016), fresh-water RAS; commercial fresh water RAS.

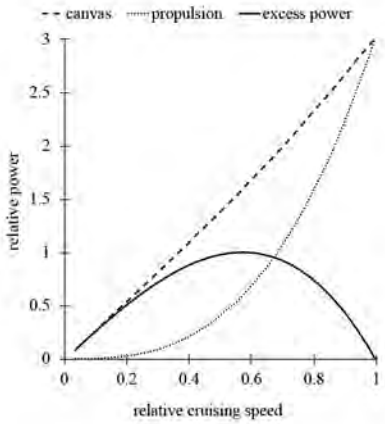

Fig. 2: Relative wind power allocation on a sail ship cruising half wind.

Method

The proposed sail ship is an aquaculture process ship tailored to the need of Atlantic salmon. A growth model based on literature data (Fig. 1) was developed, basic operations and an appropriate process chain were defined, and mass flows and energy consumption for both the fish and the technical processes were calculated. Following aspects were so far considered in the process:

- Smolt supply and transfer process, RAS for inspection of incoming fis
- Process tank, hydrodynamics, water exchange, gassing, degassing, lighting
- By-product discharge, particles, nitrogen, phosphorus, carbon dioxide
- Preliminary ship design. Ship stability and propulsion.
- Seawater intake, passive system through forward movement of ship vs. pumps
- Wind power and power allocation
- Internal ship logistics, storage and distribution of auxiliaries, e.g. feed, oxygen
- Supply logistics, bunkering, material plan, energy plan
- Economic and ecological operation, energy efficienc , emissions

(Continued on next page)

Results

The evaluation of Atlantic salmon growth in different types of aquaculture operations as shown in Fig. 1. Austreng et al. (1987), investigated the growth in a net cage operation having an optimal thermal environment of around 14°C. Davidson et al. (2016) were growing salmon at slightly higher temperature (15 - 17°C). The commercial RAS (pers. comm.) had severe temperature problems (> 18°C). The growth performance of Atlantic salmon negatively correlates with temperature so that the growth performance in an ocean-going aquaculture can be expected to match the growth observed by Austreng et al. (1987). The harvest weight is expected between 4 and 6 kilograms after one year starting with smolt of 0.1 - 0.2 kilograms stocking weight.

All further calculations were carried out based on Austreng's data because the sail ship will cruise in ocean water at optimal temperature. The cruising area will be in the North of the North Atlantic during summer and in the South during winter.

The interdisciplinary approach starting from the biology of the fish brought deep new insights into the operation. This made it possible to investigate the wind power allocation for a typical half wind course. In Fig. 2 the wind power (apparent wind) is shown in dependence from the cruising speed which is a result of vector addition. The power needed to propel the ship at a given speed was subtracted to estimate the excess power available to supply power to the process technology on board. This difference is shown by the dome shaped curve in Fig. 2 emphasizing that at intermediate speed a maximum share of wind power would be available for the aquaculture processes.

Discussion and Conclusions

Is salmon aquaculture justifiable in the ocean or is it again another kind of unsustainable industrial production process?

Open ocean aquaculture taking place in the North Atlantic is a minor discharge of organic carbon into the ocean compared to the organic carbon loss through the fisheries of seven to nine million tons every year. This applies also to losses of nitrogen, phosphorous, or other elements. Thus, a part of the European salmon aquaculture can be relocated in the open ocean using sail ships.

At the end, as in any aquaculture, severe effects, for instance genetic alterations and/or pathogen transfer, must be avoided. The escape of fish can be prevented through appropriate process technology that retain the fish safely inside the ship hull. Bio-secure breeding centres supplying pathogen free fish is by all means desirable in order to safeguard production and marine life. This, however, should be common to all aquaculture seeking for sustainable and responsible production.

Aquaculture on board sail ships can likely be powered by renewable energy and become independent from fossil energy to large extent. However, it is obvious to have additional engines on board, which can take over the energy supply in emergencies or at low wind. In the next stage of the project, photovoltaic coating on sails, wind and water powered generators, and surplus energy storage cater for an integrated and almost closed energy system.

The proposed sail ship aquaculture will be applicable to many other fish species heavily exploited by fisheries and produced in aquaculture today.

In pursuit of a viable alternative, an eight-week feeding trial was conducted to evaluate the feasibility of including reared black solider fly (BSF, *Hermetia illucens*) larvae into rainbow trout diet. A total of five diets were formulated with one being a fish meal-based basal diet (CTRL), two levels of BSF (15 %, BSF15; 30 % BSF30), and a further two diets with a supplementary protease enzyme were assigned to test potential dietary enhancement (15 %, BSF15P; 30 % BSF30P). At the conclusion of the trial there were no significant growth performance differences between the dietary treatments ($P>0.05$). However, condition factor in fish fed on 15 % BSF inclusion diet was significantly higher than 30 % +protease inclusion ($P=0.025$). Postharvest fillet quality was assessed and showed significant changes in fatty acid composition, colour and shelf-life stability ($P<0.05$). Trout fed BSF had a significantly lower ($P<0.001$) level of lipid peroxidation, with the level of malondialdehyde present decreasing with increased dietary BSF, regardless of protease. As the inclusion of black soldier fly meal (BSFM) increased the saturated fatty acid (SFA) content of the fillet significantly increased ($P<0.001$) and the monounsaturated fatty acid (MUFA) significantly decreased ($P<0.001$),

RAINBOW TROUT (*Oncorhynchus mykiss*) INTESTINAL EPITHELIAL CELLS AS A MODEL FOR STUDING GUT IMMUNE FUNCTION AND EFFECTS OF FEED ADDITIVES

Introduction
Current knowledge regarding mechanisms underlying effects of feed additives on fish gut health and function is limited largely due to lack of targeted research tools. The use of *in vitro* approaches, such as appropriate cell lines, would facilitate investigation of basic functions of the digestive tract as well as effects of feed additives. Such *in vitro* tools would strengthen the understanding of intestinal immune responses, epithelial barrier and digestive function. The objective of this study was to evaluate the suitability of the rainbow trout intestinal epithelial cell line (RTgutGC) as an *in vitro* model for studies of immune function and effects of commercially relevant aquafeed additives.

Materials and methods
Effects of lipopolysaccharide (LPS), nucleotides, mannan oligosaccharides (MOS) and beta-glucans were evaluated in RTgutGC cells grown on conventional culture plates and transwell membranes. The analyses included indicators of cell viability and cell proliferation, brush border digestive enzyme activity, tight junctions, albumin transport across the epithelial layer, reactive oxygen species (ROS) production, morphology and relevant gene and protein expression.

Results
Permeation of fluorescent albumin (Figure 1), trans-epithelial electrical resistance (TEER) (Figure 2), and tight junction protein expression confirmed the barrier function of the cells.

Brush border membrane enzyme activities were detected in the RTgutGC cells and immune related gene responses were measured at levels comparable to those observed *in vivo* in rainbow trout distal intestine. LPS produced markedly elevated expression of the genes coding for the pro-inflammatory cytokines interleukin 1β, interleukin 6, interleukin 8, and tumor necrosis factor alpha but had no clear effect on ROS production. MOS seemed to be the most potent modulator of RTgutGC immune and barrier function among the feed additives (Figure 3 and 4).

Discussion and conclusion
Our TEER measurements and fluorescent albumin translocation confirmed earlier reports (Minghetti et al. 2017, Drieschner et al. 2017) showing that RTgutGC cells grown on transwell membranes strongly attenuate fluorescent model molecules' translocation from apical to basolateral chamber. Presence of the leucine amino peptidase (LAP) and maltase activity confirmed that the cells harbor, at least some, typical brush border functions. LPS, a common model pathogen-associated molecular pattern, markedly elevated cytokine gene expression, which shows that the RTgutGC cell line isolated from the distal intestine has capacity for a range of typical mucosal immune functions (Kawano et al. 2011). The increasing albumin translocation and lower *myd88* expression induced by MOS indicate how MOS may act as homeostatic balancer of barrier function also *in vitro* (Torrecillas et al. 2015).

Conclusion: Our findings suggest that RTgutGC cells possess features characteristic of functional intestinal epithelial cells indicating a potential for use as an efficient *in vitro* model to evaluate effects of bioactive feed additives on gut immune and barrier functions and their underlying cellular mechanisms.

INFLUENCE OF PHOTOPERIOD AND TEMPERATURE ON REPRODUCTIVE DEVELOPMENT AND OOCYTE GROWTH IN THE POLYCHAETE *Hediste diversicolor*

H. Wang[1,2*], A. Hagemann[1], A.M. Malzahn[1], M. Uhre[2], A. Handå[1], K.I. Reitan[2]

[1] SINTEF Ocean, 7465 Trondheim, Norway. [2] Norwegian University of Science and Technology, Department of Biology, 7491 Trondheim, Norway

Introduction

Reproductive development, including gonad development and gametogenesis, is the initial stages of the reproductive process, whereas gamete maturation and spawning are the final stages. Both endogenous factors and environmental cues can influence different stages of the reproductive process (Bentley & Pacey, 1992). The aims of this study were to observe (1) the influence of an accelerated photoperiod transition (2.5 times fast-forward) on reproductive development, (2) effect of temperature on oocyte maturation and (3) combined effects of photoperiod and temperature on oocyte growth of the polychaete *H. diversicolor*.

Material & Methods

The study comprised three individual experiments. **Exp1:** Worms were cultivated at a constant temperature (8 °C) with mimicked (MP) or sped-up (SP) photoperiods lasting 118 and 46 days, respectively (46d). Histological analyses (n=8) and in-vitro oocyte size measurement (n=8) were performed eight times throughout the experiment. **Exp2:** To assess the effect of temperature on oocyte maturation, worms were collected in March and kept in the lab at low (2 °C, "LT") and high (8°C, "HT") temperatures. Sampling was performed 5 times throughout the experiment at lab. In Exp1 and Exp2, treatments were compared to field samplings from natural populations on coinciding day lengths (NP). **Exp3:** Worms were cultivated at long day length (16L:8D) at constant temperature (16°C, "ThPh"), or long day length at decreasing temperatures (13 to 7°C, "TlPh"), short daylength (8L:16D) at constant temperature (16°C, "ThPl"), and short daylength at decreasing temperatures ("TlPl"). Each treatment comprised 6 worms, and repeated oocyte measurements were conducted 8 times over the experimental period of 85 days.

Results

Exp1: The oocytes in the SP treatment matured significantly less than the oocytes in the MP and NP treatment (Fig. 1). **Exp2:** High temperature was found to have positive effects on oocyte maturation. The oocyte shape found for worms kept in the lab at constant temperature were circular in shape at the first sampling, whereas the natural worms displayed irregular oocyte shapes throughout. The size of maturated oocytes was Ø=196.34±3.75 µm. **Exp3:** Oocyte growth was fastest at short daylengths and decreasing temperatures (TlPl). Constant temperature and long daylength (ThPh) suppressed oocyte growth (Fig. 2). The variability in oocyte size decreased over time.

Discussion & Conclusion

The effect of sped-up photoperiods on gametogenesis were inconclusive and need further investigations. **Exp2:** Constant temperature stimulated oocyte maturation. During the final stage of oocyte maturation, increasing the temperature can boost the reproductive process. **Exp3:** The photoperiod transition from long day to short day in conjunction with reducing temperature favoured oocyte growth. This is consistent with the in-situ results of Olive et al. (1998) that photoperiod substantially controls the reproductive timing of *Nereis virens*, while temperature can also impose seasonality on the life cycle to control gametogenesis (Olive et al., 1997).

SOME CONSIDERATIONS ON THE SUSTAINABLE DEVELOPMENT OF AQUACULTURE —CHALLENGES, CONSTRAINTS AND PROSPECTS

Q. Wang

Yellow Sea Fisheries Research Institute, Chinese Academy of Fishery Sciences, Qingdao 266071 (China)
E-mail: wangqy@ysfri.ac.cn

The importance of aquaculture in food security, nutrition, poverty alleviation, income generation and so on are increasing, and its potential to meet the growing demand for aquatic products is well recognized worldwide. 《The 2030 Agenda》of United Nations presented the sustainable development goal, and aquaculture is facing more challenges to implement this goal.

Sustainable development is a broad topic, especially when aquaculture as an industry to be considered in the framework of social and economic development. In China, "Aquaculture first" policy was presented in 1980s', and tremendous achievements were made in the last 4 decades. In 2017, total aquaculture yield in China mounted to 49 million tons, accounted for 76.1% of total aquatic production in China and 60% of world aquaculture yield. The contribution of aquaculture for improving livelihood and economic development were well recognized, while its impact on local environment and ecosystem as well as its assorting with other economic sectors also raised concern widely.

In the past years, more attentions were paid on the yields and economic outputs in aquaculture. In some lakes and bays, overexploitation was observed, and natural landscape was changed. Overstocking occurred in pond farming, diseases and high mortality frequently happened. All of these evidences warned that production modes of aquaculture have to be transformed from yield and scale to quality and efficienc .

Aquaculture has to be planned and implemented as a component part of social and economic development, and sustainable development need to address properly the challenges and constraints facing the industry. This paper presents the status and developing trends of aquaculture in China based on data collected in last decades, analyzes challenges and constraints currently impacting aquaculture development, and prospects are discussed.

FOLLOWING THE INFECTION PROCESS OF VIBRIOSIS IN PACIFIC OYSTER (*Crassostrea gigas*) AND BLUE MUSSEL (*Mytilus edulis*) LARVAE USING FLUORESCENCE LABELING AND HISTOPATHOLOGY METHODS

Dongdong Wang*, Gilbert Van Stappen, Nancy Nevejan

Laboratory of Aquaculture and Artemia Reference Center, Ghent University
Coupure Links 653, 9000 Gent, Belgium
E-mail: dongdong.wang@ugent.be

Pathogens, especially vibrios, are largely responsible for larval diseases in shellfish aquaculture. In order to understand how the infection process occurs in Pacific oyster (*Crassostrea gigas*) and blue mussel (*Mytilus edulis*) larvae, it is of great importance that the anatomy of the animals is well understood. In such a way, the sequence in which the internal structures are destroyed by the invading bacteria can be unraveled. In this study, three techniques were used in combination in order to have the full picture of what is happening during the infection process. After exposure of the larvae to different pathogens during challenge tests, clinical signs such as abnormal swimming behavior and destruction of the velum were observed under the inverted microscope. At the same time, by labeling *Vibrio hemicentroti* (ME09) and *V. anguillarum* (NB10) with the Green-Fluorescence Protein (GFP), we found a proliferation of the bacteria within the visceral cavity and subsequent necrosis of digestive organs, until a completed occupied body cavity. In addition, histological sectioning confirmed the damage on the level of individual organs and cells in function of exposure time. Interestingly, ME09 and NB10 had different lethality risk in Pacific oyster and blue mussel larvae but with the same progression in the infection process. This is the first time that the invasive pathways and infection dynamics of these two *Vibrio* pathogens have been investigated in Pacific oyster and blue mussel larvae. Understanding the infection process will help improve bio-control strategies and enhance the prospects of viable larviculture for oysters and mussels.

LOW CONCENTRATION PMS/UVA-LED COMBINATION AS A POTENTIAL ALTERNATIVE DISINFECTION METHOD FOR RECIRCULATING AQUACULTURE SYSTEMS

Wanhe Qi*, Songming Zhu

College of Biosystems Engineering and Food Science, Zhejiang University, Yuhangtang Road 866, Hangzhou 310058, PR China
E-mail: wanhe.qi@aliyun.com

Introduction

Effective water disinfection played an important role in preventing the introduction and accumulation of fish pathogens in recirculating aquaculture systems (RAS)(Summerfelt et al. 2009). UV/peroxymonosulfate(PMS) based advanced oxidation was considered as a promising method in inactivating pathogenic microorganisms(Xiao et al. 2019). The present study was conducted to evaluate the feasibility of UVA-LED and 1mg·L^{-1} PMS in combination to disinfect water in RAS.

Materials and methods

Water samples (BF effluent) were collected from a RAS (*Orechromis mossambicus*) biofilter outlet. 20mL water sample containing 1mg·L^{-1} PMS(HSO_5^-) was added into a 6cm diameter petri dish and irradiated at 2cm from a UVA-LED(365nm) chip. A magnetitic stirrer was used to ensure a homogeneous solution during illumination (Fig. 1a). 0.5mL water sample was collected every 12min, quenched with 0.1M $Na_2S_2O_3$, followed by steps of 10-folds dilution with sterilized saline water, plated on a nutrient agar and incubated for 48h at 37°C to determine total bacteria.

Results

Preliminary results showed that the number of total bacteria decreased with increasing UVA-LED/PMS treatment time (Fig. 1b). Moreover, UVA-LED and 1mg·L^{-1} PMS in combination significantly reduced total bacteria number in RAS after 24↑ 60min treatment compared to original RAS biofilter effluent. Results also showed high concentration total bacteria still existed after 60min UVA-LED/PMS treatment.

Discussion and conclusion

The total bacteria inactivation performance might be due to sulfate radicals (SO_4^-) and hydroxyl radicals (·HO) generated in UVA-LED/PMS process and caused oxidative stress to bacteria (Rodríguez-Chueca et al. 2017). The high concentration total bacteria still existed after 60 min treatment may attribute to water organic compounds and alkalinity as radical scavengers. In conclusion, UVA-LED/PMS can produce free radicals, which might be used as a green, effective method to degrade pollutants and inactivate pathogens in RAS.

REDUCTION OF STOCKING DENSITY THROUGH PARTIAL HARVEST: EFFECTS ON COMPENSATORY GROWTH AND PRODUCTION PARAMETERS OF *Litopenaeus vannamei* REARED IN BIOFLOC SYSTEM

W. Wasielesky*, L.G. Silveira, V. Torres, L. Poersch and D. Krummenauer

Graduate Program in Aquaculture, Institute of Oceanography, Federal University of Rio Grande (FURG) RS, Brazil
manow@mikrus.com.br

Introduction

Several researchers have reported that aquatic organisms may exhibit compensatory growth following increased growth if they are farmed under suitable conditions (Nicieza & Metcalfe 1997; Ali et al. 2003; Oh et al. 2007). This increase in growth rates is the result of strategies adopted by the organisms, including a higher food intake in the post-stress period (hyperphagia), increased feed efficienc , reduced metabolic wastes and reduced locomotion (Quinton & Blake 1990; Jobling et al. 1994; Ali et al. 2003). Wu et al. (2000) and Wu & Dong (2002) reported compensatory growth in *Fenneropenaeus chinensis* after periods of food restriction, a protein-deficient diet and low temperature. Wasielesky et al (2013) detected compensatory growth in nurseries after the decrease of stocking densities. The purpose of this study was to evaluate the effect of the effect of partial harvest and possible occurrence of compensatory growth in white shrimp *Litopenaeus vannamei* in the growout phase reared in a biofloc culture system.

Materials and Methods

The experiment was performed in a greenhouse with twelve experimental raceways, with 35 m^2 each. The tanks were supplied with saltwater from Cassino beach and densities of 600 shrimp/m^2 were stocked at an average weight of 0.22 g. After 98 days of culture the tanks were divided in four experimental treatments in which the treatment was named by the amount of partial harvests on it, then the first partial harvest for each treatment were made. The treatment T0 had no partial harvest and was used as control treatment. Treatment T1 had one partial harvest (50% of total biomass), treatment T2 had two partial harvest (33% of total biomass each harvest) after 28 days, treatment T4 had four partial harvest (20% of total biomass) every 14 days. Also, one day before the partial harvest and on the days 1, 4 and 8 biological samples of muscle, hepatopancreas and hemolymph of three shrimps per tank were collected, and then stored at -80ºC until further processing. The samples were analyzed to obtain the amount of glucose, glycogen, lactate and triglycerides in order to increase our knowledge on how energy is mobilized in order to compensatory growth can occur. The shrimps were kept at optimal water parameters conditions and were feed three times a day. The biofloc culture was maintained a at C:N ratio of 15:1 were feed represent 9:1 from total carbon proportion an measles. The suspended solids resultant from biofloc production was controlled trough clarification if it exceeds the amount of 500 mg $^{-1}$.

Results

Our results had significant differences in the production parameters as biomass production, survival and final growth between the control treatment and the treatments with partial harvests. A quadratic regression was made in order to maximize the biomass production ($R^2 = 0.99$) that could be obtained by obtaining the best percent of partial harvest. It was detected that the use of partial harvest strategy in a superintensive biofloc culture system can improve zootechnical parameters ($P<0.05$). Results confirm that biomass production and productivity were significantly higher in treatments T2, T3 and T4 (Table 1). Also, there is evidence of significant differences between treatments in the biological sample analyses, which could give us a better understanding of how compensatory growth occurs.

Table 1. Production parameters of *L. vannamei* after 156 experimental days with different percent of partial harvest.

Treatments	Partial Harvest (%)	Survival	Biomass production (Kg)	Productivity (Kg/m^2)
T0	0%	48.23%	135.02	3.85
T1	50%	90.95%	205.09	5.85
T2	33%	90.56%	217.90	6.22
T4	20%	85.07%	214.89	6.14

(Continued on next page)

Discussion and Conclusion

The results of this study indicate that the decrease in stocking density in the partial harvests increased the growth rates and survival of shrimp in the nursery phase. These results are in agreement with those presented by Wasielesky et al (2013) that obtained better results when shrimp were transferred to lower stocking densities in nursery phase of white shrimp production. In conclusion, our results indicate that shrimp farming can increase its production not by the increase of culture densities but through maximizing growth with compensatory growth by diminishing periodically the culture densities.

NEWDEPOMOD – A MODELLING TOOL FOR BENTHIC IMPACT PREDICTION BENEATH MARINE CAGE FISH FARMS

Rebecca J. Weeks[1*], Thomas P. Adams[1], Kemmeth D. Black, Kevin Black & Adam D. Hughes[1]

Scottish Association for Marine Science, Scottish Marine Institute, Oban, Scotland, PA37 1PQ
Email: rebecca.weeks@sams.ac.uk

Introduction

NewDEPOMOD is a particle tracking modelling software, developed by the Scottish Association for Marine Science (SAMS), in conjunction with the aquaculture industry and the Scottish Environmental Protection Industry (SEPA). Its predecessor, DEPOMOD (developed between 1997 and 1999), was designed to predict impacts of marine cage fish farm discharges on the seabed and its benthic macrofauna, as a result of fish faeces and waste feed settling. Impacts depend upon the configuration of the cages and feeding rate, as well as environmental factors, such as bathymetry and water currents

AutoDEPOMOD (developed 2000-2002) iteratively runs DEPOMOD from a given starting farm biomass to obtain a compliant stocking solution, and was also adapted to incorporate residues of medicines such as Emamectin benzoate (EmBZ). AutoDEPOMOD's use has been prescribed by SEPA for fish farm development and expansion applications in Scotland for more than a decade.

The vision behind NewDEPOMOD was to remove third party software dependencies, and rewrite the AutoDEPOMOD software code in a modern programming language (Java) to allow easier maintenance and development thereafter. In addition, field and lab studies were used to improve the understanding of resuspension processes around marine cages, to enhance the predictive capabilities of the model. This was thought to be important for more dispersive sites, which are known to be of interest to the salmon farming industry as they look to expand their farmed biomass. Subsequently, the revised model was tested by SEPA to examine whether the resultant product allowed for increased accuracy in predictions, increased flexibility in its configuration, and would allow for expansion in the finfis aquaculture industry. A hindcasting approach was used to validate the model's performance against recorded seabed impacts.

Updated Resuspension Module: Fieldwork

In order to examine erosion and resuspension properties of the seabed around a variety of fish farm sites, state of the art benthic flumes were deployed by Partrac Ltd, in conjunction with the Scottish Association for Marine Science (SAMS). These 8 sites, all on the west coast of Scotland, were also previously mapped in detail using multi-beam bathymetry. A custom-built hydrodynamic lander, comprising of an acoustic Doppler current meter (ADCM), a downward looking ADC profiler (ADCP; 1m above the bed), and an upward looking ADCP (c. 2m above the bed), was also deployed above the seabed to measure its frictional effect on water movements. Deployment of this setup for a tidal cycle at each of the 8 sites allowed an estimate of bed roughness, which was discovered to be a key input parameter for enhanced accuracy of NewDEPOMOD model runs.

The results of this fieldwork allowed for a series of considerations and recommendations to be made, in order to advance the modelling of resuspension processes, known to play a significant role in more highly dispersive environments

Testing by SEPA of the revised model assessed its suitability for environmental risk assessment and determination of consent limits, to inform aquaculture-related discharge licences. The model aimed to be more accurate, more highly configurable and supportive of industry expansion. The resultant model allows for a much enhanced variety of scenarios that can be modelled, and therefore a much wider range of outcomes than AutoDEPOMOD.

Due to this high level of configurabilit , the model is capable of accurate deposition predictions, but requires an informed set up and configuration in order to achieve this. Validation work by SEPA was therefore carried out with 3 main aims: to appraise the original model (hindcast to compare AutoDEPOMOD output with site data), calibrate the new model (hindcast to compare NewDEPOMOD with site data by testing configurat on options), test consenting implications (use the outcome of aim 2 to test the implications of the new model for SEPA's consenting approach).

(Continued on next page)

The hindcasting approach provided a means to test the absolute accuracy of the model against empirical data, but had significant restrictions due to the number of well sampled sites. Testing of consenting applications therefore allowed practical questions regarding the future policy implications for SEPA to be answered, whilst adding >50 sites to the test suite. This allows for a wide range of tested scenarios with respect to environmental and operational conditions, e.g. varying flow regime and bathymetr , or cage layout and biomass etc. respectively.

Future Development

As with AutoDEPOMOD, NewDEPOMOD will be distributed by SAMS. Unlike AutoDEPOMOD, NewDEPOMOD software code can be acquired on an open source basis under a developer's licence, to encourage future development in new environments around the globe. This is with an aim to establishing a Global User and Researcher Platform, to ensure that the model will remain fit for purpose across a range of environmental and regulatory settings for the foreseeable future, as well as helping to ensure the sustainable growth of the Scottish finfish sect .

Recent and existing projects at SAMS are further developing NewDEPOMOD to improve usability and functionality, allowing closer integration with other modelling packages (such as coastal hydrodynamic models). It is expected that NewDEPOMOD will play a major role in the Scottish finfis sector in the upcoming months and years, with a view to informing sustainable regulation and expansion.

EFFECT OF A PHYTOGENIC FEED ADDITIVE ON THE GROWTH PERFORMANCE AND IMMUNITY OF PACIFIC WHITE LEG SHRIMP *Litopenaeus vannamei*, FED A LOW FISHMEAL DIET

J. Kesselring, C. Gruber, B. Standen and S. Wein*

Biomin Holding GmbH, Erber Campus 1, 3131 Getzersdorf, Austria
E-mail: silvia.wein@biomin.net

Introduction

Fishmeal has long been one of the most important ingredients in formulated aquafeeds, due to its high protein content, excellent composition of essential amino acids, and high digestibility. The aquaculture industry is currently facing sustainability and economic challenges driven by the reduced availability and concomitant increased price of fishmeal (FM) and fish oil. Consequently, FM is now used more selectively and at lower inclusion rates, while great efforts are being made to find alternative protein sources that promote more profitable and sustainable aquaculture endeavors (FAO 2018; Slater et al. 2018). Plant-derived products have been suggested to partially replace FM in aquafeeds (Olsen and Hasan 2012), however often at decreased growth performance, inflammator responses, and increased susceptibility to diseases (e.g. Sudaryono et al. 1999; Enterria et al. 2011; Zhu et al. 2013). This study assessed the effects of the commercial phytogenic feed additive Digestarom® PEP MGE on growth, nutritional performance, and immune response of *Litopenaeus vannamei*.

Materials and methods

After the acclimation period, 540 shrimp showing normal feeding behavior and no apparent sign of disease were selected, and randomly placed in 36 100-L tanks held in the same recirculating aquaculture system. Each tank was stocked with 15 mixed-sex individuals that weighed approximately 3 g. Four experimental groups were randomly assigned to the tanks (nine replicates per group), each receiving one of the following diets: i) standard formulation (control, 24 % FM), ii) low fishmeal diet (5 % FM), iii) low fishmeal diet plus 0.2 g/kg Digestarom® PEP MGE, and iv) low fishmeal diet plus 0.4 g/kg Digestarom® PEP MGE. The performance trial took 63 days. Shrimp were fed to apparent satiety six times per day. Feeding behavior, feed intake, and mortality were recorded for each tank during each meal during the day, and then used to calculate the amount of feed that should be provided in the subsequent meal. The following performance parameter were assessed: Fulton`s condition factor (FCF), Feed conversion ratio (FCR), Protein retention (PR), Protein efficiency ratio (PER), hepatosomatic index (HPI), body composition. Hemolymph was collected from 16 randomly selected shrimps in each group to determine immunity parameters: i) total hemocyte (THC), hyaline cells (HCs), semi-granular cells (SCs), and granular cells (GCs); ii) phenoloxidase (PO) activity; and iii) respiratory burst (RB).

Generalized Linear Model (GLM) (parametric) and Kruskal-Wallis tests (non-parametric) were used to analyze the significance of differences between treated groups. The relationship between the relative content of differentiated cells and other plasma parameters was obtained from linear regression analysis. All statistical analyses were performed in R-3.5.1. The significance level was defined as < 0.05

Results

Overall, shrimp fed the low FM diet showed a lower performance than shrimp fed the control diet. Particularly, survival and feed intake significantly dropped by 50 % and 28 %, respectively, with the reduction in FM level, whereas FCR, PER, and protein retention showed a significant increase of 65%, 46%, and 41%, respectively ($P < 0.05$). The PEP MGE supplementation of the low FM diet notably increased survival and feed intake, and decreased FCR, PER, and protein retention compared to the low FM treatment to levels similar to those observed in shrimp fed the control diet regardless of supplementation dosage. Similar shrimp growth performance and condition (FCF and HPI) were recorded among experimental groups ($P \geq 0.10$).

Shrimp whole-body composition was relatively similar among experimental treatments. Nevertheless, *L. vannamei* body composition changed throughout the trial duration; in particular, there was an increase of 13-17 % in protein content, a decrease of 30-34 % in ash content, and a notable decrease in carbohydrate content from 1.82 g/100 g to non-detectable levels.

(Continued on next page)

Total hemocyte count showed a 30 % decrease with the reduction in FM level ($P < 0.01$). However, PEP MGE supplementation counterbalanced such detrimental effects of low FM and higher plant-protein content up to ~$10x10^6$ cell/mL regardless of supplementation level. Hemocyte cell differentiation was similar among the four experimental treatments, as similar relative proportions of HCs, SCs, and GCs were observed regardless of FM level and PEP MGE in shrimp feed ($P \geq 0.11$). The activity of PO was also similar among groups, and ranged from 0.07 to 0.09 U/mg protein ($P = 0.12$). Similar RB results were also recorded in shrimp fed the control and LFM diets, but the inclusion of PEP MGE resulted in an increased RB response with increasing dosage of PEP MGE up to 43 % compared to the LFM treatment. In addition, PO activity was positively associated with the relative amount of GCs ($P < 0.05$), whereas RB was positively associated with the relative amount of SCs ($P < 0.05$).

Discussion and conclusion

In conclusion, the present study validates an alternative and nature-based solution for compensating the negative effects of partially replacing FM with plant-based protein in shrimp feeds. Although not directly tested, it is possible that this blend of essential oils improved gut health and performance. This would lead to the improved survival, feeding, and feed utilization observed here, despite the absence of direct effects on individual growth performance. Nevertheless, the immune stimulation of shrimp fed a low FM diet supplemented with Digestarom® PEP MGE suggests that this phytogenic can be successfully incorporated into FM diets containing as low as 5 % FM to improve *L. vannamei* health to the levels recorded in control shrimp, receiving diets containing 24 % FM.

E-Mail: weirup@gma-buesum.de

Introduction

Scientific evidence and awareness regarding the capabilities of fish experiencing pain and distress has raised the urgent need to quantify fish welfare more accurately by implementing standard procedures for welfare assessment in aquaculture. Next to commonly used welfare indicators such as fin damage, biomarkers on stress, in particular on chronic stress taking into account its deleterious effects on fish performance, reproduction, and susceptibility to disease, should be included to gain a more in-depth insight on the effect of a lifetime exposure of fish to the different aquaculture housing and management conditions.

To evaluate overall welfare of rainbow trout (*Oncorhynchus mykiss*) in commercial German aquaculture (ranging from extensive to intensive flow-through systems) fish will be examined from a behavioural, pathological-morphological, pathological-histological, microbiological, and stress physiological point of view. Hereby, chronic stress will be quantified using scale cortisol (Aerts et al., 2015; Zeytin et al., 2017; Hanke et al., 2019).

In this study, we will correlate for the first time quantitative data on chronic stress levels to a broad set of health and behavioural parameters in commercial aquaculture systems with different stocking densities to determine the overall fish welfare.

Materials and methods

On nine commercial trout farms, all equipped with flow-through systems but differing in stocking density, across Germany, 30 fish during grow-out (± 400g) per farm will be sampled for welfare evaluation in May 2019. Water quality parameters measured include O_2, pH, hardness, nitrogen compounds, iron and total bacterial load. Behaviour observations for social and health traits are conducted by three independent observers. Further, 30 fish per farm will be examined for outer morphological impairment and 10 fish will be sampled for plasma glucocorticoids, glucose, lactate, as well as for histological analysis of all organs. Ontogenetic scales will be sampled for scale cortisol.

Results and discussion

All different laboratory analyses will be performed in June 2019, after which the welfare in rainbow trout at nine commercial flow-through systems in Germany will be modelled. Correlations between and quality of particular welfare indicators as well as the impact of single indicators on overall welfare will be evaluated and presented at the conference.

TOWARDS AN ECOSYSTEM APPROACH TO AQUACULTURE: DEVELOPING A HOLISTIC FRAMEWORK FOR CARRYING CAPACITY OF SALMON AQUACULTURE IN CANADA

J. Weitzman*, R. Filgueira, J. Grant

Marine Affairs Program, Dalhousie University, Halifax, Nova Scotia (Canada), B3H 4R2
Email: jenny.weitzman@dal.ca

Introduction

The management and governance of aquaculture continues to face emerging challenges across diverse environmental and social aspects and the growing need to manage multiple objectives in increasingly crowded aquatic ecosystems. The need to take a more holistic approach to management of marine systems has prompted the development of the ecosystem approach to aquaculture (Soto et al. 2008). In recent years, carrying capacity has emerged as a potential interdisciplinary tool for the holistic analysis of pressures on the coastal zone and its ecosystem services. While carrying capacity traditionally encompasses physical, production, social, and ecological components (McKindsey et al. 2006), these components are most often studied in isolation. Despite some recent progress towards holistic assessments for shellfish (e.g. Byron et al. 2011), this approach has not been developed for finfis like Atlantic salmon (*Salmo salar*). The present research seeks to understand the requirements and capabilities of approaches for salmon aquaculture carrying capacity in Atlantic Canada to define a holistic framework based on the needs and priorities of an ecosystem approach to aquaculture.

Applying an interdisciplinary approach to build a holistic framework

This research applies interdisciplinary tools to understand the drivers of change within the social and ecological system of salmon aquaculture in Atlantic Canada (Fig. 1). A framework for holistic decision-making will be built by 1) formulating guidelines for carrying capacity based on stakeholder needs and considerations in the context of ecosystem-based management and marine spatial planning, 2) assembling information on carrying capacity indicators and thresholds, and their relationships with aquaculture, and 3) assessing the utility of new tools and approaches for integrated carrying capacity. Local case studies across different areas within Atlantic Canada will also variations in socio-economic contexts, cultures, and history of aquaculture interactions.

Preliminary results

Drawing from a review and gap analysis of carrying capacity within the literature, several principles and research needs were identified to support an agenda for better aligning carrying capacity with ecosystem-based management (able 1).

Preliminary results also emerge from discussions with key informants on the needs, values, and priorities for carrying capacity to identify relevant indicators, methods, and considerations to continue to build the framework. Further research will explore the utility of tools like expert judgement, ecosystem services, and spatial applications for holistic decision-making in Atlantic Canada. In addition, given knowledge gaps for social research in aquaculture, this work is exploring aspects of social carrying capacity, community-based participation and stakeholder engagement.

Implications for management and policy

Carrying capacity is a potentially powerful tool often considered critical to overall area management but is poorly implemented in many areas (Corner et al. 2018). Developing a framework for carrying capacity can provide managers and planners with a holistic tool to guide their decisions, such as determining suitable fish farming locations, setting appropriate monitoring thresholds, and making sustainable resource management policies (Ross et al. 2013). This research identifies relevant information about social, ecological, and economic indicators and thresholds, and tests new approaches and methods to build a holistic framework for carrying capacity. Where social aspects of aquaculture are a major challenge and still poorly studied, this research can foster a better understanding of the perceptions of local communities to aquaculture, identify conflicts, and help inform decision-makers about social acceptance issues. This work draws from experts both within and outside Atlantic Canada and can thus have applicability to management in other areas of the world, where aquaculture is also rapidly developing and where countries are increasingly recognizing the need for adopting an ecosystem approach to aquaculture.

ENVIRONMENTAL IMPACTS OF AQUACUTLURE: ASSESSING THE RISK OF FURTHER GENETIC INTROGERSSION OF DOMESTICATED SALMON IN WILD POPULATIONS IN NORWAY

Vidar Wennevik*, K.A. Glover, O. Diserud, Ø. Skaala, P. Fiske, M. Solberg, K. Hindar, T. Svåsand, S. Karlsson, L. B. Andersen and E. S. Grefsrud

Institute of Marine Research, Nordnesgaten 50, 5218, Bergen, Norway
vidar.wennevik@hi.no

Farmed Atlantic salmon are domesticated, and where significant interbreeding with wild conspecifics occurs, this may lead to changes in fitness traits, and ultimatel , less productive wild populations (Reviewed by Glover *et al.* 2017).
Widespread and in some cases extensive introgression of domesticated Atlantic salmon is already documented in wild Norwegian populations. However, one of the central questions is whether further introgression is likely to occur in the future also.
Annual risk assessments of the environmental impacts of Norwegian aquaculture have been conducted by the Institute of Marine Research and collaborators since 2010. However, recently, the method for assessing risk was upgraded. In this talk we present the methods used, and results of the risk assessment in Norway in 2019.

In total, we categorized 7, 3 and 3 of the 13 aquaculture production zones, covering the entire Norwegian coastline, as having high, moderate and low risk of further genetic introgression in native populations respectively.

NEW ANIMAL WELFARE STANDARDS IN SWITZERLAND: NOVEL APPROACHES FOR A FAIRER KILLING OF CRUSTACEANS

Elena Wernicke von Siebenthal*

Scientific Adviser for Aquatic Animals, Animal Welfare Department, Domestic and Wild Animals, Federal Food Safety and Veterinary Office FSVO
E-mail: elena.wernickevonsiebenthal@blv.admin.ch

Aquaculture production, import and diversification of aquatic species is continuously growing, also in Switzerland. Meanwhile, a rising concern on animal welfare in farmed animals has expanded through the last decades. Several studies on pain research have proved this concern, describing the potential suffering of many species, including the long forgotten crustaceans. On the 19th of September 2015 the topic reached the Swiss Federal Council through a Motion, aiming to ban the import of alive crustaceans for food purposes into Switzerland.

Due to the bilateral veterinary agreement with the EU (Annex 11 to the Agreement on trade in agricultural products; RS 0.916.026.81), it was not feasible to ban the import of alive crustaceans. Specificall , from the point of view of trade law (WTO and free trade agreements) high demands are placed on an import ban. Still, the Swiss Federal Council adapted the legislation in order to enhance welfare during the import and killing of crustaceans in the Swiss gastronomy. These modifications include the ban of transporting crayfish on ice, and when crayfish are hold for commercial purposes, it is required to pass specific training and hold a cantonal permit for the commercial husbandry of wildlife animals. Reaching a further level, crayfish can now only be killed when previously stunned. A new device to stun crustaceans was tested with different working settings and species of crayfish. After this, two different stunning devices are available on the Swiss market.

In this way, Switzerland has become the first country to ban the boiling of crayfish without previous stunning, being followed by Germany and parts of Italy. The changes allow a significant enhancement on animal welfare standards and promote fairer approaches to produce and consume aquatic invertebrates.

THE EFFECT OF DIETARY BLACK SOLDIER FLY LARVAE *Hermetia illucens* MEAL AND PASTE ON GROWTH PERFORMANCES AND IMMUNE PARAMETERS IN ATLANTIC SALMON *Salmo salar*

Introduction

The development of novel feed ingredients with functional properties offers solutions to sustainable and health concerns in salmon industry. In the last decade, there has been a growing interest in using insects as a protein source for aqua feed production. One of the most promising insect species for feed purposes is black soldier fly (BSF) (*Hermetia illucens*). It has been reported that BSF larvae comprise chitin, medium chained fatty acids, antimicrobial peptides (Caligiani et al. (2018), Vogel et al. (2018)), all of which are destined to promote both growth and health of fish (Henry et al. (2018)). BSF larvae might, therefore, be considered a functional feed ingredient. In this sense, investigation of potential functional properties of BSF larvae that provide growth and health benefits beyond traditional feeds, represents a great opportunity to guarantee the sustainable future of salmon aquaculture. Therefore, in this experiment, we studied the effect of two dietary BSF larvae products produced by two different processing methods, i.e. insect meal and insect paste, on growth performances and immune parameters in Atlantic salmon.

Materials and methods

The insect meal contained 38.0% and 28.9% of crude protein and fat respectively, whereas insect paste contained 11.3% and 9.3% of crude protein and fat respectively with 28% of dry matter content. Further, the insect paste was preserved with 2.5% inclusion level of formic acid. A total of 1260 Atlantic salmon (*Salmo salar*) with 34 g of mean initial weight were distributed into 21 fibe glass tanks (60 fish per tank), and with 3 tanks per dietary treatment. The fish were fed *ad libitum* (i.e. 10% excess) for 7 weeks. The 7 dietary treatments include 3 diets where 6.25% (6.25_IM), 12.5% (12.5_IM) and 25% (25_IM) of dietary protein was replaced by insect meal; 2 diets, in which 6.25% (6.25_IP) and 12.5% (12.5_IP) of dietary protein was replaced by insect paste and 2 control diets named Control_1 (positive control based on fishmeal, soy protein concentrate, and fish oil) & Control_2 (negative control with 0.875% formic acid equal to the formic acid level in the 12.5_IP diet). At the end of the feeding period, feces and organs/tissue of fish were collected. Spleen leukocytes were isolated and stained with different antibodies targeting IgM, IgD and CD8. The number of B and T cells were measured using flow cytometry. Macrophages were isolated from head kidney, cultured and infected with CFSE labelled *Piscericketssia salmonis* for one hour. The capability of macrophages to incorporate the pathogenic bacteria were assessed by flow cytometry and confocal microscopy. Analysis of nutrient composition of feed and feces, plasma immune responses, proteomics of skin mucus, intestinal histology and 16S rRNA sequencing of gut microbiota are ongoing.

Results and discussion

Growth performances: The fish fed diets containing insect meal and insect paste showed similar growth performances as for the control diets. The feed conversion ratio and relative feeding rate of fish were ranged from 0.70-0.75 and 1.47-1.71, respectively, and were similar among the diets.

Immune parameters: Diet 12.5_IM present an increase in the number of IgD+ cells in the spleen. However, this increase was more significant in the fish fed diet Control_2, which contained formic acid. The same trend was observed on the number of T lymphocytes, where diets Control_2 presented the higher number of CD8+ cells in the spleen. On the other hand, macrophages isolated from fish fed 12.5_IM diet were more prone to incorporated labeled-bacteria, which suggest a higher phagocytic capacity compared to the other diets. The incorporation of *P. salmonis* was confirmed by confocal microscopy.

Conclusions

Based on growth performances, both insect meal and insect paste can potentially partly replace the current protein sources used in Atlantic salmon diets. Our ongoing analyses aim to confirm its functional e fect beyond the nutritional value.

(Continued on next page)

Table I: Performance indicators of fish fed experimental diets for 7 weeks

Performance indicator	Control_1	6.25_IM	12.5_IM	25_IM	Control_2	6.25_IP	12.5_IP	SEM	P value
Initial body weight (g)	34.4	34.3	34.3	34.3	34.3	34.4	34.3	0.03	0.934

EFFICIENT GUIDE TO PRODUCERS FOR GOOD AQUACULTURE PRACTICES AT ALL STAGES OF PRODUCTION

Valeska Weymann

GLOBALG.A.P. Secretariat c/o FoodPLUS GmbH
Spichernstrasse 55
50672 Cologne, Germany
weymann@globalgap.org

The GLOBALG.A.P. Aquaculture Standard brings to the market a complete solution for buyers and suppliers, based on current market demands, covering the key sustainability aspects that the animal production for human consumption is required to achieve. Operating since 2004, certified farms feedback reflects that this certification turns into a practical guide to their operations through detailed criteria written in a friendly and clear manner satisfying GLOBALG.A.P. purpose on working hand in hand with producers. Although the ultimate goal is to obtain certification, the standard is the best tool the aquaculture sector can adopt to properly manage their operations. Currently there are 38 species certified for the finfish crustaceans and molluscs in 32 countries worldwide.

The aspects covered are those stipulated by the FAO Technical Guidelines on Aquaculture certification. With strong governance reliability, including the robust Integrity Program. This pioneering program is the first of its kind in food certification, and is designed to ensure consistent delivery and implementation of the standard worldwide. It acts as a feedback mechanism that serves the ongoing improvement of the GLOBALG.A.P. System in all its aspects, promoting transparency and integrity.

The key elements of the GLOBALG.A.P. Aquaculture standard are currently recognized and evaluated.

- Food safety: is the ONLY certifi ation scheme recognized by the Global Food Safety Initiative – GFSI for farming of fish.
- Environment: recognized by the Global Seafood Sustainability Initiative – GSSI Apr 2018.
- Animal Health: the OIE Aquatic Animal Health Code criteria for farms is covered by the standard. The robust Veterinary Health Plan requirements is a reliable backing that farms give value.
- Animal Welfare: on top of animal health, GLOBALG.A.P. Aquaculture has been recognized as the only international private standard outside the UK that covers animal welfare practices at harvest and slaughter. Further animal welfare innovative criteria is spread for all production stages.
- Workers Occupational Health & Safety: workers are key to efficient operations, appropriate training is included in the requirements.
- Workers Welfare: GLOBALG.A.P. Risk Assessment on Social Practices is compulsory to assess.

The scope covers full production chain verification of: Broodstock, Seedlings, Feed, Farming Post harvest activities up to the point of sale for final consumers.

INFLUENCE OF PHYTOGENIC FLAVONOIDS ON GROWTH (LENGTH AND BODY WEIGHT) OF YOUNG RED STRAIN ALL-MALE TILAPIA IN INDOOR RAS SYSTEM

Tilman Wilke* and Anne Möddel

Dr. Eckel Animal Nutrition GmbH & Co. KG
E-Mail: t.wilke@dr-eckel.de

A feeding trial with 468 all-male tilapia fingerlings was conducted in an in-house aquaculture facility. Aim of the trial was to assess the effect of a phytogenic feed additive (AO) rich in polyphenols on growth performance compared to a negative control (N). The feed additive (Anta®Ox Aqua, Dr. Eckel Animal Nutrition, Germany) is a natural phytogenic feed additive made from grapes, hops and green tea delivering a specific amount of flavonoids (>10%). The feed additive was added at a dose of 500 g/t of feed. Fish were kept in fresh water at 28°C in two separate indoor RAS (recirculating aquaculture system) with big (125 L) and small (40 L) glass tanks. Feed was provided manually three times per day on workdays and two times per day on weekends. Fish growth was measured at three time points (day 0, 22 and 68) by sampling 10 fish/tank and measuring individually standard-length and body weight.

Overall growth was within expected values. During the 68 days trial period fish grew on average from 0.41 g to 6.25 g live body weight and from 22.8 mm to 56.7 mm mean body length (see Fig. 1). Specific growth rate (SGR) was 3.92 % per day. Dispersion of values was within expected ranges: Coefficient of variation was in the range of 25 to 30 % for body weight and 8 to 10 % for body length.

A difference in growth performance was observed between fish kept in big and small tanks. Furthermore, growth performance (weight and length) was better in fish of the AO treatment group than in the N control group (see Fig. 2 A and B). Compared their mean bodyweight of day 0 fish of the AO group achieved a higher mean body weight than the negative control group (+16% in the small tanks and +14% in the big tanks). Analysis of variance of a linear model explaining the weight with 'system' and 'feed' as explanatory factors revealed that the 'system' effect was highly significant ($p<0.001$) and the influence of the 'feed treatment is also significant at $p<0.02$.

From the results of the present study, we conclude that addition of plant-derived flavonoids from grapes, hops and green tea can improve growth of Tilapia fingerings. The results are in line with former studies with polyphenol-rich feed additives in shrimp (Niyamosatha et al. 2015, Chuchird et al. 2017). The study results are of interest for tilapia hatcheries and hatchery feed producers worldwide. Further research could clarify which flavonoid sub-group has the biggest influence on growt

Introduction

Selenium (Se) is an important micronutrient needed for the production of selenoproteins involved in antioxidant metabolism. Total Se levels in animal feeds are regulated within the EU to a maximum of 0.5ppm. Due to the low Se content in plant protein sources, the replacement of fish meal in aquafeeds warrants an increasing attention on dietary Se supplementation over the full life cycle. Studies in poultry have shown a positive influence of parental Se transfer by supplementation of low basal Se diets on the oxidative status in progeny, especially when highly available organic Se sources were used (Zhang et al., 2014). In fish little is known about transgenerational e fects of Se (Wischhusen et al., 2019).

Material and Methods

The progeny of three groups of rainbow trout broodstock, fed either a control diet (Bctr: 0.3ppm Se) or diets containing a minimum of 0.6ppm Se by supplementation of either 0.3ppm sodium selenite (Bss) or 0.3ppm hydroxy-selenomethionine (Bso), over a 6 month period prior to spawning, were used in this feeding trial (Wischhusen et al., 2019). At the beginning of exogenous feeding, swim-up fry from each of the three parental groups were sub-divided into three groups (3 parental groups x 3 fry dietary groups, resulting in 9 treatments) and fed fry diets containing similar Se levels and sources compared to the parental diets (Fctr: 0.3ppm, Fss: 0.6ppm, Fso: 0.6ppm). Fish were sampled as whole fry at the end of an eleven-week feeding period for Se and antioxidant measures, followed by two-way ANOVA to study parental and direct feeding main effects.

Results

Neither nutritional history, nor direct Se feeding showed any significant effect on survival (97.6±0.34%) and final body weight (4.64±0.04g). However, the weight gain was higher in offspring coming from broodstock fed Bss and Bso compared to offspring of Bctr group (66±0.8 and 66±1 vs. 60±1%, respectively), without any significant effect of direct Se feeding (Fctr: 66±1; Fss: 63±1; Fso: 63±2%). Total Se content in whole-body fry was not significantly different according to the nutritional history, but was significantly increased by feeding Se supplemented diets to the fry ($P<0.01$; Table I); compared to fry fed Fctr, fry fed Fss showed +24% of whole-body Se while fry fed Fso showed +76% of whole-body Se. Preliminary results on markers of antioxidant metabolism show significant effect of both parental nutritional history and direct Se feeding. The GPX activity was increased by direct feeding of sodium selenite, but reduced in fry originating from the parental group fed sodium selenite. A similar reduction by parental Se-supplementation was noticed for GST (especially when fed directly sodium selenite) and CAT, while GST activity was also reduced by dietary organic Se supplementation of fry (especially in offspring of the Bctr group).

Discussion and conclusion

The maternal transfer of Se has been confirmed in rainbow trout recently (Wischhusen et al., 2019). In that study, Se concentration in the swim-up fry before first-feeding was the highest when the parental groups were fed an organic Se source compared to an inorganic Se source with the lowest concentrations in the negative control group. In the present study, after 11 weeks of exogenous feeding, the effect of parental Se nutrition on Se status of offspring was not detectable anymore. Nevertheless, similar to earlier studies (Fontagné-Dicharry et al., 2015), the Se status in the fry was elevated by direct feeding of Se supplemented diets with the highest level in hydroxy-selenomethionine-fed-group. Low Se levels in rainbow trout at early life stages have been associated with an increase of oxidative stress parameters (Fontagné-Dicharry et al., 2015). The present study shows a long-term parental effect in fry on the antioxidant metabolism, independent of the Se status, with a reduced activity of antioxidant enzymes, including the selenoprotein GPX, when originating from parental groups fed Se supplemented diets, in contrast to direct Se feeding and short-term parental effects described by Wischhusen et al. (2019). Pending results on oxidative stress parameters will help to ordinate the obtained results. The mechanisms behind the observed changes of this nutritional programming, possibly through epigenetic marking alteration, await further investigation.

FINANCIAL RISK EVALUATION OF COMMERCIAL PRODUCTION OF NILE TILAPIA (*Oreochromis niloticus*) IN NET-CAGES, SÃO PAULO, BRAZIL

M.R. Brande, G.W. Bueno*, N.S. Fialho, E. M. Godoy, P.G. Ojeda and R. Roubach

São Paulo State University (Unesp), Aquaculture Center of Unesp (Caunesp), R. Quirino de Andrade 215, 9º andar, Centro 01049-010 - São Paulo - SP – Brazil
E-mail: guilherme.wolff@unesp.br

Aquaculture is a sound economic alternative in the consumption of high quality protein, especially in developing countries, where food demand have presented an exceptional growth in the last years. Since it deals with the production of living organisms, the activity faces innumerable production risks, from environmental conditions to fluctuations in input prices, which may cause financial losses for the rural producer. This study aimed to evaluate the financial risk of commercial production of Nile tilapia (*Oreochromis niloticus*) in three production scenarios.

The farm comprised of 18 net-cages (43 m^3 each) located in Chavantes reservoir, São Paulo, Brazil (644.481 E, 7.413.975 N) which was used as a model during six production cycles (180 days). Productive and economic data were collected and three elaborated production scenarios were developed: scenario I (C1): production volume of 1,000m^3, scenario II (C2): production volume of 5,000m^3 and scenario III (C3): production volume of 10,000m^3. We evaluated the probability of occurrence of financial risks (N = 10,000 random interactions) in relation to the economic indicators, such as internal rate of return (IRR), net present value (NPV) and payback of capital. By means of applying the Monte Carlo Simulation method (MCS) using the @risk Software, from interactions between the productive and economic variables. The input variables productive were: production cycle, water temperature, mortality, feed conversion; and economics were: fish selling price, fry price, ration price and attractive minimum rate.

For all scenarios, the fluctuations of the variables such as fish selling price, fry price, ration price and attractive minimum rate were 1.14 to 1.52 US$.kg-¹, 0.03 to 0.07 US$.kg-¹, 0.48 to 0.61 US$.kg-¹ and 4.4 to 15.0% respectively. The initial investment value for C1 was US$ 124,522.03, for C2 of US$ 270.301,40 and C3 of US$ 444,138.00. Regarding the output variables, the probability of occurrence of values below 8% for IRR was 86.7% for C1, 47.3% C2 and 43.2% C3. For the variable NPV was 91.8% for C1, 60.2% for C2 and 55.7% for C3 in relation to values below zero. On the other hand, return of capital over 10 years, was 86.3% for C1, 44.8% C2 and 38.5% for C3 (Figure 1).

Within these results, we can conclude that aquaculture properties with a production volume of less than 5,000 m^3 presented a high financial risk (p 88.3%), while properties above 5,000 m^3 of production volume medium to low financial risk (p 48.3%), thus making it more financially sustainable and profitable

IMPROVED USE OF LOW FM AND LOW FO DIETS IN GILTHEAD SEABREAM (*Sparus Aurata*) JUVENILES OBTAINED BY COMBINED BROODSTOCK SELECTION AND NUTRITIONAL PROGRAMING

Hanlin Xu*, Shajahan Ferosekhan, Serhat Turkmen, Juan Manuel Afonso, Daniel Montero and Marisol Izquierdo

Aquaculture Research Group (GIA), Institute of Sustainable Aquaculture and Marine Ecosystems (ECOAQUA), Universidad de Las Palmas de Gran Canaria, Crta. Taliarte s/n, 35214 Telde, Spain

Introduction
Gilthead sea bream, as other marine fish species, has a restricted ability to synthesize 20:5n-3 and 22:6n-3 from their 18C fatty acid precursor, 18:3n-3, that is high in plant oils. Since this process is greatly limited by the activity of the fatty acyl desaturase 2 (fads2) enzyme, producing fish with a higher fads2 activity would improve their ability to utilize diets low in fishmeal (FM) and fish oil (FO) and containing plant oils. This could be achieved by nutritionally programing fish through broodstock nutrition as it has been previously demonstrated in sea bream (Izquierdo et al., 2015; Turkmen et al., 2017) or selecting broodstock that have a higher *fads2* activity. The later has not received sufficient attention and, therefore, the aim of this study was to determine the combined effect of selection of broodstock for their high or low fads2 gene (*fads2*) expression and feeding broodstock with diets differing in their fatty acid profiles.

Materials and methods
Sea bream juveniles were obtained from broodstock with either high (H groups) or low (L groups) *fads2* expression in blood, after being fed one month before the spawning season with low FM and low FO diets, and fed during the spawning season a diet with 100% FO (FO groups) or 20%FO/80%RO (RO groups). These four groups of juveniles (HFO, HRO, LFO and LRO) (2.3±0.01 g initial body weight, mean ± SD) were randomly distributed into 12 x 250 L tanks in triplicate and challenged with a diet containing only 7.5% FM and no FO for 45 days. At the end of the trial, liver samples were collected for biochemical and molecular analysis.

Results
The highest growth (final body weight and SGR) was found in juveniles from broodstock with a high *fads2* expression and fed RO diet (HRO) and the lowest in those from broodstock with a low *fads2* expression and fed RO diet (LRO) (Table 1). Those fish (HRO) had also the best FCR, being significant y improved in comparison to HFO juveniles. Besides, in juveniles from low *fads2* broodstock, growth was higher when broodstock had been fed FO (LFO). Therefore, there was a combined significant effect of selection of broodstock for their high or low *fads2* expression and the fatty acid profile of broodstock diets. Besides, in offspring from broodstock fed 100% FO diet, there was a higher level of 18:4n-3, 20:4n-6 and 20:5n-3 when broodstock was selected for its high *fads2* expression (Table 2).

Conclusion
In conclusion, selection based on high blood *fads2* expression and nutritional intervention of broodstock can be an effective way to increase the low FM/FO diet utilization of the progenies.

Introduction

Indonesia has a great diversity of microalgae, but has not yet received much study nor has this diversity been used for applied technology. However, relatively little information is available about microalgal resources despite their potential to be used as antiviral in the fish. *Chlorella sp.* is known as one of the fastest growing microalgae because it able to grow doubling its biomass weight in a few hours of sunlight and contains a triacylglycerol as much as 14-30%. This microalgae can yield the oil till 75% of dry weight under different condition. Algal organisms contain a rich of a novel source of biologically secondary metabolites and active primary. This metabolite may be an attractive bioactive compound for the pharmaceutical industry. Chlorella sp. contains lipid, protein, carbohydrates, minerals, and vitamins. Many functions also use *chlorella* sp. for medicine such as such as antifungal, antibacterial, and antiviral activity. The study aims to identify the Chlorella sp. from local isolate Using the Internal Transcribed Spacer (ITS) and to know its role as inhibitor stress caused by RNA *Viral Nervous Necrosis* (VNN) infection on the Humpback grouper

Methods

One way to determine *Chlorella* sp. local isolate was identified it using a gene analysis with the sequences of ITS. This study aims to determine the *Chlorella* sp. isolate and its potential as an anti-VNN virus in the Humpback grouper (*Cromileptes altivelis*). The methods were in vivo test through an administration Chlorella sp orally to the fish with treatment (A): control = normal fish, (B): fish + *Chlorella sp.*, (C): fish + VNN, and (D): fish + VNN + *Chlorella* sp.*);* analysis of *Chlorella* sp. was conducted by PCR using sequence ITS with IST-1 primer (Forward: TCCGTAGGTGAACCTGCGG) and ITS-4 (Reverse: TCCTCCGCTTATTGATGC). The stages of PCR amplification ITS included initial denaturation at 95ºC for 3 min., denaturation at 98ºC for 10 s., annealing at 53ºC for 30 s., and extension at 68ºC for 45 s. The PCR stage was carried out for 35 cycles. The sequencing results are compared and adjusted according to the order stored in the NCBI GenBank database using BLAST. The computed counts are then manually checked and corrected. The pair evaluation distance is calculated using the equations of Jukes and Cantor implemented in the MEGA6 program. Analysis of VNN Infection using a target of 294 bp with primer (Forward: CGTGTCAGTCATGTGTCGCT; Reverse: CGAGTCAACACGGGTGAAGA). The stages of PCR amplificatio of VNN included denaturation at 94ºC for 30 s., annealing at 60ºC for 30 s., and extension at 72ºC for 45 s. The PCR stage was carried out for 40 cycles. Tissue inflammatory response was conducted by the immunohistochemistry (IHC) on the kidneys tissue using IgG anti-HSP primary antibody cross-reaction with fish. The stress inhibitor response includes detecting inflammation in the tissue by IHC methods that quantified using the immunoratio technique.

Results and Discussion

Based on the results of the sequencing analysis, it is known that Chlorella sp. with ITS markers have a similarity level of 92-93% but the total score is still low, namely 738 compared to Chlorella sp. at the GenBank. Long sequence of base pairs Chlorella sp. with ITS marker which is 556 bp. PCR analyses showed VNN infection at 294bp in kidney organs. In vivo test results *Chlorella* sp., for anti-VNN, showed an inflammatory response to VNN infection through HSP-70 expression in the kidneys. The qualitative result using immunohistochemistry shows a positive anti-inflammatory reaction on the kidney tissues. Administration of Chlorella sp. to the fish increase HSP-70 expression in treatment A, B, C, and D were 19.7%, 50.0%, 63.9%, and 60.3%, respectively. Some studies mention, synthesis of HSP70 and protein coil as sitoprotektif cells that result in increased by osmotic stress stimulus (Deane dan Woo, 2004). Inflammatory reactions can also be characterized by the expression of Hsp (Yanuhar et al., 2015). The results of histopathological tests on the kidneys showed that in treatment D there was less tissue damage compared to treatments D. Damage that occurs includes necrosis, vacuolation, hyperplasia, and edema.

Conclusion

The conclusion is the identifica ion of Chlorella sp. molecularly can use ITS markers with a low score. Chlorella sp. has the potential as an antiviral VNN indicated by an increase in HSP-70 expression in Humpback Grouper kidney organs.

THE ASEAN FISHERIES EDUCATION NETWORK; ESTABLISHMENT, EXPANSION AND EXTENSION

Yeong Yik Sung, Happy Nursyam, Truong Quoc Phu, Tan Min Pau, Najiah Musa, Siti Azizah Mohd. Nor, Mieke Eggermont, David Bassett, Marieke Reuver & Patrick Sorgeloos

The ASEAN Fisheries Education Network, referred to as ASEAN-FEN, represents a consortium of university based academics, drawn from those institutions with an emphasis on fisheries and aquaculture across south east Asia. ASEAN-FEN was established in 2011 by agreement of 9 founding members for the purpose of supporting and enhancing the fisheries and aquaculture sector through education, research, and public outreach across the ASEAN region. ASEAN-FEN supports and facilitates activities of educators, scientists, and agencies responding to local, regional, national, and international issues on fisheries and aquaculture. ASEAN-FEN has developed quickly, expanding from 9 members in 2011 to representing 32 institutions in 2019. Current membership comprises academic institutions from; Malaysia, Vietnam, Thailand, Indonesia, The Philippines, Myanmar, Cambodia and Laos. As the secretariat of ASEAN-FEN, Universiti Malaysia Terengganu (UMT) has lead and coordinated academic collaboration projects from both the European Union and China, aimed at promoting capacity building, academic exchange and research collaboration. This session will consider the establishment, expansion and outreach work of ASEAN-FEN, particularly with reference to the EC Horizon 2020 funded EURASTiP project, addressing capacity building between Europe and se-Asia in aquaculture education.

This project has received funding from the European Union's Horizon 2020 research and innovation programme under Grant Agreement no. 728030 (EURASTiP). This output reflects the views of the author(s)

The classificati n of shellfish production areas (SPAs) in many shellfish producing countries is based on monitoring for faecal indicator organisms. This monitoring assesses the risk of contamination with pathogens and determines the level of post-harvest treatment necessary for the shellfish prior to sale for human consumption

This study investigated the effect of the number of *E. coli* monitoring results on the classification status of SPAs using the A, B and C classification criteria prescribed in the European Food Hygiene Regulations. The assessment was based on a database of *E. coli* results obtained from monitoring in shellfish from seven production areas (>255 sample results/SPA) on the coast of Santa Catarina (Brazil). It was found that six SPAs would be classified as B and one as C if all the available results were considered. Ten series of 50 data samples were randomly extracted from each production area dataset (12–120 results/sample, in multiples of 12). Classifications given to each data sample resulted in two production areas that had been given B status based on the full database being classified more times as A than as B when data samples with 12 results were considered. In general, the number of data samples compliant with class A decreased with the higher the number of *E. coli* results that were assessed per data sample.

The results indicate that areas with class B status can be misclassified as A during the initial classification when fewer results are available. Furthermore, areas with 'prohibited' status can be misclassified as C during the initial classification, when 12 results are considered in compliance assessments.

This study did not identify the same potential misclassification issue in relation to SPAs with classifications ranging between B and C. These classes share the same maximum limit (46,000 MPN/100g), therefore, compliance with 4,600 MPN/100g is the legal standard that differentiates the two.

This study identifies two factors that may lead to misclassific tion of a production area: the varying number of results considered in the compliance assessment; and the consideration of maximum *E. coli* result as a legislative standard. Therefore, possible ways of minimising the risk of misclassificati n include the adoption of other statistics as microbiological legislative standards rather than maximum *E. coli* result or the consistent use of a fixed amount of results to classifying SPAs during initial and ongoing monitoring.

These results emphasise the need to consider long-term monitoring datasets in compliance assessments to ensure that the classification status of S As truly reflects environmental contamination levels

HOW DIET COMPOSITION AND ENVIRONMENTAL FACTORS AFFECT THE UPTAKE AND METABOLISM OF ASTAXANTHIN IN ATLANTIC SALMON (*Salmo salar*)

Introduction:
The red flesh colour is a hallmark of salmon products, and essential for consumers' perception. Pigmentation of skeletal muscle and eggs is determined by the content of xanthophylls – oxygen containing carotenoids such as astaxanthin. Wild salmon accumulate carotenoids produced by algae and transferred via the food chain. Farmed salmon receive feeds with added astaxanthin. However, only about 1/10 of the astaxanthin added in feeds is retained in the salmon fillet, and lately there have been increasing problems with poor colour on salmon fillets in Norwegian salmon farming. The combination of low utilisation efficiency and crucial importance for product quality stimulates research on astaxanthin metabolism and factors that determine its retention and functional role in salmon. An important goal of the project was to enhance the understanding of dietary factors that affect astaxanthin uptake, metabolism and retention, since little is known about the mechanisms that regulate the deposition of astaxanthin in the salmon muscle. Astaxanthin is a precursor of retinol in salmon, but salmonids also have a reductive metabolism of astaxanthin. Astaxanthin is also a powerful antioxidant, and stress may have a negative impact on flesh pigmentation. However, the regulation of different pathways and their importance for flesh pigmentation and health have not been much studied in Atlantic salmon.

Salmon diets have gone through major changes the last decades from essentially a marine based diet with a protein/fat ratio of 3:2 in the early 90s to a diet with 70% plant ingredients and a protein/fat ratio of approximately 1:1 today. This shift in ingredients has resulted in reduced levels of the omega-3 FAs EPA and DHA, and increased pro-inflammatory omega-6 FAs content in organs and tissues. High fat diets with 70–80% plant ingredients also increase whole body lipid retention and lipid concentrations in the liver of Atlantic salmon when additional marine micronutrients are not added. The question raised in this project is how this potentially may affect the muscle deposition of astaxanthin in salmon.

Methods
The possible effects of such dietary changes on absorption, metabolism and flesh retention of astaxanthin were tested in a controlled experiment in tanks using a 2x2 factorial design with replacement of fish meal (FM) and fish oil (FO) with plant protein (PP) and plant oil (PO). Diets with different content of marine and plant ingredients were fed to Atlantic salmon post-smolts (star weight 197 g) in 1 m^3 tanks supplied with flow-through seawater (6 and 12 °C). The fish were fed a marine-based diet (Diet 1, FM/FO), a diet containing fish meal and plant oil (Diet 3, FM/PO), a diet with plant protein and fish oil (Diet 4, PP/FO) and a low marine diet with plant protein and plant oil (Diet 2, PP/PO). The low marine diet was also supplemented with concentrates of phospholipids, PL (soy lecithin, Diet 5, and a marine phospholipid product, MPL, Diet 6) to study potential effects of phospholipids on astaxanthin absorption and retention. The diet formulation is shown in Table 1. Diet 1,3 and 4 were fed on both 12 and 6°C. A low marine diet without astaxanthin (- Ax) was also fed to the salmon to study effects of astaxanthin on salmon performance and gene expression. Liver cells were isolated from marine and low marine diets and incubated with ^{13}C astaxanthin and cortisol to study effects on astaxanthin metabolism.

Table 1: Diet formulation (%)

	Diet 1 FM/FO	Diet 2 PP/PO	Diet 3 FM/PO	Diet 4 PP/FO	Diet 5 PP/PO + soy lec	Diet 6 PP/PO + MPL
Fish meal	58,7	7,5	58,7	7,5	7,5	7,5
Soy P concentrate	-	26,0	-	26,0	26,0	26,0
Wheat gluten	-	22,5	-	22,5	22,5	22,5
Wheat starch	13,5	10,0	13,5	10,0	10,0	10,0
Fish oil	22,0	6,5	5,5	25,8	6,5	6,5
Rapeseed oil	-	19,4	16,5	-	19,4	19,4

Sum EPA/DHA	4,1	1,1	1,7	3,5	1,2	1,2

(Continued on next page)

Results

The results from the study show that salmon diets with plant protein (PP) led to reduced feed intake and growth, and low digestibility of lipid and astaxanthin. There was also abnormal lipid accumulation in liver and intestine in salmon fed low FM diets without supplementation with phospholipids. Adding phospholipids increased absorption of astaxanthin and fat, and digestibility of fat and astaxanthin was at the same level in diets 1,3,5 and 6, and lower in diets 2 and 4. The digestibility of astaxanthin and lipid was highly correlated and both parameters were linearly correlated with the concentration of PL in the diet. There was however no significant effect of temperature on astaxanthin and fat digestibility. Astaxanthin retention in the fillet was dependent on both absorptive and post-absorptive processes such as metabolism of astaxanthin in various organs. The concentration of astaxantin metabolites in fillet and liver were affected by both diet composition and temperature. The concentration of the metabolite idoxanthin was higher at 6 than at 12°C. FM and supplementation with PL also increased idoxanthin. There was an interaction between diet and temperature, at 12°C there was no effect of plant oil (PO) on astaxanthin and idoxanthin concentration in muscle, but at 6°C there was a negative effect of PO on astaxanthin concentration in muscle, and an increased concentration of idoxanthin.

Stress, both in cell culture studies with liver cells and *in vivo* seemed to increase the amount of metabolic products of astaxanthin. The results on gene expression suggest different functions in liver, muscle, and intestine in salmon fed a low marin diet. In intestine the main effect of lack of astxanthin was immune suppression, in muscle there were symptoms of mild inflammation, and in liver the main effect was a stimulation of steroid biosynthesis. The largest number of differentially expressed genes were found in muscle.

Conclusion

Diet composition and temperature affect the muscle deposition and metabolism of astaxanthin, and stress seem to increase the turnover of astaxanthin. To fully understand the mechanisms that control the muscle deposition of astaxanthin, the interaction between environment and diet must be considered.

Introduction

Climate changes may result in longer and more frequent periods of elevated sea temperatures. Periods with seawater temperatures above the optimum temperatures for salmon has been shown to result in reduced appetite and growth, increased mortality and disease problems in the intensive farming of Atlantic salmon. Changes in temperature may further affect the site production, the spreading, distribution and severity of diseases and outbreaks, and the carrying capacity of the environment. For most aquaculture production areas, climate projections are only available from global or regional climate models that have coarse resolution which does not take into consideration the local conditions. Higher resolution models that focus on the coastal areas used for production would be useful for future planning. Assessment of temperature changes across spatial and temporal scales can provide information to support the industry in evaluating opportunities and risks and enable the development of adaptation, or mitigation, strategies where necessary.

We have modelled the potential impact on Atlantic salmon growth under possible future conditions, including increased sea temperature and extreme temperature events. Sea temperatures have a strong impact on productivity through several mechanisms, including fish growth and welfare. Severe temperature increase may challenge biological thermal thresholds, and thereby ruling out production or requiring costly adaptation measures. We show how observation-based bias-correction of modelled temperatures are crucial for applications at local scale. For long-term sustainability and allowing for adaptation, knowledge of both present-day situation and the potential future characteristics of a farming area are vitally important.

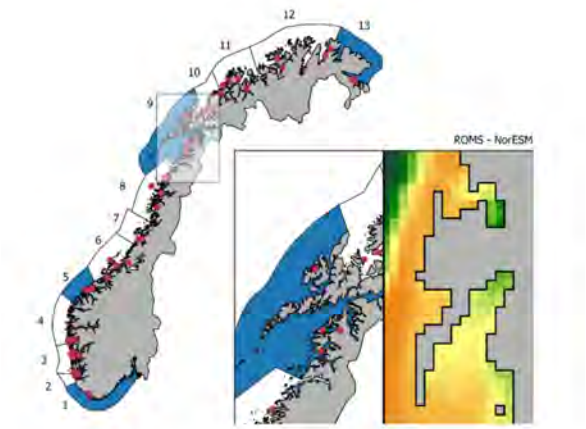

Figure 1: Map of Norway showing the 13 aquaculture production regions, red dots represent farms. Regions 1, 4, 9 and 13 are highlighted in blue and are in focus in this study. Each region had four modelled sites, resulting in a total of 52 sites. Enlarged image of regions 9 shows the ROMS-NorESM grid temperature resolution.

Materials and methods

Stakeholders provided farm data from the 13 Norwegian management regions (Fig. 1) that were used in this study. The dataset covered a wide range of geographical locations, illustrating the different impact scenarios and the need for local adaptation strategies. Four regions, 1, 5, 9 and 13, are in focus in the work presented here.

Salmon growth was modelled using a combination of the Ewos-Cargill EGI model to capture seasonal trends in feed, and a Dynamic Energy Budget model (DEB) for Atlantic salmon from Føre et al (2016).

The temperature projections were extracted from a regional downscaling of the IPCC RCP4.5 scenario simulated by the Norwegian Earth System Model (ROMS-NorESM) (Bentsen et al., 2012; Iversen et al., 2013) covering 2006 – 2070 (Skogen et al., 2019; Sandø et al, in prep). The ROMS-NorESM downscaling is one of the highest resolution regional climate simulations available for the case study area. Since only the moderate IPCC scenario (RCP4.5) at sufficient resolution was available, we wanted to evaluate the potential risk associated with more extreme summer temperatures. Scenarios were constructed based on average farm measurements to indicate how more extreme temperatures, beyond average conditions, could affect growth. Thus, "high" and "very high" summer temperatures were added to illustrate "what-if-scenarios" for more extreme temperatures,

(Continued on next page)

Results

Comparisons between climate model outputs and farm measurements revealed that the model often over- or underestimated the farm temperatures by several degrees. We therefore calibrated the projected temperatures to local farm conditions using a bias correction technique, where the difference between actual observed farm temperatures and simulated temperatures for a recent reference period were calculated and added to future climate projections (Hawkins et al., 2013). This method corrected the temperature models to local conditions and made them relevant for future projections of aquaculture along the coast of Norway.

Modelling growth and comparing temperatures scenarios with salmon thermal thresholds illustrated that farmers in the South will have to prepare for, and adapt to, unfavorable farming conditions, while farmers in the North may experience increased production due to more days closer to the thermal optimum, although there may even be at risk of higher temperatures in these regions. Also, the possible increased growth seen in the northern regions are far smaller than the reduced production observed in the South. In addition, prolonged periods of higher temperatures may further result in health and welfare issues other than increased mortality, that are not simulated in the model, as the model used in this trial only consider increased temperatures.

Conclusions

With the 52 sites considered in this study, we have demonstrated that the regional climate projections are not suitable for local forecasting, thus to generalize possible adaptation strategies directly from uncorrected predictions is impossible. In order to make functional adaptation plans, local environmental conditions and farming strategies. Extensive information on how the environment may change at the productions must be considered and this depends upon the availability of detailed environmental data at farm sites and potential future farm sites and how this may further effect on the biology of the farmed specie will be crucial for the development and implementation of the adaptation strategies.

ClimeFish

The EU financed, H2020 project ClimeFish, aim at estimating the effects of climate change on fisheries and aquaculture in Europe from today until 2050. Follow our results at the ClimeFish website: www.climefish.e

Introduction

Sea urchin is one high price seafood (up to US$100/kg). Recently, the amount of sea urchins that could be captured is decreasing in Taiwan because the market demand is growing. Therefore, much attention has been paid to farming of sea urchins by feeding seaweeds. In this study, the effects of seaweeds on the growth of purple sea urchins (*Anthocidaris crassispina*) were reported.

Materials and methods

Twenty purple sea urchins were bought from Hua-Quao Fish Market in Donggang Twon, Pingtung County on January 6, 2018. Five purple sea urchins were bred in one glass tank with aeration. One-hundred grams (wet weight) of single seaweed were fed every week. The seawater was replaced, the sea urchins were weighted and tank was washed at the same time every week.

Results

According to the results, the body weight of purple sea urchins did not increase after feeding them with seaweeds, and even slightly decreased over time (Table 1).

When fresh seaweeds were used as feed, the seawater remained clean for ten days. However, the seawater became dirty after feeding dried *S. ceylanica* for three days. It is noted that feeding dried *S. ceylanica* to sea urchins would increase seawater turbidity and cause sea urchin death.

Discussion and conclusion

The purple sea urchin (*Anthocidaris crassispina*) was fed with different seaweeds (e.g., *S. ceylanica*, *G. filicina*, *G. lemaneiformis*, and *U. lactuca*). The body weight of the purple sea urchins did not increase with time over the course of the study. It is suggested that the size of seaweeds might influence the feeding efficiency of the seaweeds. Further studies are needed to enhance the growth of the sea urchins.

Introduction

Mycosporine-like amino acids (MAAs) are a family of intracellular ultraviolet (UV)-absorbing compounds which protect aquatic organisms against solar UV radiation. Occurrence of MAAs in microalgae and macroalgae are well-known. Due to lack of pure compounds, quantitation of MAAs is still a challenging work. This work explored Pohphyra-334 contents in laver (*Porphyra dentate*) using water flush extraction methods and evaluated extraction conditions on the recovery of MAAs.

Materials and methods

The multiple extraction test (10 times) was carried out to evaluate the Porphyra-334 leachability for dried laver (Fig. 1). First of all, a half grams of dried laver was filled into a syringe. Then, extraction solvent was poured in the syringe. The leachate was collected by a beaker. Next, the leachates were lyophilized under -80^{o}C. Two mL of 0.2% HAc were used for reconstitution and then filled by 0.2 μm membrane filte . Final, high performance liquid chromatography (HPLC) was applied for Poyphyra-334 analysis.

Results

With regard to the extraction conditions (Tab. 1), the total Porphyra-334 contents in Porphyra were 3.76-5.98 mg/g. 20% methanol is best for Porphyra-334 extraction. For S/S ratio of 60 and 90, total Porphyra-334 contents were similar by different solvents. For the extraction times required for 80% efficienc , three times are needed by S/S ratio of 60 and 90. Overall, S/S of 60 and 20%-methanol are the best extraction condition (Fig. 2).

Discussion and conclusion

The effects of extraction conditions on MAAs recovery were investigated in this study. The obtained optimal parameters were S/S of 60 and 20% of methanol. This result is similar to that reported by Cardozo et al. (2011), showing that extraction with 20% methanol was the most efficient and with 50% ethanol was the least efficient among the tested combinations. Similar results were also observed by Zhang et al. (2016) who reported that optimization of extraction of MAAs from *Gloiopeltis furcata*. The conditions optimized were S/S ratio of 67, and methanol concentration 12%.

Introduction
In aquaculture sector, the information flow between the producers and relevant authorities is vital in order to sustain technology updating and access to information (Subasinghe et al., 2010). In today's word thanks to variety of media, learning activities are easily shared and knowledge is spread instantly. The app HEALTHY_FISH is an ERASMUS+ project led by the Spanish Marine Fish Farming Association (APROMAR) in collaboration with four partners: SGS Tecnos (Spain), the Italian Aquaculture Association API (Associazione Piscicoltori Italiani), (Dokuz Eylül University, Institute of Marine Sciences and Technology (DEU-IMST) and the Croatian Chamber of Economy (CCE).The objective throughout this project is to establish a "Training Program standardized at the European level for the aquaculture industry". The program will consist of training modules. The modules will compensate the needs of the professionals by e-learning tools. The second face of the project is to study the possibility of further education materials of the farm and apply e-learning method on these subject and adapt additional and up-to-date e-mobile training modules.

Materials and Methods
The first step was to consider the current training programs for the sector. Later to specify the need and evaluate extra training necessities. Moreover, for training materials, the needs of four different countries were gathered to qualify professionals in their own countries Spain, Italy, Turkey, Croatia. By the time the assessed and clarified training needs are addressed the "Standardized Aquaculture Training Program" is also made reachable on an "Open Access Moodle Learning Platform".

Results
It is inevitable that mobile devices are extremely handy as educational tools which will be used by farm workers who usually work in distant locations. The programme will be transported into an App that the content can be reviewed by users, they also can evaluate and obtain a certificate at the end. It serves in five languages English, Turkish, Italian, Croatian, and Spanish and 11 modules. The first impression of the farm workers show that they find "e-learning" user friendly, easily accessible and inspiring. The Standardized Aquaculture Training Program is available at http://www.apromar.es/healthyfish.

Discussion and Conclusion
There is a growing demand on aquaculture in accordance with that worldwide aquaculture production should be increase (FAO, 2011). The basis of this growth depends on education and training methods with regards to the need for human resources. If the aim is to increase productivity aquaculture it is fundamental that the skills of farmers and employees should be enhanced (Seixaz et al., 2015). New approaches for professional education are providing platforms that evolves Information and Communication Technologies (ICT). Many different digital learning resources see the light of day created by different types of organizations. Currently there is a fast paced production of learning and training materials on line that helps users easily access the huge potential of the digital resources (Moises et al., 2010). This training programme will also help to identify weaknesses and resolve them. Another advantage of e-learning is that subjects and matters can easily and rapidly be renewed. These are some of the reasons why e-learning is often promoted. This education program, which was developed with the aid of ICT, can function as a good example of digital learning within the aquaculture sector for each country.

The overall impacts of the project are:

During the application at farms, provision of an innovative training tool to the professionals of aquaculture is observed. Innovative training materials are created. Approaches of the sector to e-learning evaluated positively. Practice of vocational training activities for professionals was gained. Linguistic diversity for the programme which in English, Spanish, Italian, Croatian and Turkish was enabled.

In the future, this study will provide European level training to professionals and personnel of the aquaculture sector. This will also help standardization of vocational programmes.

By means of communication and debating among professionals the quality and sustainability standards will be endorsed.

Introduction

Non-starch polysaccharides (NSPs), carbohydrates present in plant ingredients, are formed by cellulose and other heteropolymers of more complex sugars such as mannose, xylose, and arabinose, among others. They give important differences in solubility, water retention capacity, interaction with other food ingredients, and in the intestinal microbiota. In many cases, NSPs form a matrix that hinders the access of digestive enzymes to the protein and starch present in seeds of cereals and legumes. Therefore, the use of enzymatic complexes capable of partially degrading NSPs, has shown positive effects in the nutritive use of feeds with high amounts of plant ingredients. Additionally, exogenous carbohydrases can promote the development of a beneficial microbiota and consequently results in a better health status. The inclusion of these enzymes has been evaluated in feed for freshwater species such as tilapia, catfish, rainbow trout and carp, but not in marine fish. Consequently, the present study aimed to assess the effect of including a commercial mixture of carbohydrases in a feed containing high amounts of plant ingredients on growth, digestion, metabolism, and gut microbiota in the gilthead seabream (*Sparus aurata*).

Materials and methods

Gilthead seabream juveniles (mass 250 ± 4 g) were randomly distributed into four 250-L tanks (for each tank N = 24), with flow-through water system at 19.5 ± 1.0 °C, and a photoperiod of 11L/13D. In two tanks the fish was fed a standard plant-based diet for this species (C-diet; including 66% of vegetable meal and 17% of animal meal), and the other two tanks the same diet was supplemented with endo-beta-glucanase (E-diet) that hydrolyses (1,3)- or (1,4)-bonds in beta-D-glucans. All tanks were fed a daily ration of 2.5 % body mass distributed in three meals. At the end of the experiment, after 3 months, fish were sampled for growth determination, and biochemical and molecular analyses. Gut content was collected for microbiome analysis. The 16S-rDNA amplicon sequencing was done by Illumina. Relative expression of genes related to growth and digestion were quantified in the whole gastrointestinal tract. Potential differences were tested by one-way ANOVA ($p < 0.05$).

Results

No significant influence of the tested diets was obtained on the studied variables, except for length, plasma triacylglycerol, and *igf* expression (Table I). Weight and other analysed parameters were generally higher (except for the alkaline proteases expression) in the E-diet group, although these differences were not statistically significant

Gut microbiota was dominated by firmicutes, followed by proteobacteria and actinobacteria. No statistical differences were detected in the taxa composition between treatments (PERMANOVA analysis), but the amount of proteobacteria was higher in fish fed the E-diet. The presence of *Photobacterium* reached at significantly higher levels in fish with E-diet. However, this difference was mainly driven by the individuals from only one tank, probably due to a tank effect rather than a diet.

Discussion and conclusion

Inclusion of endo-beta-glucanase in the diet seems to induce some beneficial changes. However, they are not evident enough, but a longer experimental on-growing period could reveal significant biological e fects.

Introduction

Understanding the factors that affect the digestion processes in fish is essential to ensure an efficient and sustainable aquaculture, given the large effect that impaired digestion can have on all downstream indicators (growth, conversion efficienc , environmental impact). In this presentation, we discuss the results of simulating the digestive processes of gilthead seabream (*Sparus aurata*) and Senegalese sole (*Solea senegalensis*) under different feeding protocols, using a mathematical model developed for Ballan wrasse [1] and calibrated for these species using ground-truth observations from a recent study by Gilannejad et al. [2].

Methods

The simulations reflected the experimental protocol of Gilannejad et al. [2], where different feeding protocols were tested. we simulate the feeding protocols sequentially: each protocol is simulated for 5 days, for a total of 20 days of simulation. In each 5 days period, the following sequence is applied: on the first two days, fish are fed with unmarked diet (to pre-condition the model state before introducing the marker); on the third day, marked diet is introduced (to evaluate yttrium wash-in dynamics); on the fourth day, the marked diet is again replaced by unmarked diet (to evaluate yttrium wash-out dynamics); on the fifth da , no feed is provided (to ensure all protocols are tested under the same initial conditions).

Results and Discussion

Results of the simulations, in terms of the some of the most important observables parameters (maximum amount of yttrium measured and apparent digestibility coefficients) can be seen in Table I. Plots displaying the time-dependent filling and emptying behavior of the different gastrointestinal tract segments can be seen in Figure 1.

The calibrated model for gilthead seabream generally displays simulated responses that are consistent with measured values in vivo (i.e. are in the correct order of magnitude). Nevertheless, current limitations in the model, particularly as it relates to feeding behavior, restrict its accuracy. When these limitations are addressed, the use of such digestion models can be useful to identify gaps in our knowledge of digestive processes, and eventually be used as predictive tools in digestive physiology and nutrition research.

Table I. Comparison between measured and simulated digestibility (dry matter and protein ADC) and marker-related responses, for the different feeding protocols in both species.

Sparus aurata	measured	simulated	
maximum yttrium (stomach)	250	148	ng/mg tissue
maximum yttrium (intestine)	150	86	ng/mg tissue
ADC protein (Protocol 1) One diurnal meal	91.5	93.4	%
ADC protein (Protocol 2) Three diurnal meals	93.6	93.8	%
ADC protein (Protocol 3) Five diurnal meals	92.1	93.5	%
ADC protein (Protocol 4) Continuous diurnal feeding	94.1	88.9	%
Solea senegalensis	measured	simulated	
maximum yttrium (stomach)	150	117	ng/mg tissue
maximum yttrium (intestine)	100	30	ng/mg tissue
ADC protein (Protocol 1) One diurnal meal	62.7	89.0	%
ADC protein (Protocol 2) Six diurnal meals	82.4	90.2	%
ADC protein (Protocol 3) Six nocturnal meals	71.6	90.2	%
ADC protein (Protocol 4) Continuous noctur. feeding	76.4	90.2	%

Introduction

The main limiting factors in aquaculture production are insufficient land and water. Intensified practices may progress an overall aquaculture production. But, indiscriminate intensification may polluting the culture water by accumulating organic materials and nutrient discharge which leads to chances of acute toxic effects and environmental impacts. Hence to sustain the fish/shrimp production as well as to safeguard the environment new technologies like, the Biofloc technology (BFT) showed promising results in rectifying the problem associated with aquaculture intensification. Present chapter encompasses wide knowledge of concept and effects biofloc technology towards the water conservation

Biofloc technology (BFT)

Biofloc technology (BFT) is an eco-friendly and limited water exchange system which is also called active suspension ponds, heterotrophic ponds, green soup and Aerobic Microbial Flocculent Technology. Biofloc is an aggregates of algae, diatoms, bacteria, protozoans, planktons and particulate organic matter such as faeces and uneaten feed. Each floc is held together in a loose matrix of mucus that is secreted by bacteria and bound by filamentous microorganisms. There are different types of biofloc is present based on microbial abundance and coloration. One is green water biofloc system (outdoor open culture) that are open to natural light. In this system, both algae and bacteria which control the water quality. And those that are not exposed to natural system is called brown- water biofloc system (indoor closed system). In this system, water quality is controlled by bacteria.

Effect of biofloc technology in water quality management

High temperature influences floc characteristics and microbial metabolism. But, it can be varies depending on the cultured species. Dissolved oxygen is a crucial parameter in biofloc systems, the oxygen demand will be higher, because of the interaction between the bacteria, algae and fish size. The recommended dissolved oxygen to be maintained is 6–8 mg/l to ensure proper functioning of the system. The pH should be ranges from 6.5 to 9 depending on the culture species. Alkalinity is the total concentration of bases in the water which includes carbonate, bicarbonate and hydroxide ions. Total alkalinity ranges from 70 to 150 mg/l which provide a well buffered environment and suitable for growth of the fish and pond primary productivity. Total alkalinity was stable in normal culture system and oscillates in biofloc system due to buffering action. Hardness is a measure of alkaline ions of Calcium, Magnesium in water with other ions like Aluminium, Zinc and Hydrogen. Acceptable range of hardness in aquaculture is 50-250 ppm. Less than 0.1ppm of NH_3 suitable for fish culture. It can be reduced by adding carbon source.

Higher biological oxygen demand (BOD) specifies the abundance of more heterotrophic bacterial population that assimilate the inorganic nitrogenous compounds. Biofloc system should operate with ranges between 200 to 500 mg/L of suspended solids are appropriate. Floc volume should be maintained within 25 to 50 ml/l to provide good nutrition for tilapia in AMF systems. In lined AMF shrimp ponds, 10 to 15 ml/l is the suitable range to provide good nutrient.

NUTRIENT DISCHARGE FROM SHRIMP POND AND IT'S MANAGEMENT BY ADVANCED TECHNOLOGY

Introduction

An indiscriminate intensificatio of aquaculture practices may polluting the environment in the form of sludge accumulation and nutrient discharge by over feeding and fertilization, antibiotics usage and poor management which leads to cause negative impacts on ecosystem. Hence, protect the environment as well as reduce the nutrient pollution we have to adopt advanced technologies like, Recirculatory Aquaculture System (RAS) and Biofloc System (BFT). These technologies can rectify the problem. Present review paper comprise the of concept technologies to ecosystem management

Nutrient discharge management by Biofloc technology (BFT)

BFT is an environmental friendly technology which can effectively control the sludge and minimize the nutrient discharge. It recycles nutrients continuously by addition of intensive aeration and carbon source which can be maintained by carbon/ nitrogen (C/N) ratio in the water which stimulates heterotrophic bacterial growth and converts ammonia into microbial biomass. If carbon and nitrogen are well balanced, bacteria briskly utilize ammonium.

The uneaten feed, faecal matter and fertilizers were the reason for sludge accumulation and nutrient discharge. The sludge accumulation can be minimized by addition of intensive aeration and carbon source. Type of aerator and position of aerator have positive impact on sludge recycling process. Low protein feed is sufficient because remaining protein has been balance from biofloc, this could effectively minimize the nutrient discharge problem. Sludge and sediment accumulation in the shrimp pond can be mechanically resuspended or removed by proper location of aerators. Resuspension is a possible solution to enhance the recycling and utilization of the feed residues as nutrient.

Nutrient discharge management by Recirculatory Aquaculture System (RAS)

Recirculatory aquaculture system (RAS) is a sustainable practice to produce safety and quality shrimps throughout the year. The culture waste water has been treated by sludge removal, mechanical filter (removes the larger particle), biofilter (removes microorganism), UV treatment (removes bacteria), aeration (oxygenation of water) which can be reused within same system. This technology effectively used to conserve the water budget and effluent removal. RAS installation investment is high. Hence, this suitable for urban area and developed countries.

Recirculatory Aquaculture System and Biofloc System supports nitrogen removal even biological oxygen demand and organic matter are higher in culture water. Adaptation of these technologies in shrimp pond offers a solution to avoid the ecological impact of high nutrient discharges and to reduce the use of artificial feed and feed cost.

REPEATED HORMONAL INDUCTION OF SPERMIATION AFFECTS STRESS BUT NOT IMMUNE RESPONSE IN PIKEPERCH (*Sander lucioperca*)

Introduction

Obtaining suitable amount of high quality sperm is a key element of successful controlled reproduction in finfishes In domesticated pikeperch (*Sander lucioperca* L.) lack of synchronization of spawning of males and females as well as low quantity of sperm are among the main bottlenecks in the production of high quality larvae. Hormonal stimulation allows the control over the maturation and spawning process in many commercial fish species, including percids. However, in the case of pikeperch typically applied hormonal preparation (human chorionic gonadotropin [hCG]) was found to cause elevated levels of cortisol (Falahatkar and Poursaeid, 2013) suggesting a stress response following its application. Besides, it is also known that hCG treatment may trigger immune response (Zohar and Mylonas, 2001) which can cause health issues of the broodstock. This has stimulated intensive research on the potential application of gonadoliberine analogs (GnRHa) in controlled reproduction of pikeperch. However, despite the significant progress observed in terms of hormonal manipulations of reproduction in this species the aspects related to the immune response following hormonal treatment was not explored yet.

The highest quantity and quality of sperm in percids were recorded between 4 and 8 days following hormonal treatment (Żarski et al., 2017). At that period typically the whole sperm is collected and used for fertilization purposes. However, very little is known about the possibilities of a second induction of spermiation and sperm collection, as it is practiced in other cultured species. This would allow facilitating the hatchery operations and the potential usage of the sperm of the most valuable individuals for fertilization of eggs coming from more female spawning at a longer time period.

The aim of this study was to evaluate the effects of repeated induction of spermiation on sperm quality and quantity in domesticated pikeperch. A special emphasis was put on the immune response following injection with either hCG or GnRHa, the most commonly used spawning agents.

Materials and methods

Mature pikeperch males (n=21), being reproduced 3 times before the experiment, were reared according to the protocol described by Żarski et al. (2019). At the beginning of the spawning period fish were treated with either NaCl (negative control, 1 ml kg^{-1}), hCG (at a dose of 500 IU kg^{-1}) or salmon GnRHa (50 µg kg^{-1}). Five days following the treatment sperm was collected from all the fish and the sperm motility parameters (using computer assisted sperm analysis, Minitub, Germany) and quantity of total sperm volume possible to be obtained were recorded. Just after this first sperm sampling fish were again treated with the same hormones and doses. After another 5 days a second sperm sampling was performed. Also, blood from each fish was collected for biochemical analysis of stress and immune response indices (cortisol and glucose levels, lysozyme and peroxidase activities as well as haemolytic activity of the alternative complement pathway). Temperature throughout the study was 12°C and photoperiod was 14 h. The data obtained were analyzed with one-way ANOVA test followed by Tukey's post-hoc at $P<0.05$ (Statistica).

Tab. 1. Results recorded during the 2nd sampling point of the experiment (see Material and methods for details). PRG – progressive spermatozoa motility; VCL – curvilinear spermatozoa velocity. Data in columns marked with different letters were significantly different ($P<0.05$).

	PRG [%]	VCL [µm s^{-1}]	Cortisol [ng ml^{-1}]	Glucose [µg ml^{-1}]	Lysozyme [U ml^{-1}]	Peroxidase [U ml^{-1}]	ACH50
NaCl	-	-	148.2 ±45.7^{b}	55.1±12.9^{b}	3130 ±527	76.1 ±20.8	110.1 ±28.0
hCG	77.1 ±19.0	166.6 ±19.0	268.5 ±99.4^{a}	71.1 ±16.6^{a}	3214 ±249	62.3 ±24.7	115.4 ±37.0
GnRH	78.1 ±13.5	152.9 ±18.0	214.4 ±84.0^{ab}	43.4 ±20.9^{b}	3614 ±610	60.4 ±20.2	124.2 ±34.6

(Continued on next page)

Results

It was not possible to strip more than 0.1 ml of sperm from control group at any of the sampling point. From the experimental groups similar sperm volume (1.5-2.6 ml kg^{-1}) was always obtained. There was no difference between the first and second sampling in terms of motility parameters among groups as well as between groups at the same sampling point ($P>0.05$). Stimulation with hCG induced higher cortisol level, when comparing to control group. Glucose level was the highest is hCG treated fish ($P<0.05$) (ab. 1). The immune status parameters were similar among all the groups (Tab. 1).

Discussion

In this study we confirmed the finding of Falahatkar and Poursaeid (2013) that application of hCG induces a stress response in pikeperch, in contrast to GnRH. However, we showed, for the first time, that despite increment of stress indices none of the hormonal preparations affected the immune markers analyzed in our study, which remained at the same level as in control fish. It was already reported, that stress-induced cortisolemia is not clearly related to circulating immune parameters in percids (Milla et al., 2010). However, the reason of elevated cortisol and glucose level following hCG injection as well as its consequences are still to be explored in future studies.

Our results indicate that GnRHa is a safe agent to be used in controlled reproduction of pikeperch from the perspective of its effects on the immune status of the fish. However, despite hCG was found to induce a stress response, the potential negative effect of this phenomenon should not be linked with immune response, as this was not confirmed in our stud .

Introduction

Gamete quality is one of the most important element of successful reproduction of aquacultured fish. This especially applies to a newly domesticated fish species, such as pikeperch (*Sander lucioperca*) in which lowered and/or variable egg quality is one the biggest obstacles toward rapid production expansion. Recently published data indicates that egg quality in response to husbandry and hatchery practices in pikeperch may be specimen-specific suggesting heritability of this trait (Żarski et al., 2019). However, mechanisms underlying pikeperch egg developmental competences remain unknown.

Finfish egg quality molecular profiling, having huge potential in understanding processes involved in shaping egg quality, has brought attention of scientists for over a decade now. Typically very few molecules (transcripts or proteins) were found to be related with egg developmental competence (Bobe and Labbé, 2010; Bizuayehu et al., 2019) which slows further progress. Besides, among the few studied fish species most were marine and model species (such as zebrafish, *Danio rerio*). Freshwater commercial fish egg quality transcriptomic profiling was performed only in rainbow trout (*Oncorhynchus mykiss*) (Bonnet et al., 2007) and Eurasian perch (*Perca fluviatilis*) (Almeida et al. – unpublished).

This study compares transcriptomes of high (HQ) and low (LQ) quality domesticated pikeperch eggs.

Materials and methods

Domesticated pikeperch broodstock was subjected to the reproduction protocol described in details by Żarski et al. (2019). From each female (n=85) an egg sample was snap-frozen for molecular analysis. From the remaining eggs other subsamples (n=3 for each female) were fertilized *in vitro* and incubated in controlled environment. Survival rate of embryos (SR) at 72 h post fertilization, hatching (HR) and deformity rates (DR) of hatched larvae were determined (for details see: Żarski et al. 2019).

Transcriptomic analysis was performed with the use of a specifically designed microarray (Agilent, 8x60k). Microarray probes were obtained by mRNA sequencing of 8 different pikeperch tissues (2x250 paired-end, Illumina). Transcriptome assembly was performed according to the pipepline described by Pasquier et al., (2016).

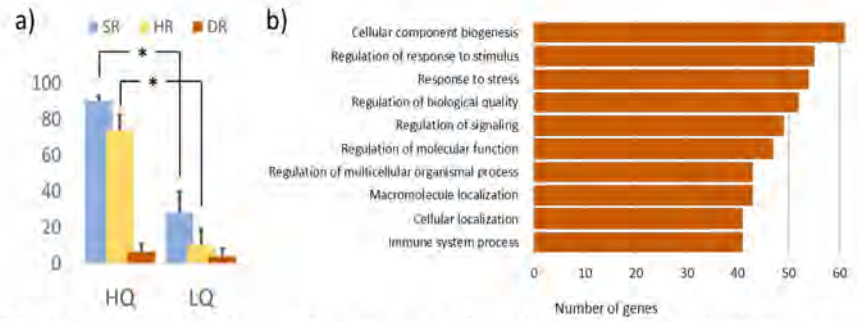

Fig. 2. Results of (a) evaluation of egg quality in pikeperch and (b) high level gene ontology of biological processes (ShinyGO v0.51, top 10 results based on the number of genes taking part in particular process). SR – survival rate at 72h post fertilization, HR – hatching rate, DR – deformity of hatched larvae. Data marked with sterisk were statistically different (ANOVA, $p<0.05$).

(Continued on next page)

Microarray sample hybridization, scanning and statistical analysis were performed according to methods described by Żarski et al., (2017). 16 samples were chosen (8 characterized by either HQ and LQ) following strict preselection procedure, where all the egg samples exhibiting any morphological alteration (lipid droplet fragmentation, signs of overmaturation, etc.) were excluded from further research. Differentially expressed genes (DEGs) between HQ and LQ were identified following analysis made with GeneSpring GX software (Agilent Technologies). Gene ontology was performed with ShinyGO v0.51 (http://bioinformatics.sdstate.edu/go/) .

Results

Samples representing HQ were characterized by higher SR and HR, when compared to LQ group. There were no difference in terms of DR between HQ and LQ (Fig. 1a).

The microarray design contained probes corresponding to 36,348 unique protein-coding genes. From among those genes expression of at least 10000 were detected in each of the sample. Analysis revealed 266 DEGs between HQ and LQ samples, from which only 7 were found to be up-regulated in LQ. All the remaining genes were up regulated in HQ. Gene ontology analysis revealed that DEGs are involved in various important processes including stress response or regulation of biological quality (Fig. 1b).

Discussion

Results obtained in this study following precisely planned operation allowed to obtain for the first time unexpected high number of differentially expressed transcripts between high and low egg quality. Typically, such an analysis allowed to reveal less than 100 egg-quality-associated transcripts (Sullivan et al., 2015). This was also probably possible due to the eggs selection procedure, in which only eggs representing very high and low quality, but not degraded by post-ovulatory ageing, were chosen, what was previously suggested to be a crucial element of such analysis (Żarski et al., 2017).

From among the DEGs we have identified 6 genes (cyclin G1, 39S ribosomal protein L4, ras and rab interactor, cell death-inducing p53-target protein 1, RING finger protein unkempt homolog) being related (but not the same) to the genes already suggested for being indicators of egg quality in other teleosts (Sullivan et al., 2015). However, the remaining 260 genes found to be differentially expressed between HQ and LQ are new candidates for determination of egg quality in teleosts.

The findings of our study bring new knowledge on the processes involved in the determination of developmental competence of pikeperch eggs as well as a new egg-quality-related gene repertoire.

Introduction

As is common for many marine fish species, there is considerable inter- and intra-cohort variation in survival and growth during the early life stages of yellowtail kingfish (Moran et. al., 2011). Different algal species have proved to be beneficial for larval performance, for instance microalgae could be used indirectly, as food for zooplankton such as rotifers which are essential food for some fish larvae. CAMAFAN (Characterisation and Industrial Application of Marennine as Aquaculture Feed Additive and Nutraceutical) is an applied research project focusing on blue-green pigment marennine. Marennine is produced by the marine diatom *Haslea ostrearia* during its life cycle. This water-soluble pigment is found intracellularly and is also released into the culture medium. Apart from the widely known colouring capabilities, recent research has shown that marennine also has antibacterial, antiviral, antiproliferative and antioxidant (Pouvreau et. al., 2018) properties. Given its properties and potential, marennine can be valuable in hatcheries for the production of fish larvae by reducing pathogenicity; have health and growth benefits, when supplied with live feeds. The present study aimed to provide new insights into the effect of enriched rotifers and artemia conditioned in different marennine concentrations (0, 0.5, 1.0 mg/L) on the growth and survival rate of yellowtail king fish larvae during the first feeding perio

Material and methods

Yellowtail kingfish larvae were fed with the live feeds rotifers (3-16 days-post-hatch) and/or Artemia (12-21 days-post-hatch) that have been enriched in 0.1 mg/L, 0.5 mg/L marennine concentration, or without marennine (control diet) from 8 days-post-hatch. Larvae were reared in 1500 L tanks with a stocking density of c.a. 40 larvae L^{-1} with feed delivered up to 6 times during the day. Growth was monitored as total length at 8, 11, 16 and 22 dph. Additionally, swim bladder inflation is observed at 8 dph. At the end of the experiment (22 dph), all remaining larvae from each tank representing each treatment larvae were counted, and total survival rate was calculated per tank as percentage of initial number of larvae.

Results

Survival rates and lengths of the larvae fed with marennine-enriched live feeds performed better than control groups (Figure. 1 and Figure 2). In terms of larval length, there were noticeable separations between control and marennine-treated groups as early as 11 dph. There were no significant differences in terms of swim bladder inflation at 8 dph between the groups.

Discussion and conclusion

The corresponding pattern of survival and growth of larvae is encouraging, which suggests that the inclusion of marennine through live feeds be a useful additive for early larval stages of finfish

EFFECTS OF DIFFERENT LIGHT COLORS ON THE GROWTH PERFORMANCE OF LARGEMOUTH BASS (MICROPTERUS SALMOIDES) IN A RECIRCULATING AQUACULTURE SYSTEM

YadongZhang*, SongmingZhu, Zhangying Ye.

College of Bio-systems Engineering and Food Science, Zhejiang University, Hangzhou, 310058, PR China
E-mail: 164516715@qq.com

Introduction

The reasons for the low survival of largemouth bass larvae include the anti-stress ability, and the infection of viruses, bacteria and parasites. Recirculating aquaculture system has the advantages of enhancing aquaculture temperature control, improving water treatment capacity, and reducing pests and diseases. Light is widely recognized as an important factor in closed industrial farming because it affects the growth and behavior of fish(Espigares, Rocha, Gómez, Carrillo, & Zanuy, 2016; Yoseda et al., 2008). Therefore, this experiment was designed to evaluate the effects of light color on survival rate and growth of largemouth bass larvae.

Materials and methods

The experiment was set up with blue (half-peak bandwidth=409-490nm), green(half-peak bandwidth=493-572nm), white (371<λ<1047) and full spectrum four light environments. The 7200 largemouth bass larvae were randomly divided into 12 culture ponds, the water temperature in the water tank was (23±1) °C, the pH was (7.5 ± 0.2), the dissolved oxygen was (5.6 ± 0.2) mg/L, and the photoperiod was light: dark = 12h: 12h. During the experiment, the growth of the larvae was recorded every 3 days, and the number of fish deaths was recorded dail .

Results

Preliminary results showed that the survival rate of larvae in green light group, full spectrum group and white light group was higher than that in blue light group; the survival rate of larval in the whole spectrum group was the highest (Table 1).

The experimental results also showed that the body length and weight of the larvae in the white light group and the full spectrum group were greater, which indicated that the larvae grew faster in these light environments. However, under blue light conditions, the larvae were the lightest and grew slowly.

Table 1
Effect of light color on the survival and growth performance of largemouth bass larvae at the end of the experiment (16 days). The data were presented by means±S.D. (n=5).

Parameters	Blue Light	Green Light	Full spectrum	White Light
Initial length (mm)	6.52 ±0.23	6.52 ±0.23	6.52 ±0.23	6.52 ±0.23
Final length (mm)	12.1±0.4	12.2±0.1	12.4±0.3	12.3±0.03
Final weight (mg)	16.7±1.0	16.8±1.5	18.4±0.2	18.4±2.7
Survival (%)	11.6±0.7	17.7±2.4	33.5±3.5	20.4±4.6

(Continued on next page)

Discussion and conclusion

In the long-term evolution process, organisms adapt to changes in light through various aspects such as morphology, behavior, and physiological response (Villamizar, García-Alcazar, & Sánchez-Vázquez, 2009). In this experiment, the survival rate of larvae was lower under blue light, and the growth of larvae was lower than other groups, which fully indicated that blue light may be a stress factor for largemouth bass larvae, the larvae could not self-adjust to adapt to this lighting condition through a series of behavioral and physiological mechanisms, so the mortality rate was higher.

The early growth and development of the largemouth bass were greatly affected by light. Inappropriate lighting conditions (blue light) at this stage may result in slow growth and low survival rates, which can impair the productivity of the fish and should be avoided. In conclusion, full-spectrum light can increase the survival rate of largemouth bass larvae and promote their growth performance in this experiment.

EFFECTS OF DIETARY *Bacillus subtilis natto* SUPPLEMENTATION ON GROWTH, OXIDATIVE STATUS AND IMMUNE RESPONSE OF RED SEA BREAM (Pagrus major)

Yukun Zhang*, Manabu Ishikawa, Shunsuke Koshio, Saichiro Yokoyam

The United Graduate School of Agriculture Sciences, Kagoshima University, Japan
tyouyoukon@hotmail.com

In this study, *Bacillus subtilis natto* was evaluated on the growth, digestive enzyme activity, blood chemistry, oxidative status, immune response and the growth-related genes' expression in the skeletal muscle of red sea bream (Pagrus major). Fish fed five different levels of *B. s. natto* at 0 (BN0), 1×10^5 (BN1), 1×10^7 (BN2), 1×10^9 (BN3) and 1×10^{11} (BN4) CFU kg^{-1} diet for 56 days. The fish of BN3 and BN4 groups displayed better growth performance and feed conversion ratio (FCR) than the BN0 groups ($P < 0.05$). Compared with the BN0 and BN1 groups, there were significant increases ($P < 0.05$) in whole-body protein content in BN3and BN4 groups. *B. s. natto* supplementation significantly improved the specific activities of amylase, protease and lipase enzymes when compared to the control group ($P < 0.05$). Furthermore, the plasma total protein was increased significantly in fish fed BN4 diet when compared with the control diet ($P < 0.05$). Hemoglobin and the nitro blue tetrazolium values up regulated significantly upon *B. s. natto*, especially in case of BN3 and BN4 diets ($P < 0.05$). Serum peroxidase activity enhanced significantly in fish fed BN2 and BN3 diets ($P < 0.05$). Compared with the fish of BN0 growth-related genes' expressions increased ($P < 0.05$), and the myostatin and myocyte enhancer factor C mRNAs were downregulated ($P < 0.05$) in the fish of BN3 and BN4 groups. The specific growth rate analysis and expressional regulation of the growth-related genes stimulated by *B. s. natto* suggest the potential application of *B. s. natto* in improving the growth performance on the red sea bream. Additionally, the supplementation of *B. s. natto* in the diet of red sea bream at 1×10^9 and 1×10^{11} CFU kg^{-1} diet could improve the growth, feed utilization, health condition and immune response.

DEEP LEARNING-BASED MONITORING OF THE LOCAL UNUSUAL BEHAVIORS FOR FISH SCHOOL IN INTENSIVE AQUACULTURE

Jian Zhao*, Shengyu Hang, Yanci Wen, Songming Zhu, Zhangying Ye

College of Biosystems Engineering and Food Science, Zhejiang University
Yuhangtang Road 866, Hangzhou 310058, PR China

Introduction

Behavior change is an effective reference index of fish welfare in aquaculture. Compared to the global unusual behaviors, most unusual behaviors occur within the relatively small areas (i.e., local unusual behaviors), such as aggressive behaviors, abnormal swimming behaviors associated with clinical symptoms of poor health or parasitic infections (Ashley, 2007). For the monitoring of the local unusual behaviors, computer vision based-tracking, apparently, is the most accurate measure. However, this type of technology is difficult to be applied in production, especially in practical intensive aquaculture (Delcourt *et al*., 2013). Therefore, a practical method, mainly based on Graph Networks and Recurrent Neural Networks (RNN), was developed to detect, localize and recognize the local unusual behaviors of fish school on the basis of the algorithm proposed in Zhao, *et al*., (2018).

Materials and methods

Tilapia (*Oreochromis niloticus*) were used in this study. Before the experiment, all tilapia have been kept in the laboratory RAS for about three months. To obtain enough samples of the local unusual behaviors, experiment in this study was carried out based on the emptying of the gastrointestinal contents. And the behavior dataset was made manually following All Occurrences Sampling. Totally 1000 verified video clips of 4 clusters are contained in this behavior dataset, and each cluster is presented by a representative behavior.

Results

According to the results, the proposed method demonstrates better performance than many other state-of-art methods (Zhao, *et al*., 2018), and reaches the accuracies of 98.91%, 91.67% and 94.16% of the detection, localization and recognition of the local unusual behaviors, respectively.

Discussion and conclusion

Benefiting from the properties of Graph Networks and RNN, the proposed method in this study shows a lot of improvement in recognition in contrast to that in Zhao, *et al*., (2018). And how to enhance performance of the front-end would be the focus of further research. In conclusion, although challenges still exist, method presented in this study has revealed its potential in practical monitoring of the local unusual behaviors for fish school in intensive aquaculture, and could be applied to assess the status of fish school.

Introduction

Koi herpesvirus disease (KHVD) can cause severe mortality in farmed carp populations (Novotny et al., 2010). In Europe, KHVD is on the list of notifiable diseases. Prevention is a sensible strategy for tackling this disease and improved resistance of carp strains is a desirable goal. Previous study showed KHVD resistance to be heritable trait that can be improved by selection (Palaiokostas et al., 2018). In selective breeding, selection for a single trait can lead to unwanted genetic changes in other traits. Hence, the main aim of this study was to investigate the genetic relationship of KHVD resistance to other production traits in Amur mirror carp.

Materials and methods

A population of Amur Mirror Carp was created from four factorial crosses of five dams and ten sires. One-year fish (n=1500) of Amur Mirror Carp were pit-tagged and finclipped. They were challenged to KHV, alongside with a small (n = 215) sample of Koi carp. Koi carp were a positive control, since they are highly susceptible to KHV. Mortality of individual fish was recorded twice a day for a period of 35 days post infection until mortalities were negligible. Resistance was measured as 0 = died and 1 = survived. Presence of KHV on a sample of dead fish was confirmed by PCR. Before the challenge, juvenile growth-related traits (body weight and Fulton's condition factor, FC) were measured in the same individuals. Traits like FC, visceral index, hepatosomatic index, muscle fat, and fat, glycogen and protein analysed in hepatopancreas, as well as energy content in hepatopancreas measured in the first spring were recorded in siblings of the challenged fish. An additional set of the same families were phenotyped before and after second wintering and at third summer (market size) and measured for absolute and relative muscle fat change, weight change during winter expressed as specific growth rate, survival, condition factor, muscle fat content, body weight, log-log residuals of headless carcass yield and fillet yield. The genetic correlations between KHVD resistance and production traits were estimated using DMU statistical software. All traits were recorded from the same families and had a common pedigree (family structure) but KHVD resistance and other performance traits were recorded from different individuals. As a result, residual covariance was set to zero between these traits. Moreover, mating design (for KHVD resistance and energetic reserves) and sex (for production traits) were set as fixed e fects in the statistical model.

Results

Almost all genetic correlations between KHVD resistance and other production traits were insignificant. Genetic correlations between KHVD resistance and energetic reserves were also weak and insignificant. The genetic correlation between FC after the second overwintering and KHVD resistance was significantly different from zero and negative (r_g = -0.32 ± 0.14). Likewise, intermediate genetic correlations were found between KHVD resistance and slaughter yields at market size (log-log residuals of headless carcass yield and fillet yield, respectively) r_g = 0.37 ± 0.14 and 0.44 ± 0.13, respectively).

(Continued on next page)

Discussion and conclusion

Almost all genetic associations between KHVD resistance and production traits as well as energetic reserves were insignificant. In conclusion, selection for improved production efficiency would not increase the susceptibility of fish to KHV and vice versa. Only genetic correlation between FC after overwintering and KHVD resistance was significantly different from zero and negative. So, KHV resistant families had genetically lower FC after the second overwintering. In previous studies (Prchal et al., 2018) it was shown that FC is in Amur mirror carp genetically related to the body shape (e.g. relative body height). So, such negative correlation might be related to typically more prolonged body shape of Amur carp, one of the parental lines of Amur mirror carp, which is more resistant to KHV than other farmed carp breeds (Piackova et al., 2013). Intermediate genetic correlations between KHVD resistance and slaughter yields suggest that selection for KHVD resistance might lead to slightly higher muscling of fish and vice versa.

Vibrio harveyi, a marine Gram-negative luminous bacterium, has become recognized as a serious pathogen of the aquatic animals. Once its outbreaks, it causes significant losses in the aquaculture industry, particularly in economically important penaeid shrimp (Austin and Zhang 2006). Plant-based extracts, namely essential oils (EOs), concentrated hydrophobic liquid containing volatile chemical compounds, are complex mixtures of secondary plant metabolites. EOs contain many EO components (EOCs), which are pure and single chemical compositions (Randrianarivelo, Sarter et al. 2009, Manju, Malaikozhundan et al. 2016). Several EOs and EOCs have been known for exerting a multitude of biological effects, such as bactericidal and fungicidal, which have documented *in vitro* studies (Feyaerts, Mathé et al. 2017, Feyaerts, Mathe et al. 2018). However, some studies have concentrated exclusively on one oil. While these data are useful, the results are not directly comparable due to different methodologies such as the selection of plant extract(s), the extraction parts of the plant and antimicrobial test methods. The aim of this study is to determine a large number of essential oils and their components against *V. harveyi* and to investigate the putative effect of EO(c)s in *vivo* using the highly controlled gnotobiotic *Artemia* model system.

In the present study, we evaluated the vapour-phase-mediated antimicrobial activity (VMAA), different concentration of antimicrobial activity and specific quorum sensing-inhibitory activity (AQSI) of 22 essential oils and 12 essential oil components, against V. harveyi. And then, we tested the toxicity of the selected essential oils and determine the challenge test in Artemia. Results showed that the VMAA of a volatile spread symmetrically across a microtiter plate and one-quarter of the tested essential oils and their components showed growth-inhibitory VMAA at 24h. Then, six essential oils and three essential oil components inhibited 50% of the growth at 0.0001%, compared to the control. Moreover, just the four most active essential oils inhibited quorum sensing at 0.001%, with A_{QSI} higher than 2. We selected the three best candidates and then using them to control *V. harveyi* in Artemia system. The selected essential oils can improve the survival rate of brine shrimp at certain doses.

In conclusion, the anti-*Vibrio* activity of essential oils and their components both in broth cultures and via their vapour-phase. Not all the essential oils and their components are able to inhibit quorum sensing in *V. harveyi*. And these three essential oils were considered to be highly promising to control *V. harveyi* in aquaculture.

Background
The parasitic problem in Atlantic salmon (*Salmo salar* L) caused by sea lice infestation is still a major challenge for the salmon industry in Norway. To use cleaner fish for delousing is an alternative to medicine treatment. One of these species is lumpfish which is useful particularly at the low temperatures in winter (Powell, et al., 2018). Accordingly, as harvesting from the wild stocks is not sustainable, cultivation of lumpfish in Norway has increased in recent years. The number of lumpfish used in salmon production in Norway reached 3.8 million in 2018. However, in the build-up of capacity for cultivation several knowledge gaps must be filled, not at least regarding nutrient requirement. The results to be presented are part of an experiment conducted to estimate the macronutrient requirement of lumpfish. Effects of diet composition on intestinal function and health were evaluated, including digestive enzyme activity, expression of functional genes in the gut mucosa as well as histomorphology of the gut wall.

Material and methods
Twelve diets were designed according to a three-component mixture design. The proportion of protein, lipid and carbohydrate varied between all diets, ranging from 43% to 68%, 4% to 17% and 6% to 18%, respectively. After a 41-day feeding trial, six fish from each tank were sacrificed, opened and the whole intestine was sampled. The intestine was divided into three sections, i.e. proximal intestine (PI), mid intestine (MI) and distal intestine (DI), according to the morphological structure. For each section, the intestine was opened to collect digesta for the measurement of trypsin activity and bile salts concentration, but only MI contained sufficient digesta for analysis. Tissue was taken from the remaining intestine for measurement of digestive enzyme activity and gene expression, and for evaluation of histology.

Tissue samples from all sampled fish were processed for analyses of leucine aminopeptidase (LAP) and maltase activity. Gut tissue samples from fish given five selected diets, i.e. the diet of medium macronutrient composition and four other diets of extreme macronutrient composition, were processed to observe expression of genes involved in the immune and osmoregulatory apparatus, including proliferating cell nuclear antigen (pcna), immunogobulin M (IgM), inhibitor of nuclear factor kappa B kinase subunit beta (IKBKB), nuclear factor kappa B p65 subunit (RelA), cyclooxygenase-2 (cox-2) and aquaporin 1 (aqp1). Four out of the five selected diets groups were evaluated regarding histological changes. Length and fusion of mucosal folds, width of the lamina propria and submucosa, cellularity of lamina propria and submucosa and enterocyte vacuolization were evaluated for each section. The degree of changes was graded as normal, mild, moderate and severe, depending on the morphological characteristics.

Results
In PI, the specific activity of LAP and maltase showed a significant relationship with feed composition ($p < 0.05$). The highest activity appeared in fish fed with diets of high level of carbohydrate, medium level of protein and low level of lipid. In MI, the same significant trend (Fig.1, $p < 0.05$) was shown for both the specific activity and total capacity of LAP and maltase. In DI, neither the specific activity nor the total capacity of LAP and maltase were affected by the variation in diet composition. Moreover, the trypsin activity and the concentration of bile salts in the collected gut contents in MI did not show significant relationship with diet composition.

Expression of the IKBKB gene in MI, a key element in the immune apparatus, was higher in fish fed the diet with lowest level of lipid and carbohydrate and highest level of protein than in fish fed the diet with lowest level of protein and highest level of lipid and carbohydrate. However, none of the other investigated genes showed differences in expression related to variation in diet composition in any of the gut sections. Enterocyte vacuolization, which is often associated with lipid steatosis (Gu, et al., 2014), increased in PI and MI as the dietary lipid level increased as often observed also in Atlantic salmon. In DI, however, no such effect was apparent.

(Continued on next page)

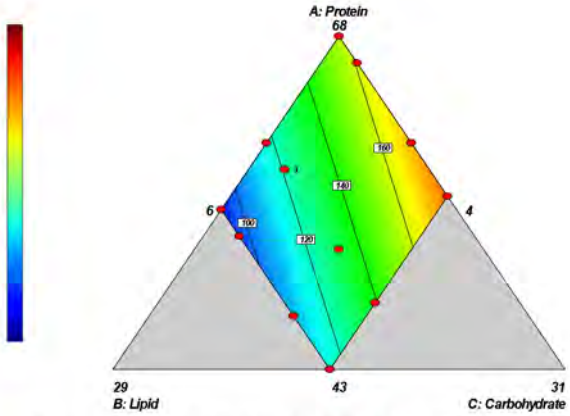

Fig.1. Specific activity of LAP in MI. The colour from blue to red represents an increasing level of activity.

Conclusions

1) Variation in macronutrient composition affected the specific activity of the brush border enzymes LAP and maltase in both PI and MI.
2) Variation in macronutrient composition affected expression of the IKBKB gene, a key element in the immune apparatus but did not change expression of the other observed genes related to intestinal immunity and osmoregulation.
3) Lipid steatosis increased in PI and MI as lipid level increased.

EVALUATING THE EFFECT OF DIFFERENT FEED PHOSPHATES ON BLOOD PARAMETERS, CORPSE ANALYSIS, INTESTINAL HISTOLOGY AND GROWTH RATE OF KOI CARP *Cyprinus carpio*

Sjo Zwart*, Frank Ruyseveldt

Aliphos Belgium, Av. Jean Monnet 1, 1348 Louvain-la-Neuve, Belgium
animalnutrition@aliphos.com

Introduction

A study was undertaken to evaluate the effect of two supplemental phosphorus sources: Windmill® Aquaphos (Aquaphos) and Aliphos® Monocal (MCP) and *Spirulina* on blood chemical factors, corpse analysis, intestinal histology and growth rate on koi carp (*Cyprinus carpio*).

Trial protocol

Triplicate groups of 38 carp with an average weight of 17g, were fed one of the trial diets for 8 weeks. 10 trial diets were formulated to contain increasing inclusion levels of Windmill® Aquaphos and one inclusion of Aliphos® Monocal, with and without *Spirulina*, including two control feeds (with and without *spirulina* without addition of feed phosphates). Carp were fed 2 times daily at a feeding rate of 2% of the body weight. Stagnant water tanks of 220 l were used to enable to study the effects of the different feed phosphates on water quality. At day one, three fish from each tank were randomly selected for determining blood chemical factors and histological analysis of the intestine. Same fish were used for carcass and vertebrae analysis. At day 63 carp were also sampled for determining blood chemical factors, histological, carcass and vertebrae analysis.

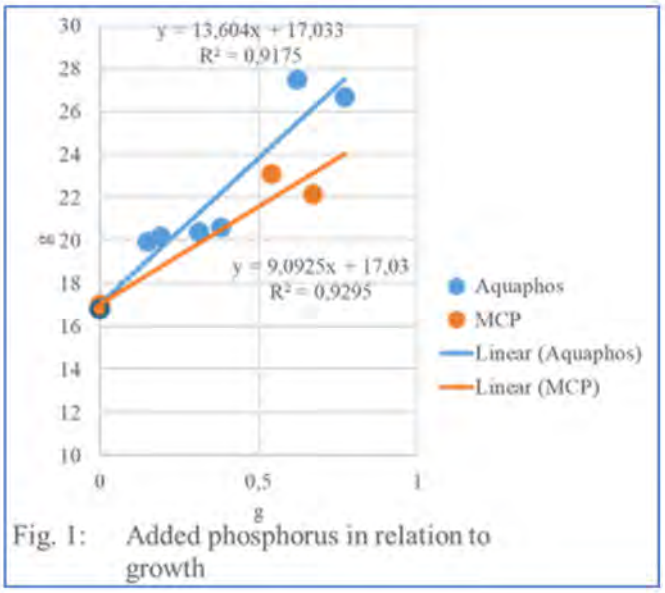

Fig. 1: Added phosphorus in relation to growth

Results

Growth (g) ranged from 17g, for the control diet, up to 27g for the diet including 3% Aquaphos. Increasing levels of Aquaphos showed an increase in both blood and bone phosphorus content.

Other blood parameters showed no significant differences over the groups. However, highest alkaline phosphatase levels were observed in the two control groups, without addition of any feed phosphate. The groups fed diets containing spirulina showed a higher muscle protein content. Histological analysis of the intestine showed that the intestinal *villi* were better developed in the diet with 3% Aquaphos against the diet with 3% MCP.

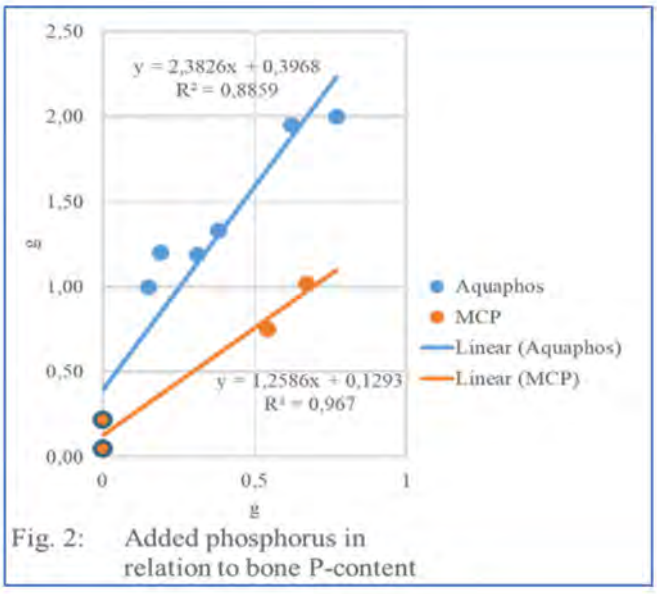

Fig. 2: Added phosphorus in relation to bone P-content

Between the different groups there were no differences in ammonia content of the water, confirming that the inclusion of Aquaphos had no negative effect on the possible increase of ammonia in the water. Lowest phosphorus levels in the water were seen with the control groups. Highest P-level was observed with the diet containing MCP at 3% inclusion with *spirulina*.

Conclusions

These trial results suggest that Windmill® Aquaphos has a significantly higher phosphorus-bioavailability than in case of Aliphos® Monocal for carp.
